Code	Escalation level	Topic	Severity	Event name	Message template	Comment
0x22008105	ADMIN		ERROR	Service Transitions Missed	Service '{0}' ('{1}') is in phase '{2}' but should be in phase '{3}' according to the state reported by MWM. It is probable that one or more phase transitions were missed. Any hooks associated with those transitions were probably not executed.	This happens when the phase of a service as recorded by MWS differs from the phase expected according to the state of the service's jobs as reported by MWM. This means that one or more phase transitions were missed and thus any hooks on those transitions did not execute. This problem is most likely caused by either the message queue being misconfigured or MWS being down while MWM is running.
0x22008480	ADMIN		ERROR	Health Retrieval Failed	The health summary could not be retrieved successfully: {1}	This means a serious error occurred while attempting to retrieve the contents of the health summary REST resource from MWS.
0x22008481	ADMIN		ERROR	Health Create Failed	The notification condition for the failed health check could not be created: {1}	This marks when a notification condition failed to be created based on a health check.

Appendix D: Adjusting Default Limits

Moab is distributed in a configuration capable of supporting multiple architectures and systems ranging from a few processors to several thousand processors. However, in spite of its flexibility, for performance reasons, it still contains a number of default object limits parameters and static structures defined in header files. These limits constrain such things as the maximum number of jobs, reservations, and nodes that Moab can handle and are set to values that provide a reasonable compromise between capability and memory consumption for most sites. However, many site administrators want to increase some of these settings to extend functionality, or decrease them to save consumed memory. The most common parameters are listed in what follows. Parameters listed in the Moab configuration file (`moab.cfg`) can be modified by restarting Moab. To change parameters listed in `moab.h`, please contact technical support.

CLIENTMAXCONNECTIONS

Location	<code>moab.cfg</code> (dynamic parameter)
Default	128
Max tested	---
Description	Maximum number of connections that can simultaneously connect to Moab.

JOBMAXNODECOUNT

Location	<code>moab.cfg</code> (dynamic parameter)
Default	1024
Max tested	8192
Description	Maximum number of compute nodes that can be allocated to a job. After changing this parameter, Moab must be restarted for changes to take effect. The value cannot exceed that of the MAXNODE on page 1141 parameter (specified in <code>moab.cfg</code>). If you specify a value higher than the limit set for the MAXNODE parameter, the value will match MAXNODE . JOBMAXNODECOUNT can also be specified within configure using <code>--with-maxjobsiz=<NODECOUNT></code> .

MAXGRES

Location	<code>moab.cfg</code> (dynamic parameter)
Default	512
Max tested	---
Description	Total number of distinct generic resources that can be managed.

MAXJOB

Location	<code>moab.cfg</code> (dynamic parameter)
Default	4096
Max tested	500,000
Description	Maximum number of jobs that can be evaluated simultaneously. (Can also be specified within configure using --with-maxjobs=<JOBCOUNT> .)

MAXRSVPERNODE

Location	<code>moab.cfg</code> (dynamic parameter)
Default	48
Max tested	1024
Description	Maximum number of reservations a node can simultaneously support.

MMA_ATTR

Location	<code>moab.h</code>
Default	128
Max tested	512

MMAX_ATTR

Description	Total number of distinct node attributes (PBS node attributes/LL node features) that can be tracked.
--------------------	--

MMAX_CLASS

Location	moab.h
Default	24
Max tested	64
Description	Total number of distinct job classes/queues available.

MMAX_FSDEPTH

Location	moab.h
Default	24
Max tested	32
Description	Number of active fairshare windows.

MAXNODE

Location	moab.cfg (dynamic parameter)
Default	5120
Max tested	160000
Description	Maximum number of compute nodes supported.

MMAX_PAR

Location	moab.h
-----------------	--------

MMAX_PAR	
Default	32
Max tested	32
Description	Maximum number of partitions supported.

MMAX_QOS	
Location	moab.h
Default	128
Max tested	128
Description	Total number of distinct QoS objects available to jobs.

MMAX_RACK	
Location	moab.h
Default	200
Max tested	200
Description	Total number of distinct rack objects available within cluster.

MMAX_RANGE	
Location	moab.h
Default	2048
Max tested	2048

MMAX_RANGE**Description**

Total number of distinct timeframes evaluated.

Note: This is proportional to the size of the cluster and the number of simultaneously active jobs in the cluster. (Can be specified within `./configure` using `--with-maxrange=<RANGECOUNT>`.) Increasing this value will not increase the size of total memory consumed by Moab but may result in minor slowdowns in the evaluation and optimization of reservations.

MMAX_REQ_PER_JOB**Location**

`moab.h`

Default

5

Max tested

64

Description

Total number of unique requirement structures a job can have. Limits the number of `-w` clauses in the `mshow -a` command. It also limits the number of `-l nodes=X+Y+Z` a normal HPC job can have.

JOBMAXTASKCOUNT**Location**

`moab.cfg` (dynamic parameter)

Default

4096

Max tested

250000

Description

Total number of tasks allowed per job.

Moab currently possesses hooks to allow sites to create local algorithms for handling site specific needs in several areas. The `contrib` directory contains a number of sample local algorithms for various purposes. The `MLocal.c` module incorporates the algorithm of interest into the main code. The following scheduling areas are currently handled via the `MLocal.c` hooks.

- Local Job Attributes
- Local Node Allocation Policies
- Local Job Priorities
- Local Fairness Policies

Related Topics

[Appendix I: Considerations for Large Clusters](#)

Appendix E: Security

Moab provides role and host based authorization, encryption*, and DES, HMAC, and MD5 based authentication. The following sections describe these features in more detail.

- [Authorization](#)
 - [Role Based Authorization Security Configuration](#)
- [Authentication](#)
 - [Mauth Authentication](#)

 - [Medium Host Security Enforcement](#)
 - [Strict Host Security Enforcement](#)
- [Access Portal Security](#)

Authorization

Role Based Authorization Security Configuration

Moab provides access control mechanisms to limit how the scheduling environment is managed. The primary means of accomplishing this is through limiting the users and hosts that are trusted and have access to privileged commands and data.

With regard to users, Moab breaks access into three distinct levels.

Level 1 Moab Admin (Administrator Access)

Level 1 Moab administrators have global access to information and unlimited control over scheduling operations. By default, they are allowed to control scheduler configuration, policies, jobs, reservations, and all scheduling functions. They are also granted access to all available statistics and state information. Level 1 administrators are specified using the [ADMINCFG\[1\]](#) parameter.

Level 2 Moab Admin (Operator Access)

Level 2 Moab administrators are specified using the [ADMINCFG\[2\]](#) parameter. By default, the users listed under this parameter are allowed to change all job attributes and are granted access to all informational Moab commands.

Level 3 Moab Admin (Help Desk Access)

Level 3 administrators are specified via the [ADMINCFG\[3\]](#) parameter. By default, they are allowed access to all informational Moab commands. They cannot change scheduler or job attributes.

Configuring Role Based Access

Moab allows site specific tuning of exactly which functions are available to each administrator level. Moab also provides two additional administrator levels (**ADMINCFG[4]** and **ADMINCFG[5]**) that may be used for site specific needs.

To configure Moab role based access, use the [ADMINCFG](#) parameter.

```
ADMINCFG[1]    USERS=root,john SERVICES=ALL NAME=admin
ADMINCFG[3]    USERS=joe,mary  SERVICES=mddiag,mrsvctl,mcredctl NAME=power
ADMINCFG[5]    USERS=joy,blake SERVICES=NONE NAME=users
...
```

i A **NONE** in services will still allow users to run [showq](#) and [checkjob](#) on their own jobs.

To determine the role of system users and what commands they can run, use the [mcredctl -q role user:<USERID>](#) command.

Using the **SERVICES** attribute of the **ADMINCFG** parameter, access to an arbitrary selection of services can be enabled on a per administrator-level basis. Possible services include the following:

Service	Description
changeparam	Change any scheduling policy or parameter (This command is deprecated. Use mschedctl -m instead).
checkjob	View detailed information for any job.
checknode	View detailed information for any node.
mbal	Perform real-time load-balancing of interactive commands.
mcredctl	View and modify credential attributes.

Service	Description
<u>mdiag</u>	Provide diagnostic reports for resources, workload, and scheduling.
<u>mjobctl</u>	Modify, control, and view jobs.
<u>mnodectl</u>	Modify, control, and view nodes.
<u>mrnctl</u>	Modify, control, and view resource managers.
<u>mrsvctl</u>	Modify, control, and view reservations.
<u>mschedctl</u>	Modify, control, and view scheduler behavior.
<u>mshow</u>	View existing configuration and predicted resource availability.
<u>showstats</u>	View all scheduler and credential statistics.
<u>releaseres</u>	Release all reservations (This command is deprecated. Use <u>mrsvctl -r</u> instead).
runjob	Immediately execute any job (see <u>mjobctl -x</u>).
<u>setqos</u>	Set QoS on any job (This command is deprecated. Use <u>mjobctl -m</u> instead).
<u>setres</u>	Create any reservation (This command is deprecated. Use <u>mrsvctl -c</u> instead).
<u>setspri</u>	Set system priority on any job (This command is deprecated. Use <u>mjobctl -p</u> instead).
<u>showconfig</u>	Show all scheduler configuration parameters (This command is deprecated. Use <u>mschedctl -l</u> instead).
<u>showres</u>	Show detailed information for any reservation.
<u>showstate</u>	Show detailed information for all jobs, including their locations, and display job error messages, if any.

Account and Class/Queue Admins

While the **ADMINCFG** parameter allows organizations to provide controlled access to scheduling objects, it does not allow for distribution along organizational boundaries. For example, a site may set up a level 3 administrator to be able to view statistics, diagnose jobs, and modify job priorities; it does not provide a way to differentiate one type of job from

another. If a site administrator wanted to allow control based on the queue or account associated with a job, they would best accomplish this using the credential **MANAGERS** attribute.

A credential manager allows a user to be trusted to administer workload and policies for an associated subgroup of jobs. For example, in the configuration below, a number of queue and account managers are configured.

```
CLASSCFG[orion] MANAGERS=johns
CLASSCFG[xray]  MANAGERS=steve2
CLASSCFG[gamma] MANAGERS=steve2,jpw
ACCOUNTCFG[bio] MANAGERS=charles
```

By default, the specified managers can do anything to a job that the actual job owner could do. By default, this would include the ability to view cumulative and per job statistics, see job details, modify job priorities and holds, cancel and preempt jobs, and otherwise adjust policies and constraints within the associated credential.

Authentication (Interface Security)

Moab supports password-challenge, DES, HMAC, and MD5 based authentication. Authentication protocols may be specified on a per interface basis allowing independent realms of trust with per realm secret keys and even per realm authentication protocols.

Mauth Authentication

Mauth is a tool provided with Moab that provides client authentication services. With mauth enabled, each client request is packaged with the client ID, a timestamp, and an encrypted key of the entire request generated using the shared secret key.

This tool is enabled by providing a secret key. A random key is selected when the Moab `./configure` script is run and may be regenerated at any time by rerunning `./configure` and rebuilding Moab. If desired, this random key may be overridden by specifying a new key in the protected `.moab.key` file as in the example below:

Moab must be shut down before setting a new secret key. Use the `service moab stop` or `mschedctl -k` commands to shut down Moab.

```
> vi /opt/moab/etc/.moab.key
(insert key)
> cat /opt/moab/etc/.moab.key
XXXXXXXXXX
# secure file by setting owner read-only permissions
> chmod 400 /opt/moab/etc/.moab.key
# verify file is owned by root and permissions allow only root to read file
> ls -l /opt/moab/etc/.moab.key
-r----- 1 root root 15 2007-04-05 03:47 /opt/moab/.moab.key
```

- i** All directories in the path containing `.moab.key` must be owned by the root or primary Moab user. It must not be writable by "other" in its permissions.
- i** If `.moab.key` is used, this protected file will need to be on each host that is authorized to run Moab client commands.
- i** By default, this file will be owned by the user root and its contents will be read by the mauth tool which provides client authorization services. If desired, the ownership of this file can be changed so long as this file is readable by the Moab server and the mauth tool. This can be accomplished if the Moab primary administrator, the owner of mauth, and the owner of `.moab.key` are the same.
- i** By default, it is up to the individual cluster administrators to determine whether to use the `.moab.key` file. For sites with source code, the use of `.moab.key` can be mandated by using `./configure --with-keyfile`.
- i** By default, mauth is located in the `install bin` directory. If an alternate name or alternate file location is desired, this can be specified by setting the **AUTHCMD** attribute of the CLIENTCFG parameter within the `moab.cfg` file as in the following example.

```
CLIENTCFG AUTHCMD=/opt/sbin/mauth
```

Configuring Peer-Specific Secret Keys

Peer-specific secret keys can be specified using the CLIENTCFG parameter. This key information must be kept secret and consequently can only be specified in the `moab-private.cfg` file. With regard to security, there are two key attributes that can be set. (Other resource managers or clients such as Moab Accounting Manager or a SLURM/Wiki interface can also use the attributes to configure their authentication algorithms. The default, unless otherwise stated, is always *DES*. These attributes are listed in the table below:

AUTH	
Format	one of <i>ADMIN1</i> , <i>ADMIN2</i> , or <i>ADMIN3</i>
Default	---
Description	Specifies the level of control/information available to requests coming from this source/peer.

AUTH**Example**

```
CLIENTCFG[RM:clusterB] AUTH=admin1 KEY=14335443
```

AUTHTYPE**Format**

one of *DES*, *HMAC*, *HMAC64*, or *MD5*.

Default

DES

Description

Specifies the encryption algorithm to use when generating the message checksum.

Example

```
CLIENTCFG[AM:mam] AUTHTYPE=HMAC64
```

HOST**Format**

<*STRING*>

Default

Description

Specifies the hostname of the remote peer. Peer requests coming from this host will be authenticated using the specified mechanism. This parameter is optional.

Example

```
CLIENTCFG[RM:clusterA] HOST=orx.pb13.com KEY=banana6
```

KEY**Format**

<*STRING*>

Default

Description

Specifies the shared secret key to be used to generate the message checksum.

Example

```
CLIENTCFG[RM:clusterA] KEY=banana6
```

The **CLIENTCFG** parameter takes a string index indicating which peer service will use the specified attributes. In most cases, this string is simply the defined name of the peer service. However, for the special cases of resource and

accounting managers, the peer name should be prepended with the prefix `RM:` or `AM:` respectively, as in `CLIENTCFG [AM:mam]` or `CLIENTCFG [RM:devcluster]`.

i The first character of any secret key can be viewed by trusted administrators using specific diagnostic commands to analyze Moab interfaces. If needed, increase the length of the secret keys to maintain the desired security level.

Munge Authentication

Moab also integrates with MUNGE, an open source authentication service created by Lawrence Livermore National Laboratory (<http://home.gna.org/munge/>). MUNGE works with Moab to authenticate user credentials being passed between the Moab client and the Moab server or from Moab server to Moab server.

To set up MUNGE in a cluster or grid, download and install MUNGE on every node in the cluster or grid by following the installation steps found at <http://home.gna.org/munge/>. The MUNGE secret key must reside on each node in the cluster or grid. Before starting the Moab daemon, the MUNGE daemon must be running on all nodes.

To enable Moab to use MUNGE for authentication purposes, specify the MUNGE executable path in the `moab.cfg` file using `CLIENTCFG` and `AUTHCMD` as in the following example. The MUNGE executable path must reside in each client's `moab.cfg` file as well.

```
CLIENTCFG AUTHCMD=/usr/bin/munge
```

i Moab requires that the MUNGE and UNMUNGE executable names be "munge" and "unmunge" respectively. It also assumes that the UNMUNGE executable resides in the same directory as the MUNGE executable.

Configuring Munge Command Options

Moab also integrates with MUNGE command line options. For example, to set up Moab to use a specific socket that was created when the MUNGE daemon was started, use `CLIENTCFG` and `AUTHCMDOPTIONS` to specify the newly created socket. The `AUTHCMDOPTIONS` attribute, like `AUTHCMD`, must also reside in the client's `moab.cfg` file.

```
CLIENTCFG AUTHCMD=/usr/bin/munge
CLIENTCFG AUTHCMDOPTIONS="-S /var/run/munge/munge.socket.2"
```

Server Response Control

If a request is received that is corrupt or cannot be authenticated, Moab will report some limited information to the client indicating the source of the

failure, such as "bad key," "malformed header," and so forth. In the case of highly secure environments, or to minimize the impact of sniffing or denial of service attacks, Moab can be configured to simply drop invalid requests. This is accomplished by adding the **DROPBADREQUEST** attribute to the **CLIENTCFG** parameter in the `moab-private.cfg` file as in the following example:

```
CLIENTCFG[DEFAULT] DROPBADREQUEST=TRUE
```

Interface Development Notes

Sample checksum generation algorithm code can be found in the [Socket Protocol Description](#) document.

Host Security for Compute Resources

Host level security can vary widely from one site to another with everything from pure on-your-honor based clusters to complete encrypted VLAN based network security and government approved per job scrubbing procedures being used. The following documentation describes some best practices in use throughout the industry.

Minimal Host Security Enforcement

For minimal host security, no additional configuration is required.

Medium Host Security Enforcement

- Login Access
 - PAM — Enable/disable access by modifying `/etc/security/access.conf`.
- Processes
 - Kill all processes associated with job user (dedicated).
 - Kill all processes associated with job session (dedicated/shared). Use `ps -ju <USER>` or `ps -js <SESSID>`.
- IPC (Inter-Process Communication)
 - Remove shared memory, semaphores, and message queues (use `ipcs/ipcrm`).
 - Remove named pipes.
- Network/Global File System Access
 - Explicitly unmount user home and global file systems.

- Local Temporary File Systems
 - Where possible, mount local file systems read-only.
 - Clear `/tmp`, `/scratch` and other publicly available local file systems.
 - Remove user files with `shred`; `shred` is a Linux command that first overwrites files completely before removing them, preventing remnant data from surviving on the hard drive.

Strict Host Security Enforcement

- VLAN creation
- Host rebuild
 - U.S Dept. of Energy Disk/File Sanitization ([SCRUB](#))
 - U.S Dept. of Defense Scrubbing [Software](#) (DOD-5520)

Moab Access Portal Security Overview

The Moab Access Portal (MAP) security model is composed of several different components. First, users will use a Web browser to log in and interact with the Web server running MAP. This communication can be encrypted using industry standard SSL to protect usernames/passwords and other sensitive information that may be accessed by the user. (Instructions on how to set up SSL connections with popular Web servers and servlet engines are readily available on the Internet. A guide for setting up SSL with Apache is available in the [MAP documentation](#).)

When a user logs in via their Web browser, the JSP interface passes this request to a back-end Java infrastructure that then uses an encrypted SSH connection to authenticate the user's credentials at the cluster/grid head node. After the credentials are authenticated and the SSH connection established, further communication between MAP and the cluster/grid head node occurs over the encrypted SSH connection. These three components provide an end-to-end security solution for Web-based job submission and workload management.

Appendix F: Initial Moab Testing

Moab has been designed with a number of key features that allow testing to occur in a *no risk* environment. These features allow you to safely run Moab in test mode even with another scheduler running whether it be an earlier version of Moab or another scheduler altogether. In test mode, Moab collects real-time job and node information from your resource managers and acts as if it were scheduling live. However, its ability to actually affect jobs (that is, start, modify, cancel, charge, and so forth) is disabled.

Moab offers the following test modes to provide a means for verifying such things as proper configuration and operation:

- [Minimal Configuration Required To Start](#)
 - [Normal Mode](#)
 - [Monitor Mode](#)
 - [Interactive Mode](#)
 - [Simulation Mode](#)

Scheduler Modes

Central to Moab testing is the **MODE** attribute of the [SCHEDCFG](#) parameter. This parameter attribute allows administrators to determine how Moab will run. The possible values for **MODE** are *NORMAL*, *MONITOR*, *INTERACTIVE*, and *SIMULATION*. For example, to request monitor mode operation, include the following in the `moab.cfg` file:

```
SCHEDCFG MODE=MONITOR
```

Normal Mode

If initial evaluation is complete or not required, you can place the scheduler directly into *production* by setting the **MODE** attribute of the **SCHEDCFG** parameter to *NORMAL* and (re)starting the scheduler.

Monitor Mode (or Test Mode)

Monitor mode allows evaluation of new Moab releases, configurations, and policies in a risk-free manner. In monitor mode, the scheduler connects to the resource manager(s) and obtains live resource and workload information. Using the policies specified in the `moab.cfg` file, the monitor-mode Moab behaves identical to a live or normal-mode Moab except the ability to start, cancel, or modify jobs is disabled. In addition, allocation management does not occur in monitor mode. This allows safe diagnosis of the scheduling state and behavior using the various diagnostic client commands. Further, the log output can also be evaluated to see if any unexpected situations have arisen. At any point, the scheduler can be dynamically changed from monitor to normal mode to begin *live* scheduling.

To set up Moab in monitor mode, do the following:

```
> vi moab.cfg
  (change the MODE attribute of the SCHEDCFG parameter from NORMAL to MONITOR)
> moab
```

Remember that Moab running in monitor mode will not interfere with your production scheduler.

Running Multiple Moab Instances Simultaneously

If running multiple instances of Moab, whether in simulation, normal, or monitor mode, make certain that each instance resides in a different home directory to prevent conflicts with configuration, log, and statistics files. Before starting each additional Moab, set the **MOABHOMEDIR** environment variable in the execution environment to point to the local home directory. Also, each instance of Moab should run using a different [port](#) to avoid conflicts.

i If running multiple versions of Moab, not just different Moab modes or configurations, set the `$PATH` variable to point to the appropriate Moab binaries.

To *point* Moab client commands (such as [showq](#)) to the proper Moab server, use the appropriate command line [arguments](#) or set the environment variable **MOABHOMEDIR** in the client execution environment as in the following example:

```
# point moab clients/server to new configuration
> export MOABHOMEDIR=/opt/moab-monitor
# set path to new binaries (optional)
> export PATH=/opt/moab-monitor/bin:/opt/moab-monitor/sbin:$PATH
# start Moab server
> moab
# query Moab server
> showq
```

i `moabd` is a safe and recommended method of starting Moab if things are not installed in their default locations.

Interactive Mode

Interactive mode allows for evaluation of new versions and configurations in a manner different from monitor mode. Instead of disabling all resource and job control functions, Moab sends the desired change request to the screen and asks for permission to complete it. For example, before starting a job, Moab may post something like the following to the screen:

```
Command:  start job 1139.ncsa.edu on node list test013,test017,test018,test021
Accept:   (y/n) [default: n]?
```

The administrator must specifically accept each command request after verifying that it correctly meets desired site policies. Moab will then execute the specified command. This mode is useful in validating scheduler behavior and can be used until configuration is appropriately tuned and all parties are comfortable with the scheduler's performance. In most cases, sites will want to set the scheduling mode to normal after verifying correct behavior.

Simulation Mode

Simulation mode is of value in performing a *test drive* of the scheduler or when a stable production system exists and an evaluation is desired of how various

policies can improve the current performance. See the Simulations documentation for more information.

Appendix G: Integrating Other Resources with Moab

Moab can interface with most popular resource managers, many cluster services, and numerous general protocols. The following links provide additional information.

Moab-TORQUE Integration Guide

- [Overview](#)
- [Integration Steps](#)
 - [Install TORQUE](#)
 - [Install Moab](#)
 - [Configure TORQUE](#)
 - [TORQUE/Moab Considerations](#)
- [Current Limitations](#)
- [Troubleshooting](#)

Install TORQUE

- Install TORQUE

i Keep track of the PBS target directory, `$PBSTARGDIR`

Install Moab

- Untar the Moab distribution file.
- Change the directory to the `moab-<version>` directory.
- Run `./configure`.
- Specify the PBS target directory (**\$PBSTARGDIR** from step 2.1) when queried by `./configure`.

Moab interfaces to PBS by utilizing a few PBS libraries and include files. If you have a non-standard PBS installation, you may need to modify `Makefile` and change **PBSIP** and **PBSLP** values and references as necessary for your local site configuration.

The `./configure` script automatically sets up Moab so that the user running `configure` will become the default Primary Moab Administrator (**\$MOABADMIN**). This can be changed by modifying the `ADMINCFG[1] USERS=<USERNAME>` line in the Moab configuration file (`moab.cfg`). The primary administrator is the first user listed in the **USERS** attribute and is the ID under which the Moab daemon runs.

Some Tru64 and IRIX systems have a local `libnet` library that conflicts with PBS's `libnet` library. To resolve this, try setting **PBSLIB** to `'${PBSLIBDIR}/libnet.a -lpbs'` in the Moab `Makefile`.

Moab is 64-bit compatible. If PBS/TORQUE is running in 64-bit mode, Moab likewise needs to be built in this manner to use the PBS scheduling API (i.e., for IRIX compilers, add `-64` to **OSCCFLAGS** and **OSLDLFLAGS** variables in the `Makefile`).

When starting both TORQUE and Moab it is best to have a small delay between starting the servers. In general (and especially for very fast or very large systems) this is recommended startup procedure:

- Start TORQUE.
- Start Moab with scheduling paused ([moab -P](#)) to give it a chance to load everything in the checkpoint file and to sync with TORQUE.
- Unpause Moab with [mschedctl -r](#).

General Configuration for All Versions of TORQUE

- Make \$MOABADMIN a PBS admin.
 - By default, Moab only communicates with the `pbs_server` daemons and the `$MOABADMIN` should be authorized to talk to this daemon (See [suggestions](#) for more information.).
- (OPTIONAL) Set default PBS queue, nodecount, and walltime attributes. (See [suggestions](#) for more information.)
- (OPTIONAL - TORQUE Only) Configure TORQUE to report completed job information by setting the `qmgr` **keep_completed** parameter: >

```
> qmgr -c 'set server keep_completed = 300'
```

i PBS nodes can be configured as *time shared* or *space shared* according to local needs. In almost all cases, space shared nodes provide the desired behavior.

i PBS/TORQUE supports the concept of virtual nodes. Using this feature, Moab can individually schedule processors on SMP nodes. The online [TORQUE](#) documentation describes how to set up the `$PBS_HOME/server_priv/nodes` file to enable this capability. (For example, `<NODENAME> np=<VIRTUAL NODE COUNT>`)

Version-Specific Configuration for [TORQUE](#)

Do not start the `pbs_sched` daemon. This is the default scheduler for TORQUE; Moab provides this service.

i Moab uses PBS's scheduling port to obtain real-time event information from PBS regarding job and node transitions. Leaving the default `qmgr` setting of `set server scheduling=True` allows Moab to receive and process this real-time information.

Configure Moab

By default, Moab automatically interfaces with TORQUE/PBS when it is installed. Consequently, in most cases, the following steps are not required:

- Specify PBS as the primary resource manager by setting **RMCFG** `[base] TYPE=PBS` in the Moab configuration file (`moab.cfg`).

If a non-standard PBS installation/configuration is being used, additional Moab parameters may be required to enable the Moab/PBS interface as in the line **RMCFG** `[base] HOST=$PBSSERVERHOST PORT=$PBSSERVERPORT`. See the [Resource Manager Overview](#) for more information.

i Moab's user interface port is set using the [SCHEDCFG](#) parameter and is used for user-scheduler communication. This port must be different from the PBS scheduler port used for resource manager-scheduler communication.

TORQUE/Moab Considerations

The default meaning of a node for TORQUE and Moab are not the same. By default, a node is a host in TORQUE. The node may have one or more execution slots (procs) allocated to it in the [\\$TORQUE_HOME/server_priv/nodes](#) file. However, the number of nodes recognized by TORQUE is equivalent to the number of node entries in the [\\$TORQUE_HOME/server_priv/nodes](#) file. A node specification from `qsub` such as `-l nodes=2:ppn=2` will direct TORQUE to allocate to execution slots on two separate nodes.

Moab is more liberal in its interpretations of a node. To Moab, the `qsub` request above would be interpreted to mean allocate four tasks with at least two tasks on a node. Where TORQUE would require two nodes for the request, Moab will place all four tasks on the name node (host) if four execution slots are available.

If a cluster has four nodes with eight processors each, TORQUE still sees only four nodes. Moab sees 32 nodes. However, if a user made a `qsub` request with `-l nodes=10`, TORQUE would reject the request because there are only four nodes available. To enable TORQUE to accommodate Moab's more liberal node interpretation, the server parameter [available_resources.nodect](#) can be set as a server parameter in TORQUE. The value of [available_resources.nodect](#) should equal at least the number of execution slots in the cluster.

For our example, cluster [available_resources.nodect](#) should be **32**. With this parameter set, the user can now make a request such as `-l nodes=8:ppn=2`. In this example, the user is still limited to a maximum node request of 32.

With [available_resources.nodect](#) set in TORQUE, Moab can be directed to honor the default TORQUE behavior by setting [JOBNODEMATCHPOLICY](#) to **EXACTNODE**.

PBS Features Not Supported by Moab

Moab supports basic scheduling of all PBS node specifications.

Moab Features Not Supported by PBS

PBS does not support the concept of a job QoS or other extended scheduling features by default. This can be handled using the techniques described in the [PBS Resource Manager Extensions](#) section. See the [Resource Manager Extensions Overview](#) for more information.

Troubleshooting

On TRU64 systems, the PBS `libpbs` library does not properly export a number of symbols required by Moab. This can be worked around by modifying the Moab `Makefile` to link the PBS `rm.o` object file directly into Moab.

TORQUE/PBS Integration Guide - RM Access Control

Server Configuration

Using the PBS [qmgr](#) command, add the Moab administrator as both a *manager* and *operator*.

```
> qmgr
Qmgr: set server managers += <MOABADMIN>@*.<YOURDOMAIN>
Qmgr: set server operators += <MOABADMIN>@*.<YOURDOMAIN>
Qmgr: quit
```

For example:

```
> qmgr
Qmgr: set server managers += staff@*.ucsd.edu
Qmgr: set operators += staff@*.ucsd.edu
Qmgr: quit
```

i If desired, the Moab administrator can be enabled as a manager and operator only on the host on which Moab is running by replacing "`*.<YOURDOMAIN>`" with "`<MOABSERVERHOSTNAME>`".

Mom Configuration (optional)

If direct Moab to `pbs_mom` communication is required, the `mom_priv/config` file on each compute node where `pbs_mom` runs should be set as in the following example:

```
$restricted *.<YOURDOMAIN>
$clienthost <MOABSERVERHOSTNAME>
```

i For security purposes, sites may want to run Moab under a non-root user id. If so, and Moab-`pbs_mom` communication is required, the `mom_priv/config` files must be world-readable and contain the line `'$restricted *.<YOURDOMAIN>'`. (i.e., `'$restricted *.uconn.edu'`)

TORQUE/PBS Config - Default Queue Settings

Default Queue

To set the default queue (the queue used by jobs if a queue is not explicitly specified by the user), issue the following:

```
>> qmgr
Qmgr: set system default_queue = <QUEUENAME>
Qmgr: quit
```

Queue Default Node and Walltime Attributes

To set a default of one node and 15 minutes of walltime for a particular queue, issue the following:

```
> qmgr
Qmgr: set queue <QUEUENAME> resources_default.nodect = 1
Qmgr: set queue <QUEUENAME> resources_default.walltime = 00:15:00
Qmgr: quit
```

Default System Wide Node and Walltime Attributes

To set system wide defaults, set the following:

```
> qmgr
Qmgr: set server resources_default.nodect = 1
Qmgr: set server resources_default.walltime = 00:15:00
Qmgr: quit
```

Moab-SLURM Integration Guide

- [Overview](#)
- [SLURM Configuration Steps](#)
- [Moab Configuration Steps](#)
 - [Configuration for Standby and Expedite](#)
 - [Configuration for the Quadrics Switch](#)
 - [Authentication](#)
 - [Queue/Class Support](#)
 - [Policies](#)
 - [Moab Queue and RM Emulation](#)
 - [SLURM High Availability](#)

Overview

Moab can be used as the scheduler for the [SLURM](#) resource manager. In this configuration, the SLURM handles the job queue and the compute resources while Moab determines when, where and how jobs should be executed according to current cluster state and site mission objectives.

The documentation below describes how to configure Moab to interface with SLURM.

i For Moab-SLURM integration, Moab 6.0 or higher and SLURM 2.2 or higher are recommended. From the [downloads](#) page, the generic version is needed to install SLURM.

SLURM Configuration Steps

To configure SLURM to utilize Moab as the scheduler, the **SchedulerType** parameters must be set in the `slurm.conf` config file located in the SLURM `etc` directory (`/usr/local/etc` by default)

```
# slurm.conf
SchedulerType=sched/wiki2
```

The **SchedulerType** parameter controls the communication protocol used between Moab and SLURM. This interface can be customized using the [wiki.conf](#) configuration file located in the same directory and further documented in the SLURM [Admin Manual](#).

Note: To allow sharing of nodes, the SLURM partition should be configured with 'Shared=yes' attribute.

Moab Configuration Steps

By default, Moab is built with WIKI interface support (which is used to interface with SLURM) when running the standard `configure` and `make` process.

To configure Moab to use SLURM, the parameter '**RMCFG**' should be set to use the **WIKI:SLURM** protocol as in the example below.

```
# moab.cfg

SCHEDCFG[base] MODE=NORMAL
RMCFG[base] TYPE=WIKI:SLURM
...
```

Note: The **RMCFG** index (set to *base* in the example above) can be any value chosen by the site. Also, if SLURM is running on a node other than the one on which Moab is running, then the **SERVER** attribute of the **RMCFG** parameter should be set.

Note: SLURM possesses a **SchedulerPort** parameter which is used to communicate with the scheduler. Moab will auto-detect this port and communicate with SLURM automatically with no explicit configuration required. Do NOT set Moab's **SCHEDCFG[] PORT** attribute to this value, this port controls Moab client communication and setting it to match the **SchedulerPort** value will cause conflicts. With no changes, the default configuration will work fine.

Note: If the SLURM client commands/executables are not available on the machine running Moab, SLURM partition and other certain configuration information will not be automatically imported from SLURM, thereby requiring

a manual setup of this information in Moab. In addition, the SLURM [VERSION](#) should be set as an attribute on the [RMCFG](#) parameter. If it is not set, the default is version 1.2.0. The following example shows how to set this line if SLURM v1.1.24 is running on a host named Node01 (set using the [SERVER](#) attribute).

```
# moab.cfg with SLURM on Host Node01

RMCFG[base] TYPE=WIKI:SLURM SERVER=Node01 VERSION=10124
...
```

Configuration for Standby and Expedite Support

SLURM's 'Standby' and 'Expedite' options are mapped to the Moab [QoS](#) feature. By default, when a SLURM interface is detected, Moab will automatically create a 'standby' and an 'expedite' QoS. By default, the 'standby' QoS will be globally accessible to all users and on all nodes and will have a lower than normal priority. Also by default, the 'expedite' QoS will not be accessible by any user, will have no node constraints, and will have a higher than normal priority.

Authorizing Users to Use 'Expedite'

To allow users to request 'expedite' jobs, the user will need to be added to the 'expedite' QoS. This can be accomplished using the [MEMBERLIST](#) attribute as in the following example:

```
MEMBERLIST

# allow josh, steve, and user c1443 to submit 'expedite' jobs
QOSCFG[expedite] MEMBERLIST=josh,steve,c1443
...
```

Excluding Nodes for 'Expedite' and 'Standby' Usage

Both 'expedite' and 'standby' jobs can be independently excluded from certain nodes by creating a QoS-based [standing reservation](#).

Specifically, this is accomplished by creating a reservation with a logical-*not* QoS ACL and a hostlist indicating which nodes are to be exempted as in the following example:

```
MEMBERLIST

# block expedite jobs from reserved nodes
SRCFG[expedite-blocker] QOSLIST=!expedite
SRCFG[expedite-blocker] HOSTLIST=c001[3-7],c200
SRCFG[expedite-blocker] PERIOD=INFINITY

# block standby jobs from rack 13
SRCFG[standby-blocker] QOSLIST=!standby
SRCFG[standby-blocker] HOSTLIST=R:r13-[0-13]
SRCFG[standby-blocker] PERIOD=INFINITY
...
```

Quadrics Integration

If managing a cluster with a Quadrics high speed network, significant performance improvement can be obtained by instructing Moab to allocate contiguous collections of nodes. This can be accomplished by setting the [NODEALLOCATIONPOLICY](#) parameter to *CONTIGUOUS* as in the example below:

```
# moab.cfg
SCHEDCFG[cluster1]  MODE=NORMAL SERVER=head.cluster1.org
RMCFG[slurm]        TYPE=wiki:slurm
NODEALLOCATIONPOLICY CONTIGUOUS
...
```

Setting Up Authentication

By default, Moab will not require server authentication. However, if SLURM's `wiki.conf` file (default location is `/usr/local/etc`) contains the **AuthKey** parameter or a secret key is specified via SLURM's `configure` using the `--with-key` option, Moab must be configured to honor this setting. Moab configuration is specified by setting the resource manager **AUTHTYPE** attribute to *CHECKSUM* and the **KEY** value in the [moab-private.cfg](#) file to the secret key as in the example below.

```
# /usr/local/etc/wiki.conf
AuthKey=4322953
...
```

```
# moab.cfg
RMCFG[slurm]          TYPE=wiki:slurm AUTHTYPE=CHECKSUM
...
```

```
# moab-private.cfg
CLIENTCFG[RM:slurm]  KEY=4322953
...
```

Note: For the *CHECKSUM* authorization method, the key value specified in the `moab-private.cfg` file must be a decimal, octal, or hexadecimal value, it cannot be an arbitrary non-numeric string.

Queue/Class Support

While SLURM supports the concept of classes and queues, Moab provides a flexible alternative queue interface system. In most cases, sites can create and manage queues by defining partitions within SLURM. Internally, these SLURM partitions are mapped to Moab [classes](#) which can then be managed and configured using Moab's [CLASSCFG](#) parameter and [mdia -c](#) command.

Policies

By default, SLURM systems only allow tasks from a single job to utilize the resources of a compute node. Consequently, when a SLURM interface is detected, Moab will automatically set the [NODEACCESSPOLICY](#) parameter to *SINGLEJOB*. To allow node sharing, the SLURM partition attribute '**Shared**' should be set to *FORCE* in the `slurm.conf` as in the example below:

```
# slurm.conf

PartitionName=batch Nodes=node[1-64] Default=YES MaxTime=INFINITE State=UP
Shared=FORCE
```

Moab Queue and RM Emulation

With a SLURM system, jobs can be submitted either to SLURM or to Moab. If submitted to SLURM, the standard SLURM job submission language must be used. If jobs are submitted to Moab using the [msub](#) command, then either LSF*, PBS, or Loadleveler* job submission syntax can be used. These jobs will be translated by Moab and migrated to SLURM using its native job language.

SLURM High Availability

If SLURM high availability mode is enabled, Moab will automatically detect the presence of the SLURM BackupController and utilize it if the primary fails. To verify SLURM is properly configured, issue the SLURM command '`scontrol show config | grep Backup`'. To verify Moab properly detects this information, run '`mdiag -R -v | grep FallBack`'.

Note: To use SLURM high availability, the SLURM parameter **StateSaveLocation** must point to a shared directory which is readable and writable by both the primary and backup hosts. See the `slurm.conf` man page for additional information.

Installation Notes for Moab and TORQUE for Cray

Overview

Moab and TORQUE can be used to manage the batch system for Cray. This document describes how to configure Moab and TORQUE to bring Moab's unmatched scheduling capabilities to the Cray.

New to TORQUE 4.1, TORQUE now handles all communication with ALPS, specifically the `pbs_mom`. Previously, communication with ALPS was handled

by a combination of Moab, scripts and TORQUE. In the new model, Moab treats TORQUE as a regular TORQUE cluster without any special configuration. TORQUE now uses an extra MOM called the `alps_reporter` MOM to communicate with ALPS regarding configured and available resources. From the information reported by the `alps_reporter` mom, TORQUE creates a virtual node for each Cray compute node. Previously, TORQUE only reported the login nodes.

Note: For clarity this document assumes that your SDB node is mounting a persistent `/var` filesystem from the bootnode. If you have chosen not to use persistent `/var` filesystems please be aware that the instructions below would have to be modified for your situation.

Upgrade Notes

When upgrading to TORQUE 4.1.0 and using the new Cray model as described in this document, there should be no running jobs. Jobs may be queued but not running.

Installing TORQUE on a Cray

i These instructions are written for a partitioned system, with separate SDB and boot nodes. A combined SDB/boot node configuration is not supported.

For non-partitioned systems, change `sdb-p1` to `sdb` in these instructions.

Before beginning, note the SDB and login nodes' IDs as you will need them throughout the install process.

```
crayadm@smw> ssh root@boot-p1
boot# grep sdb /etc/hosts
10.128.0.32      nid00031      c0-0c0s0n3      sdb001  sdb002
10.131.255.253 sdb sdb-p1 syslog syslog-p1 ufs ufs-p1
```

```
boot# grep login /etc/hosts
10.128.0.3      nid00002      c0-0c0s1n0      login   login-p1      login1  castor-p1
```

In this example, and throughout this page, the login node has NID 2 and the SDB has NID 31.

1. Copy Moab/TORQUE software to SMW and boot node

```
workstation> scp -p /cray/css/release/cray/build/batch/moab-
torque/torque.<version>.tar.gz crayadm@smw:/home/crayadm/<yourusername>
workstation> scp -p /cray/css/release/cray/build/batch/moab-torque/moab-<version>-
SUSE11-linux-x86_64-torque.tar.gz crayadm@smw:/home/crayadm/<yourusername>

crayadm@smw> cd /home/crayadm//<yourusername>
crayadm@smw> scp -p torque-<version>.tar.gz root@boot-p1:/rr/current/software
crayadm@smw> scp -p moab-<version>-SUSE11-linux-x86_64-torque.tar.gz root@boot-
p1:/rr/current/software
```

2. Install TORQUE. SSH to the boot node and unpack the TORQUE tarball within `xtopview`.

```
crayadm@smw> ssh root@boot-p1
boot# xtopview -m "Installing TORQUE"
default:/# cd /software/
default:/# tar -zxvf torque-<version>.tar.gz

(or, if installing on an esMS)
esms# cd /path/to/software/
esms# tar -zxvf torque-<version>.tar.gz
```

3. Configure, build, and install TORQUE within `xtopview`.

```
default:/# cd torque-<version>
default:/# ./configure --prefix=/opt/torque/<version> --with-server-
home=/var/spool/torque --with-default-server=sdb-p1 --enable-syslog --disable-gcc-
warnings --with-debug --with-modulefiles=/opt/modulefiles --with-job-create
CFLAGS="-DCRAY_MOAB_PASSTHRU"

(or, if installing on an esMS)
esms# cd /path/to/software/torque-<version>
esms# ./configure --prefix=/opt/torque/<version> --with-server-
home=/var/spool/torque --with-default-server=this-esms --enable-syslog --disable-
gcc-warnings --with-debug --with-modulefiles=/cm/local/modulefiles CFLAGS="-DCRAY_
MOAB_PASSTHRU"
```

The server name in the example is `sdb-p1`. Change this to `sdb` on a non-partitioned system.

4. Make and install TORQUE.

```
default:/# make
default:/# make packages
default:/# make install
default:/# ln -sf /opt/torque/<version> /opt/torque/default # The previous
default symlink might need to be deleted first if it exists
default:/# exit
```

5. Copy the TORQUE server directory to the Moab server host.

```
boot# cd /rr/current/var/spool
boot# cp -pr torque /snv/31/var/spool
boot# cp -pr torque /snv/2/var/spool
```

In this example, the SDB node has NID 31, and the login node NID 2.

6. Set up TORQUE on the SDB node.

```

boot# ssh sdb-pl
sdb# export PATH=/opt/torque/default/sbin:/opt/torque/default/bin:$PATH
sdb# cd /software/torque-5.1.0
sdb# ./torque.setup root
root
pbs_server port is: 15001
trqauthd daemonized - port 15005
trqauthd successfully started
initializing TORQUE (admin: root@boot)

You have selected to start pbs_server in create mode.
If the server database exists it will be overwritten.
do you wish to continue y/(n)?

# Type y

sdb# qmgr
Qmgr: set server keep_completed = 60 # Number of seconds to keep completed jobs in
qstat
unset queue batch resources_default.nodes
set server acl_host_enable = true
set server acl_hosts += nid00002
set server acl_hosts += castor-pl # Where castor-pl is the hostname of the login
node
set server acl_hosts += sdb-pl
set server submit_hosts += login
set server submit_hosts += login-pl # Only needed on partitioned systems
set server submit_hosts += castor-pl # Where castor-pl is the hostname of the login
node
set server submit_hosts += nid00002 # Where nid00002 is the NID of the login node
set server tcp_timeout = 30
set server query_other_jobs = True
set server disable_server_id_check = True
set queue batch resources_default.mppnppn=16 # On Cascade systems with aprun -jl
set as default
set server cray_enabled = True
set server resources_default.partition = castor # Where "castor" is the same as the
RMCFG[clustername] in moab.cfg
exit

```

7. Get the number of nodes available on the system.

```
sdb# echo Node count is $(( $(apstat -v | grep XT | awk '{print $3}') ))
```

In the *nodes* / *nodect* commands, put in your system's number of nodes.

```

sdb# qmgr
set server resources_available.nodes = 20
set server resources_available.nodect = 20
set queue batch resources_available.nodes = 20
set queue batch resources_available.nodect = 20
exit

```

8. Create TORQUE nodes file.

```
sdb# vi /var/spool/torque/server_priv/nodes  
  
    castor-pl alps_login np=1000 # Where "castor-pl" is the hostname of your login  
    node  
    sdb-pl alps_reporter  
  
sdb# exit
```

The `np` attribute is the number of processes that can be running at once. This number should be set appropriately high, depending on the number of nodes on the system.

9. Install the `torque_server` `init.d` script on the SDB node.

i There is a known issue with some of the init scripts included with TORQUE. If the included init script doesn't work for you, use the process below to create a workaround `torque_server` `init.d` script for your system.

```

boot# xtopview -n 31 -m "torque_server init.d"
node/31:/ # touch /etc/init.d/torque_server
node/31:/ # xtspec -n 31 /etc/init.d/torque_server
node/31:/ # chmod a+x /etc/init.d/torque_server
node/31:/ # vi /etc/init.d/torque_server

#!/bin/sh
#
# pbs_server      This script will start and stop the PBS Server
#
### BEGIN INIT INFO
# Provides:      pbs_server
# Required-Start: $local_fs network
# Should-Start:
# Required-Stop:
# Should-Stop:
# Default-Start: 2 3 5
# Default-Stop:
# Description: Torque is a versatile batch system for SMPs and clusters
### END INIT INFO

PBS_DAEMON=/opt/torque/default/sbin/pbs_server
PBS_HOME=/var/spool/torque
PIDFILE=$PBS_HOME/server_priv/server.lock
export PBS_DAEMON PBS_HOME PIDFILE

# Source the library functions
. /etc/rc.status
rc_reset

[ -f /etc/sysconfig/pbs_server ] && . /etc/sysconfig/pbs_server
[ -x $PBS_DAEMON ] || exit

# How were we called
case "$1" in
    start)
        echo -n "Starting TORQUE Server: "
        ulimit -c unlimited
        if [ -r $PBS_HOME/server_priv/serverdb ]
        then
            startproc $PBS_DAEMON $SERVER_ARGS
        else
            startproc $PBS_DAEMON -t create $DAEMON_ARGS
        fi
        rc_status -v
        ;;
    stop)
        echo -n "Shutting down TORQUE Server: "
        killproc -p $PIDFILE $PBS_DAEMON
        rc_status -v
        ;;
    status)
        echo -n "Checking TORQUE Server: "
        checkproc -p $PIDFILE pbs_server
        rc_status -v
        ;;
    restart)
        $0 stop

```

```

        $0 start
        rc_status
        ;;
    try-restart)
        $0 status >/dev/null && $0 restart
        rc_status
        ;;
    reload|force-reload)
        echo -n "Reloading TORQUE Server: "
        killproc -p $PIDFILE pbs_server -HUP
        rc_status -v
        ;;
    *)
        echo "Usage: torque_server {start|stop|status|try-
restart|restart|force-reload|reload}"
        exit 1
    esac
rc_exit

```

10. Install the `torque_mom` `init.d` script on the SDB (or other node that runs the `alps_reporter` service for TORQUE) and login nodes.

i There is a known issue with some of the init scripts included with TORQUE. If the included init script doesn't work for you, use the process below to create a workaround `torque_mom` `init.d` script for your system.

Example 3-186: SDB node

```

boot# xtopview -n 31 -m "torque_mom init.d"
node/31:/ # touch /etc/init.d/torque_mom
node/31:/ # xtspec -n 31 /etc/init.d/torque_mom
node/31:/ # chmod +x /etc/init.d/torque_mom
node/31:/ # vi /etc/init.d/torque_mom

#!/bin/sh
#
# pbs_mom          This script will start and stop the PBS Mom
#
### BEGIN INIT INFO
# Provides:        pbs_mom
# Required-Start:  $local_fs
# Should-Start:    pbs_server pbs_sched
# Required-Stop:
# Should-Stop:
# Default-Start:   2 3 5
# Default-Stop:
# Description:     Torque is a versatile batch system for SMPs and clusters
### END INIT INFO

PBS_DAEMON=/opt/torque/default/sbin/pbs_mom
PBS_HOME=/var/spool/torque
PIDFILE=$PBS_HOME/mom_priv/mom.lock
export PBS_DAEMON PBS_HOME PIDFILE

ulimit -n 32768
# Source the library functions
. /etc/rc.status
rc_reset

[ -f /etc/sysconfig/pbs_mom ] && . /etc/sysconfig/pbs_mom
[ -x $PBS_DAEMON ] || exit

args=""
if [ -z "$PREVLEVEL" ];then
# being run manually, don't disturb jobs
args="-p"
fi

# How were we called
case "$1" in
    start)
        echo -n "Starting TORQUE Mom: "
        #ulimit -c unlimited
        /sbin/startproc $PBS_DAEMON $args $DAEMON_ARGS
        rc_status -v
        ;;
    purge)
        [ -f /var/lock/subsys/pbs_mom ] && $0 stop
        echo -n "Starting TORQUE Mom with purge: "
        startproc $PBS_DAEMON -r $DAEMON_ARGS
        rc_status -v
        ;;
    stop)
        echo -n "Shutting down TORQUE Mom: "
        /sbin/killproc -p $PIDFILE $PBS_DAEMON
        rc_status -v
        ;;

```

```

status)
    echo -n "Checking TORQUE Mom: "
    checkproc -p $PIDFILE $PBS_DAEMON
    rc_status -v
    ;;
restart)
    $0 stop
    sleep 1
    $0 start -p
    rc_status
    ;;
try-restart)
    $0 status >/dev/null && $0 restart
    rc_status
    ;;
reload|force-reload)
    echo -n "Re-reading TORQUE Mom config file: "
    killproc -p $PIDFILE -HUP pbs_mom
    rc_status -v
    ;;
*)
    echo "Usage: torque_mom {start|stop|status|try-restart|restart|force-
reload|reload|purge}"
    exit 1
esac

```

Example 3-187: Login nodes

```

boot# xtopview -c login -m "torque_mom init.d"
class/login:/ # touch /etc/init.d/torque_mom
class/login:/ # xtspec -c login /etc/init.d/torque_mom
class/login:/ # chmod +x /etc/init.d/torque_mom
class/login:/ # vi /etc/init.d/torque_mom

# Use the same script as the SDB node above

```

11. Create the MOM configuration file. This must be done on every login node and also the `alps_reporter` node (typically the SDB) specified in the TORQUE `server_priv/nodes` file.

- a. First, determine if the ALPS path needs to be configured in the MOM configuration file.

```

login# which apbasil
/usr/bin/apbasil
# No configuration change needed

login# which apbasil
/opt/cray/alps/5.0.2-2.0500.7827.1.1.ari/bin/apbasil
# MOM configuration change is needed. This path needs to be declared in the mom_
priv/config file.

```

- b. Create and populate the MOM configuration file on the nodes.

```
login and sdb# vi /var/spool/torque/mom_priv/config

$usecp */ufs /ufs
$usecp */home /home
$usecp */home/users /home/users
$usecp */scratch /scratch
$usecp */lus /lus
$usecp */extlus /extlus
$login_node true # For login node
$reporter_mom true # For SDB node
$apbasil_protocol 1.2
$prologalarm 120
$apbasil_path /opt/cray/alps/default/bin/apbasil # Only if needed. Use the path
discovered above.
```

- c. If needed, you can add CPR information to the MOM configuration on the login nodes .

```
$checkpoint_run_exe /opt/cray/blcr/default/bin/cr_run
$checkpoint_script /opt/cray/cprbatchutils/default/libexec/checkpoint.torque
$restart_script /opt/cray/cprbatchutils/default/libexec/restart.torque
$remote_checkpoint_dirs /lus/scratch/BLCR_checkpoint_dir
```

12. Create the `torque.cfg` file (useful if having issues with LDAP users submitting jobs) on the SDB node.

```
sdb# vi /var/spool/torque/torque.cfg
```

```
QSUBSENDUID true
VALIDATEPATH FALSE
```

13. Install the `trqauthd` init.d script on the SDB and login nodes.

```
boot# xtopview -n <SDB or login> -m "trqauthd"
node/<SDB or login>:/ # cp /software/torque-5.1.0/contrib/init.d/suse.trqauthd
/etc/init.d/trqauthd
node/<SDB or login>:/ # chmod +x /etc/init.d/trqauthd
node/<SDB or login>:/ # vi /etc/init.d/trqauthd

PBS_DAEMON=/opt/torque/default/sbin/trqauthd
```

14. Start the `trqauth` daemon on the SDB and login nodes.

```
<SDB or login># /etc/init.d/trqauthd start
```

Enabling Node Features for Cray Compute Nodes

Node features can be set for Cray compute nodes. To add node features to a Cray compute node, use the `cray_compute` keyword on designated nodes in the `nodes` file.:

```
# node_id cray_compute feature_name
2 cray_compute bigmem
```

Configuring TORQUE for ALPS 1.3

To configure TORQUE for ALPS 1.3, configure the `apbasil_protocol` parameter in `mom_priv/config` and set the `nppcu` server parameter. The `nppcu` parameter has three options that determine whether to use Hyper-Threading:

Table 3-6: `nppcu` values

Value	Description
0	Allow ALPS to choose
1	Hyper-Threading disabled (default)
2	Hyper-Threading enabled

When `nppcu` is set to **0** or **2**, `pbs_nodes` reports twice as many cores.

`apbasil_protocol:`

```
$apbasil_protocol 1.3
$loglevel 3
```

`nppcu:`

```
qmgr -c 'set server nppcu=1'
```

Installing Moab Workload Manager

1. Unpack the Moab tarball within `xtopview`.

```
boot# xtopview -m "Installing Moab"
default://# cd /software/
default://# tar -zxvf moab-<version>-linux-x86_64-torque-xt4.tar.gz
default://# cd moab-<version>
```

2. Configure, build, and install Moab within `xtopview`.

```
default/./# ./configure --prefix=/opt/moab/<version> --with-homedir=/var/spool/moab
--with-torque=/opt/torque/default --with-modulefiles=/opt/modulefiles --with-xt4

(or, if installing on an esMS)
default/./# ./configure --prefix=/opt/moab/<version> --with-homedir=/var/spool/moab
--with-torque=/opt/torque/default --with-modulefiles=/cm/local/modulefiles --with-
xt4

default/./# make install
default/./# ln -sf /opt/moab/<version> /opt/moab/default # The previous default
symlink may need to be deleted first if it exists
default/./# exit
```

3. Configure the `moab.cfg` file.

```

boot# cd /rr/current/var/spool/moab/etc
boot# vi moab.cfg

    Change the value of SCHEDCFG[Moab] to SERVER=sdb-pl:42559 # Leave the port
    number as whatever default is present
    Change ADMINCFG[1] USERS=root to USERS=root,crayadm # Where "crayadm" is the
    administrative user
    If applicable, change TOOLSDIR from /opt/moab/8.1.0/tools to
    /opt/moab/default/tools

    Change RMCFG[boot]      TYPE=PBS to
    RMCFG[castor]    TYPE=TORQUE # "castor" can be any logical name for the
    partition

    For Moab version 6.x, use TYPE=NATIVE:XT4

    Example:
    RMCFG[tuna]  TYPE=TORQUE SUBMITCMD=/opt/torque/default/bin/qsub
    FLAGS=asyncstart

    Add:
    RMPOLLINTERVAL      00:00:10
    DEFERTIME           00:05:00
    JOBNODEMATCHPOLICY  EXACTNODE
    NODECFG[DEFAULT]    OS=linux ARCH=XT
    NODEACCESSPOLICY    SINGLEJOB
    JOBMIGRATEPOLICY    IMMEDIATE
    NODEALLOCATIONPOLICY PRIORITY
    NODECFG[DEFAULT]    PRIORITYF='PRIORITY'
    NODECFG[castor-pl]  Partition=login # Use a logical name such as "login" to
    keep the MOM nodes in a separate
                                # partition from the compute nodes
                                # "castor-pl" in this case is the hostname
of the login node
    CLIENTCFG[DEFAULT]  DEFAULTSUBMITPARTITION=castor # Where "castor" is the name
of the partition (see RMCFG[castor] above)
    JOBMAXTASKCOUNT    <total number of processors>

    # Comment out USEDATABASE    INTERNAL

    # If using a re-purposed compute node as the alps_reporter MOM, add:
    NODECFG[nid00060]    Partition=login # Where nid00060 is the nid of the RCN

    # If necessary to ignore nodes (such as 24 core nodes on a primarily 32 core
    system), add:
    IGNORENODES    57,58 # Where "57" and "58" are node hostnames

```

4. Configure the config.xt4.pl file.

```
boot# vi config.xt4.pl

$basilProtocol = "1.2";

# Uncomment the %loginReplaceTable line, and update the hostnames:
%loginReplaceTable = (nid00002 => "login-p1"); # Where "login-p1" is the exact
hostname of the login node, for example, "castor-p3"

# Uncomment:
$topologyOrdering = 1;

# If on a system that has undergone ALPS standardization (See the apbasil notes
above), replace the $torquePath line with:
my $torquePath = "/opt/torque/default/bin:/usr/bin:/opt/cray/alps/default/bin";
```

5. Copy Moab to the SDB node.

```
boot# cd /rr/current/var/spool/
boot# cp -pr moab /snv/31/var/spool/

For Moab version 6.x only:
boot# mv /snv/31/var/spool/moab/etc/moab.cfg /snv/31/var/spool/moab/

For all versions:
boot# mkdir -p /snv/2/var/spool/moab/etc /snv/2/var/spool/moab/log
boot# cp moab/etc/moab.cfg /snv/2/var/spool/moab/etc/
boot# cp moab/etc/config.xt4.pl /snv/2/var/spool/moab/etc/
```

6. Install the moab init.d script

i There is a known issue with some of the init scripts included with Moab. If the included init script doesn't work for you, use the process below to create a workaround `moab` init.d script for your system.

```

boot# xtopview -n 31 -m "Moab init.d"
node/31:/ # touch /etc/init.d/moab
node/31:/ # xtspec -n 31 /etc/init.d/moab
node/31:/ # chmod a+x /etc/init.d/moab
node/31:/ # vi /etc/init.d/moab
#!/bin/bash
#
# Starts the Moab daemon
#
# chkconfig: 345 96 6
# description: Moab Workload Manager
# processname: moab
#
### BEGIN INIT INFO

# Required-Stop: $local_fs $syslog $network $named
# Default-Start: 3 5
# Default-Stop: 0 1 2 6
# Short-Description: Moab daemon management
# Description: Start Moab Workload Manager
### END INIT INFO
#
# 1. This file should be installed as /etc/init.d/moab
#
# 2. Start Moab with:
#
#     /etc/init.d/moab start
#
# Source function library.
[ -f /etc/rc.status ] || exit 0
. /etc/rc.status

export MOABHOMEDIR=/var/spool/moab
export MOABPARCLEANUP=Full
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/torque/default/lib

prog=moab
path=/opt/moab/default/sbin
RETVAL=0

function start()
{
    echo -n "Starting $prog: "
    ulimit -s unlimited    # Increase stack size to unlimited
    ulimit -c unlimited    # Uncomment to preserve core files

    export MOABNOALLOCMASTER=1
    sleep 2
    startproc $path/moab

    RETVAL=$?
    echo
    [ $RETVAL -eq 0 ] && touch /var/lock/subsys/moab
    return $RETVAL
}

```

```

function stop()
{
    echo -n "Shutting down $prog: "
    killproc moab
    RETVAL=$?
    echo
    [ $RETVAL -eq 0 ] && rm -f /var/lock/subsys/moab
    return $RETVAL
}

function restart()
{
    stop
    sleep 2
    start
}

function condrestart()
{
    if [ -f /var/lock/subsys/capi ] ; then
        restart
    fi
}

function reload()
{
    echo -n $"Reloading $prog: "
    schedctl -R
    RETVAL=$?
    echo
    return $RETVAL
}

case "$1" in
    start)
        start
        rc_status -v
        ;;
    status)
        status moab
        RETVAL=$?
        rc_status -v
        ;;
    stop)
        stop
        rc_status -v
        ;;
    restart)
        restart
        rc_status -v
        ;;
    condrestart)
        condrestart
        ;;
    reload)
        reload
        rc_status -v
        ;;
    *)

```

```

        echo "Usage: $prog {start|stop|restart|reload|status|condrestart}"
        exit 1
    esac

    exit $RETVAL

```

7. For versions of Moab earlier than 7.1.3 and TORQUE 4.1.4, root must be allowed to submit jobs.

```

boot# ssh sdb
sdb# module load moab torque
sdb# qmgr
qmgr> set server acl_roots = root
qmgr> exit
sdb# /etc/init.d/torque_server restart

sdb# vi /var/spool/moab/etc/moab.cfg # or /var/spool/moab/moab.cfg for Moab version
6

Add
ALLOWROOTJOBS TRUE

sdb# /etc/init.d/moab restart
or
sdb# mschedctl -R

```

8. For versions of Moab newer than 7.1.3, the root user can submit jobs as another user.

```

sdb# qmgr
qmgr> set server managers += root@*
qmgr> exit

sdb# ssh login

login# qsub -I -l mppwidth=1 -P <otherusername>

```

9. Copy your Moab license file to the SDB node in the `/var/spool/moab/` directory.

Provisioning Resource Managers

Validating an xCAT Installation for Use with Moab

- [Introduction to Validating xCAT Configuration](#)
- [Verifying Node List](#)
- [Reporting Node Status](#)
- [Verifying Hardware Management Configuration](#)
- [Verifying Provisioning Images](#)
- [Verifying VM Migration](#)

Introduction to Validating xCAT Configuration

This document describes a series of steps to validate xCAT configuration prior to configuring Moab to manage hardware via xCAT. It is assumed the reader is familiar with xCAT and the xCAT configuration on the target site. This document does not provide xCAT configuration documentation or troubleshooting information; please refer to the [xCAT documentation](#) for such information.

Verifying Node List

Verify that all nodes that Moab will manage are known to xCAT with the xCAT `nodes` command. Ensure that all expected (and no unexpected) nodes are listed. You may find it useful to create new group names to identify Moab-managed nodes.

```
[root@h0 moab]# nodes hyper,compute
h1
h2
h3
h4
h5
h7
kvmm1
kvmm10
kvmm2
kvmm3
kvmm4
kvmm5
kvmm6
kvmm7
kvmm8
[root@h0 moab]#
```

Reporting Node Status

Verify that all nodes report their status correctly using the xCAT `nodestat` command. Ensure that all nodes show the correct status (`sshd`, `installing`, `noping`, and so forth); there should not be any timeouts or error messages.

```
[root@h0 moab]# nodestat hyper,compute |sort
h1: pbs,sshd
h2: pbs,sshd
h3: pbs,sshd
h4: pbs,sshd
h5: pbs,sshd
h7: noping
kvmm10: noping
kvmm1: pbs,sshd
kvmm2: pbs,sshd
kvmm3: pbs,sshd
kvmm4: pbs,sshd
kvmm5: pbs,sshd
kvmm6: pbs,sshd
kvmm7: pbs,sshd
kvmm8: noping
kvmm9: noping
[root@h0 moab]#
```

Verifying Hardware Management Configuration

Verify that all nodes that Moab will manage have hardware management interfaces correctly configured using the xCAT `nodehs` and `rpowers` commands. After each of the `rpowers` commands, verify the requested state was achieved with `rpowers stat`.

```
[root@h0 moab]# nodehs h1,kvmm1 nodehm.mgt nodehm.power
h1: nodehm.power: ilo
h1: nodehm.mgt: ilo
kvmm1: nodehm.power: kvm
kvmm1: nodehm.mgt: kvm
[root@h0 moab]# rpowers h1,kvmm1 off
h1: off
kvmm1: off
[root@h0 moab]# rpowers h1,kvmm1 stat
h1: off
kvmm1: off
[root@h0 moab]# rpowers h1,kvmm1 boot
h1: on reset
kvmm1: on reset
[root@h0 moab]# rpowers h1,kvmm1 stat
h1: on
kvmm1: on
[root@h0 moab]#
```

Verifying Provisioning Images

Verify that all operating system images that Moab uses are configured correctly in xCAT. For stateful images, test that all combinations of operating system, architecture, and profile install correctly.

```
[root@h0 moab]# rinstall -o centos5.3 -a x86_64 -p hyper h1
h1: install centos3.2-x86_64-hyper
h1: on reset
[root@n100 ~]# sleep 15 && nodestat n05
n05: ping install centos5.3-x86_64-hyper
[root@h0 moab]#
```

For stateless images, test that nodes are able to network boot the images.

```
[root@h0 moab]# nodech h5 nodetype.os=centos5.3 nodetype.arch=x86_64
nodetype.profile=hyper
[root@h0 moab]# nodeset h5 netboot
h5: netboot centos5.3-x86_64-hyper
[root@h0 moab]# rpowers h5 boot
h5: on reset
[root@h0 moab]# sleep 60 && nodestat h5
h5: pbs, sshd
[root@h0 moab]#
```

Verifying VM Migration

If you use VM migration, verify that xCAT can successfully perform migrations using the `rmigrate` command.

```
[root@h0 moab]# rmigrate kvmm7 h1
kvmm7: migrated to h1
[root@h0 moab]# ssh h1 virsh list
Id Name State
-----
33 kvmm1 running
34 kvmm2 running
35 kvmm7 running
```

Hardware Integration

- [Moab-NUMA Integration Guide](#) on page 1406

Moab-NUMA Integration Guide

Scheduling a shared-memory NUMA type system (not the same as a modern SMP-based individual compute node, which cannot share memory between compute nodes) requires some special configuration. Additionally, Moab can use [NODESETS](#) to guarantee feasibility of large memory jobs and to enforce node allocation based on the system's interconnect network topology.

Configuration

To integrate Moab and NUMA

1. Configure Moab to schedule large memory jobs. Because Moab creates a partition for each resource manager by default, you must configure the cluster controlled by the resource manager to be a shared-memory system to support jobs spanning multiple nodes/blades. To do so, use the [PARCFG](#) parameter.

```
RMCFG[sys-uv] TYPE=TORQUE
PARCFG[sys-uv] FLAGS=SharedMem
```

Cluster `sys-uv` is now configured as a shared-memory system to Moab.

2. Configure **NODESETS** as shown below.

```
NODESETISOPTIONAL FALSE
NODESETATTRIBUTE FEATURE
NODESETPOLICY ONEOF
NODESETPRIORITYTYPE FIRSTFIT
```

*The **NODESET** parameters tell Moab that performing node allocation using node sets is required, that the node set name is a feature name assigned to compute nodes, that a job must fit within the available nodes of one node set, and that Moab should use the first node set that contains sufficient available nodes to satisfy the job's request.*

3. To configure Moab to perform topology-aware node allocation using node sets, you must create a node set definition for each set of nodes that has the same number of maximum network "hops" from any node to every other node within the node set. For an example, see the following sample scenario:

Use case

The SGI UV 1000 has a two-socket blade with a physical organization of 16 blades within a blade chassis (SGI term is Intra-Rack Unit or IRU), two blade chassis (IRUs) within a rack, and up to four racks within a single UV system. The UV 1000 interconnect network has a topology that requires zero hops between the two sockets on the same physical blade, one hop between an even-odd blade pair (e.g. blades 0 and 1, 2 and 3, etc.), two hops between all even-numbered or all odd-numbered blades within an IRU, three hops maximum between all blades within an IRU, four hops maximum between all even-numbered blades or all odd-numbered blades within a UV system, and five hops maximum between all blades within a UV system.

- a. Define topology-aware node definitions to parallel the compute nodes reachable within a specific hop count. For the UV 1000, this means the sockets of each blade will belong to six separate node set definitions; i.e., one each for 0, 1, 2, 3, 4, and 5 hops).
- b. Define multiple node sets for different nodes reachable in a specific hop count based on the context of where they are in the network topology; that is, you must create a separate and distinct node set definition for each pair of blades reachable with one hop, for each IRU for its nodes reachable in three hops, etc.
- c. Moab node sets are usually defined as compute node features; that is, each node set defined to Moab should appear as a "feature" name on one or more compute nodes. Which node set/feature names appear on each compute node depends on where the compute node is in the interconnect network topology.

Since the SGI UV operating system identifies each blade socket as a separate NUMA node, each NUMA node within a UV system is traditionally an individual compute node to Moab (although TORQUE has the ability to redefine a compute node definition by grouping OS NUMA nodes, which some UV installations do to define a blade as a compute node).

For the sake of illustration, this example assumes each OS NUMA node, which is a UV blade socket, is also a compute node in Moab. This means each compute node (blade socket) will have six feature names assigned, where each feature name must reflect both the compute node's location

in the network topology and the hop count the name represents. A feature name is constructed by using the same root name for a hop count and a number for the topology location at the hop-count level.

For example, the root feature name "blade" represents the zero-hop count and the numbers "0", "1", etc, represent the consecutively numbered blades throughout the entire UV system, which yields feature names of "blade0" for the first blade in the system, "blade1" for the second blade, etc, to "blade127" for the last blade in a fully populated 4-rack UV system. To illustrate further, the root feature name "iru" represents the 3-hops count and the numbers "0" through "7" represent the eight IRUs within a full 4-rack UV system.

- d. For each compute node, configure the correct feature name for each of the hop counts possible and its location within the topology at the hop-count level (e.g., blade (0 hops), blade pair (1 hop), odd- or even-numbered nodes within an IRU (2 hops), IRU (3 hops), odd- or even-numbered nodes within the UV (4 hops), and UV system (5 hops)). The following example illustrates the feature names assigned to the compute nodes for an SGI UV 1000 system using the following root feature names.

- blade (0 hops)
- pair (1 hop)
- eiru (2 hops for even-numbered blades within an IRU)
- oiru (2 hops for odd-numbered blades within an IRU)
- iru (3 hops)
- esys (4 hops for even-numbered blades within a UV system)
- osys (4 hops for odd-numbered blades within a UV system)
- sys (5 hops)

Note that nodes 0 and 1 are not given any feature names. This is because the operating system instance for the UV system runs on the first blade and in order to not adversely affect OS performance, no jobs should run on the same compute resources as the operating system; hence, these nodes have no node set feature names and therefore will never be chosen to run jobs. In addition, some of the first feature names at a specific hop count-level are omitted (such as pair0) since it makes no sense to define them when the first blade is a substantial part of the nodes making up a node set.

The node name of a UV system has the same name as the UV system's host name plus the NUMA node's relative socket number.

```

4. Define the order in which Moab should check node sets for available nodes. Since the [NODESETPRIORITYTYPE](#) has a value of *FIRSTFIT*, the node sets must be ordered from smallest to largest so Moab will always choose the node set with the fewest nodes required to satisfy the job's request. This means listing all blades, blade pairs, even and odd IRUs, IRUs, even and odd system, and system, respectively.

```
moab.cfg:
NODESETLIST
blade1,blade2,blade3,...,blade127,pair1,pair2,pair3,...,pair63,eiru0,oiru0,eirul,oirul,
...,eiru7,oiru7,iru0,irul,...,iru7,esys,osys,sys
```

5. Configure Moab to use the **PRIORITY NODEALLOCATIONPOLICY**. This allocation policy causes Moab to allocate enough nodes to fulfill a job's processor and memory requirement.

```
NODEALLOCATIONPOLICY PRIORITY
```

6. Set **NODEACCESSPOLICY** to **SINGLEJOB** to ensure that Moab will schedule large memory requests correctly and efficiently. This is necessary even when a job uses only the memory of a NUMA node.

```
NODEACCESSPOLICY SINGLEJOB
```

The policy **SINGLEJOB** tells Moab not to allow jobs to share NUMA resources (cores and memory), which for a shared-memory system is very important for fast job execution. For example, if Moab scheduled a job to use the cores of a NUMA node where memory is used by another job, both jobs would execute slowly (up to 10 times more slowly).

Job Submission

Jobs can request processors and memory using the `-l nodes=<number of cpus>` and `-l mem=<amount of memory>` syntaxes. You should not have **JOBNODEMATCHPOLICY EXACTNODE** configured on a NUMA system. You must use the `sharedmem` job flag on submission to force the job to run only on a `sharedmem` partition or cluster and to indicate that the job can span multiple nodes. For example:

```
qsub -l nodes=3,mem=640sgb,flags=sharedmem
```

Appendix H: Interfacing with Moab (APIs)

Moab provides numerous interfaces allowing it to monitor and manage most services and resources. It also possesses flexible interfaces to allow it to interact with peer services and applications as both a broker and an information service. This appendix is designed to provide a general overview and links to more detailed interface documentation.

- [H.1 Moab Query and Control APIs](#)
 - Allow external portals and services to obtain information about compute resources, workload, and usage statistics.
- [H.2 Resource Management Interfaces](#)
 - Allow Moab to monitor, schedule, and control services and resources.

- [H.3 Identity and Credential Management Interfaces](#)
 - Allow monitoring and active management of user configuration, credentials, policies, and usage information.
- [H.4 Accounting and Event Interfaces](#)
 - Allow import/export of accounting and event information to external entities.
- [H.5 Job Submission and Management Interface](#)
 - Query resource availability, submit, modify, and manage jobs, and query the status of active and completed jobs.
- [H.6 Grid Services API](#)
 - Provide and use information, data, job, and resource management services in a distributed environment.

Moab interfaces to systems providing various services and using various protocols. This appendix is designed to assist users who want to enable Moab in new environments using one of the existing interfaces. It does not cover the steps required to create a new interface.

H.1 Query and Control APIs

The Moab Cluster and Grid Suites provides a (Moab) workload manager server that supports a broad array of client services. These services can be directly accessed via Moab client commands.

H.1.1 CLI (Command Line Interface) XML API

All Moab client commands can report results in XML format to allow the information to be easily integrated into peer services, portals, databases, and other applications. To request that a client command report its output in XML, specify the `--format=xml` flag as in the following example:

```

> showq --format=xml
<Data>
<Object>queue</Object>
<cluster LocalActiveNodes="1" LocalAllocProcs="1" LocalIdleNodes="0"
LocalIdleProcs="3" LocalUpNodes="1"
  LocalUpProcs="4" RemoteActiveNodes="0" RemoteAllocProcs="0" RemoteIdleNodes="0"
RemoteIdleProcs="0"
  RemoteUpNodes="0" RemoteUpProcs="0" time="1128451812"></cluster>
<queue count="1" option="active">
<job AWDuration="11672" EEDuration="1128451812" Group="[DEFAULT]" JobID="Moab.2"
MasterHost="cw2" PAL="2"
  QOS="bug3" ReqAWDuration="54000" ReqNodes="1" ReqProcs="1" RsvStartTime="1128451812"
RunPriority="0"
  StartPriority="1" StartTime="1128451812" StatPSDed="11886.580000"
StatPSUtl="11886.580000" State="Running"
  SubmissionTime="1128451812" SuspendDuration="0" User="smith"></job>
</queue>
<queue count="1" option="eligible">
<job EEDuration="1128451812" Group="jacksond" JobID="customer.35" QOS="bug"
ReqAWDuration="3600"
  ReqProcs="1" StartPriority="1" StartTime="0" State="Idle"
SubmissionTime="1128451812" SuspendDuration="0"
  User="johnson"></job>
<queue><queue count="0" option="blocked"></queue>
</Data>

```

Common Query/Control Services

- jobs
 - query status - [mdiag -j](#) (XML details)
 - submit - [msub](#) (XML format)
 - cancel - [mjobctl -c](#)
- nodes
 - query status - [mdiag -n](#) (XML details)
 - create resource reservation - [mrsvctl -c](#)
 - destroy resource reservation - [mrsvctl -r](#)

H.2 Resource Management Interfaces

Moab can monitor, schedule, and control services and resources using multiple protocols. These protocols include the following:

- [LDAP](#)
- [script/flat file](#)
- [Resource Manager Specific Interfaces](#) - LSF, SGE, TORQUE, PBSPro, Loadleveler, and so forth

Using the resource manager interfaces, Moab can do the following:

- monitor resources (compute host, network, storage, and software license based resources)
 - load configuration, architecture, and feature information
 - load state, utilization, and workload information
 - load policy and ownership information
- manage resources
 - dynamically reconfigure and reprovision resource hardware (processors, memory, etc.)
 - dynamically reconfigure and reprovision resource software (operating system, application software, filesystem mounts, etc.)
 - dynamically reconfigure and reprovision resource security (VPN's, VLAN's, host security, etc.)
- monitor workload (batch jobs, interactive jobs, persistent services, dynamic services, distributed services)
 - load state, resource requirement, and required environment information
 - load user, group, and credential information
 - load utilization, resource allocation, and policy information
- manage workload
 - migrate jobs from one resource to another (intra-cluster and inter-cluster)
 - modify jobs for translation and optimization purposes
 - suspend, resume, checkpoint, restart, and cancel jobs
- query cluster policies and configuration

H.3 Identity and Credential Management Interfaces

Moab's identity and credential management interfaces allow Moab to exchange credential and user configuration, access, policy, and usage information.

- [Identity Manager](#)
- [Accounting Manager](#)
- [Moab Workload Manager for Grids](#)

H.4 Accounting Interfaces

Moab accounting interfaces allow Moab to export local utilization statistics, events, and accounting information to site specific scripts.

- [Accounting Interface](#)

H.6 Job Submission and Management Interface

Moab provides interfaces to enable the following services:

- Resource Availability Query
 - Determine quantity, state, and configuration of configured resources (idle, busy, and down nodes)
 - Determine quantity and configuration of all available resources (idle nodes)
 - Determine resources available subject now and in the future for potential job
 - Determine best target cluster destination for potential job
 - Determine largest/longest job which could start immediately
 - Determine estimated start time for potential job
 - Determine earliest guaranteed start time for potential job
- Reserve Resources
 - Reserve specific resources for desired time frame
- Submit Job ([XML format](#))
 - Submit job to specific cluster
 - Submit job to global job queue
- Manage Job
 - Hold job
 - Adjust job priority
 - Modify job executable, args, data requirements, job dependencies, duration, hostcount, or other attributes
 - Suspend/resume job
 - Checkpoint/requeue job
 - Cancel job
 - Migrate job
 - Adjust job quality of service (QoS)
- Query Job
 - Determine job state, utilization, or output results for idle, active, or completed job
 - Determine estimated start time
 - Determine guaranteed start time

H.7 Grid Interfaces

Moab provides interfaces to allow interaction with various grid brokers and services. These interfaces allow Moab to provide services as well as utilize services.

Services Utilized

- Information Services (import and utilize information service data in making scheduling decisions)
- Job Migration
- Data Migration
- Credential Mapping
- Security and Delegation

See [Moab Workload Manager for Grids](#) for more information on utilized services.

Services Provided

- Information Services (provide resource, workload, and credential information)
- Job Migration
- Data Migration
- Credential Mapping

See [Moab Workload Manager Grid Basics](#) for more information on provided services.

Appendix I: Considerations for Large Clusters

- [I.1 Resource Manager Scaling](#)
- [I.2 Handling Large Numbers of Jobs](#)
- [I.3 Handling Large Numbers of Nodes](#)
- [I.4 Handling Large Jobs](#)
- [I.5 Handling Large SMP Systems](#)
- [I.6 Server Sizing](#)

There are several key considerations in getting a batch system to scale.

I.1 Resource Manager Scaling

Proper Resource Manager Configuration

- [TORQUE](#)
 - [General Scaling Overview](#)
- OpenPBS/PBSPPro
 - Manage Direct Node Communication with [NODEPOLLFREQUENCY](#)

I.2 Handling Large Numbers of Jobs

Set a Minimum RMPOLLINTERVAL

With event driven resource managers like TORQUE, each time a job is submitted the resource manager notifies the scheduler. In an attempt to minimize response time, the scheduler starts a new scheduling cycle to determine if the newly submitted job can run. In systems with large numbers of jobs submitted at once, this might not result in the desired behavior for two reasons. First, by scheduling at every job submission Moab schedules newly submitted jobs onto available resources in a first come, first served basis rather than evaluating the entire group of new jobs at once and optimizing the placement accordingly. Second, by launching a scheduling iteration for every job submitted, Moab places a heavy load on the resource manager. For example, if a user were to submit 1000 new jobs simultaneously, for each job submitted, the resource manager contacts the scheduler, the scheduler starts a new iteration, and in this iteration, the scheduler contacts the resource manager requesting updated information on all jobs and resources available.

Setting a minimum **RMPOLLINTERVAL** causes the scheduler to not process jobs as quickly as they are submitted, but rather to wait a minimum amount of time to allow more jobs be submitted and to process these new jobs in groups.

```
RMPOLLINTERVAL 30, 60
```

If the system is busy, schedule every 30 seconds. If it is not busy, schedule every 60 seconds.

Reduce Command Processing Time

If your system's scheduling cycle regularly takes longer than the **CLIENTTIMEOUT** value, you can configure Moab to fork a copy of itself that will respond to certain information-only client commands ([checkjob](#), [showbf](#), [showres](#), and [showstart](#)). This enables you to run intense diagnostic commands while Moab is in the middle of its scheduling process.

When you set **UIMANAGEMENTPOLICY FORK CLIENTUIPORT <port number>** on the server side, Moab forks a copy of itself that will listen for client commands on a separate port. For example, systems that run client commands, such as submit hosts, can set **CLIENTUIPORT 41560**. This will allow the clients to run commands

such as `checkjob`, `showbf`, `showres` and `showstart` and have cached information returned from the previous scheduling iteration. Moab prints a disclaimer at the top of each command that was populated by the forked process stating that the information may be a few seconds stale..

i See **CLIENTTIMEOUT** on page 1085, **CLIENTUIPORT** on page 1085, and **UIMANAGEMENTPOLICY** on page 1209 for parameter information.

Example 3-188: Sample configuration

```
UIMANAGEMENTPOLICY    FORK
CLIENTUIPORT          41560
```

Moab forks a copy of itself on port 41560, where it will watch for `checkjob`, `showbf`, `showres`, and `showstart` commands until the main scheduling process completes.

Example 3-189: Sample command output

```
$ checkjob 34
```

```
-----
NOTE: The following information has been cached by the remote server
and may be slightly out of date.
-----
```

```
job 34
```

```

Limited Job Checkpointing

Use the **LIMITEDJOB** on page 1134 parameter. By default, Moab will checkpoint information about every job it reads from its resource managers. When a cluster routinely runs more than 15000 jobs, they may see some speed-ups by limiting which jobs are checkpointed. When **LIMITEDJOB** is set to **TRUE**, Moab will only checkpoint jobs that have a hold, a system priority, jobs that have had their QoS modified, and a few other limited attributes. Some minimal statistical information is lost for jobs that are not checkpointed.

Minimize Job Processing Time

Use the [ENABLEHIGHTHROUGHPUT on page 1097](#) parameter. By default, Moab processes all job attributes, filters, remap classes, job arrays, and other information when a job is submitted. This requires full access to the Moab configuration and significantly increases the processing time Moab needs when jobs are submitted. By setting **ENABLEHIGHTHROUGHPUT** to **TRUE**, Moab stores the job information in an internal queue and returns the job ID immediately. The internal queue is processed when Moab begins its next scheduling iteration. This enables Moab to process hundreds of jobs per second rather than 20-30 per second. Because the jobs are processed in a separate queue after the job has been returned, it is recommended that [MAILPROGRAM](#) be configured. Moab will send an email to the user if a job is rejected.

Because the job is not fully processed, some attributes may change after the job has been submitted. For example, when a job class is remapped, the new class is not reflected until Moab begins its next scheduling iteration. Additionally, job arrays are not instantiated until Moab begins its next scheduling cycle.

i If **ENABLEHIGHTHROUGHPUT** on page 1097 is **TRUE**, you must set **NODEALLOCATIONPOLICY** on page 1146 to **FIRSTAVAILABLE**.

Load all Non-Completed Jobs at Startup

Use the [LOADALLJOB](#)CP on page 1135 parameter. By default, Moab loads non-complete jobs for active resource managers only. By setting **LOADALLJOB**CP to **TRUE**, Moab will load all non-complete jobs from all checkpoint files at startup, regardless of whether their corresponding resource manager is active.

Reducing Job Start Time

Use the [ASYNCSTART](#) parameter. By default, Moab will launch one job at a time and verify that each job successfully started before launching a subsequent job. For organizations with large numbers of very short jobs (less than 2 minutes in duration), the delay associated with confirming successful job start can lead to productivity losses. If tens or hundreds of jobs must be started per minute, and especially if the workload is composed primarily of serial jobs, then the resource manager **ASYNCSTART** flag may be set. When set, Moab will launch jobs optimistically and confirm success or failure of the job start on the subsequent scheduling iteration. Also consider adding the **ASYNCDELETE** flag if users frequently cancel jobs.

Reducing Job Reservation Creation Time

Use the [RMCFG](#) on page 1183 [JOBRSVRECREATE](#) on page 728 attribute. By default, Moab destroys and re-creates job reservations each time a resource manager updates any aspect of a job. Historically, this stems from the fact that certain resource managers would inadvertently or intentionally migrate job

tasks from originally requested nodes to other nodes. To maintain synchronization, Moab would re-create reservations each iteration thus incorporating these changes. On most modern resource managers, these changes never occur, but the effort required to handle this case grows with the size of the cluster and the size of the queue. Consequently, on very large systems with thousands of nodes and thousands of jobs, a noticeable delay is present. By setting **JOBRSVRECREATE** to **FALSE** on resource managers that do not exhibit this behavior, significant time savings per iteration can be obtained.

Optimizing Backfill Time

Use the **OPTIMIZEDBACKFILL** flag. Speeds up backfill when a system reservation is in use.

Constraining Moab Logging - LOGLEVEL

Use the **LOGLEVEL** on page 1137 parameter. When running on large systems, setting **LOGLEVEL** to 0 or 1 is normal and recommended. Only increase **LOGLEVEL** above 0 or 1 if you have been instructed to do so by Moab support.

Preemption

When preemption is enabled Moab can take considerably more time scheduling jobs for every scheduling iteration. Preemption increases the number of options available to Moab and therefore takes more time for Moab to optimally place jobs. If you are running a large cluster or have more than the usual amount of jobs (>10000), consider disabling preemption. If disabling preemption is not possible, consider limiting its scope to only a small subset of jobs (as both preemptors and preemptees).

Handling Transient Resource Manager Failures

Use the **RMCFG MAXITERATIONFAILURECOUNT** on page 730 attribute.

Constrain the number of jobs preempted per iteration

Use the **JOBMAXPREEMPTPERITERATION** parameter.

i For very large job count systems, configuration options controlling the maximum supported limits may need to be adjusted including the maximum number of reservations and the maximum number of supported evaluation ranges.

Scheduler settings

If using Moab, there are a number of parameters which can be set on the scheduler which may improve TORQUE performance. In an environment containing a large number of short-running jobs, the **JOBAGGREGATIONTIME**

parameter can be set to reduce the number of workload and resource queries performed by the scheduler when an event based interface is enabled. Setting **JOBAGGREGATIONTIME** instructs the scheduler to ignore events coming from the resource manager and to scheduling at regular intervals, rather than around resource manager events. If the `pbs_server` daemon is heavily loaded and PBS API timeout errors (i.e. "Premature end of message") are reported within the scheduler, the **TIMEOUT** attribute of the **RMCFG** parameter may be set with a value of between 30 and 90 seconds.

I.3 Handling Large Numbers of Nodes

For very large clusters ($\geq 10,000$ processors) default scheduling behavior may not scale as desired. To address this, the following parameters should be considered:

Parameter	Recommended Settings
<u>RMPOLLINTERVAL</u>	In large node environments with large and long jobs, scheduling overhead can be minimized by increasing RMPOLLINTERVAL above its default setting. If an event-driven resource management interface is available, values of two minutes or higher may be used. Scheduling overhead can be determined by looking at the scheduling load reported by mdia -S .
<u>LIMITEDNODECP</u>	Startup/shutdown time can be minimized by disabling full node state checkpointing that includes some statistics covering node availability.
SCHEDCFG FLAGS="FASTRSVSTARTUP" on page 1565	When you have reservations on a large number of nodes, it can take Moab a long time to recreate them on startup. Setting the FASTRSVSTARTUP scheduler flag greatly reduces startup time.

* For clusters where the number of nodes or processors exceeds 50,000, the maximum stack size for the shell in which Moab is started may need to be increased (as Moab may crash if the stack size is too small). On most Unix/Linux based systems, the command `ulimit -s unlimited` may be used to increase the stack size limit before starting Moab. This may be placed in your Moab startup script.

i See [Appendix D](#) for further information on default and supported object limits.

Avoid adding large numbers of **NODECFG** lines in the `moab.cfg` or `moab.d/*.cfg` files to keep the Moab boot time low.

For example, adding a configuration line to define features for each node in a large cluster (such as `NODECFG[x] Features+=green,purple`) can greatly increase the Moab boot time. If Moab processes 15 node configuration lines per

second for a 50,000-node system, it could add approximately 55 minutes of node configuration processing to the Moab boot time.

In this case, it is better to define the node features in the resource manager configuration.

1.4 Handling Large Jobs

For large jobs, additional parameters beyond those specified for [large node](#) systems may be required. These include settings for the maximum number of [tasks per job](#), and the maximum number of [nodes per job](#).

1.5 Handling Large SMP Systems

For large-way SMP systems (> 512 processors/node) Moab defaults may need adjustment.

Parameter	Recommended Settings
MAXRSVPERNODE	By default, Moab does not expect more than 48 jobs per node to be running or have future reservations. Increasing this parameter to a value larger than the expected maximum number of jobs per node is advised.

1.6 Server Sizing

See Hardware and Software Requirements for recommendations.

Appendix J: Configuring Moab as a Service

Scripts that follow can be used to start up Moab services automatically upon a reboot. To enable a service script, copy the script to `/etc/rc.d/init.d/S97moab`, edit the file to make needed localization changes (adjust binary paths, execution user, etc), and add links to the `rc3.d` and `rc5.d` directories as in the example that follows:

```
> cp mwm.service /etc/rc.d/init.d/S97moab
> vi /etc/rc.d/init.d/S97moab
   (make needed localizations)
> ln -s /etc/rc.d/init.d/S97moab /etc/rc.d/rc3.d
> ln -s /etc/rc.d/init.d/S97moab /etc/rc.d/rc5.d
```

Appendix K: Migrating from 3.2

Overview

This guide is intended to help facilitate migrating from Maui to Moab. If you do not have Moab yet, you can download a [free evaluation version](#). At a high level, migrating from Maui 3.2 to Moab involves minimal effort. In fact, Moab fully supports all Maui parameters and commands. Migration can consist of nothing more than renaming `maui.cfg` to `moab.cfg` and launching Moab using the `moab` command. With this migration, the biggest single issue is becoming aware of all the new facilities and capabilities available within Moab. Beyond this, migration consists of a few minor issues that may require attention such as some [statistics and priorities](#).

Another approach of migrating from Maui to Moab is to configure Moab in Monitor mode and run it beside Maui. Maui will continue to perform the scheduling and control workload. Moab will simply monitor the cluster environment using the policies configured in `moab.cfg`. Moab will not have the ability to affect workload, providing a safe and risk-free environment to evaluate Moab without affecting your production environment. You can also have Moab capture resource and workload trace files and allow Moab to simulate what it would have done if it controlled workload. When you feel comfortable with and want to run Moab live on your cluster, all you need to do is change the mode to NORMAL, stop Maui, and restart Moab. Current jobs will remain running and Moab will take over control of scheduling.

As with any migration, we suggest that you back up important files such as the following: `maui.cfg`, `maui.log` and `maui.ck`.

[View the Flash demo of migrating from Maui to Moab.](#)

Migrating from Maui to Moab

1. Install Moab Workload Manager. (Installation Instructions)
2. Copy your `maui.cfg` file to the `MOABHOMEDIR/etc (/opt/moab/etc)` and rename it `moab.cfg`.
3. Stop Maui.

4. Start Moab.
5. If Applicable: Re-apply those configurations found in the [Statistics and Checkpointing](#) section that need adjustment after migration as well as any parameters in `moab.cfg` that point to a Maui file like `maui.log`.

Running Maui and Moab Side-By-Side

1. Install Moab Workload Manager on your cluster. (Installation steps will differ slightly from a typical installation.)
 - a. Run `./configure`.
 - b. Run `make`.
 - c. You will need to set your `MOABHOMEDIR` environment variable to the location where you built Moab by typing `export MOABHOMEDIR=[make directory]`.
2. To have Moab use all the same policies as Maui, copy `maui.cfg` to the `MOABHOMEDIR/etc` and rename it `moab.cfg`.
 - You can also start your `moab.cfg` file from scratch. Just use the `moab.cfg` already in the `MOABHOMEDIR/etc`.
3. Make sure that the port in `moab.cfg` is different than the port used in `maui.cfg`.
4. In the `moab.cfg` file, add the parameter, `SERVERMODE=MONITOR`.
 - If you used the `moab.cfg` from scratch, on the **SCHEDCFG** line add `MODE=MONITOR`.
5. You will need to either put the Moab commands in your environment path (located in `MOABHOMEDIR/bin`) or run the commands from their location if you still want to use the Maui commands in your environment path.
6. Run Moab Workload Manager using the `moab` command located in `MOABHOMEDIR/bin`.

Other Notes

The following are minor differences between Maui and Moab and changes you may need to make:

File Naming

Moab uses slightly different naming than Maui. The following table displays these changes:

File	Maui	Moab
executable	maui	moab
logs	maui.log	moab.log
configuration file	maui.cfg	moab.cfg

Statistics and Checkpointing

Moab supports Maui version 3.2 or higher workload traces (statistics) allowing it to process historical statistics based on these traces as well as generate simulations based on them. No changes are required to use these statistics. See the Simulation Configuration documentation for more information on trace files. You can also view a [flash demonstration](#) of the simulation mode.

Moab does not support the Maui 3.2 checkpointing format. Because of this, state information checkpointed under Maui will not be available at the time of the migration. The loss of this information will have the following impact:

- Admin reservations, if any, will need to be re-created.
- Processed credential and scheduler statistics (displayed by `showstats`) will be lost.
- Admin job system priority configured by the `setspri` command and QoS assignments configured by the `setqos` command, if any, will be lost.

Verify Configuration File Compatibility

The command `mdiag -C` will perform diagnostics on your new configuration file and may prove helpful in identifying any issues.

Environment Variables

Scheduler environment variables are supported under Moab with obvious naming changes. Sample environment variables follow:

Maui	Moab
MAUIHOMEDIR	MOABHOMEDIR
MAUIDEBUG	MOABDEBUG
MAUICRASHVARIBALE	MOABCRASHVARIABLE

Maui	Moab
MAUIENABLELOGBUFFERING	MOABENABLELOGBUFFERING
MAUIRECOVERYACTION	MOABRECOVERYACTION
MAUI-COMMANDS-PATH	MOAB-COMMANDS-PATH
MAUIENABLELOGBUFFERING	MOABENABLELOGBUFFERING

Appendix L: Cray-Specific Power Management and Energy-Consumption-by-Job Accounting

Moab Workload Manager - Enterprise Edition 8.1.0 supports power management and green computing for Cray XC systems (running CLE 5.2 or later). Moab also has the ability to charge and record a cost for the electrical energy consumed by a job.

- [Cray Power Management Overview on page 1425](#)
- [Enable Moab/Cray Power Management on page 1426](#)
- [Moab Energy-Consumption-by-Job Accounting on page 1430](#)

Cray Power Management Overview

The Cray XC30 and XC40 systems can perform power management using various schemes supported by the Moab Workload Manager, which includes power management of actively running compute nodes as well as management of power states for idle compute nodes.

Cray XC Systems Power Management

For the management of the energy consumption of actively running compute nodes, Cray XC systems provide processor P-state and Linux power governor policy management support. For the management of the energy consumption of idle compute nodes, Cray XC systems provide S-state support.

Actively Running Node Power Management

The Cray ALPS system provides processor P-state and Linux power governor policy management at the time of job start; that is, a user can submit a job and request the job's compute nodes operate at a specific clock frequency (P-state) or with a specific Linux power governor policy for the duration of the job. The Cray ALPS subsystem sets the requested frequency or power governor policy when it sets up the job's node allocation reservation. ALPS cannot change the

requested frequency or power governor policy while the job executes. After the job finishes, the nodes' frequency or power governor policy are restored to the setting before ALPS set up the node reservation.

Idle Node Power Management

The new Cray Advanced Power Monitoring and Control (CAPMC) system provides a means for the Moab Workload Manager to manage the power state of individual compute nodes. Specifically, the CAPMC system can power up (S0 state) or shut down (S5 state) compute nodes.

At the time of the Cray XC30 system introduction, only a system administrator using the System Management Workstation (SMW) could perform all Cray XC power management functions. Since that time, Cray has provided a new command line utility named "capmc" that allows administrators and/or workload managers to manage the power state of compute nodes from "login" nodes.

Moab Power Management on Cray XC Systems

Moab has two methods of performing power management; Moab-only and Moab+Moab Web Services (Moab+MWS). The two methods are described in the Green Computing Overview of the Moab Administrator's Guide Version 8.1.0.

8.1.0 uses the Moab-only method of power management for Cray XC systems, which requires four Cray-specific power management scripts Cray ported from Moab's OpenIPMI-based "reference" scripts to the XC.

Enable Moab/Cray Power Management

Enabling Moab power management for Cray XC systems requires enabling Moab power management using the Moab-only method. It is the same regardless of the type of system Moab will manage. The only difference between systems, such as Cray XC and non-Cray, lies in the commands executed by the Moab-only power management scripts.

Install Moab Power Management Scripts

Adaptive Computing provides working Moab power management "reference" scripts that execute `ipmitool` commands.

i Any HPC site that uses different, usually vendor-specific, commands requires the administrator to modify the reference scripts so they use site-specific commands.

The four reference scripts are located in the `$MOABHOMEDIR/tools/ipmi` directory, where `$MOABHOMEDIR` represents the Moab installation directory. The default `$MOABHOMEDIR` is `/opt/moab`, which may not match the default location on the Cray XC system (e.g. `/var/spool/moab`).

Configure Moab Cray-Specific Power Management

Adaptive Computing and Cray have worked together to provide working Cray-specific power management “reference” scripts for Cray XC systems. These scripts are located in the `$MOABHOMEDIR/tools/ipmi/cray` sub-directory and have the same names as the four ipmitool-based reference scripts.

i If your Moab HPC Suite download does not contain the Cray-specific power management scripts, you can obtain them from Adaptive Computing’s Technical Support and install them in the default installation directory as illustrated by the commands below. This directory is where a Moab installation will place them.

```
cd $MOABHOMEDIR/tools/ipmi
mkdir cray
chmod 755 cray
chgrp root cray # should match group of tools/ipmi directory
chown moab cray # should match owner of tools/ipmi directory
cd cray
cp <CraySpecificFileNames>
chmod 755 *.py
chgrp root *.py # should match group of tools/ipmi/*.py files
chown moab *.py # should match owner of tools/ipmi/*.py files
```

Set up the Moab Cray-Specific Power Management Scripts

1. Copy the Moab Cray-specific power management reference scripts to a directory where you can customize them and not have the customized version overwritten on a Moab upgrade.
2. Edit `moab.cfg` for green computing. See "To enable green computing with just Moab" in [Enabling Green Computing on page 852](#).
3. Set the **CLUSTERQUERYURL** and **NODEPOWERURL** parameters to point to the copied, Cray-specific, cluster query (`ipmi.mon.py`) and node power control (`ipmi.power.py`) scripts.

Example:

```
NODECFG[DEFAULT] POWERPOLICY=OnDemand
RMCFG[ipmi] TYPE=NATIVE RESOURCETYPE=PROV
RMCFG[ipmi] CLUSTERQUERYURL=exec://$MOABHOMEDIR/etc/cray/ipmi.mon.py
RMCFG[ipmi] NODEPOWERURL=exec://$MOABHOMEDIR/etc/cray/ipmi.power.py
```

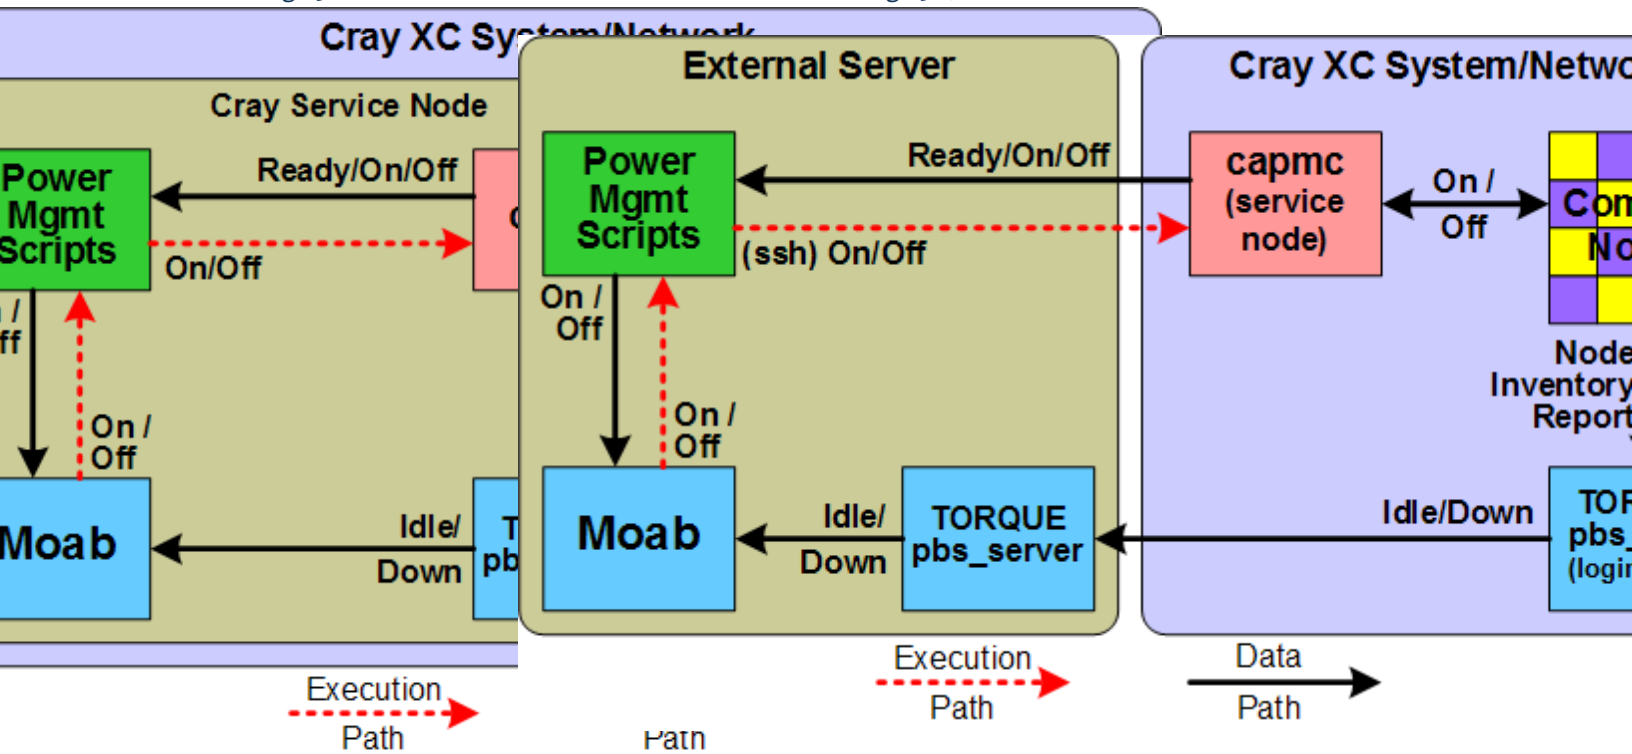

This example assumes the `$MOABHOMEDIR/etc/cray` directory is the location to which the scripts were copied.

4. Determine which Cray-system architecture to use for Moab and TORQUE. Moab and TORQUE can operate in one of two architectures with a Cray system.

- **Internal** - Moab and the TORQUE pbs_server execute on a Cray service node which functions as the Moab head node. This the first (original) architecture.
- **External** - Moab and the TORQUE pbs_server daemon execute on a non-Cray external server which is the Moab head node. This architecture is recommended by Adaptive Computing.

Image 3-16: Internal Architecture

Image 3-17: External Architecture

i The Moab/TORQUE architecture of your Cray site determines what values you will assign to Python variables in the Cray-specific, power management scripts you must customize.

5. Edit the `config.py` file you copied and set the value of the variable assignments as necessary for your architecture.

Text Line	Instructions
<code>self.homeDir</code>	Path to the Moab installation directory.
<code>self.etcDir</code>	Path to the Moab configuration directory.

Text Line	Instructions
<code>self.capmcBinDir</code>	Path to the Cray "capmc" command binary image file.
<code>self.capmcRemote</code>	Set to "Y" if Moab and TORQUE pbs_server are operating in the external architecture; otherwise, set to "N" if they are operating in the internal architecture.
<code>self.capmcServer</code>	Fully-qualified domain name (FQDN) of the server with the "capmc" command binary image file.
<code>self.pollInterval</code>	Set the power state (cluster query) polling interval in seconds to a reasonable value; less than Moab's RMPOLLINTERVAL in the moab.cfg file, at least 60 seconds, etc.
<code>self.pidFile</code>	Leave as is; unless the directory path should be different.
<code>self.ipmifile</code>	Leave as is; unless the directory path should be different.
<code>self.daemon</code>	Path to the power state query daemon script (<code>_mon.ipmi.py</code>).
<code>os.environ["OS_CACERT"] = ...</code> <code>os.environ["OS_KEY"] = ...</code> <code>os.environ["OS_CERT"] = ...</code> <code>os.environ["OS_SERVICE_URL"] = ...</code>	Set the appropriate values for the four OS_... variables, especially the OS_SERVICE_URL value. These variables have to do with authentication (key file, certificate, etc) for the Cray "capmc" command.
<code>self.omapFormat</code>	If the Cray is part of a Moab "peer-to-peer" grid that uses the Moab "OMAP" feature to rename compute nodes, this variable may require modification to map Cray node id numbers into a remapped node id known to Moab. If so, follow the instructions in the script comments accompanying this variable assignment and modify as appropriate.

Testing Moab Power Management Scripts on Cray XC Systems

After configuring the `moab.cfg` and `config.py` files, restart Moab. You should now be able to power on, powered-down Cray XC compute nodes and shut down, powered-on Cray XC compute nodes using the `mnodectl -m power=xxx` command.

Example:

```
mnodectl -m power=off <NodeExpr>
mnodectl -m power=on <NodeExpr>
```

"<NodeExpr>" is a compute node host name, a regular expression that matches multiple host names, or a comma-separated list of host names.

If the Moab power management has been correctly configured for Cray-specific operation, executing the commands above for a Cray compute node should shut down the node and then power it up. Ensure you wait sufficient time after powering off the node before powering it up.

Cray XC systems have a minimum time limit between executing commands that power on and power off a compute node to ensure a command does not attempt to interrupt a compute node already executing a previous command. For example, commanding a node to power off and then shortly thereafter commanding it to power on while it is in the process of shutting down is forbidden by the Cray system and if so commanded, may have unknown behavior or consequences. See the Cray XC documentation or contact Cray Technical Support for authoritative information.

Enabling Moab Green Policy on Cray XC Systems

There is no difference between enabling green policy on Cray XC systems versus non-Cray systems. Follow the green policy configuration instructions to enable automated power management via "Green Computing" for a Cray XC system using the Moab-only method.

Ensure the moab.cfg file contains appropriate values for the following parameters to ensure a command does not attempt to interrupt a compute node already executing a previous command. See the warning earlier in this topic for more information regarding the minimum time limit between executing commands that power on and power off a compute node.

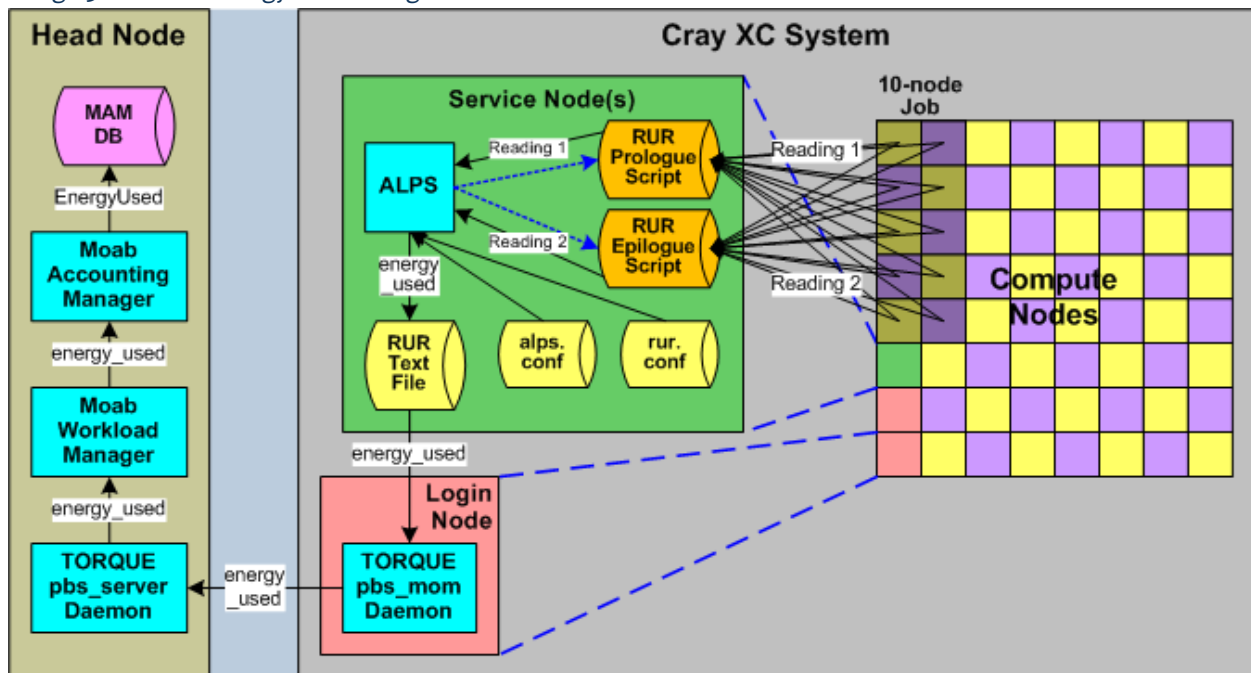

- NodePowerOffDuration
- NodePowerOnDuration

Moab Energy-Consumption-by-Job Accounting

A Cray XC system, running CLE 5.2 or later, can monitor and compute the energy consumed by each compute node used by a job. These energy consumption values can be used to compute the energy consumption of a job and charge for the cost of the energy consumed.

The figure that follows identifies the Moab HPC Suite and the Cray system components that, working together, permit a Cray site to charge a user for the energy a job consumes.

Image 3-18: Moab Energy Accounting Architecture and Information Flow

Cray XC Systems Energy Monitoring

In order to monitor and gather energy consumption by job, the Cray ALPS subsystem must execute a job step "prologue" and "epilogue" that together allow it to compute the energy consumption of each compute node allocated to a job and sum them for total energy consumption by a job step. The prologue and epilogue scripts must be configured or ALPS will not perform any energy consumption computation and recording.

Cray Resource Utilization Record (RUR) and Job Energy Consumption

The Cray ALPS subsystem records the resource usage of a job step in a Resource Utilization Record (RUR). These records can be stored in a system RUR file. Each time a job executes the `aprun` command, which defines a "job step", the ALPS system records one RUR entry for the job step in the RUR file, which entry includes the energy used by the job's compute nodes during the job step.

Computing the energy used by a job step requires ALPS to execute the job step prologue script to record the current "power meter reading" of all compute nodes allocated to the job and then execute the job step epilogue script to record the new current "power meter reading" of each compute node, compute the differences between the first and second readings, and then sum the differences to obtain the job step's `energy_used` value. The `energy_used` units is joules (1 joule = 1 watt-second; 1 kilo-watt hour = 3.6 million joules).

To compute the energy consumption for a job, the `energy_used` value from each RUR entry for a job's job steps must be summed to compute a job's total `energy_used` value.

RUR File Processing and "energy_used" Generic Metric

If the RUR file is present, TORQUE automatically extracts the RUR entries for a job as part of the `pbs_mom`'s job termination processing and sums the job steps' `energy_used` values to obtain a single `energy_used` "generic metric" for the job, which the `pbs_mom` passes on to the TORQUE `pbs_server` daemon as part of the job's resource usage information. The `pbs_server` daemon delivers the generic metric to the Moab Workload Manager, where it becomes part of the job's information in Moab.

"EnergyUsed" Generic Metric and Moab Accounting Manager (MAM)

If the Moab Workload Manager passes job information to the Moab Accounting Manager (MAM), the `energy_used` generic metric is part of the job information passed. If received, MAM converts the Moab job generic metric into its own `EnergyUsed` metric associated with the job. If MAM must compute a cost for the energy a job used, the system administrator must configure MAM with a charge that uses the `EnergyUsed` metric's value to compute the energy cost of the job.

Related Topics

[Cray RUR Configuration on page 1432](#)

[Moab Job Energy Consumption Accounting Configuration on page 1434](#)

[Tracing Energy Usage from the Cray XC System to MAM on page 1435](#)

[Appendix L: Cray-Specific Power Management and Energy-Consumption-by-Job Accounting on page 1425](#)

Cray RUR Configuration

To enable the recording of RUR file entries for jobs, the system administrator must configure the Cray XC system so it will generate RUR file entries in the system RUR file for each job step. In addition, the system administrator must enable RUR in the Cray system's compute nodes.

The following information identifies items the administrator must configure.

i Configuration instructions may change over time without Adaptive Computing's knowledge. The administrator should consult Cray documentation for authoritative information and work with Cray Technical Support to ensure a correct configuration.

RUR Prologue and Epilogue Path Configuration

Verify the `alps.conf` file contains valid RUR prologue and epilogue path names, similar to the blue lines in the example below. If their paths are not specified, ALPS will not execute the RUR prologue and/or epilogue scripts. Both scripts are needed for ALPS to compute energy consumption by a job step.

```
boot-pl:~ # xtopview
default:/ # vi /etc/opt/cray/alps/alps.conf
...
    prologPath      /opt/cray/rur/default/bin/rur_prologue.py
    epilogPath      /opt/cray/rur/default/bin/rur_epilogue.py
    prologTimeout    30
    epilogTimeout    30
...
```

The RUR prologue script "reads" the "power meter" of each compute nodes allocated to a job. The RUR epilogue script again reads the power meters and then computes the difference between each node's power meter readings. The sum of the differences computes the energy consumption of a job step, which "energy_used" value ALPS records in the RUR entry for the job step.

RUR File Generation and Path Configuration

The RUR system can record RUR information in different ways. One recording method is a text file. For Moab job energy accounting, the Cray XC system must record the RUR information in a system RUR text file, which recording method requires configuration.

Verify the `rur.conf` file has the "file plug-in" enabled, similar to the blue line in the example below, or ALPS will not record RUR job-step entries in a text file.

```
boot-pl:~ # xtopview
default:/ # vi /etc/opt/cray/rur/rur.conf
...
# Output Plugins section Configuration
# Define which output plugins are supported, and enable/
# disable them. Plugins defined as "Plugin: False" will
# not run, but will be parsed for correct config file
# syntax.
[outputplugins]
llm: true
file: true
user: false
...
```

In addition, verify the "file output argument" contains the valid path name of the system RUR file.

```

...
# The File output plugin.
# Write RUR output to a single plain text file
# Arg - The destination text file
[file]
output: /opt/cray/rur/default/bin/file_output.py
#arg: path-to-flat-textfile
arg: /lus/scratch/RUR/output/rur.output
...

```

These two configuration items direct ALPS to record RUR information in a text file (also referred to as the system RUR file mentioned in this document).

Related Topics

[Moab Energy-Consumption-by-Job Accounting on page 1430](#)

[Appendix L: Cray-Specific Power Management and Energy-Consumption-by-Job Accounting on page 1425](#)

Moab Job Energy Consumption Accounting Configuration

Moab Workload Manager may need a modification to its configuration file and the Moab Accounting Manager will need modification of its configuration for them to charge for the energy a job uses.

Moab Workload Manager Configuration

The `energy_used` generic metric is an additional unique generic metric name the Moab Workload Manager must track. If the quantity of unique generic metric names Moab is tracking is equal to the maximum unique generic metric names configured in the `moab.cfg` file by the `MAXGMETRIC` parameter before configuring use of the `energy_used` generic metric, the value of the `MAXGMETRIC` parameter must be incremented by one before Moab can process the `energy_used` generic metric.

The default value for the `MAXGMETRIC` parameter is 10. To err on the side of caution, it should be at least 25, and more if Nvidia GPUs and/or Intel MICs are present in the HPC cluster as they produce many metrics recorded by TORQUE and Moab.

Moab Accounting Manager Configuration

In order for the Moab Accounting Manager (MAM) to charge for the new `EnergyUsed` generic metric, MAM must be configured so its Usage Record will contain the generic metric.

1. Add the new `EnergyUsed` field to the MAM Usage Record configuration by executing the following command:

```
$ goldsh Attribute Create Object=UsageRecord Name=EnergyUsed DataType=Float
Description=\"Energy Used\"
```

2. Configure the glsusage command so MAM will display the new EnergyUsed field by executing the following command to edit MAM's configuration file.

```
$ vi /opt/mam/etc/gold.conf
```

3. Modify the usagerecord.show assignment, similar to the example below.

```
usagerecord.show =
Id,Type,Instance,Charge,Stage,User,Group,Account,Organization,Class,QualityOfService,Machine,Nodes,Processors,Memory,EnergyUsed,Duration,StartTime,EndTime,Description
```

4. Save the file and exit the editor.
5. Now add a charge rate for calculating the cost of the energy used by executing the following command:

```
$ gmkrate -n EnergyUsed -z 0.15/3600000 -d "15 cents per kilowatt-hour
(3.6M joules)"
```

The Moab Accounting Manager now has the configuration information it needs to compute a cost for the energy used by a job.

Tracing Energy Usage from the Cray XC System to MAM

This section contains screenshots that show the progression of the energy used by a job from the Cray XC system to the Moab Accounting Manager. The job submission requested 10 compute nodes with 32 cores on each node. The job submission was assigned job ID 121.

Cray RUR File and Energy Consumption

The Cray XC system, from which the following screenshots and information were obtained, had configured the location of its RUR file in its rur.conf file as illustrated:

```
# The File output plugin.
# Write RUR output to a single plain text file
# Arg - The destination text file
[file]
output: /opt/cray/rur/default/bin/file_output.py
#arg: path-to-flat-textfile
arg: /lus/scratch/RUR/output/rur.output
```

The screenshot that follows shows the RUR file is accessible on the login node from a known path (see cat command parameter) to which the actual path has been mapped. The command's output displays the `energy_used` metric in one of the RUR entries for job 121.sdb in the Cray RUR file.

```
login:~ # cat /etc/opt/cray/RUR/rur.output | grep 121.sdb
uid: 12795, apid: 9648, jobid: 121.sdb, cmdname: /home/crayadm/calc, plugin: energy
['energy_used', 3353472]
uid: 12795, apid: 9648, jobid: 121.sdb, cmdname: /home/crayadm/calc, plugin: timestamp
APP_START 2014-10-20T22:44:32CDT APP_STOP 2014-10-20T23:03:44CDT
```

From these screenshots, you can see the job used 3,353,472 joules (plugin: energy). In addition, ALPS indicated the job's application (ALPS job step) executed for 1,152 seconds as computed from the application's start and stop timestamps (plugin: timestamp).

TORQUE Resource Manager and Energy Consumption

This TORQUE resource manager `qstat` command output screenshot shows the `energy_used` generic metric is part of the TORQUE job's resource usage information:

```
sdb:~ # qstat -f 121
Job Id: 121.sdb
Job_Name = hello
Job_Owner = crayadm@snake-p1
resources_used.cput = 00:00:00
resources_used.energy_used = 3353472
resources_used.mem = 6112kb
resources_used.vmem = 141256kb
resources_used.walltime = 00:19:14
job_state = C
queue = batch
server = sdb
```

In addition, according to TORQUE, job 121 took 1,154 seconds to execute, which includes 2 additional seconds for ALPS and TORQUE processing overhead, including the RUR-based energy consumption data extraction process.

Moab Workload Manager (MWM) and Energy Consumption

This Moab workload manager screenshot shows the `energy_used` generic metric is part of the Moab job's generic metrics information:

```

login:~ # checkjob -v 121

job 121 (RM job '121.sdb')

AName: calc

```

In addition, according to Moab, job 121 took 1,157 seconds to execute, which includes ALPS, TORQUE, and Moab processing overhead with 3 additional seconds for TORQUE and Moab job processing overhead.

Moab Accounting Manager (MAM), Energy Consumption, and Charging

This MAM screenshot shows the charge rates set up that will apply to job 121:

```

sdb:~ # glsrate
Name      Value Amount      Description
-----
EnergyUsed 0.15/3600000 15 cents/kilowatt-hour (3.6M joules)
Processors 0.03/h       3 cents/processor-hour

```

Notice that the EnergyUsed charge rate is 15 cents per kilowatt-hour (1 kWh = 3,600,000 joules) and the Processors charge rate is 3 cents per core-hour.

This MAM screenshot shows the job ID, the job's processor count, the job runtime in seconds, and the job's energy usage; all of which will be involved in the job charge computation.

```
sdb:~ # glsusage -J 121 --show Instance,Processors,Duration,EnergyUsed
-----
Instance Processors Duration EnergyUsed
-----
121       320       1157       3353472
```

This MAM screenshot shows the charge computed by MAM using the job time in seconds, the processor count, and the energy usage with the rates identified in the previous example.

```
sdb:~ # glsusage -J 121
Id Type Instance Charge Stage User Group Account Organization Class
QualityOfService Machine Nodes Processors EnergyUsed Memory Duration StartTime
EndTime Description
-----
6 Job 121 5.28 Charge crayadm crayadm chemistry sciences batch
snake 10 320 3353472 1157 2014-10-20 22:44:29 2014-10-
20 23:03:49
```

The cost of \$3.23 is the sum of the energy rate × energy usage (\$0.15 per kWh × 3,353,472 joules ÷ 3,600,000 joules per kWh) plus the processor-seconds rate × processor-seconds (\$0.03 per core-hour × 320 processors × 1,157 seconds ÷ 3,600 seconds/hour) = \$0.14 (\$0.139728 rounded) + \$3.09 (\$3.085333 rounded) = \$3.23.

This MAM screenshot identifies the individual charges described in the previous example that make up the job's total charge.

```
sdb:~ # glscharge -J 121
UsageRecord Instance Name Value Duration Rate ScalingFactor Amount
CreationTime Description
-----
3182 121 EnergyUsed 3353472 0.15/3600000 1 0.14
2014-10-20 23:03:51
3182 121 Processors 320 1157 0.03/h 1 5.14
2014-10-20 23:03:51
```

i All MAM configurations necessary for computing a charge (e.g., defining charge precision, etc) are not identified here since the intent of this section is to illustrate how an administrator can trace energy consumption for a job through the various software components and systems involved. See the Moab Accounting Manager documentation for any additional generic charging configuration needed.

R.1 Overview

Each time Moab schedules a job, it must choose the nodes on which the job will run. Moab uses the Node Allocation policy to select the available nodes to be used. Because there are so many different systems and cluster topologies, you now have the ability to create and use a node allocation plugin for allocating nodes based on your cluster's interconnect topology.

The plugin policy allows you to write your own algorithm to choose which nodes will be used. This algorithm is contained in a shared library that Moab loads at run time.

To obtain the Plug-in Developer Kit (PDK) with the header file and example code, contact your sales representative.

R.1.1 Writing the Plugin

A plugin is a shared library that has specific functions and variables that will be called directly from Moab. The plugin conforms to a C language API. The API is specified through an include file: `moab-plugin.h`. This file must be included in the plugin code. The include file provides function definitions, structures and variables that will be used when communicating with Moab.

When you write the plugin, you need to ensure that the plugin code is robust. If the plugin crashes, Moab will crash. You will need to handle your own memory appropriately. If the plugin has memory leaks, Moab will have similar issues. If you want to maintain logs, the plugin will need to be responsible for its own logging.

R.1.1.1 API and Data Structures

The Application Programmer Interface (API) for the Moab Node Allocation Plugin consists of three data items and three entry points that must be supplied to Moab by the plugin.

Plugin Supplied Data	Description
const char *PLUGIN_NAME = "Node Allocation plugin 1.1";	This character pointer is used by Moab when logging information regarding the operation of the plugin.
const char *PLUGIN_TYPE = PLUGIN_TYPE_ NAME_ NODEALLOCATION;	This character pointer is used by Moab to verify the type of plugin. The value of this data is supplied by the <code>moab-plugin.h</code> source file. The plugin must set this as shown so that Moab does not attempt to use a plugin incorrectly. Moab uses this to determine whether the plugin API type is correct and to allow Moab to correctly communicate with the plugin.
const char *PLUGIN_VERSION = PLUGIN_API_ VERSION;	This character pointer is used by Moab to verify the API version number. The value of this data is supplied by the <code>moab-plugin.h</code> source file. The plugin must set this as shown so that the correct version of the <code>moab-plugin.h</code> is supplied to Moab. Moab uses this to determine whether the API version is correct and to allow Moab to correctly communicate with the plugin.

Load Time API	Description
initialize()	<pre>int initialize(const char *name, void **data_handle)</pre> <p>The plugin must supply an <code>initialize()</code> entry point. This entry point is called for each use instance of the plugin. For example, if the plugin is used on two different partitions, the <code>initialize()</code> entry point will be called once for each partition.</p> <ul style="list-style-type: none"> • Name — The name is the unique identifier which is used to distinguish multiple instances of the plugin and for logging. When configured globally, the name "ALL" will be given. • Data handle — The <code>data_handle</code> points to a location where the plugin should store a pointer to any internal data needed by the plugin between calls to the API. The actual format and structure of the data is up to the plugin. Moab will supply this pointer back to the plugin each time a plugin entry point is called. This data can provide context for the plugin usage instance.
Return codes	<p>The <code>initialize()</code> entry point should return one of two return statuses as defined in <code>moab-plugin.h</code>:</p> <pre>#define PLUGIN_RC_SUCCESS 0 #define PLUGIN_RC_FAILURE 1</pre>

Load Time API	Description
Gathering node info	The initialize() entry point must gather any information about system nodes, their topology, interconnection, and configuration that it needs to make correct node allocations. Since Moab does not know what information the plugin may need, the plugin must gather this information itself.
Memory considerations	The plugin may allocate memory for temporary or persistent data as needed, but <i>must</i> de-allocate or return the memory when finished. Not returning memory can result in memory leaks and unstable operation on the part of Moab.
Multiple access	A given loaded plugin can be used by more than one partition. This means that the plugin must maintain its internal data in such a way that calls to the plugin for the separate partitions do not conflict. It is recommended that internal data be allocated and a pointer to the data be kept in the data_handle described above as opposed to using global or static variables. Any global or static data will be shared between possible multiple instances of the plugin.

Runtime API	Description
node_allocate 0	<pre> int node_allocate (void *data_handle, const char *job_name, int container_count, nalloc_container_t container[]) </pre> <p>The plugin must provide a node_allocate() entry point. This entry point is called each time Moab needs to determine where (on what nodes) a job will eventually run. Note that this entry point can be called many times before the job is actually scheduled to run.</p> <ul style="list-style-type: none"> • Data structures — Moab uses C data structures to pass information and lists of nodes to the plugin and receive them back from the plugin. See <code>moab-plugin.h</code> for the definitions of these structures and for information on how they relate to one another.

Runtime API	Description																																																																								
Operations	<p>A node allocation request consists of one or more requirements. Each of these requirements is provided within a “container” structure. The container has information regarding the requirement to be met, the count and list of all nodes that are available to meet the requirement and a place to return the list of nodes that the plugin has chosen to use for the job.</p>																																																																								
	<table><tr><th>Command</th><th>Moab Job Task Count</th><th>Job Node Count</th><th>Job Tasks Per Node</th><th>Node CFG Procs</th><th>Node AVL Procs</th><th>Plugin Node Mapped TC</th><th>requirement ->taskcount</th><th>return_node_count</th></tr><tr><td colspan="9">Non-ExactNode</td></tr><tr><td>-l nodes=12</td><td>12</td><td>0</td><td>0</td><td>8</td><td>8</td><td>8</td><td>12</td><td>2</td></tr><tr><td>-l nodes-s=12:ppn=2</td><td>24</td><td>0</td><td>2</td><td>8</td><td>8</td><td>8</td><td>24</td><td>3</td></tr><tr><td colspan="9">ExactNode</td></tr><tr><td>-l nodes=4</td><td>4</td><td>4</td><td>0</td><td>8</td><td>8</td><td>1</td><td>4</td><td>4</td></tr><tr><td>-l nodes-s=4:ppn=2</td><td>8</td><td>4</td><td>2</td><td>8</td><td>8</td><td>2</td><td>8</td><td>4</td></tr><tr><td>-l nodes=12</td><td>12</td><td>0</td><td>0</td><td>8</td><td>6</td><td>6</td><td>12</td><td>2</td></tr></table>	Command	Moab Job Task Count	Job Node Count	Job Tasks Per Node	Node CFG Procs	Node AVL Procs	Plugin Node Mapped TC	requirement ->taskcount	return_node_count	Non-ExactNode									-l nodes=12	12	0	0	8	8	8	12	2	-l nodes-s=12:ppn=2	24	0	2	8	8	8	24	3	ExactNode									-l nodes=4	4	4	0	8	8	1	4	4	-l nodes-s=4:ppn=2	8	4	2	8	8	2	8	4	-l nodes=12	12	0	0	8	6	6	12	2
	Command	Moab Job Task Count	Job Node Count	Job Tasks Per Node	Node CFG Procs	Node AVL Procs	Plugin Node Mapped TC	requirement ->taskcount	return_node_count																																																																
	Non-ExactNode																																																																								
	-l nodes=12	12	0	0	8	8	8	12	2																																																																
	-l nodes-s=12:ppn=2	24	0	2	8	8	8	24	3																																																																
	ExactNode																																																																								
	-l nodes=4	4	4	0	8	8	1	4	4																																																																
	-l nodes-s=4:ppn=2	8	4	2	8	8	2	8	4																																																																
	-l nodes=12	12	0	0	8	6	6	12	2																																																																
	<p>The duty of the plugin is to use the information that it has previously gathered (during the initialization) to select from the available nodes those that will best fulfill the requirements.</p>																																																																								
	<p>The basic algorithm is to consume all the taskcount and memory on each node until the consumed task count is greater than or equal to the container's task_count and memory requirements.</p>																																																																								
	<p>A job's taskcount is calculated differently based on the JOBNODEMATCHPOLICY parameter. By default, it isn't defined and <code>-l nodes=#</code> actually requests the number of tasks without respect to the number of nodes. In this case, the plugin should consume all the tasks of each chosen node until the taskcount is greater and/or equal to the container's taskcount requirement. The plugin is for node allocation and not task placement.</p>																																																																								

Runtime API	Description
	<p>When the JOBNODEMATCHPOLICY EXACTNODE is configured, then <code>-l nodes=#</code> means the job wants # of nodes with 1 task per node. In this case, the nodes passed to the plugin will have a taskcount that is mapped down to what the job can only use on that node. Each node's taskcount should be consumed on each node until the summed amount is equal to the container's requirement taskcount requirement.</p> <p>The following table shows how commands are interpreted by Moab and translated to the plugin and what is expected of the plugin.</p>
Errors and return codes	<p>The plugin may internally log any errors encountered and must return a success or error status as defined in <code>moab-plugin.h</code>:</p> <pre>#define PLUGIN_RC_SUCCESS 0 #define PLUGIN_RC_FAILURE 1</pre>
Multiple access safe	<p>The <code>node_allocate()</code> entry point must support multiple access as described above.</p>

Unload Time API	Description
finish()	<pre>void finish(void *data_handle)</pre> <p>The plugin must supply a <code>finish()</code> entry point. This entry point is called when Moab is preparing to disable and/or unload an instance of the plugin.</p>
Memory/resource cleanup	<p>The plugin must de-allocate and free up any resources acquired either during the <code>initialize()</code> entry point or during any calls to the <code>node_allocate()</code> entry point. When the last entry point returns, there should be no allocated memory or other resources still in use by the plugin instance.</p>
Multiple access safe	<p>The <code>finish()</code> entry point must support multiple access as described above.</p>

R.1.2 Moab Configuration

The actual loading of a plugin is accomplished by specifying the plugin in the Moab configuration file, `moab.cfg`.

R.1.2.1 Moab.cfg

We recommend that you store all Moab plugins in the `$MOABHOMEDIR/lib` directory (e.g., `/opt/moab/lib`) as shared libraries (`*.so`). The name of the actual plugin shared library file is up to the plugin developer, which means you must give the correct name in the `moab.cfg` file to form the absolute plugin filename.

If a plug-in's specified shared library filename starts with a forward slash (`/`), it is an absolute file path name and Moab simply uses it without alteration. For example, if a plugin's specified shared library filename is `/opt/moab/plugins/plugin.so`, Moab will use it as the absolute plugin file path name.

If a plugin's specified shared library filename does not start with a forward slash (`/`), it is a plugin name and Moab forms the plugin's absolute path name by concatenating the Moab home directory, `"/lib/lib"`, the specified plugin name, and `".so"` to obtain the absolute path name. For example, if the `$MOABHOMEDIR` environment variable contains `/opt/moab` and the plugin name is `plugin`, Moab will create `/opt/moab/lib/libplugin.so` and use it as the absolute plugin file path name.

R.1.2.2 Syntax rules

In order for Moab to use a plugin for the Node Allocation policy, instead of a built-in Moab policy, you must configure the policy in the `moab.cfg` file with the value `"PLUGIN:"` followed by the plugin's shared library file name. The examples below assume the environment variable `$MOABHOMEDIR` has a value of `/opt/moab`. Note the use of relative and absolute plugin shared library file path names in the parameter value and how they affect Moab's construction of the full path name.

Par-tition	Plug-in Name	moab.cfg Parameter	Moab-derived Full Path Name
global	<code>plugin.so</code>	NODEALLOCATIONPOLICY <i>PLUGIN:plugin.so</i>	<code>/opt/moab/lib/libplugin.so</code>
global	<code>/usr/local/plugins/plugin.so</code>	NODEALLOCATIONPOLICY <i>PLUGIN:/usr/local/plugins/plugin.so</i>	<code>/usr/local/plugins/plugin.so</code>
abc	<code>plugin.so</code>	PARCFG[abc] NODEALLOCATIONPOLICY <i>=PLUGIN:plugin.so</i>	<code>/opt/moab/lib/libplugin.so</code>
xyz	<code>/usr/local/plugins/plugin.so</code>	PARCFG[xyz] NODEALLOCATIONPOLICY= <i>PLUGIN:/usr/local/plugins/plugin.so</i>	<code>/usr/local/plugins/plugin.so</code>

R.1.2.3 Troubleshooting

There are several commands that can be used to confirm that the Plugin Node Allocation Policy was loaded properly.

mschedctl -l

mschedctl -l is used to print out Moab's in memory configurations. If the plugin policy, with its full path, doesn't show for the configured partition then Moab failed to load the partition. Note that when the **NODEALLOCATIONPOLICY** is configured globally, it is configured on the "ALL" partition.

```
$ mschedctl -l -v|grep ^NODEALLOCATIONPOLICY
NODEALLOCATIONPOLICY[ALL]  PLUGIN:/opt/moab/lib/libfirstavailable.so
NODEALLOCATIONPOLICY[a]   PLUGIN:/opt/moab/lib/liblastavailable.so
NODEALLOCATIONPOLICY[b]   CONTIGUOUS
NODEALLOCATIONPOLICY[c]   PLUGIN:/opt/moab/lib/libfirstavailable.so
NODEALLOCATIONPOLICY[d]   [NONE]
```

mdiag -C

mdiag -C is used to validate the moab.cfg configuration. With a plugin node allocation policy, Moab will validate that it can successfully load the plugin and that all of the required symbols are present.

```
$ mdiag -C
...
INFO: line #35 is valid: 'NODEALLOCATIONPOLICY PLUGIN:firstavailable'
INFO: line #36 is valid: 'PARCFG[a]NODEALLOCATIONPOLICY=PLUGIN:lastavailable'
INFO: line #37 is valid: 'PARCFG[b]NODEALLOCATIONPOLICY=CONTIGUOUS'
INFO: line #38 is valid: 'PARCFG[d]NODEALLOCATIONPOLICY=PLUGIN:firstavailable'
```

Scalable Systems Software Job Object Specification

SSS Job Object Specification
Draft Release Version 3.1.0
26 April 2011

Scott Jackson, PNNLStringDavid Jackson, Ames Lab
Brett Bode, Ames Lab

Status of This Memo

This document describes the job object to be used by Scalable Systems Software compliant components. It is envisioned for this specification to be used in conjunction with the SSSRMAP protocol with the job object passed in the Data field of Requests and Responses. Queries can be issued to a job-cognizant component in the form of modified XPATH expressions to the Get field to extract specific information from the job object as described in the SSSRMAP protocol.

Abstract

This document describes the syntax and structure of the SSS job object. A job model is described that is flexible enough to support the specification of very simple jobs as well as jobs with elaborate and complex specification requirements in a way that avoids complex structures and syntax when it is not needed. The basic assumption is that a solitary job specification should be usable for all phases of the job lifecycle and can be used at submission, queuing, staging, reservations, quotations, execution, charging, accounting, etc. This job specification provides support for multi-step jobs, as well as jobs with disparate task descriptions. It accounts for operational requirements in a grid or meta-scheduled environment where the job is executed by multiple hosts in different administrative domains that support different resource management systems.

1.0 Introduction

This specification proposes a standard XML representation for a job object for use by the various components in the SSS Resource Management System. This object will be used in multiple contexts and by multiple components. It is anticipated that this object will be passed via the Data Element of SSSRMAP Requests and Responses.

1.1 Goals

There are several goals motivating the design of this representation.

The representation needs to be inherently flexible. We recognize we will not be able to exhaustively include the ever-changing job properties and capabilities that constantly arise.

The representation should use the same job object at all stages of that job's lifecycle. This object will be used at job submission, queuing, scheduling, charging and accounting, hence it may need to distinguish between requested and delivered properties.

The design must account for the properties and structure required to function in a meta or grid environment. It needs to include the capability to support local mapping of properties, global namespaces, etc.

The equivalent of multi-step jobs must be supported. Each step (job) can have multiple logical task descriptions.

Many potential users of the specification will not be prepared to implement the complex portions or fine-granularity that others need. There needs to be a way to allow the more complicated structure to be added as needed while leaving more straightforward cases simple.

There needs to be guidance for how to understand a given job object when higher order features are not supported by an implementation, and which parts are required, recommended and optional for implementers to implement.

It needs to support composite resources.

It should include the ability to specify preferences or fuzzy requirements.

1.2 Non-Goals

Namespace considerations and naming conventions for most property values are outside of the scope of this document.

1.3 Examples

Example 3-190: Very Simple Example

This example shows a simple job object that captures the requirements of a simple job.

```
<Job>
  <Id>PBS.1234.0</Id>
  <State>Idle</State>
  <User>scottmo</User>
  <Executable>/bin/hostname</Executable>
  <Processors>16</Processors>
  <Duration>3600</Duration>
</Job>
```

Example 3-191: Moderate Example

This example shows a moderately complex job object that uses features such as required versus delivered properties.

```
<Job>
  <Id>PBS.1234.0</Id>
  <Name>Heavy Water</Name>
  <Project>nwchemdev</Project>
  <User>peterk</User>
  <Application>NWChem</Application>
  <Executable>/usr/local/nwchem/bin/nwchem</Executable>
  <Arguments>-input basis.in</Arguments>
  <InitialWorkingDirectory>/home/peterk</InitialWorkingDirectory>
  <Machine>Colony</Machine>
  <QualityOfService>BottomFeeder</QualityOfService>
  <Queue>batch_normal</Queue>
  <State>Completed</State>
  <StartTime>1051557713</StartTime>
  <EndTime>1051558868</EndTime>
  <Charge>25410</Charge>
  <Requested>
    <Processors op="GE">12</Processors>
    <Memory op="GE" units="GB">2</Memory>
    <Duration>3600</Duration>
  </Requested>
  <Delivered>
    <Processors>16</Processors>
    <Memory metric="Average" units="GB">1.89</Memory>
    <Duration>1155</Duration>
  </Delivered>
  <Environment>
    <Variable name="PATH">/usr/bin:/home/peterk</Variable>
  </Environment>
</Job>
```

Example 3-192: Elaborate Example

This example uses a job group to encapsulate a multi-step job. It shows this protocol's ability to characterize complex job processing capabilities. A component that processes this message is free to retain only that part of the information that it requires. Superfluous information can be ignored by the component or filtered out (by XSLT for example).

```

<JobGroup>
  <Id>workflow1</Id>
  <State>Active</State>
  <Name>ShuttleTakeoff</Name>
  <JobDefaults>
    <StagedTime>1051557859</StagedTime>
    <SubmitHost>asteroid.lbl.gov</SubmitHost>
    <SubmitTime>1051556734</SubmitTime>
    <Project>GrandChallenge18</Project>
    <GlobalUser>C=US,O=LBNL,CN=Keith Jackson</GlobalUser>
    <User>keith</User>
    <Environment>
      <Variable name="LD_LIBRARY_PATH">/usr/lib</Variable>
      <Variable name="PATH">/usr/bin:~/bin:</Variable>
    </Environment>
  </JobDefaults>
  <Job>
    <Id>fr15n05.1234.0</Id>
    <Name>Launch Vector Initialization</Name>
    <Executable>/usr/local/gridphys/bin/lvcalc</Executable>
    <Queue>batch</Queue>
    <State>Completed</State>
    <Machine>SMP2.emsl.pnl.gov</Machine>
    <StartTime>1051557713</StartTime>
    <EndTime>1051558868</EndTime>
    <Quote>http://www.pnl.gov/SMP2#654321</Quote>
    <Charge units="USD">12.75</Charge>
    <Requested>
      <Duration>3600</Duration>
      <Processors>2</Processors>
      <Memory>1024</Memory>
    </Requested>
    <Delivered>
      <Duration>1155</Duration>
      <Processors consumptionRate="0.78">2</Processors>
      <Memory metric="Max">975</Memory>
    </Delivered>
    <TaskGroup>
      <TaskCount>2</TaskCount>
      <TaskDistribution type="TasksPerNode">1</TaskDistribution>
      <Task>
        <Node>node1</Node>
        <Process>99353</Process>
      </Task>
      <Task>
        <Node>node12</Node>
        <Process>80209</Process>
      </Task>
    </TaskGroup>
  </Job>
  <Job>
    <Id>fr15n05.1234.1</Id>
    <Name>3-Phase Ascension</Name>
    <Queue>batch_normal</Queue>
    <State>Idle</State>
    <Machine>Colony.emsl.pnl.gov</Machine>
    <Priority>1032847</Priority>
    <Hold>System</Hold>
    <StatusMessage>Insufficient funds to start job</StatusMessage>
    <Requested>

```

```
<Duration>43200</Duration>
</Requested>
<TaskGroup>
  <TaskCount>1</TaskCount>
  <Name>Master</Name>
  <Executable>/usr/local/bin/stage-coordinator</Executable>
  <Memory>2048</Memory>
  <Resource name="License" type="ESSL2">1</Resource>
  <Feature>Jumbo-Frame</Feature>
</TaskGroup>
<TaskGroup>
  <Name>Slave</Name>
  <TaskDistribution type="Rule">RoundRobin</TaskDistribution>
  <Executable>/usr/local/bin/stage-slave</Executable>
  <NodeCount>4</NodeCount>
  <Requested>
    <Processors group="-1">12</Processors>
    <Processors conj="Or" group="1">16</Processors>
    <Memory>512</Memory>
    <Node aggregation="Pattern">fr15n.*</Node>
  </Requested>
</TaskGroup>
</Job>
</JobGroup>
```

2.0 Conventions Used in This Document

2.1 Keywords

The keywords **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **RECOMMENDED**, **MAY**, and **OPTIONAL** in this document are to be interpreted as described in [RFC2119](#).

2.2 Table Column Interpretations

The columns of the property tables in this document have the following meanings:

Element Name	Name of the XML element (xsd;element) see [DATATYPES]
Type	Data type defined by xsd (XML Schema Definition) as: <ul style="list-style-type: none">• String — xsd:string (a finite length sequence of printable characters)• Integer — xsd:integer (a signed finite length sequence of decimal digits)• Float — xsd:float (single-precision 32-bit floating point)• Boolean — xsd:boolean (consists of the literals “true” or “false”)• DateTime — xsd:int (a 32-bit unsigned long in GMT seconds since the EPOCH)• Duration — xsd:int (a 32-bit unsigned long measured in seconds)

Element Name	Name of the XML element (xsd;element) see [DATATYPES]
Description	Brief description of the meaning of the property
Appearance	<p>An indication of whether the given property must appear in the parent element. It assumes the following meanings:</p> <ul style="list-style-type: none"> • MUST — This property is REQUIRED when the parent is specified • SHOULD — This property is RECOMMENDED when the parent is specified. • MAY — This property is OPTIONAL when the parent is specified.
Compliance	<p>An indication of the relative importance of supporting the given property.</p> <ul style="list-style-type: none"> • MUST — A compliant implementation MUST support this property. • SHOULD — A compliant implementation SHOULD support this property. • MAY — A compliant implementation MAY support this property.
Categories	<p>Some properties may be categorized into one of several categories. Letters in this column indicate that the given property can be classified in the following property categories.</p> <ul style="list-style-type: none"> • R — This property can be encompassed in a Requested element. • D — This property can be encompassed in a Delivered element.

2.3 Element Syntax Cardinality

Selected elements in the element syntax sections use regular expression wildcards with the following meanings:

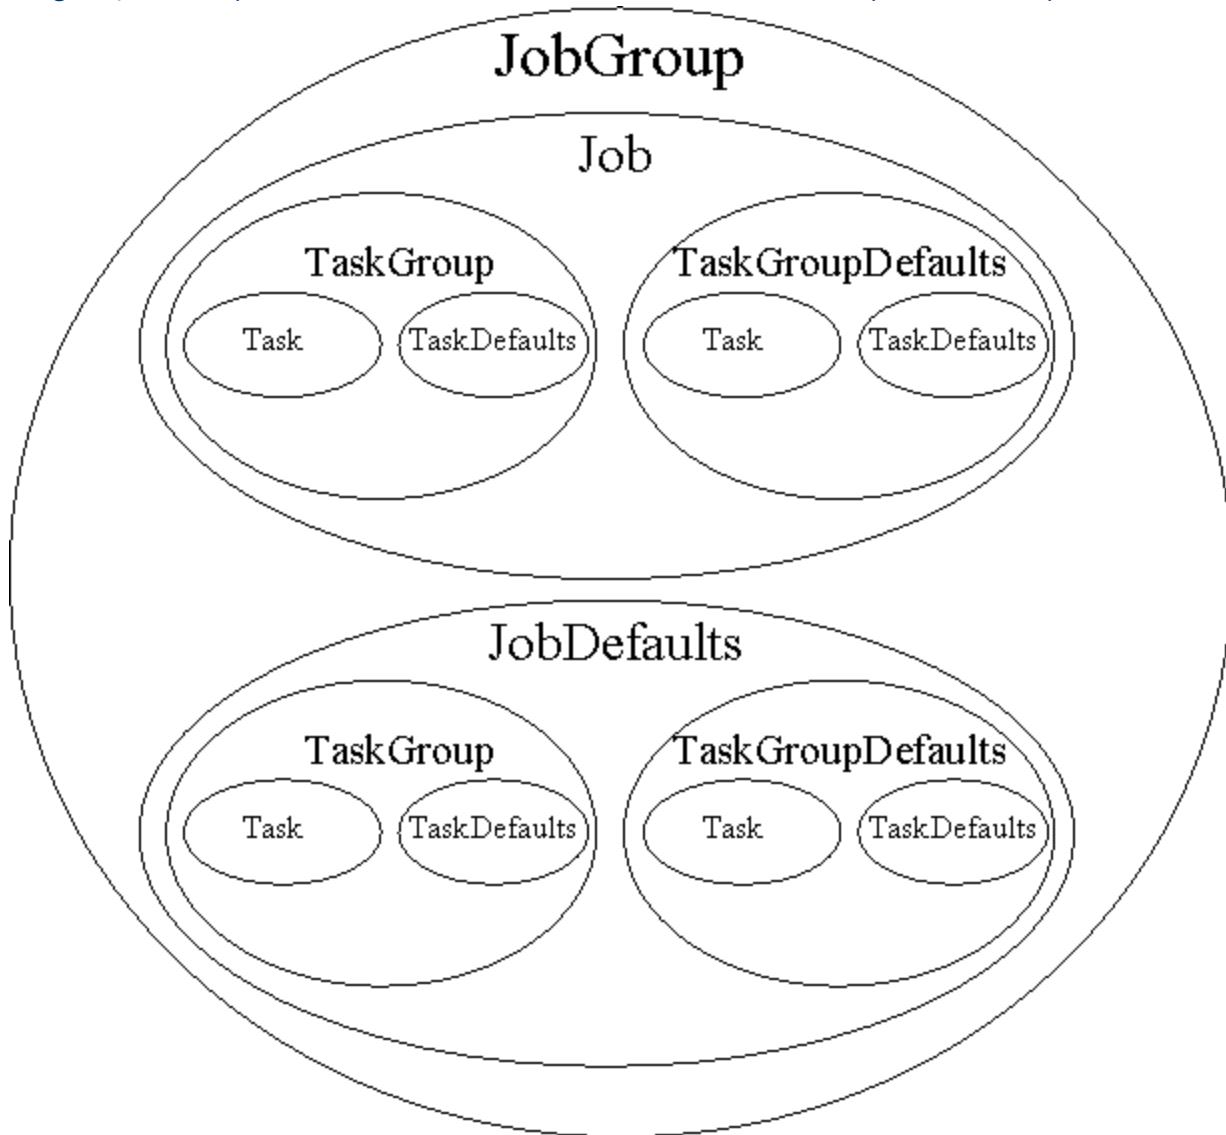

Wildcard	Description
*	Zero or more occurrences
+	One or more occurrences
?	Zero or one occurrences

The absence of one of these symbols implies exactly one occurrence.

3.0 The Job Model

The primary object within the job model is a job. A job can be thought of as a single schedulable entity and will be the object normally seen in job queues.

Image 3-19: JobGroup contains Job and JobDefaults, which contain TaskGroup and TaskGroupDefaults

Jobs with dependencies on other jobs may be submitted in a job group. Jobs within a job group form a DAG (directed acyclic graph) where the nodes are jobs and the edges represent dependencies on the status of previous jobs. A job group will consist of at least one job. A job group can optionally specify job defaults which are a set of job properties to be assumed by all jobs within the job group unless overridden within the job.

A job may consist of multiple tasks, which are the finest grained work unit and represent an endpoint for executing a given process instance. For example, a job that requests 3 nodes and 4 processors will have 4 tasks, two on one node and one on each of two nodes. Tasks may be grouped into task groups, which are logical aggregations of tasks and their common properties. Submit filters, prologs, epilogs, notification scripts, etc. run once only for each job. Whereas

task groups function as logical descriptions of tasks and their properties, they also describe the number of such tasks and the nodes that they run on. As an example, a master task group (consisting of a single task) might ask for a node with a MATLAB license, 2GB of memory and an Internet connected network adapter while a slave task group (consisting of 12 tasks) could be targeted for nodes with more CPU bandwidth -- all within the same job and utilizing a common MPI ring. Tasks (and hence taskgroups) can have different executables or environments, specify different consumable resources or node properties. A job, therefore, may specify one or more task group. A job that does not specify an explicit task group is considered as having a single implicit task group. A job can optionally specify task group defaults which are a set of task group properties to be assumed by all task groups within the job unless overridden within a task group.

A task group may specify one or more tasks. A task group that does not specify an explicit task is considered as having a single implicit task. A task group can optionally specify task defaults which are a set of task properties to be assumed by all tasks within the task group unless overridden within a task.

4.0 JobGroup Element

A JobGroup is an optional element that aggregates one or more interdependent jobs. Some resource managers support the submission of job groups (multi-step jobs) and queries on the status of an entire job group.

- A compliant implementation MAY support this element.
- A JobGroup MUST specify one or more JobGroup Properties.
- A JobGroup MUST contain one or more Jobs.
- A JobGroup MAY contain zero or more JobsDefaults.

The following illustrates this element's syntax:

```
C<JobGroup>
  <!-- JobGroup Properties -->+
  <Job/>+
  <JobDefaults/>?
</JobGroup>
```

4.1 JobGroup Properties

JobGroup Properties are properties that apply to the job group as a whole. These include the job group id, jobs and job defaults, and other simple optional job properties.

Simple JobGroup Properties

Simple (unstructured) job group properties are enumerated in the table below.

Table 3-7: Simple JobGroup Properties

Element Name	Type	Description	Appearance	Compliance
CreationTime	DateTime	Date and time that the job group was instantiated	MAY	MAY
Description	String	Description of the job group	MAY	MAY
Id	String	Job group identifier	MUST	MUST
Name	String	Name of the job group	MAY	SHOULD
State	String	State of the job group as a whole. Valid states may include NotQueued, Unstarted, Active, and Completed.	MAY	SHOULD

Job

A job group **MUST** contain one or more jobs.

See the next section for element details.

JobDefaults

A job group **MAY** contain zero or one job defaults.

See the next section for element details.

4.2 JobGroup Reference

When a simple reference to a predefined job group is needed in an encapsulating element, a JobGroup element is used with the text content being the job group id:

```
<JobGroup> workflow1</JobGroup>
```

5.0 Job and JobDefaults Element

The Job and JobDefaults elements are of the same structure. A Job element encapsulates a job and may be expressed as a standalone object. A JobDefaults element may only appear within a JobGroup and represents the defaults to be taken by all jobs within the job group. Job properties in Job elements override any properties found in a sibling JobDefaults element.

- A compliant implementation **MUST** support the Job element.
- A compliant implementation **MAY** support the JobDefaults element only if it supports the JobGroup element.
- A job **MUST** specify one or more Job Properties.
- One or more TaskGroup elements **MAY** appear at this level.
- Zero or one TaskGroupDefaults elements **MAY** appear at this level.

The following illustrates this element's syntax:

```
<Job>
  <!-- Job Properties -->+
  <TaskGroup/>*
  <TaskGroupDefaults/>?
</Job>
```

5.1 Job Properties

Job Properties apply to a particular job or as default properties to all jobs. They include the job id, job credentials, task groups, task group defaults, and other simple optional properties.

Simple Job Properties

Simple (unstructured) job properties are enumerated in the table below.

Table 3-8: Simple Job Properties

Element Name	Type	Description	Appearance	Compliance	Categories
Application	String	Type of application such as Gaussian or Nwchem	MAY	MAY	

Element Name	Type	Description	Appearance	Compliance	Categories
Architecture	String	Type architecture for the nodes on which this job must run	MAY	MAY	RD
Arguments	String	The arguments for the executable	MAY	SHOULD	
Charge	Float	The amount charged for the job	MAY	SHOULD	
Checkpointable	Boolean	Can this job be checkpointed?	MAY	MAY	
CpuDuration	Duration	Number of cpu seconds used by the job	MAY	SHOULD	
DeadlineTime	DateTime	Date and time that a job must end by	MAY	MAY	
EligibleTime	DateTime	Date and time that a job must start after	MAY	MAY	
EndTime	DateTime	Date and time that a job ended (independent of success or failure)	MAY	MUST	
Executable	String	Executable. This may be an absolute or relative path or a URI.*	MAY	MUST	

Element Name	Type	Description	Appearance	Compliance	Categories
ExitCode	Integer	Exit code for the job	MAY	SHOULD	
GlobalJob	String	Globally unique job identifier (possibly in the form of a URI)	MAY	SHOULD	
Hold	String	Hold(s) on the job. There may be multiple instances of this element if there is more than one ld on the job	MAY	SHOULD	
InitialWorking-Directory	String	Initial working directory	MAY	SHOULD	
Interactive	Boolean	Is this an interactive job?	MAY	SHOULD	
Id	String	A local job identifier assigned to the job by the local resource manager	MUST	MUST	
Name	String	Name of the job	MAY	SHOULD	
State	String	State of the job. Valid states may include Idle, Hold, Running, Suspended, or Completed	MAY	MUST	

Element Name	Type	Description	Appearance	Compliance	Categories
Type	String	Type of job. Meaning of this extension property is context specific.	MAY	MAY	
Machine	String	Name of the system or cluster that runs the job	MAY	MUST	RD
Network	String	Type of network adapter required by the job	MAY	MAY	RD
NodeCount	Integer	Number of nodes used by the job	MAY	MUST	RD
OperatingSystem	String	Operating System required by the job	MAY	MAY	RD
Partition	String	Name of the partition in which the job should run	MAY	MAY	RD
Priority	Integer	Current queue priority (or rank) for the job	MAY	SHOULD	
QualityOfService	String	Name of the Quality of Service (QoS)	MAY	SHOULD	RD
Queue	String	Name of the Queue (or class) that the job runs in	MAY	SHOULD	RD

Element Name	Type	Description	Appearance	Compliance	Categories
Quote	String	Identifier for a guaranteed charge rate quote obtained by the job	MAY	MAY	
Reservation	String	Identifier for a reservation used by the job	MAY	MAY	RD
ReservationTime	DateTime	Date and time that a reservation was placed for the job	MAY	MAY	
ResourceManagerType	String	Type of resource manager required to run this job	MAY	MAY	RD
Restartable	Boolean	Can this job be restarted?	MAY	MAY	
Shell	String	Specified the shell necessary to interpret the job script	MAY	MAY	
StagedTime	DateTime	Date and time that a job was staged to the local resource management system	MAY	MAY	
StartCount	Integer	Number of times the scheduler tried to start the job	MAY	MAY	

Element Name	Type	Description	Appearance	Compliance	Categories
StartTime	DateTime	Date and time that the job started	MAY	MUST	
StatusMessage	String	Natural language message that can be used to provide detail on why a job failed, isn't running, etc.	MAY	SHOULD	
SubmitTime	DateTime	Date and time that a job was submitted	MAY	SHOULD	
SubmitHost	String	FQDN of host where the job was submitted from	MAY	SHOULD	
Suspendable	Boolean	Can this job be suspended?	MAY	MAY	
SuspendDuration	Integer	Number of seconds the job was in the Suspended state	MAY	MAY	
TimeCategory	String	This allows the specification of shifts like PrimeTime for charging purposes	MAY	MAY	
Duration	Duration	Number of seconds in the Running state	SHOULD	MUST	RD

* The Executable may be a script or a binary executable. If it is already on the target system it may be referenced by an absolute or relative pathname (relative to InitialWorkingDirectory). If it is passed with the job in a File object

(see SSSRMAP), it can be referenced by an absolute or relative URI. An absolute URI would specify a URL where the file can be downloaded (like with wget). A relative URI is specified by preceding an identifier by a pound sign, as in

```
<Executable>#Script</Executable>
```

It will be found in a File object included along with the Job object with the Script as an identifier, as in

```
<File id="Script">echo hello world</File>
```

Feature Element

The Feature element connotes an arbitrary named feature of a node.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or one times within a given set of Job Properties.
- This element is of type String.
- This element MAY have an `aggregation` attribute of type String that provides a way to indicate multiple values with a single expression. A compliant implementation MAY support the `aggregation` attribute if the Feature element is supported. Possible values for this attribute include:
 - List — a comma-separated list of features
 - Pattern — a regular expression (perl5) matching desired features
- If an `aggregation` attribute is specified with the value of List, this element MAY also have a `delimiter` attribute of type String that indicates what delimiter is used to separate list elements. The default list delimiter is a comma.
- This element MAY be categorized as a requested or delivered property by being encompassed by the appropriate element.

The following is an example of a feature element:

```
<Feature aggregation="List">feature1,feature2</Feature>
```

OutputFile Element

The `OutputFile` element specifies the name of the file to which the output stream (stdout) from the job will be written.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate output file is auto-determined by the queuing system.

- This element MAY have a `redirectList` attribute which is a comma-separated list of output redirection attributes of type String. A compliant implementation SHOULD support this attribute if `OutputFile` is supported. Possible values for this attribute include:
 - Append — opens the output file for append
 - Close — closes and discards the output stream
 - Flush — output is written to output file as it is generated
 - Keep — leave the output file on the execution host
 - Merge — merges the output stream into the error stream

Note that when using the `redirectList` attributes, the cumulative effect of the `ErrorFile` and `OutputFile` directives may be order dependent.

The following is an example of an `OutputFile` element:

```
<OutputFile redirectList="Append">~/myjob.out</OutputFile>
```

ErrorFile Element

The `ErrorFile` element specifies the name of the file to which the error stream (stderr) from the job will be written.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate error file is auto-determined by the queuing system.
- This element MAY have a `redirectList` attribute which is a comma-separated list of error redirection attributes of type String. A compliant implementation SHOULD support this attribute if `ErrorFile` is supported. Possible values for this attribute include:
 - Close — closes and discards the error stream
 - Append — opens the error file for append
 - Flush — output is written to output file as it is generated
 - Keep — leave the output file on the execution host
 - Merge — merges the error stream into the output stream

Note that when using the `redirectList` attributes, the cumulative effect of the `ErrorFile` and `OutputFile` directives may be order dependent.

The following is an example of an `ErrorFile` element:

```
<ErrorFile redirectList="Merge"></ErrorFile>
```

InputFile Element

The `InputFile` element specifies the name of the file from which the input stream (stdin) for the job will be read.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate input file is auto-determined by the queuing system.
- This element MAY have a `redirectList` attribute which is a comma-separated list of input attributes of type String. A compliant implementation SHOULD support this attribute if `InputFile` is supported. Possible values for this attribute include:
 - Close — closes and discards the input stream

The following is an example of an `InputFile` element:

```
<InputFile redirectList="Close"></InputFile>
```

NotificationList Element

The `NotificationList` element specifies the job-related events or conditions for which a notification will be sent.

- This element's character content is a comma-separated list of events or conditions for which a notification should be sent. Possible values for the elements of this list include:
 - JobStart — send a notification when the job starts
 - JobEnd — send a notification when the job ends
 - All — send notifications for all notifiable events
 - None — do not send notifications for any events
- This element MAY have a `uri` attribute of type String which indicates where the notification is to be sent. A compliant implementation MAY support this attribute if `NotificationList` is supported. The `uri` is in the format: `[scheme://]authority` with the scheme being `smtp` and the authority being an email address by default.

The following is an example of a `NotificationList` element:

```
<NotificationList uri="smith@business.com">JobStart,JobEnd</NotificationList>
```

ResourceLimitElement

The `ResourceLimit` element represents a resource limit with its name and value.

- This element **MUST** have a `name` attribute of type String. A compliant implementation **MUST** support the name attribute if ResourceLimit is supported.
- This element **MAY** have a `type` attribute of type String that may have the values `Hard` or `Soft`. If the limit is enforced by the operating system, a hard limit is one that cannot be increased once it is set while a soft limit may be increased up to the value of the hard limit. If the type attribute is omitted, both the soft and hard limits are set.
- This element's character content is the resource limit's value.

Some typical names include:

Name	Description
CoreFileSize	Maximum core file size
CpuTime	CPU time in seconds
DataSegSize	Maximum data size
FileSize	Maximum file size
MaxMemorySize	Maximum resident set size
MaxProcesses	Maximum number of processes
MaxSwap	Virtual memory limit
MaxMemLock	Maximum locked-in-memory address space
MaxProcessors	Maximum processors
MaxMemory	Maximum memory
MaxDisk	Maximum disk space
MaxNetwork	Maximum network bandwidth
MaxFileIO	Maximum file i/o

Name	Description
OpenFiles	Maximum number of open files
Stacksize	Maximum stack size

The following is an example of a `ResourceLimit` element:

```
<ResourceLimit name="CPUTime">1000000</ResourceLimit>
```

Credentials

Credentials are a special group of job properties that characterize an authenticated token or id. They can be categorized in both requested and delivered forms.

Credential job properties are enumerated in the table below.

Table 3-9: Credential Job Properties

Element Name	Type	Description	Appearance	Compliance	Categories
Project	String	Name of the Project or Charge Account	MAY	SHOULD	RD
GlobalUser	String	Globally unique user identifier. This may be an X.509 DN for example	MAY	SHOULD	RD
Group	String	Name of the local group id	MAY	MAY	RD
User	String	Name of the local user id for the job	MAY	MUST	RD

Environment Element

The Environment element encapsulates environment variables.

- This element MAY have an export attribute of type Boolean that which if set to `True` indicates that all environment variables in the context of the job submission process should be exported in the job's execution environment.
- A compliant implementation SHOULD support this element.

- An Environment element MAY appear zero or one times within a given set of Job (or TaskGroup) Properties.
- An Environment element MAY contain one or more Variable elements.

The following illustrates this element's syntax:

```
<Environment>
  <Variable/>+
</Environment>
```

Variable Element

The Variable element represents an environment variable with its name and value.

This element MUST have a `name` attribute of type String. A compliant implementation MUST support the `name` attribute if Variable is supported. This element's character content is the environment variable's value.

The following is an example of a Variable element:

```
<Variable name="PATH">/usr/bin:/home/sssdemo</Variable>
```

Node Element

The Node element represents a node.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or one times within a given set of Job Properties.
- This element is of type String.
- This element MAY have an `aggregation` attribute of type String that provides a way to indicate multiple values with a single expression. A compliant implementation MAY support the `aggregation` attribute if the Feature element is supported. Possible values for this attribute include:
 - List - a comma-separated list of features
 - Pattern - a regular expression (perl5) matching desired features
 - Range - a range of nodes of the form: `<prefix>[5-23,77]`
- If an `aggregation` attribute is specified with the value of List, this element MAY also have a `delimiter` attribute of type String that indicates what delimiter is used to separate list elements. The default list delimiter is a comma.
- This element MAY have a `count` attribute of type Integer that indicates the instance count of the specified node(s).

- This element MAY be categorized as a requested or delivered property by being encompassed by the appropriate element.

The following is an example of a Node element:

```
<Node aggregation="Pattern">node[1-5]</Node>
```

TaskDistribution Element

The `TaskDistribution` element describes how tasks are to be mapped to nodes. This mapping may be expressed as a rule name, a task per node ratio or an arbitrary geometry.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or one times in a given set of Job (or TaskGroup) Properties.
- This element is of type String.
- This element MAY have a `type` attribute of type String that provides a hint as to the type of mapping guidance provided. It may have values including `Rule`, `TasksPerNode`, `ProcessorsPerTask` or `Geometry`. A compliant implementation MAY support the `type` attribute if the `TaskDistribution` element is supported.
- It is possible to use `Processors`, `NodeCount` and `TaskCount` elements to specify a set of mutually contradictory task parameters. When this occurs, components are responsible for resolving conflicting requirements.

The following are three examples of a `TaskDistribution` element:

```
<TaskDistribution type="TasksPerNode">2</TaskDistribution>
<TaskDistribution type="Rule">RoundRobin</TaskDistribution>
<TaskDistribution type="Geometry">{1,4}{2}{3,5}</TaskDistribution>
```

Dependency Element

The `Dependency` element allows a job's execution to depend on the status of other jobs. In a job group (multi-step job), some jobs may delay execution until the failure or success of other jobs creating in general a Directed Acyclic Graph relationship between the jobs. This element's content is of type String and represents the job that the current job is dependent upon. Since a job may have two or more dependencies, this element may appear more than once in a given job scope. A compliant implementation SHOULD support this element if job groups are supported.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times in a given set of Job (or TaskGroup) Properties.
- This element is of type String and contains the `JobId` that the current job is dependent upon.
- This element MAY have a `condition` attribute of type String that indicates the basis for determining when the current job executes in relation to the

specified job. A compliant implementation **MUST** support this attribute if this element is supported.

Possible values for this attribute include:

- `OnSuccess` this job should run after the referenced job only if it completes successfully (this is the default if the `type` attribute is omitted)
- `OnFailure` this job should run after the referenced job only if it fails
- `OnExit` this job should run after the referenced job exits
- If the `condition` attribute is equal to `OnExit`, this element **MAY** have a `code` attribute of type Integer that indicates the exit code that will trigger this job to run. If the `code` attribute is omitted, then the current job should run after the referenced job for any exit status.
- This element **MAY** have a `designator` attribute of type String that indicates that indicates the property of the job that identifies it as the dependent job. A compliant implementation **MAY** support this attribute if this element is supported.

Possible values for this attribute include:

- `JobId` the job this job is dependent upon is specified by `JobId` (this is the default if the `designator` attribute is omitted)
- `JobName` the job(s) this job is dependent upon are specified by `JobName`

The following is an example of a Dependency element:

```
<Dependency condition="OnSuccess" designator="JobId">PBS.1234.0</Dependency>
```

Consumable Resources

Consumable Resources are a special group of properties that can have additional attributes and can be used in multiple contexts. In general a consumable resource is a resource that can be consumed in a measurable quantity.

- A consumable resource **MAY** have a `context` attribute of type String that indicates the sense in which the resource is used. A compliant implementation **MAY** support this attribute. Possible values for this attribute include:
 - `Configured` — run this task only on nodes having the specified configured resources
 - `Available` — run this task only on nodes having the specified available resources. (this is the default if the `context` attribute is omitted)

- Used — the task used the indicated resources (this is analogous to being including in a Delivered block)
- Dedicated — the indicated amount of the resource should be dedicated to the task
- A consumable resource MAY have a `units` attribute that is of type String that specifies the units by which it is being measured. If this attribute is omitted, a default unit is implied. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `metric` attribute that is of type String that specifies the type of measurement being described. For example, the measurement may be a Total, an Average, a Min or a Max. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `duration` attribute of type Duration that indicates the amount of time for which that resource was used. This need only be specified if the resource was used for a different amount of time than the duration for the job. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `consumptionRate` attribute of type Float that indicates the average percentage that a resource was used over its duration. For example, an overbooked SMP running 100 jobs across 32 processors may wish to scale the usage and charge by the average fraction of processor usage actually delivered. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `dynamic` attribute of type Boolean that indicates whether the resource allocated for this job should be allowed to grow or shrink dynamically. For example, if processors is specified with dynamic equal to True, the job may be dynamically allocated more processors as they become available. The growth bounds can be indicated via the `op` attribute which is inherited when a consumable resource element is encapsulated within a *Requested* element. A compliant implementation MAY support this attribute if the element is supported.

A list of simple consumable resources is listed in the table below.

Table 3-10: Simple Consumable Resources

Element Name	Type	Description	Appearance	Compliance	Categories
Disk	Float	Amount of disk	MAY	SHOULD	RD

Element Name	Type	Description	Appearance	Compliance	Categories
Memory	Float	Amount of memory	MAY	SHOULD	RD
Network	Float	Amount of network	MAY	MAY	RD
Processors	Integer	Number of processors	MAY	MUST	RD
Swap	Float	Amount of virtual memory	MAY	MAY	RD

The following are two examples for specifying a consumable resource:

```
<Memory metric="Max" units="GB">483</Memory>
<Processors duration="1234" consumptionRate="0.63">4</Processors>
```

Resource Element

In addition to the consumable resources enumerated in the above table, an extensible consumable resource is defined by the Resource element.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times within a given set of job (or task group) properties.
- Like the other consumable resources, this property MAY be categorized as a requested or delivered property by being encompassed in the appropriate element.
- This element is of type Float.
- This element shares the *same properties and attributes as the other consumable resources* but it requires an additional `name` (and optional `type`) attribute to describe it.
- It MUST have a `name` attribute of type String that indicates the type of consumable resource being measured. A compliant implementation MUST support this attribute if the element is supported.
- It MAY have a `type` attribute of type String that distinguishes it within a general resource class. A compliant implementation SHOULD support this attribute if the element is supported.

The following are two examples for specifying a Resource element:

```
<Resource name="License" type="MATLAB">1</Resource>
<Resource name="Telescope" type="Zoom2000" duration="750" metric="KX">10</Resource>
```

Extension Element

The Extension element provides a means to pass extensible properties with the job object.

Some applications may find it easier to use a named extension property than discover and handle elements they do not understand or anticipate by name.

- A compliant implementation MAY support this element.
- This element MUST have a `name` attribute of type String that gives the extension property's name. A compliant implementation MUST support this attribute if this element is supported.
- This element MAY have a `type` attribute of type String that characterizes the context within which the property should be understood. A compliant

implementation SHOULD support this attribute if this element is supported.

- This element's character content, which is of type String, is the extension property's value.

The following is an example of an Extension element:

```
<Extension type="Scheduler" name="Restartable">true</Extension>
```

TaskGroup

A job MAY specify one or more task groups.

See the next section for element details.

TaskGroupDefaults

A job MAY specify zero or more task group defaults.

See the next section for element details.

5.2 Job Reference

When a simple reference to a predefined job is needed in an encapsulating element, a Job element is used with the text content being the job id:

```
<Job> job123</Job>
```

6.0 TaskGroup and TaskGroupDefaults Element

The `TaskGroup` and `TaskGroupDefaults` elements have the same structure. A `TaskGroup` element aggregates tasks. A `TaskGroupDefaults` element may only appear within a Job (or JobDefaults) and represents the defaults to be taken by all task groups within the job. Task group properties in `TaskGroup` elements override any properties found in a sibling `TaskGroupDefaults` element.

- A compliant implementation MAY support the `TaskGroup` element.
- A compliant implementation MAY support the `TaskGroupDefaults` element.
- A task group MUST specify one or more TaskGroup Properties.
- One or more Task elements MAY appear at this level.
- Zero or one TaskDefaults elements MAY appear at this level.

The following illustrates this element's syntax:

```
<TaskGroup>
  <!-- TaskGroup Properties -->+
  <!-- Job Properties -->*
  <Task>+
  <TaskDefaults>?
</TaskGroup>
```

6.1 TaskGroup Properties

TaskGroup Properties apply to a particular task group or as default properties to encompassed task groups. These properties include the task group id, its tasks, task defaults, and other simple task group properties.

Simple TaskGroup Properties

Simple (unstructured) task group properties are enumerated in Table 6.

Table 3-11: Simple TaskGroup Properties

Element Name	Type	Description	Appearance	Compliance	Categories
TaskCount	Integer	Number of tasks in this taskgroup	MAY	MUST	
Id	String	A task group identifier unique within the job	MAY	MAY	
Name	String	A task group name (such as Master)	MAY	SHOULD	

Task

A task group MAY specify zero or more tasks.

See the next section for element details.

TaskDefaults

A task group MAY specify zero or more task defaults.

See the next section for element details.

6.2 TaskGroup Reference

When a simple reference to a predefined task group is needed in an encapsulating element, a TaskGroup element is used with the text content being the task group id:

```
<TaskGroup> tgl</TaskGroup>
```

7.0 Task and TaskDefaults Element

The `Task` and `TaskDefaults` elements have the same structure. A `Task` element contains information specific to a task (like the process id or the host it ran on). A `TaskDefaults` element may only appear within a `TaskGroup` (or `TaskGroupDefaults`) element and represents the defaults for all tasks within the task group. Task properties in `Task` elements override any properties found in a sibling `TaskDefaults` element.

- A compliant implementation MAY support the `TaskGroup` element.
- A compliant implementation MAY support the `TaskGroupDefaults` element.
- A task group MUST specify one or more `TaskGroup` Properties.
- One or more `Task` elements MAY appear at this level.
- Zero or one `TaskDefaults` elements MAY appear at this level.

The following illustrates this element's syntax:

```
<Task>
  <!-- Task Properties -->+
  <!-- Job Properties -->*
</Task>
```

7.1 Task Properties

Task Properties are properties that apply to a particular task or as default properties to encompassed tasks. These properties include the task id and other task properties.

Simple Task Properties

Simple (unstructured) task properties are enumerated in the table below.

Table 3-12: Simple Task Properties

Element Name	Type	Description	Appearance	Compliance	Categories
Node	String	Name of the node this task ran on	MAY	MUST	

Element Name	Type	Description	Appearance	Compliance	Categories
Session	Integer	Session id for the task group or job	MAY	MAY	
Id	String	A task identifier unique within the taskgroup	MAY	MAY	

7.2 Task Reference

When a simple reference to a predefined task is needed in an encapsulating element, a `Task` element is used with the text content being the task id:

```
<Task>1</Task>
```

8.0 Property Categories

Certain properties need to be classified as being in a particular category. This is done when it is necessary to distinguish between a property that is requested and a property that was delivered. When no such distinction is necessary, it is recommended that the property not be enveloped in one of these elements. In general, a property should be enveloped in a category element only if it is expected that the property will need to be attributed to more than one property category, or if it needs to make use of some of the special attributes inherited from the category.

8.1 Requested Element

A requested property reflects properties as they were requested. A disparity might occur between the requested value and the value delivered if a preference was expressed, if multiple options were specified, or if ranges or pattern matching was specified.

- A compliant implementation SHOULD support this element.

The following illustrates the syntax of this element:

```
<Requested>
  <!-- Requested Properties -->+
</Requested>
```

The following describes the attributes and elements for the example above:

/Requested

This element is used to encapsulate requested properties.

/Requested/<Requested Property>

Requested properties appear at this level.

Requested Properties inherit some additional attributes.

- A requested property MAY have an `op` attribute of type String that indicates a conditional operation on the value. A compliant implementation SHOULD support this attribute. Valid values for the `op` attribute include EQ meaning equals (which is the default), NE meaning not equal, LT meaning less than, GT meaning greater than, LE meaning less than or equal to, GE meaning greater than or equal to, Match which implies the value is a pattern to be matched.
- A requested property MAY have a `conj` attribute of type String that indicates a conjunctive relationship with the previous element. A compliant implementation MAY support this attribute. Valid values for the `conj` attribute include And (which is the default), Or, Nand meaning and not, and Nor meaning or not.
- A requested property MAY have a `group` attribute of type Integer that indicates expression grouping and operator precedence much like parenthetical groupings. A compliant implementation MAY support this attribute. A positive grouping indicates the number of nested expressions being opened with the property while a negative grouping indicates the number of nested expressions being closed with the property.
- A requested property MAY have a `preference` attribute of type Integer that indicates a preference for the property along with a weight (the weights are taken as a ratio to the sum of all weights in the same group). A compliant implementation MAY support this attribute. If a group of positive valued preference alternatives are specified, at least one of the preferences must be satisfied for the job to run. If a group of negative valued preferences are specified, the preferences will try to be met according to their weights but the job will still run even if it can't satisfy any of the preferred properties. (Weight ranking can be removed by making all weights the same value (1 or -1 for example)).
- A requested property MAY have a `performanceFactor` attribute of type Float that provides a hint to the scheduler of what performance tradeoffs to make in terms of resources and start time. A compliant implementation MAY support this attribute.

The following are four examples of using Requested Properties:

```

<Requested>
  <Processors op="GE">8</Processors>
  <Processors op="LE">16</Processors>
  <Duration>3600</Duration>
</Requested>
<Requested>
  <NodeCount>1</NodeCount>
  <Node aggregation="Pattern">fr15.*</Node>
</Requested>
<Requested>
  <User group="1">scottmo</User>
  <Account group="-1">mscfops</Account>
  <User conj="Or" group="1">amy</User>
  <Account group="-1">chemistry</Account>
</Requested>
<Requested>
  <Memory preference="2">1024</Memory>
  <Memory preference="1">512</Memory>
</Requested>

```

8.2 Delivered Element

A delivered property reflects properties as they were actually utilized, realized or consumed. It reflects the actual amounts or values that are used, as opposed to a limit, choice or pattern as may be the case with a requested property.

- A compliant implementation SHOULD support this element.

The following illustrates the syntax of this element:

```

<Delivered>
  <!-- Delivered Properties -->+
</Delivered>

```

The following describes the attributes and elements for the example above:

/Delivered

This element is used to encapsulate delivered properties.

/Delivered/<Delivered Property>

Delivered properties appear at this level.

Delivered Properties inherit some additional attributes.

- A delivered property MAY have a `group` attribute of type Integer that indicates expression grouping and operator precedence much like parenthetical groupings. A compliant implementation MAY support this attribute. A positive grouping indicates the number of nested expressions being opened with the property while a negative grouping indicates the number of nested expressions being closed with the property. The

purpose of this attribute would be to logically group delivered properties if they were used in certain aggregations (like a job that spanned machines).

The following are the same four examples distinguishing the delivered amounts and values:

```

<Delivered>
  <Processors>12</Processors>
  <Duration>1234</Duration>
</Delivered>
<Delivered>
  <Node>fr15n03</Node>
</Delivered>
<Delivered>
  <User>scottmo</User>
  <Account>mscfops</Account>
</Delivered>
<Delivered>
  <Memory>1024</Memory>
</Delivered>

```

9.0 AwarenessPolicy Attribute

A word or two should be said about compatibility mechanisms. With all the leeway in the specification with regard to implementing various portions of the specification, problems might arise if an implementation simply ignores a portion of a job specification that is critical to the job function in certain contexts. Given this situation, it might be desirable in some circumstances for jobs to be rejected by sites that fail to fully support that job's element or attributes. At other times, it might be desirable for a job to run, using a best-effort approach to supporting unimplemented features. Consequently, we define an `awarenessPolicy` attribute which can be added as an optional attribute to the Job element or any other containment or property element to indicate how the property (or the default action for the elements that the containment element encloses) must react when the implementation does not understand an element or attribute.

An awareness policy of `Reject` will cause the server to return a failure if it receives a client request in which it does not support an associated element name or attribute name or value. It is reasonable for an implementation to ignore (not even look for) an element or attribute that would not be critical to its function as long as ignoring this attribute or element would not cause an incorrect result. However, any element or attribute that was present that would be expected to be handled in a manner that the implementation does not support must result in a failure.

An awareness policy of `Warn` will accept the misunderstood element or attribute and continue to process the job object on a best effort basis. However a warning **MUST** be sent (if possible) to the requestor enumerating the elements and attributes that are not understood.

An awareness policy of `Ignore` will accept the unsupported element or attribute and continue to process the job object on a best effort basis. The action could be to simply ignore the attribute.

- This name of this attribute is `awarenessPolicy`.
- This attribute is of type `String`.
- This attribute can have values of `Reject`, `Warn` or `Ignore`.
- A compliant implementation MAY support this attribute.
- An implementation that does not support an attribute MUST reject any job object which contains elements or attributes that it does not support. Furthermore, it SHOULD return a message to the requestor with an indication of the element or attribute name it did not understand.
- This attribute MAY be present in a property or containment element.
- If an implementation does support the attribute, but it is absent, the default value of `Reject` is implied.
- Individual elements in the job object may override the containing object's awareness policy default by including this attribute. For example, a job might specify an `awarenessPolicy` of `Reject` at its root (the `Job` element) but may want to allow a particular subset of elements or attributes to be ignored if not understood. Conversely, a job with a default `awarenessPolicy` of `Ignore` might want to classify a subset of its optional elements as `Reject` if they are indispensable to its correct interpretation. An implementation can opt to check or not check for this attribute at any level it wants but must assume a `Reject` policy for any elements it does not check.

Scalable Systems Software Resource Management and Accounting Protocol (SSSRMAP) Message Format

Resource Management Interface Specs

Release v. 3.0.4

18 JUL 2005

Scott Jackson
Brett Bode
David Jackson
Kevin Walker

Status of This Memo

This is a specification defining an XML message format used between Scalable Systems Software components. It is intended that this specification will continue to evolve as these interfaces are implemented and thoroughly tested by time and experience.

Abstract

This document is a specification describing a message format for the interaction of resource management and accounting software components developed as part of the Scalable Systems Software Center. The SSSRMAP Message Format defines a request-response syntax supporting both functional and object-oriented messages. The protocol is specified in XML Schema Definition. The message elements defined in this specification are intended to be framed within the Envelope and Body elements defined in the SSSRMAP Wire Protocol specification document.

1.0 Introduction

A major objective of the Scalable Systems Software [SSS] Center is to create a scalable and modular infrastructure for resource management and accounting on terascale clusters including resource scheduling, grid-scheduling, node daemon support, comprehensive usage accounting and user interfaces emphasizing portability to terascale vendor operating systems. Existing resource management and accounting components feature disparate APIs (Application Programming Interfaces) requiring various forms of application coding to interact with other components.

This document proposes a common message format expressed in an XML request-response syntax to be considered as the foundation of a standard for communications between and among resource management and accounting software components. In this document this standard is expressed in two levels of generality. The features of the core SSSRMAP protocol common to all resource management and accounting components in general are described in the main body of this document. The aspects of the syntax specific to individual components are described in component-specific binding documents.

2.0 Conventions Used in This Document

2.1 Keywords

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC2119 [RFC2119].

2.2 XML Case Conventions

In order to enforce a consistent capitalization and naming convention across all SSSRMAP specifications “Upper Camel Case” (UCC) and “Lower Camel Case” (LCC) Capitalization styles shall be used. UCC style capitalizes the first character of each word and compounds the name. LCC style capitalizes the first character of each word except the first word. [XML_CONV][FED_XML]

1. SSSRMAP XML Schema and XML instance documents SHALL use the following conventions:
 - Element names SHALL be in UCC convention (example: `<UpperCamelCaseElement/>`).
 - Attribute names SHALL be in LCC convention (example: `<UpperCamelCaseElement lowerCamelCaseAttribute="Whatever"/>`).
2. General rules for all names are:
 - Acronyms SHOULD be avoided, but in cases where they are used, the capitalization SHALL remain (example: XMLSignature).
 - Underscores (_), periods (.) and dashes (-) MUST NOT be used (example: use JobId instead of JOB.ID, Job_ID or job-id).

2.3 Schema Definitions

SSSRMAP Schema Definitions appear like this

In case of disagreement between the schema file and this specification, the schema file takes precedence.

3.0 Encoding

Encoding tells how a message is represented when exchanged. SSSRMAP data exchange messages SHALL be defined in terms of XML schema [XML_SCHEMA].

3.1 Schema Header and Namespaces

The header of the schema definition is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema
  xmlns="http://www.w3.org/2001/XMLSchema"
  xmlns:sssrmap="http://scidac.org/ScalableSystems/SSSRMAP"
  targetNamespace="http://www.scidac.org/ScalableSystems/SSSRMAP"
  elementFormDefault="qualified">
```

3.2 Element Descriptions

The following subsections describe the elements that make up SSSRMAP messages. SSSRMAP messages are transmitted in the Body and Envelope

elements as described in the SSSRMAP Wire Protocol specification [WIRE_PROTOCOL].

The Request Element

The `Request` element specifies an individual request. An object-oriented request will have at least one `Object` element while a functional request will not have one. Depending on context, the `Request` element MAY contain one or more `Get` elements or one or more `Set` elements and any number of `Where` elements. `Option`, `Data`, `File` or `Count` elements may also be included. If a component supports it, chunking may be requested where large response data is possible. Setting the chunking attribute to "True" requests that the server break a large response into multiple chunks (each with their own envelope) so they can be processed in separate pieces.

Only an `action` attribute is required. All other attributes are optional.

Attribute	Description
action	Specifies the action or function to be performed
actor	The authenticated user sending the request
id	Uniquely maps the request to the appropriate response
chunking	Requests that segmentation be used for large response data if set to "True"
chunkSize	Requests that the segmentation size be no larger than the specified amount

```
<complexType name="RequestType">
  <choice minOccurs="0" maxOccurs="unbounded">
    <element ref="sssrmap:Object" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmap:Option" minOccurs="0" maxOccurs="unbounded"/>
    <choice minOccurs="0" maxOccurs="1">
      <element ref="sssrmap:Get" minOccurs="1" maxOccurs="unbounded"/>
      <element ref="sssrmap:Set" minOccurs="1" maxOccurs="unbounded"/>
    </choice>
    <element ref="sssrmap:Where" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmap>Data" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmap:Count" minOccurs="0" maxOccurs="1"/>
    <any namespace="##other" minOccurs="0" maxOccurs="unbounded"/>
  </choice>
  <attribute name="action" type="string" use="required"/>
  <attribute name="actor" type="string" use="required"/>
  <attribute name="id" type="string" use="optional"/>
  <attribute name="chunking" type="sssrmap:BoolType" use="optional"/>
  <attribute name="chunkSize" type="positiveInteger" use="optional"/>
</complexType>

<element name="Request" type="sssrmap:RequestType"/>
```

The Object Element

The `Object` element is used in an object-oriented request to specify the object receiving the action. It is possible to have multiple `Object` elements in a request if an implementation supports multi-object queries.

The object class name is specified as text content. All attributes are optional.

- `join` – the type of join to be performed with the preceding object
 - A `join` attribute of “Inner” specifies an inner join. This is the default.
 - A `join` attribute of “FullOuter” specifies a full outer join.
 - A `join` attribute of “LeftOuter” specifies a left outer join.
 - A `join` attribute of “RightOuter” specifies a right outer join.
 - A `join` attribute of “Cross” specifies a cross join.
 - A `join` attribute of “Union” specifies a union join.

```
<complexType name="ObjectType">
  <simpleContent>
    <extension base="string">
      <attribute name="join" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Object" type="sssrmap:ObjectType"/>
```

The Get Element

The `Get` element is used to indicate the data fields to be returned in a query. `Get` is typically used within requests with `action="query"`. Multiple `Get` elements cause the fields to be returned in the order specified. If no `Get` elements are specified, the query will return a default set of fields.

Only a `name` attribute is required. All other attributes are optional.

Attribute	Description
name	The name of the data field to be returned. This MUST be of the form of a “Modified XPATH expression” as described in a later section.

Attribute	Description
op	<p>The operator to be used to aggregate or perform an operation on the returned values.</p> <ul style="list-style-type: none"> • An <i>op</i> attribute of “Sort” specifies an ascending sort operation • An <i>op</i> attribute of “Tros” specifies a descending sort operation • An <i>op</i> attribute of “Sum” returns the sum (only valid for numeric values) • An <i>op</i> attribute of “Max” returns the maximum value • An <i>op</i> attribute of “Min” returns the minimum value • An <i>op</i> attribute of “Count” returns the number of values • An <i>op</i> attribute of “Average” returns the average of the values • An <i>op</i> attribute of “GroupBy” signifies that aggregates are grouped by this field
object	Specifies the object for which you want the named attribute in a multi-object query.
units	The units in which to return the value (if applicable)

```

<complexType name="GetType">
  <attribute name="name" type="string" use="required"/>
  <attribute name="object" type="string" use="optional"/>
  <attribute name="op" type="sssrmap:GetOperatorType" use="optional"/>
  <attribute name="units" type="string" use="optional"/>
</complexType>

<element name="Get" type="sssrmap:GetType"/>

<simpleType name="GetOperatorType">
  <restriction base="string">
    <enumeration value="Sort"/>
    <enumeration value="Tros"/>
    <enumeration value="Count"/>
    <enumeration value="Sum"/>
    <enumeration value="Max"/>
    <enumeration value="Min"/>
    <enumeration value="Average"/>
    <enumeration value="GroupBy"/>
  </restriction>
</simpleType>

```

The Set Element

The **Set** element is used to specify the object data fields to be assigned values. **Set** is typically used within requests with `action="Create"` or `action="Modify"`. The use of **Get** or **Set** elements within a request is mutually exclusive.

The assignment value (to which the field is being changed) is specified as the text content. A **Set** element without a value may be used as an assertion flag. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
name	The name of the field being assigned a value. This MUST be of the form of a “Modified XPATH expression” as described in a later section.
op	<p>The operator to be used in assigning a new value to the name. If an <code>op</code> attribute is not specified and a value is specified, the specified value will be assigned to the named field (“assign”).</p> <ul style="list-style-type: none"> • An <code>op</code> attribute of “Assign” assigns value to the named field • An <code>op</code> attribute of “Inc” increments the named field by the value • An <code>op</code> attribute of “Dec” decrements the named field by the value
units	The units corresponding to the value being set

```

<complexType name="SetType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmap:SetOperatorType" use="optional"/>
      <attribute name="units" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Set" type="sssrmap:SetType"/>

<simpleType name="SetOperatorType">
  <restriction base="string">
    <enumeration value="Assign"/>
    <enumeration value="Inc"/>
    <enumeration value="Dec"/>
  </restriction>
</simpleType>

```

The Where Element

A `Request` element may contain one or more `Where` elements that specify the search conditions for which objects the action is to be performed on.

The condition value (against which the field is tested) is specified as the text content. A `Where` element without a value may be used as a truth test. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
name	The name of the data field to be tested. This MUST be of the form of a “Modified XPATH expression” as described in a later section.

Attribute	Description
op	<p>The operator to be used to test the name against the value. If an <code>op</code> attribute is not specified and a value is specified, the field will be tested whether it is equal to the value ("EQ").</p> <ul style="list-style-type: none"> • An <code>op</code> attribute of "EQ" specifies an equality comparison • An <code>op</code> attribute of "LT" specifies a "less than" comparison • An <code>op</code> attribute of "GT" specifies a "greater than" comparison • An <code>op</code> attribute of "LE" specifies a "less than or equal to" test • An <code>op</code> attribute of "GE" specifies a "greater than or equal to" test • An <code>op</code> attribute of "NE" specifies a "not equal to" test • An <code>op</code> attribute of "Match" specifies a regular expression matching comparison
conj	<p>Indicates whether this test is to be anded or ored with the immediately preceding where condition</p> <ul style="list-style-type: none"> • A <code>conj</code> attribute of "And" specifies an "and" conjunction • A <code>conj</code> attribute of "Or" specifies an "or" condition • A <code>conj</code> attribute of "AndNot" specifies an "and not" conjunction • A <code>conj</code> attribute of "OrNot" specifies an "or not" condition
group	<p>Indicates an increase or decrease of parentheses grouping depth</p> <ul style="list-style-type: none"> • A positive number indicates the number of left parentheses to precede the condition, i.e. <code>group="2"</code> represents "((condition". • A negative number indicates the number of right parentheses to follow the condition, i.e. <code>group="-2"</code> represents "condition))".
object	Specifies the object for the first operand in a multi-object query.
subject	Specifies the object for the second operand in a multi-object query.
units	Indicates the units to be used in the value comparison

```

<complexType name="WhereType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmap:OperatorType" use="optional"/>
      <attribute name="conj" type="sssrmap:ConjunctionType" use="optional"/>
      <attribute name="group" type="integer" use="optional"/>
      <attribute name="units" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Where" type="sssrmap:WhereType"/>

<simpleType name="WhereOperatorType">
  <restriction base="string">
    <enumeration value="EQ"/>
    <enumeration value="GT"/>
    <enumeration value="LT"/>
    <enumeration value="GE"/>
    <enumeration value="LE"/>
    <enumeration value="NE"/>
    <enumeration value="Match"/>
  </restriction>
</simpleType>

```

The Option Element

The `Option` element is used to indicate processing options for the command. An option might be used to indicate that command usage or special formatting is desired, or that the command is to be invoked with particular options.

The option value is specified as the text content. An `Option` element without a value may be used as an assertion flag. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
name	The name of the field being assigned a value
op	The operator to be used to disassert the option <ul style="list-style-type: none"> An <code>op</code> attribute of "Not" specifies that the option is not asserted
conj	Indicates whether this test is to be anded or ored with the immediately preceding where condition <ul style="list-style-type: none"> A <code>conj</code> attribute of "And" specifies an "and" conjunction A <code>conj</code> attribute of "Or" specifies an "or" condition A <code>conj</code> attribute of "AndNot" specifies an "and not" conjunction A <code>conj</code> attribute of "OrNot" specifies an "or not" condition

```
<complexType name="OptionType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmap:OptionOperatorType" use="optional"/>
      <attribute name="conj" type="sssrmap:ConjunctionType" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Option" type="sssrmap:OptionType"/>

<simpleType name="OptionOperatorType">
  <restriction base="string">
    <enumeration value="Not"/>
  </restriction>
</simpleType>
```

The Data Element

A Request or Response element may have one or more Data elements that allow the supplying of context-specific data. A request might pass in a structured object via a Data element to be acted upon. Typically a query will result in a response with the data encapsulated within a Data element.

The following attributes are optional:

Attribute	Description
name	Object name describing the contents of the data
type	Describing the form in which the data is represented <ul style="list-style-type: none">A type attribute of "XML" indicates the data has internal xml structure and can be recursively parsed by an XML parserA type attribute of "Binary" indicates the data is an opaque dataset consisting of binary dataA type attribute of "String" indicates the data is an ASCII stringA type attribute of "Int" indicates the data is an integerA type attribute of "Text" indicates the data is in formatted human-readable textA type attribute of "HTML" indicates the data is represented in HTML

```
<complexType name="DataType">
  <sequence>
    <any namespace="##any" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute name="name" type="string" use="optional"/>
  <attribute ref="sssrmap:Type" use="optional"/>
</complexType>

<element name="data" type="sssrmap:DataType"/>
```

The File Element

A Request or Response element may have one or more File elements of type String that allow the inclusion of files. The files may be either text or binary and

may be referenced by objects inside the Data element. A file may be compressed using the gzip algorithm [ZIP]. A binary file or a compressed file must be base64 encoded as defined in XML Digital Signatures ("http://www.w3.org/2000/09/xmldsig#base64"). Metadata describing the modes and properties of the resulting file are passed as parameters. The text or base64 encoded file data forms the string content of the `File` element.

The following attributes are optional:

Attribute	Description
id	Specifies an identifier that allows the file to be referenced from within another object. If more than one File elements are specified, this attribute is REQUIRED in each of them.
name	Specifies the name to give the file upon creation on the target system. This can be an absolute or relative pathname (relative to the InitialWorkingDirectory).
owner	Indicates what owner the file should be changed to. By default it will be changed to the UserId that the authenticated actor maps to on the target system. Note that this function should succeed only if the requestor has the privileges to do so (i.e. authenticated as root).
group	Indicates what group the file should be changed to. By default it will be set to the primary groupid of the UserId that the authenticated actor maps to on the target system. Note that this function should succeed only if the requestor has the proper privileges.
mode	Indicates the permissions the file should possess. By default it will be set according to the default umask for the UserId that the authenticated actor maps to on the target system. Note that this function should not set permissions for the file that exceed the privileges for the actor. These permissions can be specified using either an octal number or symbolic operations (as accepted by the GNU <code>chmod(1)</code> command).
compressed	Indicates whether the file has been compressed <ul style="list-style-type: none"> • A <code>compressed</code> attribute of "True" indicates the file has been compressed. • A <code>compressed</code> attribute of "False" indicates the file has not been compressed. This is the default.
encoded	Indicates whether the file has been base64 encoded <ul style="list-style-type: none"> • An <code>encoded</code> attribute of "True" indicates the file has been encoded. • An <code>encoded</code> attribute of "False" indicates the file has not been encoded. This is the default.

```
<complexType name="FileType">
  <sequence>
    <any namespace="##any" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute name="name" type="string" use="optional"/>
  <attribute name="owner" type="string" use="optional"/>
  <attribute name="group" type="string" use="optional"/>
  <attribute name="mode" type="string" use="optional"/>
  <attribute name="compressed" type="boolean" use="optional"/>
  <attribute name="encoded" type="boolean" use="optional"/>
</complexType>

<element name="file" type="sssrmap:FileType"/>
```

The Count Element

A single `Count` element may be included within a `Request` or `Response` and is context-specific. This can be used to represent the number of objects acted upon or returned.

```
<element name="Count" type="positiveInteger"/>
```

The Response Element

The `Response` element specifies an individual response. It **MUST** contain a `Status` element. It **MAY** also contain `Count` and any number of `Data` or `File` elements. If chunking has been requested and is supported by the server, a large response may be broken up into multiple chunks (each with their own envelope). The `chunkNum` attribute can be used to indicate which chunk the current one is. The `chunkMax` attribute can be used to determine when all the chunks have been received (all chunks have been received if `chunkNum=chunkMax` or `chunkMax=0`).

It **MAY** have any of the following attributes:

Attribute	Description
id	Uniquely maps the response to the corresponding request
chunkNum	Integer indicating the current chunk number [1 is implied when this attribute is missing or blank]
chunkMax	Integer indicating the number of chunks expected [-1 means unknown but more chunks to follow; 0 means unknown but this is the last chunk; 0 is implied if this attribute is missing or blank]

```

<complexType name="ResponseType">
  <choice minOccurs="0" maxOccurs="unbounded">
    <element ref="sssrmap:Status" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:Count" minOccurs="0" maxOccurs="1"/>
    <element ref="sssrmap:Data" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmap:File" minOccurs="0" maxOccurs="unbounded"/>
    <any minOccurs="0" maxOccurs="unbounded" namespace="##other"/>
  </choice>
  <attribute name="object" type="string" use="optional"/>
  <attribute name="action" type="string" use="optional"/>
  <attribute name="id" type="string" use="optional"/>
  <attribute name="chunkNum" type="integer" use="optional"/>
  <attribute name="chunkMax" type="integer" use="optional"/>
</complexType>

<element name="Response" type="sssrmap:ResponseType"/>

```

The Status Element

A **Response** element **MUST** contain a single **Status** element that indicates whether the reply represents a success, warning or failure. This element is composed of the child elements **Value**, **Code** and **Message**. Of these, **Value** and **Code** are required, and **Message** is optional.

```

<complexType name="StatusType">
  <choice minOccurs="1" maxOccurs="unbounded">
    <element ref="sssrmap:Value" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:Code" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:Message" minOccurs="0" maxOccurs="1"/>
    <any minOccurs="0" maxOccurs="unbounded" namespace="##other"/>
  </choice>
</complexType>

<element name="Status" type="sssrmap:StatusType"/>

```

The Value Element

The **Value** element is of type **String** and **MUST** have a value of "Success", "Warning" or "Failure".

```

<simpleType name="StatusValueType">
  <restriction base="string">
    <enumeration value="Success"/>
    <enumeration value="Warning"/>
    <enumeration value="Failure"/>
  </restriction>
</simpleType>

<element name="Value" type="sssrmap:StatusValueType"/>

```

The Code Element

A **Response** element must contain a single **Code** element that specifies the 3-digit status code for the response. Refer to the next section on Error Reporting for a description and listing of supported status codes.

```
<simpleType name="CodeType">
  <restriction base="string">
    <pattern value="[0-9]{3}" />
  </restriction>
</simpleType>

<element name="Code" type="sssrmap:CodeType"/>
```

The Message Element

A `Response` element may contain a single `Message` element that is context specific to the success or failure response. The message should be an error message if status is false. If present for a successful response, it may be used as a human readable message for a user interface.

```
<element name="Message" type="string"/>
```

3.3 Modified XPATH Expressions

The `name` attribute used within the `Get`, `Set` and `Where` Elements MUST have the form of a modified XPATH expression as defined in this section. Usually this will just be the simple name of the object property. Some complex objects, such as the SSS Job Object and the SSS Node Object, however, are represented in a structured way with nested elements. In order to define a consistent and flexible way to access and manipulate these objects as well as keeping the flat XML objects simple and straightforward, SSSRMAP specifies that a "Modified XPATH" syntax be used.

In essence, "Modified XPATH" is defined to be an XPATH [XPATH] expression with the exception that the `"/"` may be omitted from the beginning of the expression when a document search is desired. Thus, on the server side, a standard XPATH routine can be used by prepending `"/"` to any expression that does not begin with a `"/"`.

The response data should always include all of the structure of the queried object necessary to place the requested data in its proper context.

See the XPATH specification for a full description of XPATH. The XPath 1.0 Recommendation is <http://www.w3.org/TR/1999/REC-xpath-19991116>. The [latest version of XPath 1.0](http://www.w3.org/TR/xpath) is available at <http://www.w3.org/TR/xpath>.

Sample Modified XPATH Expressions

Consider the following hypothetical object(s) (which might be returned within a `Data` element).

```

<Job>
  <JobId>PBS.1234.0</JobId>
  <Requested>
    <Memory op="GE">512</Memory>
    <Processors>2</Processors>
    <WallDuration>P3600S</WallDuration>
  </Requested>
  <Utilized>
    <Memory metric="Average">488</Memory>
    <WallDuration>P1441S</WallDuration>
  </Utilized>
</Job>

```

To get everything above for this job you would not need a `Get` element:

```

<Request action="Query">
  <Object>Job</Object>
  <Where name="JobId">PBS.1234.0</Where>
</Request>

```

If you used `<Get name="JobId"/>` you would get back:

```

<Job>
  <JobId>PBS.1234.0</JobId>
</Job>

```

If you used `<Get name="Memory"/>` (or `name="/Job/*/Memory"`) you would get:

```

<Job>
  <Requested>
    <Memory op="GE">512</Memory>
  </Requested>
  <Utilized>
    <Memory metric="Average">488</Memory>
  </Utilized>
</Job>

```

If you used `<Get name="Requested/Memory"/>` (or `name="/Job/Requested/Memory"`) you would get:

```

<Job>
  <Requested>
    <Memory op="GE">512</Memory>
  </Requested>
</Job>

```

If you used `<Get name="Memory[@metric='Average']"/>` (or `name="Memory[@metric]"`) you would get:

```

<Job>
  <Utilized>
    <Memory metric="Average">488</Memory>
  </Utilized>
</Job>

```

3.4 Examples

Sample Requests

Requesting a list of nodes with a certain configured memory threshold (batch format):

```
<Request action="Query" id="1">
  <Object>Node</Object>
  <Get name="Name" />
  <Get name="Configured/Memory" />
  <Where name="Configured/Memory" op="GE" units="MB">512</Where>
</Request>
```

Activating a couple of users:

```
<Request action="Modify">
  <Object>User</Object>
  <Set name="Active">True</Set>
  <Where name="Name">scott</Where>
  <Where name="Name" conj="Or"/>brett</Where>
</Request>
```

Submitting a simple job:

```
<Request action="Submit">
  <Object>Job</Object>
  <Data>
    <Job>
      <User>xdp</User>
      <Account>youraccount</Account>
      <Command>myprogram</Command>
      <InitialWorkingDirectory>/usr/home/scl/xdp</InitialWorkingDirectory>
      <RequestedNodes>4</RequestedNodes>
      <RequestedWCTime>100</RequestedWCTime>
    </Job>
  </Data>
</Request>
```

Sample Responses

A response to the available memory nodes query (batch format)

```

<Response id="1">
  <Status>
    <Value>Success</Value>
    <Code>000</Code>
  </Status>
  <Count>2</Count>
  <Data>
    <Node>
      <Name>fr01n01</Name>
      <Configured>
        <Memory>512</Memory>
      </Configured>
    </Node>
    <Node>
      <Name>fr12n04</Name>
      <Configured>
        <Memory>1024</Memory>
      </Configured>
    </Node>
  </Data>
</Response>

```

Two users successfully activated

```

<Response>
  <Status>
    <Code>000</Code>
    <Message>Two users were successfully modified</Message>
  </Status>
  <Count>2</Count>
</Response>

```

A failed job submission:

```

<Response>
  <Status>
    <Value>Failure</Value>
    <Code>711</Code>
    <Message>Invalid account specified. The job was not submitted.</Message>
  </Status>
</Response>

```

4.0 Error Reporting

SSSRMAP requests will return a status and a 3-digit response code to signify success or failure conditions. When a request is successful, a corresponding response is returned with the `status` element set to `Success` and the `code` element set to "000". When a request results in an error detected by the server, a response is returned with the `status` element set to `Failure` and a 3-digit error code in the `code` element. An optional human-readable message may also be included in a failure response providing context-specific detail about the failure. The default message language is US English. (The status flag makes it easy to signal success or failure and allows the receiving peer some freedom in the amount of parsing it wants to do on failure [BXXP]).

Success codes:

Code	Response Text in US English
0xx	Request was successful
000	General Success
010	Help/usage reply
020	Status reply
030	Subscription successful
035	Notification successful (Ack)
040	Registration successful
050-079	Component-defined
080-099	Application-defined

Warning codes:

Code	Response Text in US English
1xx	Request was successful but includes a warning
100	General warning (examine message for details)
102	Check result (Did what you asked but may not have been what you intended -- or information is suspect)
110	Wire Protocol or Network warning
112	Redirect
114	Protocol warning (something was wrong with the protocol, but best effort guesses were applied to fulfill the request)
120	Message Format warning

Code	Response Text in US English
122	Incomplete specification (request missing some essential information -- best effort guess applied)
124	Format warning (something was wrong with the format but best effort guesses were applied to fulfill the request)
130	Security warning
132	Insecure request
134	Insufficient privileges (Response was sanitized or reduced in scope due to lack of privileges)
140	Content or action warning
142	No content (The server has processed the request but there is no data to be returned)
144	No action taken (nothing acted upon -- i.e. deletion request did not match any objects)
146	Partial content
148	Partial action taken
150-179	Component-defined
180-199	Application-defined

Wire protocol codes:

Code	Response Text in US English
2xx	A problem occurred in the wire protocol or network
200	General wire protocol or network error
210	Network failure
212	Cannot resolve host name

Code	Response Text in US English
214	Cannot resolve service port
216	Cannot create socket
218	Cannot bind socket
220	Connection failure
222	Cannot connect
224	Cannot send data
226	Cannot receive data
230	Connection rejected
232	Timed out
234	Too busy
236	Message too large
240	Framing failure
242	Malformed framing protocol
244	Invalid payload size
246	Unexpected end of file
250-279	Component-defined
280-299	Application-defined

Message format codes:

Code	Response Text in US English
3xx	A problem occurred in the message format
300	General message format error
302	Malformed XML document
304	Validation error(XML Schema)
306	Namespace error
308	Invalid message type (Something other than Request or Response in Body
310	General syntax error in request
311	Object incorrectly (or not) specified
312	Action incorrectly (or not) specified
313	Invalid Action
314	Missing required element or attribute
315	Invalid Object (or Object-Action combination
316	Invalid element or attribute name
317	Illegal value for element or attribute
318	Illegal combination
319	Malformed Data
320	General syntax error in response
321	Status incorrectly (or not)specified
322	Code incorrectly (or not)specified

Code	Response Text in US English
324	Missing required element or attribute
326	Invalid element or attribute name
327	Illegal value for element or attribute
328	Illegal combination
329	Malformed Data
340	Pipelining failure
342	Request identifier is not unique
344	Multiple messages not supported
346	Mixed messages not supported (Both requests and responses in same batch)
348	Request/response count mismatch
350-379	Component-defined
380-399	Application-defined

Security codes:

Code	Response Text in US English
4xx	A security requirement was not fulfilled
400	General security error
410	Negotiation failure
412	Not understood
414	Not supported

Code	Response Text in US English
416	Not accepted
420	Authentication failure
422	Signature failed at client
424	Authentication failed at server
426	Signature failed at server
428	Authentication failed at client
430	Encryption failure
432	Encryption failed at client
434	Decryption failed at server
436	Encryption failed at server
438	Decryption failed at client
440	Authorization failure
442	Authorization failed at client
444	Authorization failed at server
450-479	Component-defined
480-499	Application-defined

Event management codes:

Code	Response Text in US English
5xx	Failure conditions in event messaging

Code	Response Text in US English
500	General Event Management failure
510	Subscription failed
520	Notification failed
550-579	Component-defined
580-599	Application-defined

Reserved codes:

Code	Response Text in US English
6xx	Reserved for future use

Server application codes:

Code	Response Text in US English
7xx	A server-side application-specific error occurred
700	General failure
710	Not supported
712	Not understood
720	Internal error
730	Resource unavailable (insufficient resources -- software, hardware or a service I rely upon is down)
740	Business logic
750-779	Component-defined
780-799	Application-defined

Client application codes:

Code	Response Text in US English
8xx	A client-side application-specific error occurred
800	General failure
810	Not supported
812	Not understood
820	Internal error
830	Resource unavailable
840	Business logic
850-879	Component-defined
880-899	Application-defined

Miscellaneous codes:

Code	Response Text in US English
9xx	Miscellaneous failures
999	Unknown failure

Scalable Systems Software Node Object Specification

SSS Node Object Specification
Release Version 3.1.0
26 April 2011

Scott Jackson, PNNL
David Jackson, Ames Lab
Brett Bode, Ames Lab

Status of This Memo

This is a specification of the node object to be used by Scalable Systems Software compliant components. It is envisioned for this specification to be used in conjunction with the SSSRMAP protocol with the node object passed in the Data field of Requests and Responses. Queries can be issued to a node-cognizant component in the form of modified XPATH expressions to the Get field to extract specific information from the node object as described in the SSSRMAP protocol.

Abstract

This document describes the syntax and structure of the SSS node object. This node model takes into account various node property categories such as whether it represents a configured, available or utilized property.

1.0 Introduction

This specification proposes a standard XML representation for a node object for use by the various components in the SSS Resource Management System. This object will be used in multiple contexts and by multiple components. It is anticipated that this object will be passed via the Data Element of SSSRMAP Requests and Responses.

1.1 Goals

There are several goals motivating the design of this representation.

It needs to be inherently flexible. We recognize we will not be able to exhaustively include the ever-changing node properties and capabilities that constantly arise.

The same node object should be used at all stages of its lifecycle. This object needs to distinguish between configured, available and utilized properties of a node.

Its design takes into account the properties and structure required to function in a meta or grid environment. It should eventually include the capability of resolving namespace and locality issues, though the earliest versions will ignore this requirement.

One should not have to make multiple queries to obtain a single piece of information — i.e. there should not be two mutually exclusive ways to represent a node resource.

It needs to support resource metric as well as unit specifications.

1.2 Examples

Simple Example

This example shows a simple expression of the Node object.

```
<Node>
  <Id>Node64</Id>
  <Configured>
    <Processors>2</Processors>
    <Memory>512</Memory>
  </Configured>
</Node>
```

Elaborate Example

This example shows a more elaborate Node object.

```

<Node>
  <Id>64</Id>
  <Name>Netpipe2</Name>
  <Feature>BigMem</Feature>
  <Feature>NetOC12</Feature>
  <Opsys>AIX</Opsys>
  <Arch>Power4</Arch>
  <Configured>
    <Processors>16</Processors>
    <Memory units="MB">512</Memory>
    <Swap>512</Swap>
  </Configured>
  <Available>
    <Processors>7</Processors>
    <Memory metric="Instantaneous">143</Memory>
  </Available>
  <Utilized>
    <Processors wallDuration="3576">8</Processors>
    <Memory metric="Average" wallDuration="3576">400</Memory>
  </Utilized>
</Node>

```

2.0 Conventions Used in This Document

2.1 Keywords

The keywords MUST, MUST NOT, REQUIRED, SHALL, SHALL NOT, SHOULD, RECOMMENDED, MAY, and OPTIONAL in this document are to be interpreted as described in [RFC2119](#).

2.2 Table Column Interpretations

In the property tables, the columns are interpreted to have the following meanings:

Property	Description
Element Name	Name of the XML element (xsd:element)

Property	Description
Type	<p>Data type defined by xsd (XML Schema Definition) as:</p> <ul style="list-style-type: none"> String — xsd:string(a finite length sequence of printable characters) Integer — xsd:integer(a signed finite length sequence of decimal digits) Float — xsd:float (single-precision 32-bit floating point) Boolean — xsd:boolean (consists of the literals “true” or “false”) DateTime — xsd:dateTime (discreet time values are represented in ISO 8601 extended format CCYY-MM-DDThh:mm:ss where CC represents the century, YY the year, MM the month and DD the day. The letter T is the date/time separator and hh, mm, ss represent hour, minute and second respectively. This representation may be immediately followed by a Z to indicate Coordinated Universal Time (UTC) or, to indicate the time zone, i.e. the difference between the local time and Coordinated Universal Time, immediately followed by a sign, + or –, followed by the difference from UTC.) Duration — xsd:duration (a duration of time is represented in ISO 8601 extended format PnYnMnDTnHnMnS, where nY represents the number of years, nM the number of months, nD the number of days, T is the date/time separator, nH the number of hours, nM the number of minutes and nS the number of seconds. The number of seconds can include decimal digits to arbitrary precision.)
Description	Brief description of the meaning of the property
Appearance	<p>This column indicates whether the given property has to appear within the parent element. It assumes the following meanings:</p> <ul style="list-style-type: none"> MUST — This property is REQUIRED when the parent is specified. SHOULD — A compliant implementation SHOULD support this property. MAY — A compliant implementation MAY support this property.
Compliance	<p>The column indicates whether a compliant implementation has to support the given property.</p> <ul style="list-style-type: none"> MUST — A compliant implementation MUST support this property. SHOULD — A compliant implementation SHOULD support this property. MAY — A compliant implementation MAY support this property.
Categories	<p>Some properties may be categorized into one of several categories. Letters in this column indicate that the given property can be classified in the following property categories.</p> <ul style="list-style-type: none"> C — This property can be encompassed in a Configured element. A — This property can be encompassed in an Available element. U — This property can be encompassed in a Utilized element.

2.3 Element Syntax Cardinality

The cardinality of elements in the element syntax sections may make use of regular expression wildcards with the following meanings:

Wildcard	Description
*	Zero or more occurrences
+	One or more occurrences
?	Zero or one occurrences

The absence of one of these symbols implies one and only one occurrence.

3.0 The Node Model

The primary element within the node model is a node. One can speak of some node properties as being a configured, available or utilized property of the node.

4.0 Node Element

The Node element is the root element of a node object and is used to encapsulate a node.

- A node object **MUST** have exactly one Node element.
- A compliant implementation **MUST** support this element.
- A node **MUST** specify one or more Node Properties.

4.1 Uncategorized Node Properties

Uncategorized Node Properties are properties that apply to the node as a whole and do not need to be distinguished between being configured, available or utilized. These include the node id and other optional node properties.

Simple Node Properties

Simple (unstructured) node properties are enumerated in the table below.

Table 3-13: Simple Node Properties

Element Name	Type	Description	Appearance	Compliance
Id	String	Node identifier	MUST	MUST
Name	String	Node name or pattern	MAY	MAY

Element Name	Type	Description	Appearance	Compliance
OpSys	String	Operating System	MAY	SHOULD
Arch	String	Architecture	MAY	SHOULD
Description	String	Description of the node	MAY	MAY
State	String	State of the node. Valid states may include Offline, Configured, Unknown, Idle, and Busy.	SHOULD	MUST
Features	String	Arbitrary named features of the node (comma-delimited string)	MAY	SHOULD

Extension Element

The `Extension` element provides a means to pass extensible properties with the node object. Some applications may find it easier to deal with a named extension property than discover and handle elements for which they do not understand or anticipate by name.

- A compliant implementation MAY support this element.
- This element MUST have a name attribute that is of type String and represents the name of the extension property. A compliant implementation MUST support this attribute if this element is supported.
- This element MAY have a type attribute that is of type String and provides a hint about the context within which the property should be understood. A compliant implementation SHOULD support this attribute if this element is supported.
- The character content of this element is of type String and is the value of the extension property.

The following is an example of an `Extension` element:

```
<Extension type="Chemistry" name="Software">NWChem</Extension>
```

4.2 Property Categories

Certain node properties (particularly consumable resources) need to be classified as being in a particular category. This is done when it is necessary to distinguish between a property that is configured versus a property that is available or utilized. For example, a node might be configured with 16 processors. At a particular time, 8 might be utilized, 7 might be available and 1 disabled. When a node property must be categorized to be understood

properly, the property **MUST** be enveloped within the appropriate Property Category Element.

Configured Element

A configured node property reflects resources pertaining to the node that could in principle be used though they may not be available at this time. This information could be used to determine if a job could ever conceivably run on a given node.

- A compliant implementation **MUST** support this element.

The following is an example of using Configured Properties:

```
<Configured>
  <Processors>16</Processors>
  <Memory units="MB">512</Memory>
</Configured>
```

Available Element

An available node property refers to a resource that is currently available for use.

- A compliant implementation **SHOULD** support this element.

The following is an example of specifying available properties:

```
<Available>
  <Processors>7</Processors>
  <Memory units="MB">256</Memory>
</Available>
```

Utilized Element

A utilized node property reflects resources that are currently utilized.

- A compliant implementation **SHOULD** support this element.

The following is an example of specifying utilized properties:

```
<Utilized>
  <Processors>8</Processors>
  <Memory metric="Average">207</Memory>
</Utilized>
```

4.3 Categorized Node Properties

Consumable Resources

Consumable Resources are a special group of node properties that can have additional attributes and can be used in multiple categories. In general a consumable resource is a resource that can be consumed in a measurable quantity.

- A consumable resource **MUST** be categorized as being a configured, available or utilized node property by being a child element of a Configured, Available or Utilized element respectively.
- A consumable resource **MAY** have a units attribute that is of type String that specifies the units by which it is being measured. If this attribute is omitted, a default unit is implied. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a metric attribute that is of type String that specifies the type of measurement being described. For example, the measurement may be a Total, an Average, a Min or a Max. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a wallDuration attribute of type Duration that indicates the amount of time for which that resource was used. This need only be specified if the resource was used for a different amount of time than the wallDuration for the step. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a consumptionRate attribute of type Float that indicates the average percentage that a resource was used over its wallDuration. For example, an overbooked SMP running 100 jobs across 32 processors may wish to scale the usage and charge by the average fraction of processor usage actually delivered. A compliant implementation **MAY** support this attribute if the element is supported.

A list of simple consumable resources is listed in the table below.

Table 3-14: Consumable Resource Node Properties

Element Name	Type	Description	Appearance	Compliance	Categories
Processors	Integer	Number of processors	MAY	MUST	CAU
Memory	Float	Amount of memory	MAY	SHOULD	CAU
Disk	Float	Amount of disk	MAY	SHOULD	CAU
Swap	Float	Amount of virtual memory	MAY	MAY	CAU
Network	Float	Amount of network	MAY	MAY	CAU

The following are two examples for specifying a consumable resource:

```
<Memory metric="Max" units="GB">483</Memory>
<Processors wallDuration="1234" consumptionRate="0.63">4</Processors>
```

Resource Element

In addition to the consumable resources enumerated in the above table, an extensible consumable resource is defined by the Resource element.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times within a given set of node properties.
- Like the other consumable resources, this property MUST be categorized as a configured, available or utilized property by being encompassed in the appropriate elements.
- This element is of type Float.
- It shares the other same properties and attributes as the other consumable resources but it requires an additional name (and optional type) attribute to describe it.
- This element MUST have a name attribute of type String that indicates the type of consumable resource being measured. A compliant implementation MUST support this attribute if the element is supported.
- This element MAY have a type attribute of type String that distinguishes it within a general resource class. A compliant implementation SHOULD support this attribute if the element is supported.

The following are two examples for specifying a Resource element:

```
<Resource name="License" type="MATLAB">1</Resource>
<Resource name="Telescope" type="Zoom2000" wallDuration="750"
metric="KX">10</Resource>
```

4.4 Node Reference

When a simple reference to a predefined node is needed in an encapsulating element, a Node element is used with the text content being the node id:

```
<Node>node1</Node>
```

- This element MAY have an aggregation attribute of type String that provides a way to indicate multiple values with a single expression. A compliant implementation MAY support the aggregation attribute if the Feature element is supported. Possible values for this attribute include:
 - List a comma-separated list of features
 - Pattern a regular expression (perl5) matching desired features
 - Range a range of nodes of the form: `<prefix>[5-23, 77]`
- If an aggregation attribute is specified with the value of List, this element MAY also have a delimiter attribute of type String that indicates what

delimiter is used to separate list elements. The default list delimiter is a comma.

- This element MAY have a count attribute of type Integer that indicates the instance count of the specified node(s).

The following is another example of a `Node` element:

```
<Node aggregation="Pattern">node[1-5]</Node>
```

Appendix A

Units of Measure Abbreviations

Abbreviation	Definition	Quantity
B	byte	1 byte
KB	Kilobyte	2 ¹⁰ bytes
MB	Megabyte	2 ²⁰ bytes
GB	Gigabyte	2 ³⁰ bytes
TB	Terabyte	2 ⁴⁰ bytes
PB	Petabyte	2 ⁵⁰ bytes
EB	Exabyte	2 ⁶⁰ bytes

Scalable Systems Software Resource Management and Accounting
Protocol (SSSRMAP) Wire Protocol

Resource Management Interface Specs
Release v. 3.0.3
13 May 2004

Scott Jackson
Brett Bode
David Jackson
Kevin Walker

Status of This Memo

This is a specification defining a wire level protocol used between Scalable Systems Software components. It is intended that this specification will continue to evolve as these interfaces are implemented and thoroughly tested by time and experience.

Abstract

This document is a specification describing a connection-oriented XML-based application layer client-server protocol for the interaction of resource management and accounting software components developed as part of the Scalable Systems Software Center. The SSSRMAP Wire Protocol defines a framing protocol that includes provisions for security. The protocol is specified in XML Schema Definition and rides on the HTTP protocol.

1.0 Introduction

A major objective of the Scalable Systems Software [SSS] Center is to create a scalable and modular infrastructure for resource management and accounting on terascale clusters including resource scheduling, grid-scheduling, node daemon support, comprehensive usage accounting and user interfaces emphasizing portability to terascale vendor operating systems. Existing resource management and accounting components feature disparate APIs (Application Programming Interfaces) requiring various forms of application coding to interact with other components.

This document proposes a wire level protocol expressed in an XML envelope to be considered as the foundation of a standard for communications between and among resource management and accounting software components. Individual components additionally need to define the particular XML binding necessary to represent the message format for communicating with the component.

2.0 Conventions Used in this Document

2.1 Keywords

The keywords **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **RECOMMENDED**, **MAY**, and **OPTIONAL** in this document are to be interpreted as described in [RFC2119](#).

2.2 XML Case Conventions

In order to enforce a consistent capitalization and naming convention across all SSSRMAP specifications "Upper Camel Case" (UCC) and "Lower Camel Case" (LCC) Capitalization styles shall be used. UCC style capitalizes the first character of each word and compounds the name. LCC style capitalizes the first character of each word except the first word. [XML_CONV][FED_XML]

1. SSSRMAP XML Schema and XML instance documents SHALL use the following conventions:
 - Element names SHALL be in UCC convention (example: `<UpperCamelCaseElement/>`).
 - Attribute names SHALL be in LCC convention (example: `<UpperCamelCaseElement lowerCamelCaseAttribute="Whatever"/>`).
2. General rules for all names are:
 - Acronyms SHOULD be avoided, but in cases where they are used, the capitalization SHALL remain (example: XMLSignature).

- Underscores (`_`), periods (`.`) and dashes (`-`) MUST NOT be used (example: use `JobId` instead of `JOB.ID`, `Job_ID` or `job-id`).

2.3 Schema Definitions

SSSRMAP Schema Definitions appear like this

In case of disagreement between the schema file and this specification, the schema file takes precedence.

3.0 Encoding

Encoding tells how a message is represented when exchanged. SSSRMAP data exchange messages SHALL be defined in terms of XML schema [XML_SCHEMA].

3.1 Schema Header and Namespaces

The header of the schema definition is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>

<schema
  xmlns="http://www.w3.org/2001/XMLSchema"
  xmlns:sssrmap="http://www.scidac.org/ScalableSystems/SSSRMAP"
  targetNamespace="http://www.scidac.org/ScalableSystems/SSSRMAP"
  elementFormDefault="qualified">
```

3.2 The Envelope Element

SSSRMAP messages and replies are encapsulated in the `Envelope` element. There are two possibilities for the contents of this element. If the contents are unencrypted, this element MUST contain a `Body` element and MAY contain a `Signature` element (refer to the section on [Security](#)). If the contents are encrypted, this element MUST contain exactly one `EncryptedData` element (refer to the section on [Security](#)). The `Envelope` element MAY contain namespace and other xsd-specific information necessary to validate the document against the schema. In addition, it MAY have any of the following attributes which may serve as processing clues to the parser:

Attribute	Description
type	A message type providing a hint as to the body contents such as "Request" or "Notification"
component	A component type such as "QueueManager" or "LocalScheduler"
name	A component name such as "OpenPBS" or "Maui"
version	A component version such as "2.2p12" or "3.2.2"

```

<complexType name="EnvelopeType">
  <choice minOccurs="1" maxOccurs="1">
    <choice minOccurs="1" maxOccurs="2">
      <element ref="sssrmap:Signature" minOccurs="0" maxOccurs="1"/>
      <element ref="sssrmap:Body" minOccurs="1" maxOccurs="1"/>
    </choice>
    <element ref="sssrmap:EncryptedData" minOccurs="1" maxOccurs="1"/>
  </choice>
  <attribute name="type" type="string" use="optional"/>
  <attribute name="component" type="string" use="optional"/>
  <attribute name="name" type="string" use="optional"/>
  <attribute name="version" type="string" use="optional"/>
</complexType>

<element name="Envelope" type="sssrmap:EnvelopeType"/>

```

3.3 The Body Element

- SSSRMAP messages and replies are encapsulated in the `Body` element. This element **MUST** contain exactly one `Request` or `Response` element.

```

<complexType name="BodyType">
  <choice minOccurs="1" maxOccurs="1">
    <element ref="sssrmap:Request" minOccurs="0" maxOccurs="1"/>
    <element ref="sssrmap:Response" minOccurs="0" maxOccurs="1"/>
    <any minOccurs="0" maxOccurs="1" namespace="##other"/>
  </choice>
</complexType>

<element name="Body" type="sssrmap:BodyType"/>

```

4.0 Transport Layer

This protocol will be built over the connection-oriented reliable transport layer TCP/IP. Support for other transport layers could also be considered, but native support for TCP/IP can be found on most terascale clusters and automatically handles issues such as reliability and connection fullness for the application developer implementing the SSSRMAP protocol.

5.0 Framing

Framing specifies how the beginning and ending of each message is delimited. Given that the encoding will be expressed as one or more XML documents, clients and servers need to know when an XML document has been fully read in order to be parsed and acted upon.

SSSRMAP uses the HTTP 1.1 [HTTP] protocol for framing. HTTP uses a byte-counting mechanism to delimit the message segments. HTTP chunked encoding is used. This allows for optional support for batched messages, large message segmentation and persistent connections.

5.1 Message Header Requirements

The HTTP request line (first line of the HTTP request header) begins with POST and is followed by a URI and the version of the HTTP protocol that the client

understands. It is suggested for this protocol that the URI consist of a single slash, followed by the protocol name in uppercase (i.e. /SSSRMAP), though this field is not checked and could be empty, a single slash or any URI.

The Content-Type must be specified as test/xml. Charset may be optionally specified and defaults to US-ASCII. It is recommended that charset be specified as "utf-8" for maximum interoperability.

The Transfer-Encoding must be specified as chunked. The Content-Length must NOT be specified as the chunk size is specified in the message chunk.

Other properties such as User-Agent, Host and Date are strictly optional.

5.2 Message Chunk Format

A message chunk consists of a chunk size in hexadecimal format (whose value is the number of bytes in the XML message not including the chunk size and delimiter) delimited by a CR/LF "\r\n" and followed by the message payload in XML that consists of a single XML document having a root element of `Envelope`.

5.3 Reply Header Requirements

The HTTP response line (first line of the HTTP response header) begins with HTTP and a version number, followed by a numeric code and a message indicating what sort of response is made. These response codes and messages indicate the status of the entire response and are as defined by the HTTP standard. The most common response is 200 OK, indicating that the message was received and an appropriate response is being returned.

The Content-Type must be specified as text/xml. Charset may be optionally specified and defaults to US-ASCII. It is recommended that charset be specified as "utf-8" for maximum interoperability.

The Transfer-Encoding MUST be specified as chunked. The Content-Length must NOT be specified.

Other properties such as Server, Host and Date are strictly optional.

5.4 Reply Chunk Format

A reply chunk consists of a chunk size in hexadecimal format (whose value is the number of bytes in the XML reply not including the chunk size and delimiter) delimited by a CR/LF "\r\n" and followed by the reply payload in XML that consists of a single XML document having a root element of `Envelope`.

5.5 Message and Reply Tail Requirements and Multiple Chunks

This specification only requires that single chunks be supported. A server may optionally be configured to handle requests with persistent connections (multiple chunks). It will be the responsibility of clients to know whether a

particular server supports this additional functionality. After all chunks have been sent, a connection is terminated by sending a zero followed by a carriage return-linefeed combination (0\r\n) and closing the connection.

5.6 Examples

Sample SSSRMAP Message Embedded in HTTP Request

```
POST /SSSRMAP HTTP/1.1\r\n
Content-Type: text/xml; charset="utf-8"\r\n
Transfer-Encoding: chunked\r\n
\r\n
9A\r\n
<Envelope .../>
0\r\n
```

Sample SSSRMAP Reply Embedded in HTTP Response

```
HTTP/1.1 200 OK\r\n
Content-Type: text/xml; charset="utf-8"\r\n
Transfer-Encoding: chunked\r\n
\r\n
2B4\r\n
<Envelope .../>
0\r\n
```

6.0 Asynchrony

Asynchrony (or multiplexing) allows for the handling of independent exchanges over the same connection. A widely-implemented approach is to allow pipelining (or boxcarring) by aggregating requests or responses within the body of the message or via persistent connections and chunking in HTTP 1.1. Pipelining helps reduce network latency by allowing a client to make multiple requests of a server, but requires the requests to be processed serially [RFC3117]. Parallelism could be employed to further reduce server latency by allowing multiple requests to be processed in parallel by multi-threaded applications.

Segmentation may become necessary if the messages are larger than the available window. With support for segmentation, the octet-counting requirement that you need to know the length of the whole message before sending it can be relegated to the segment level – and you can start sending segments before the whole message is available. Segmentation is facilitated via “chunking” in HTTP 1.1.

The current SSSRMAP strategy supports only a single request or response within the Body element. A server may optionally support persistent connections from a client via HTTP chunking. Segmentation of large responses is also optionally supported via HTTP chunking. Later versions of the protocol could allow pipelined requests and responses in a single Body element.

7.0 Security

SSSRMAP security features include capabilities for integrity, authentication, confidentiality, and non-repudiation. The absence or presence of the various security features depend upon the type of security token used and the protection methods you choose to specify in the request.

For compatibility reasons, SSSRMAP specifies six supported security token types. Extensibility features are included allowing an implementation to use alternate security algorithms and security tokens. It is also possible for an implementation to ignore security features if it is deemed nonessential for the component. However, it is highly RECOMMENDED that an implementation support at least the default security token type in both authentication and encryption.

7.1 Security Token

A security token may be included in either the Signature block, and/or in the EncryptedData block (both described later) as an implicit or explicit cryptographic key. If this element is omitted, the security token is assumed to be a secret key shared between the client and the server.

The SecurityToken Element

This element is of type String. If the security token conveys an explicit key, this element’s content is the value of the key. If the key is natively expressed in a binary form, it must be converted to base64 encoding as defined in XML Digital Signatures (“<http://www.w3.org/2000/09/xmldsig#base64>”). If the type is not specified, it is assumed to be of type “Symmetric”.

It may have any of the following optional attributes:

Attribute	Description
type	<p>The type of security token (described subsequently)</p> <ul style="list-style-type: none">• A type attribute of “Symmetric” specifies a shared secret key between the client and server. This is the default.• A type attribute of “Asymmetric” specifies the use of public private key pairs between the client and server.• A type attribute of “Password” encrypts and authenticates with a user password known to both the client and server.• A type attribute of “Cleartext” allows the passing of a cleartext username and password and depends on the use of a secure transport (such as SSL or IPSec).• A type attribute of “Kerberos5” specifies a kerberos token.• A type attribute of “X509v3” specifies an X.509 certificate.

Attribute	Description
name	The name of the security token which serves as an identifier for the actor making the request (useful when the key is a password, or when the key value is implicit as when a public key is named but not included)

```

<complexType name="SecurityTokenType" mixed="true">
  <simpleContent>
    <extension base="string">
      <attribute name="type" type="string" use="optional">
        <attribute name="name" type="string" use="optional">
      </extension>
    </simpleContent>
  </complexType>

  <element name="SecurityToken" type="sssrmap:SecurityTokenType"/>

```

Security Token Types

SSSRMAP defines six standard security token types:

Symmetric Key

The default security token specifies the use of a shared secret key. The secret key is up to 128-bits long and known by both client and server. When using a symmetric key as a security token, it is not necessary to specify the `type` attribute with value "Symmetric" because this is assumed when the attribute is absent. The `name` attribute should be specified indicating the actor issuing the request. If the user provides a password to be sent to the server for authentication, then the password is encrypted with the secret key using a default `method="kw-tripledes"` (XML ENCRYPTION <http://www.w3.org/2001/04/xmlenc#kw-tripledes>), base64 encoded and included as the string content of the `SecurityToken` element. If the client authenticated the user, then the `SecurityToken` element is empty. The same symmetric key is used in both authentication and encryption.

Asymmetric Key

Public and private key pairs can be used to provide non-repudiation of the client (or server). The client and the server must each have their own asymmetric key pairs. This mode is indicated by specifying the type attribute as "Asymmetric". The `name` attribute should be specified indicating the actor issuing the request. If the user provides a password to be sent to the server for authentication, then the password is encrypted with the server's public key using a default `method="rsa-1_5"` (XML ENCRYPTION http://www.w3.org/2001/04/xmlenc#rsa-1_5), base64 encoded and included as the string content of the `SecurityToken` element. If the client authenticated the user, then the `SecurityToken` element is empty. The sender's private key is used in authentication (signing) while the recipient's public key is used for encryption.

Password

This mode allows for a username password combination to be used under the assumption that the server also knows the password for the user. This security token type is indicated by specifying a value of "Password" for the *type* attribute. The password itself is used as the cryptographic key for authentication and encryption. The *name* attribute contains the user name of the actor making the request. The *SecurityToken* element itself is empty.

Cleartext

This security mode is equivalent to passing the username and password in the clear and depends upon the use of a secure transport (such as SSL or IPsec). The purpose of including this security token type is to enable authentication to occur from web browsers over SSL or over internal LANs who use IPsec to encrypt all traffic. The password (or a hash of the password like in /etc/passwd) would have to be known by the server for authentication to occur. In this mode, neither encryption nor signing of the hash is performed at the application layer. This mode is indicated by specifying a value of "Cleartext" for the *type* attribute. The *name* attribute contains the user name of the actor making the request and the string content of the *SecurityToken* element is the unencrypted plaintext password.

Kerberos

The use of a Kerberos version 5 token is indicated by specifying "Kerberos5" in the *type* attribute. The *name* attribute is used to contain the kerberos user id of the actor making the request. The *SecurityToken* element contains two sub elements. The *Authenticator* element contains the authenticator encoded in base64. A *Ticket* element contains the service-granting ticket, also base64 encoded.

GSI (X.509)

The Grid Security Infrastructure (GSI) which is based on public key encryption, X.509 certificates, and the Secure Sockets Layer (SSL) communication protocol can be indicated by specifying a *type* attribute of "X509v3". The *name* attribute contains the userid used that the actor was mapped to in the local system. The string content of the *SecurityToken* element is the GSI authentication message including the X.509 identity of the sender encoded in base64.

Example

```
<SecurityToken type="Asymmetric" name="scottmo">
  MIIIEZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
</SecurityToken>
```

7.2 Authentication

Authentication entails how the peers at each end of the connection are identified and verified. Authentication is optional in an SSSRMAP message or reply. SSSRMAP uses a digital signature scheme for authentication that borrows from concepts in XML Digital Signatures [XML_DSIG]. In addition to

authentication, the use of digital signatures also ensures integrity of the message, protecting exchanges from third-party modification.

When authentication is used, a `Signature` element is prepended as the first element within the `Envelope` element. All of the security modes will create a digest of the data for integrity checking and store this in base64 encoding in a `DigestValue` element as a child of the `Signature` element. The digital signature is created by encrypting the hash with the appropriate security token and storing this value in a `SignatureValue` element as a child of the `Signature` element. The security token itself is included as a child of the `Security` element within a `SecurityToken` element.

There are a number of procedural practices that must be followed in order to standardize this approach. The digest (or hash) is created over the contents of the `Envelope` element (not including the `Element` tag or its attributes). This might be over one or more `Request` or `Notify` elements (or `Response` or `Ack` elements) and necessarily excludes the `Signature` Element itself. (Note that any data encryption is performed after the creation of the digital signature and any decryption is performed before authenticating so the `EncryptedData` element will not interfere with this process. Hence, the signature is always based on the (hashed but) unencrypted data). For the purposes of generating the digest over the same value, it is assumed that the data is first canonicalized to remove extraneous whitespace, comments, etc according to the XML Digital Signature algorithm ("<http://www.w3.org/TR/2001/REC-xml-c14n-20010315>") and a transform is applied to remove namespace information. As a rule, any binary values are always transformed into their base64 encoded values when represented in XML.

The Signature Element

The `Signature` element **MUST** contain a `DigestValue` element that is used for integrity checking. It **MUST** also contain a `SecurityToken` element that is used to indicate the security mode and token type, and to verify the signature. It **MUST** contain a `SignatureValue` element that contains the base64 encrypted value of the signature wrought on the hash **UNLESS** the security token type indicates Cleartext mode where a signature would be of no value with the encryption key being sent in the clear -- in this case we use the password itself for authentication).

```
<complexType name="SignatureType">
  <choice minOccurs="2" maxOccurs="3">
    <element ref="sssrmap:DigestValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:SignatureValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:SecurityToken" minOccurs="0" maxOccurs="1"/>
  </choice>
</complexType>

<element name="Signature" type="sssrmap:SignatureType"/>
```

The DigestValue Element

The `DigestValue` element contains the cryptographic digest of the message data. As described above, the hash is generated over the `Body` element. The data to be hashed must first be canonicalized and appropriately transformed before generating the digest since typically an application will read in the XML document into an internal binary form, then marshal (or serialize) the data into a string which is passed as input to the hash algorithm. Different implementations marshal the data differently so it is necessary to convert this to a well-defined format before generating the digest or the clients will generate different digest values for the same XML. The SHA-1 [SHA-1] message digest algorithm (<http://www.w3.org/2000/09/xmldsig#sha1>) SHALL be used as the default method for generating the digest. A `method` attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate message digest algorithms.

It MAY have a `method` attribute:

Attribute	Description
<code>method</code>	<p>The message digest algorithm.</p> <ul style="list-style-type: none">A <code>method</code> attribute of "sha1" specifies the SHA-1 message digest algorithm. This is the default and is implied if this attribute is omitted.

```
<complexType name="DigestValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="DigestValue" type="sssrmap:DigestValueType"/>
```

The SignatureValue Element

The `SignatureValue` element contains the digital signature that serves the authentication (and potentially non-repudiation) function. The string content of the `SignatureValue` element is a base64 encoding of the encrypted digest value. The HMAC algorithm [HMAC] based on the SHA1 message digest (<http://www.w3.org/2000/09/xmldsig#hmac-sha1>) SHALL be used as the default message authentication code algorithm for user identification and message integrity. A `method` attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate digital signature algorithms.

It MAY have a `method` attribute:

Attribute	Description
method	<p>The digest signature algorithm.</p> <ul style="list-style-type: none"> A <code>method</code> attribute of “<code>hmac-sha1</code>” specifies the HMAC SHA-1 digital signature algorithm. This is the default and is implied if this attribute is omitted.

```

<complexType name="SignatureValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="SignatureValue" type="sssrmap:SignatureValueType"/>

```

Signature Example

Pre-authentication:

```

<Envelope>
  <Body>
    <Request action="Query" actor="kenneth">
      <Object>User</Object>
      <Get name="EmailAddress"></Get>
      <Where name="Name">scott</Where>
    </Request>
  </Body>
</Envelope>

```

Post-authentication:

```

<Envelope>
  <Signature>
    <DigestValue>
      LyLsF0Pi4wPU...
    </DigestValue>
    <SignatureValue>
      DJbchm5gK...
    </SignatureValue>
    <SecurityToken type="Asymmetric" name="kenneth">
      MIEZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
    </SecurityToken>
  </Signature>
  <Body>
    <Request action="Query" actor="kenneth">
      <Object>User</Object>
      <Get name="EmailAddress"></Get>
      <Where name="Name">scottmo</Where>
    </Request>
  </Body>
</Envelope>

```

7.3 Confidentiality

Confidentiality involves encrypting the sensitive data in the message, protecting exchanges against third-party interception and modification. Confidentiality is optional in an SSSRMAP message or reply. When confidentiality is required, SSSRMAP sessions use block cipher encryption with concepts borrowed from the emerging XML Encryption [XML_ENC] standard.

When confidentiality is used, encryption is performed over all child elements of the `Envelope` element, i.e. on the message data as well as any signature (The encrypted data is not signed -- rather the signature is encrypted). This data is replaced in-place within the envelope with an `EncryptedData` element. The data is first compressed using the gzip algorithm [ZIP]. Instead of encrypting this compressed data with the security token directly, a 192-bit random session key is generated by the sender and used to perform symmetric encryption on the compressed data. This key is itself encrypted with the security token and included with the encrypted data as the value of the `EncryptedKey` element as a child of the `EncryptedData` element. The ciphertext resulting from the data being encrypted with the session key is passed as the value of a `CipherValue` element (also a child of the `EncryptedData` element). As in the case with authentication, the security token itself is included as a child of the `Security` element within a `SecurityToken` element.

The EncryptedData Element

When SSSRMAP confidentiality is required, the `EncryptedData` element MUST appear as the only child element in the `Envelope` element. It directly replaces the contents of these elements including the data and any digital signature. It MUST contain an `EncryptedKey` element that is used to encrypt the data. It MUST contain a `CipherValue` element that holds the base64 encoded ciphertext. It MAY also contain a `SecurityToken` element that is used to indicate the security mode and token type. If the `SecurityToken` element is omitted, a Symmetric key token type is assumed. Confidentiality is not used when a security token type of "Cleartext" is specified since it would be pointless to encrypt the data with the encryption key in the clear.

```
<complexType name="EncryptionDataType">
  <choice minOccurs="0" maxOccurs="1">
    <element ref="sssrmap:EncryptedKey" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:CipherValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:SecurityToken" minOccurs="1" maxOccurs="1"/>
  </choice>
</complexType>

<element name="EncryptedData" type="sssrmap:EncryptionDataType"/>
```

The EncryptedKey Element

The `EncryptedKey` element is a random session key encrypted with the security token. This approach is used for a couple of reasons. In the case where public key encryption is used, asymmetric encryption is much slower than symmetric encryption and it makes sense to use a symmetric key for

encryption and pass along it along by encrypting it with the recipient's public key. It is also useful in that the security token which does not change very often (compared to the session key which changes for every connection) is used on a very small sampling of data (the session key), whereas if it was used to encrypt the whole message an attacker could more effectively exploit an attack against the ciphertext. The CMS Triple DES Key Wrap algorithm "kw-tripledes" SHALL be used as the default method for key encryption. The session key is encrypted using the security token, base64 encoded and specified as the string content of the `EncryptedKey` element. A `method` attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate key encryption algorithms.

It is REQUIRED that an implementation use a cryptographically secure Pseudo-Random number generator. It is RECOMMENDED that the session key be cryptographically generated (such as cyclic encryption, DES OFB, ANSI X9.17 PRNG, SHA1PRNG, or ANSI X12.17 (used by PGP)).

It MAY have a `method` attribute:

Attribute	Description
method	<p>The key encryption algorithm.</p> <ul style="list-style-type: none"> A <code>method</code> attribute of "kw-tripledes" specifies the CMS Triple DES Key Wrap algorithm. This algorithm is specified by the XML Encryption [XML_ENC] URI "http://www.w3.org/2001/04/xmlenc#kw-tripledes". It involves two Triple DES encryptions, a random and known Initialization Vector (IV) and a CMS key checksum. A 192-bit key encryption key is generated from the security token, lengthened as necessary by zero-padding. No additional padding is performed in the encryptions. This is the default and is implied if this attribute is omitted.

```
<complexType name="EncryptedKeyType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="EncryptedKey" type="sssrmap:EncryptedKeyType"/>
```

The CipherValue Element

The `CipherValue` element contains the message (and possibly signature) data encrypted with the random session key. The ciphertext is compressed using the gzip algorithm [ZIP], encrypted by the designated method, base64 encoded and included as the string content of the `CipherValue` element. The Triple DES algorithm with Cipher Block Chaining (CBC) feedback mode SHALL be used as the default method for encryption. A `method` attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate data encryption algorithms.

It MAY have a `method` attribute:

Attribute	Description
method	<p>The data encryption algorithm.</p> <ul style="list-style-type: none"> A <code>method</code> attribute of “tripledes-cbc” specifies the Triple DES algorithm with Cipher Block Chaining (CBC) feedback mode. This algorithm is specified by the XML Encryption [XMLENC] URI identifier “http://www.w3.org/2001/04/xmlenc#tripledes-cbc”. It specifies the use of a 192-bit encryption key and a 64-bit Initialization Vector (IV). Of the key bits, the first 64 are used in the first DES operation, the second 64 bits in the middle DES operation, and the third 64 bits in the last DES operation. The plaintext is first padded to a multiple of the block size (8 octets) using the padding scheme described in [XMLENC] for Block Encryption Algorithms (Padding per PKCS #5 will suffice for this). The resulting cipher text is prefixed by the IV. This is the default and is implied if this attribute is omitted.

```

<complexType name="CipherValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="CipherValue" type="sssrmap:CipherValueType"/>

```

Encryption Example

In this example, a simple request is demonstrated without a digital signature for the sake of emphasizing the encryption plaintext replacement.

Pre-encryption:

```

<Envelope>
  <Body>
    <Response>
      <Status>true</Status>
      <Code>000</Code>
      <Count>1</Count>
      <Data>
        <User>
          <EmailAddress>Scott.Jackson@pn1.gov</EmailAddress>
        </User>
      </Data>
    </Response>
  </Body>
</Envelope>

```

Post-encryption:

```

<Envelope>
  <EncryptedData>
    <EncryptedKey>
      NAKe9iQofYhyOfiHZ29kkEFVJ30CAwEAAaMSM...
    </EncryptedKey>
    <CipherValue>
      mPCadVfOMx1NzDaKMHNgFkR9upTW4kgBxyPW...
    </CipherValue>
    <SecurityToken type="Asymmetric" name="kenneth">
      MIIeZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
    </SecurityToken>
  </EncryptedData>
</Envelope>

```

Appendix W: Moab Resource Manager Language Interface Overview

The Moab RM Language (formerly called WIKI) is the language that some resource managers use to communicate with Moab, specifically a native RM. Generally each line represents a single resource or workload in Moab. The line contains the name of the resource or workload followed by a set of `<attr>=<val>` pairs. Although the Moab RM language follows the same data format for all RMs, each RM type receives and returns it differently. For instructions and examples on using Moab RM language with SLURM or a native RM, see [W.2 Managing Resources with SLURM on page 1547](#) and [Managing Resources Directly with the Native Interface on page 781](#) respectively.

- [W.1.2 Query Workload Data Format](#)

W.1.1 Query Resources Data Format

NAME	FORMAT	DEFAULT	DESCRIPTION
ADISK	<code><INTEGER></code>	0	Available local disk on node (in MB)
AFS	<code><fs id="X" size="X" io="Y" rcount="X" wcount="X" ocoun- t="X"></fs>[...]</code>	0	Available filesystem state
AMEMORY	<code><INTEGER></code>	0	Available/free RAM on node (in MB)
APROC	<code><INTEGER></code>	1	Available processors on node
ARCH	<code><STRING></code>	---	Compute architecture of node

NAME	FORMAT	DEFAULT	DESCRIPTION
ARES	one or more comma delimited <NAME>: <VALUE> pairs (ie, MATLAB:6,COMPILER:100)	---	Arbitrary consumable resources currently available on the node
ASWAP	<INTEGER>	0	Available swap on node (in MB)
CCLASS	one or more bracket enclosed <NAME>: <COUNT> pairs (ie, [batch:5] [sge:3])	---	Run classes supported by node. Typically, one class is 'consumed' per task. Thus, an 8 processor node may have 8 instances of each class it supports present, ie [batch:8] [interactive:8]
CDISK	<INTEGER>	0	Configured local disk on node (in MB)
CFS	<STRING>	0	Configured filesystem state
CMEMORY	<INTEGER>	0	Configured RAM on node (in MB)
CONTAINERNODE	<STRING>	---	The physical machine that is host- ing the virtual machine. Only valid on VMs.
CPROC	<INTEGER>	1	Configured processors on node
CPULOAD	<DOUBLE>	0.0	One minute BSD load average
CPUSPEED	<INTEGER>	---	The node's processor speed in MHz
CRES	one or more comma delimited <NAME>: <VALUE> pairs (ie, MATLAB:6,COMPILER:100)	---	Arbitrary consumable resources supported and tracked on the node, ie software licenses or tape drives
CSWAP	<INTEGER>	0	Configured swap on node (in MB)

NAME	FORMAT	DEFAULT	DESCRIPTION
FEATURE	one or more colon delimited <STRING>'s (ie, WIDE:HSM)	---	Generic attributes, often describing hardware or software features, associated with the node
GEVENT	GEVENT [<EVENTNAME>] = <STRING>	---	Generic event occurrence and context data
GMETRIC	GMETRIC [<METRICNAME>] = <DOUBLE>	---	Current value of generic metric , i.e., 'GMETRIC [temp] = 103.5'.
IDLETIME	<INTEGER>	---	Number of seconds since last detected keyboard or mouse activity (often used with desktop harvesting)
MAXTASK	<INTEGER>	<CPROC>	Maximum number of tasks allowed on the node at any given time
NETADDR	<STRING>	---	The IP address of the machine
NODEINDEX	<INTEGER>	---	The node's index
OS	<STRING>	---	Operating system running on node
OSLIST	One or more comma delimited <STRING>'s with quotes if the string has spaces (ie. "SAS7 AS3 Core Baseline Build v0.1.0", "RedHat AS3-U5Development Build v0.2").	---	Operating systems accepted by node
OTHER	<ATTR>=<VALUE> [, <ATTR>=<VALUE>] . . .	---	Opaque node attributes assigned to node
PARTITION	<STRING>	DEFAULT	Partition to which node belongs
POWER	<BOOLEAN>		Whether the machine is on or off
PRIORITY	<INTEGER>	---	Node allocation priority

NAME	FORMAT	DEFAULT	DESCRIPTION
RACK	<INTEGER>	0	Rack location of the node
SLOT	<INTEGER>	0	Slot location of the node
STATE*	one of the following: Idle, Running, Busy, Unknown, Drained, Draining, or Down	Down	State of the node
UPDATETIME*	<EPOCHTIME>	0	Time node information was last updated
VARATTR	<ATTR1>=<VAL1>[=<displayName1>] [+<ATTR2>=<VAL2> [=<displayName2>]]...	---	<p>Plus-delimited (+) list of <ATTR>=<VAL> [=<displayName>] pairs that jobs can request. You can replace any of the equals signs with colons if desired.</p> <p>Specifying a display name allows you to choose a name that will be displayed in the Mongo database instead of the unique ID (the <VALUE>).</p> <div>  If you give two different attributes the same value and one of them also has a display name specified, both attributes will appear with the same display name. </div>
VARIABLE	<ATTR>=<VAL>	---	Generic variables to be associated with node
VMOSLIST	<STRING>	---	Comma-delimited list (,) of supported virtual machine operating systems for this node
XRES	one or more comma delimited <NAME>:<VALUE> pairs (ie, MATLAB:6, COMPILER:100)	---	Amount of external usage of a particular generic resource

* indicates required field

Node states have the following definitions:

State	Description
Busy	Node is running some jobs and will not accept additional jobs
Down	Resource Manager problems have been detected. Node is incapable of running jobs.
Draining	Node is responding but will not accept new jobs
Idle	Node is ready to run jobs but currently is not running any.
Running	Node is running some jobs and will accept additional jobs
Unknown	Node is capable of running jobs but the scheduler will need to determine if the node state is actually Idle, Running, or Busy.

W.1.2 Query Workload Data Format

NAME	FORMAT	DEFAULT	DESCRIPTION
ACCOUNT	<STRING>	---	AccountID associated with job
ARGS	<STRING>	---	job command-line arguments
COMMENT	<STRING>	0	job resource manager extension arguments including qos, dependencies, reservation constraints, etc
COMPLETETIME*	<EPOCHTIME>	0	time job completed execution
DDISK	<INTEGER>	0	quantity of local disk space (in MB) which must be dedicated to each task of the job
DGRES	name:value [, name:value]	---	Dedicated generic resources per task.
DPROCS	<INTEGER>	1	number of processors dedicated per task
DSWAP	<INTEGER>	0	quantity of virtual memory (swap, in MB) which must be dedicated to each task of the job
ENDDATE	<EPOCHTIME>	[ANY]	time by which job must complete

NAME	FORMAT	DEFAULT	DESCRIPTION
ENV	<STRING>	---	job environment variables
ERROR	<STRING>	---	file to contain STDERR
EVENT	<EVENT>	---	event or exception experienced by job
EXEC	<STRING>	---	job executable command
EXITCODE	<INTEGER>	---	job exit code
FLAGS	<STRING>	---	job flags
GEOMETRY	<STRING>	---	String describing task geometry required by job
GNAME*	<STRING>	---	GroupID under which job will run
HOSTLIST	comma or colon delimited list of hostnames - suffix the hostlist with a caret (^) to mean superset; suffix with an asterisk (*) to mean subset; otherwise, the hostlist is interpreted as an exact set	[ANY]	list of required hosts on which job must run. (see TASKLIST) A subset means the specified hostlist is used first to select hosts for the job. If the job requires more hosts than are in the hostlist, they will be obtained from elsewhere if possible. If the job does not require all of the jobs in the hostlist, it will use only the ones it needs. A superset means the hostlist is the <i>only</i> source of hosts that should be considered for running the job. If the job can't find the necessary resources in the hosts in this list it should <i>not</i> run. No other hosts should be considered in allocating the job.
INPUT	<STRING>	---	file containing STDIN
IWD	<STRING>	---	job's initial working directory
NAME	<STRING>	---	User specified name of job
NODES	<INTEGER>	1	Number of nodes required by job (See Node Definition for more info)
OUTPUT	<STRING>	---	file to contain STDOUT

NAME	FORMAT	DEFAULT	DESCRIPTION
PARTITIONMASK	one or more colon delimited <i><STRING></i> s	[ANY]	list of partitions in which job can run
PREF	colon delimited list of <i><STRING></i> s	---	List of preferred node features or variables. (See PREF for more information.)
PRIORITY	<i><INTEGER></i>	---	system priority (absolute or relative - use '+' and '-' to specify relative)
QOS	<i><INTEGER></i>	0	quality of service requested
QUEUETIME*	<i><EPOCHTIME></i>	0	time job was submitted to resource manager
RARCH	<i><STRING></i>	---	architecture required by job
RCLASS	list of bracket enclosed <i><STRING></i> : <i><INTEGER></i> pairs	---	list of <i><CLASSNAME></i> : <i><COUNT></i> pairs indicating type and number of class instances required per task. (ie, [batch:1] or [batch:2] [tape:1])
RDISK	<i><INTEGER></i>	0	local disk space (in MB) required to be configured on nodes allocated to the job
RDISKCMP	one of >=, >, ==, <, or <=	>=	local disk comparison (ie, node must have > 2048 MB local disk)
REJCODE	<i><INTEGER></i>	0	reason job was rejected
REJCOUNT	<i><INTEGER></i>	0	number of times job was rejected
REJMESSAGE	<i><STRING></i>	---	text description of reason job was rejected
REQRSV	<i><STRING></i>	---	Name of reservation in which job must run
RESACCESS	<i><STRING></i>	---	List of reservations in which job can run
RFEATURES	colon delimited list <i><STRING></i> 's	---	List of features required on nodes

NAME	FORMAT	DEFAULT	DESCRIPTION
RMEM	<INTEGER>	0	real memory (RAM, in MB) required to be configured on nodes allocated to the job
RMEMCMP	one of '>=', '>', '==', '<', or '<='	>=	real memory comparison (ie, node must have >= 512MB RAM)
ROPSYS	<STRING>	---	operating system required by job
RSOFTWARE	<RESTYPE>[{+ :} <COUNT>] [@<TIMEFRAME>]	---	software required by job
RSWAP	<INTEGER>	0	virtual memory (swap, in MB) required to be configured on nodes allocated to the job
RSWAPCMP	one of '>=', '>', '==', '<', or '<='	>=	virtual memory comparison (ie, node must have ==4096 MB virtual memory)
SID	<STRING>	---	system id (global job system owner)
STARTDATE	<EPOCHTIME>	0	earliest time job should be allowed to start
STARTTIME*	<EPOCHTIME>	0	time job was started by the resource manager
STATE*	one of Idle , Running, Hold, Suspended, Completed, or Removed	Idle	State of job
SUSPENDTIME	<INTEGER>	0	Number of seconds job has been suspended
TASKLIST	one or more comma-delimited <STRING>'s	---	list of allocated tasks, or in other words, comma-delimited list of node ID's associated with each active task of job (i.e., cl01, cl02, cl01, cl02, cl03) The tasklist is initially selected by the scheduler at the time the StartJob command is issued. The resource manager is then responsible for starting the job on these nodes and maintaining this task distribution information throughout the life of the job. (see HOSTLIST)

NAME	FORMAT	DEFAULT	DESCRIPTION
TASKS*	<INTEGER>	1	Number of tasks required by job (See Task Definition for more info)
TASKPERNODE	<INTEGER>	0	exact number of tasks required per node
UNAME*	<STRING>	---	UserID under which job will run
UPDATETIME*	<EPOCHTIME>	0	Time job was last updated
WCLIMIT*	[[HH:]MM:]SS	864000	walltime required by job

* indicates required field

Job states have the following definitions:

State	Definition
Completed	Job has completed
Hold	Job is in the queue but is not allowed to run
Idle	Job is ready to run
Removed	Job has been canceled or otherwise terminated externally
Running	Job is currently executing
Suspended	job has started but execution has temporarily been suspended

i Completed and canceled jobs should be maintained by the resource manager for a brief time, perhaps 1 to 5 minutes, before being purged. This provides the scheduler time to obtain all final job state information for scheduler statistics.

W.2.1 Commands

All commands are requested via a socket interface, one command per socket connection. All fields and values are specified in ASCII text.

Supported Commands are:

- [Query Resources](#)
- [Query Workload](#)
- [Start Job](#)
- [Cancel Job](#)
- [Suspend Job](#)
- [Resume Job](#)

- [Requeue Job](#)
- JOBADDTASK
- JOBRELEASETASK

W.2.1.1 Moab RM Language Query Resources

W.2.1.1.1 Moab RM Language Query Resources Request Format

```
CMD=GETNODES ARG={ <UPDATETIME>:<NODEID>[:<NODEID>] . . . |
<UPDATETIME>:ALL }
```

Only nodes updated more recently than *<UPDATETIME>* will be returned where *<UPDATETIME>* is specified as the epoch time of interest. Setting *<UPDATETIME>* to 0 will return information for all nodes. Specify a colon delimited list of *NODEIDs* if specific nodes are desired or use the keyword `ALL` to receive information for all nodes.

W.2.1.1.2 Moab RM Language Resources Response Format

The query resources response format is one or more line of the following format (separated with a new line):

```
<NODEID><ATTR>=<VALUE> [ ; <ATTR>=<VALUE> ] . . .
```

<ATTR> is one of the names in the [table below](#) and the format of *<VALUE>* is dependent on *<ATTR>*.

Example 3-193: Moab RM language resource query and response

Request:

```
CMD=GETNODES ARG=0:node001:node002:node003
```

Response:

```
node001 UPDATETIME=963004212;STATE=Busy;OS=AIX43;ARCH=RS6000...
node002 UPDATETIME=963004213;STATE=Busy;OS=AIX43;ARCH=RS6000...
...
```

W.2.1.2 Moab RM Language Query Workload

W.2.1.2.1 Moab RM Language Query Workload Request Format

```
CMD=GETJOBS ARG={ <UPDATETIME>:<JOBID>[:<JOBID>] . . . |
<UPDATETIME>:ALL }
```

Only jobs updated more recently than *<UPDATETIME>* will be returned where *<UPDATETIME>* is specified as the epoch time of interest. Setting *<UPDATETIME>* to 0 will return information for all jobs. Specify a colon delimited list of *JOBID*'s if information for specific jobs is desired or use the keyword `ALL` to receive information about all jobs.

W.2.1.2.2 Moab RM Language Query Workload Response Format

```
SC=<STATUSCODE> ARG=<JOBCOUNT>#<JOBID>:<FIELD>=<VALUE>;
[<FIELD>=<VALUE>;] ... [#<JOBID>:<FIELD>=<VALUE>;
[<FIELD>=<VALUE>;] ...] ...
```

or

```
SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

FIELD is either the text name listed below or A<FIELDNUM>
(ie, UPDATETIME or A2)

STATUSCODE values:

- 0 SUCCESS
- -1 INTERNAL ERROR

RESPONSE is a statuscode sensitive message describing error or state details.

W.2.1.2.3 Moab RM Language Query Workload Example

Request:

```
CMD=GETJOBS ARG=0:ALL
```

Response:

```
ARG=2#nebo3001.0:UPDATETIME=9780000320;STATE=Idle;WCLIMIT=3600;...
```

W.2.1.3 StartJob

The **StartJob** command may only be applied to jobs in the `Idle` state. It causes the job to begin running using the resources listed in the `NodeID` list.

```
send CMD=STARTJOB ARG=<JOBID> TASKLIST=<NODEID>[:<NODEID>] ...
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

STATUSCODE >= 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message possibly further describing an error or state

Example 3-194: Job start

```
# Start job nebo.1 on nodes cluster001 and cluster002
# send
CMD=STARTJOB ARG=nebo.1 TASKLIST=cluster001:cluster002
# receive
SC=0;RESPONSE=job nebo.1 started with 2 tasks
```

W.2.1.4 CancelJob

The **CancelJob** command, if applied to an active job, will terminate its execution. If applied to an idle or active job, the **CancelJob** command will change the job's

state to Canceled.

send CMD=CANCELJOB ARG=<JOBID> TYPE=<CANCELTYPE>

<CANCELTYPE> is one of the following:

ADMIN (command initiated by scheduler administrator)

WALLCLOCK (command initiated by scheduler because job exceeded its specified wallclock limit)

receive SC=<STATUSCODE> RESPONSE=<RESPONSE>

STATUSCODE >= 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message further describing an error or state

Example 3-195: Job cancel

```
# Cancel job nebo.2

# send
CMD=CANCELJOB ARG=nebo.2 TYPE=ADMIN'
# receive
SC=0 RESPONSE=job nebo.2 canceled
```

W.2.1.5 SuspendJob

The **SuspendJob** command can only be issued against a job in the state **Running**. This command suspends job execution and results in the job changing to the **Suspended** state.

send CMD=SUSPENDJOB ARG=<JOBID>

receive SC=<STATUSCODE> RESPONSE=<RESPONSE>

STATUSCODE >= 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message possibly further describing an error or state

Example 3-196: Job suspend

```
# Suspend job nebo.3

# send
CMD=SUSPENDJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 suspended
```

W.2.1.6 ResumeJob

The **ResumeJob** command can only be issued against a job in the state **Suspended**. This command resumes a suspended job returning it to the **Running** state.

send CMD=RESUMEJOB ARG=<JOBID>

receive SC=<STATUSCODE> RESPONSE=<RESPONSE>

STATUSCODE ≥ 0 indicates SUCCESS
STATUSCODE < 0 indicates FAILURE
RESPONSE is a text message further describing an error or state

Example 3-197: Job resume

```
# Resume job nebo.3
# send
CMD=RESUMEJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 resumed
```

W.2.1.7 RequeueJob

The **RequeueJob** command can only be issued against an active job in the state **Starting** or **Running**. This command **requeues** the job, stopping execution and returning the job to an idle **state** in the queue. The requeued job will be eligible for execution the next time resources are available.

```
send CMD=REQUEUEJOB ARG=<JOBID>
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

STATUSCODE ≥ 0 indicates SUCCESS
STATUSCODE < 0 indicates FAILURE
RESPONSE is a text message further describing an error or state

Example 3-198: job requeue

```
# Requeue job nebo.3
# send
CMD=REQUEUEJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 requeued
```

W.2.1.8 SignalJob

The **SignalJob** command can only be issued against an active job in the state **Starting** or **Running**. This command signals the job, sending the specified signal to the master process. The signaled job will remain in the same state it was before the signal was issued.

```
send CMD=SIGNALJOB ARG=<JOBID> ACTION=signal VALUE=<SIGNAL>
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

STATUSCODE ≥ 0 indicates SUCCESS
STATUSCODE < 0 indicates FAILURE
RESPONSE is a text message further describing an error or state

Example 3-199: Job signal

```
# Signal job nebo.3

# send
CMD=SIGNALJOB ARG=nebo.3 ACTION=signal VALUE=13
# receive
SC=0 RESPONSE=job nebo.3 signaled
```

W.2.1.9 ModifyJob

The **ModifyJob** command can be issued against any active or queued job. This command modifies specified attributes of the job.

```
send CMD=MODIFYJOB ARG=<JOBID> [BANK=name] [NODES=num]
[PARTITION=name] [TIMELIMIT=minutes]
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

STATUSCODE ≥ 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message further describing an error or state

Example 3-200: Job modify

```
# Signal job nebo.3

# send
CMD=MODIFYJOB ARG=nebo.3 TIMELIMIT=9600
# receive
SC=0 RESPONSE=job nebo.3 modified
```

W.2.1.10 JobAddTask

The **JobAddTask** command allocates additional tasks to an active job.

```
send CMD=JOBADDTASK ARG=<JOBID> <NODEID> [<NODEID>] ...
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

STATUSCODE ≥ 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message possibly further describing an error or state

Example 3-201: Job addtask

```
# Add 3 default tasks to job nebo30023.0 using resources located on nodes cluster002,
cluster016, and cluster112.

# send
CMD=JOBADDTASK ARG=nebo30023.0 DEFAULT cluster002 cluster016 cluster112
# receive
SC=0 RESPONSE=3 tasks added
```

W.2.1.11 JobRemoveTask

The **JobRemoveTask** command removes tasks from an active job.

send CMD=JOBREMOVETASK ARG=<JOBID> <TASKID> [<TASKID>] ...

receive SC=<STATUSCODE> RESPONSE=<RESPONSE>

STATUSCODE ≥ 0 indicates SUCCESS

STATUSCODE < 0 indicates FAILURE

RESPONSE is a text message further describing an error or state

Example 3-202: Job removetask

```
# Free resources allocated to tasks 14, 15, and 16 of job nevo30023.0

# send
CMD=JOBREMOVETASK ARG=nevo30023.0 14 15 16
# receive
SC=0 RESPONSE=3 tasks removed
```

W.2.2 Rejection Codes

- 0xx - success - no error
 - 00x - success
 - 000 - success
 - 01x - usage/help reply
 - 010 - usage/help reply
 - 02x - status reply
 - 020 - general status reply
- 1xx - warning
 - 10x - general warning
 - 100 - general warning
 - 11x - no content
 - 110 - general wire protocol or network warning
 - 112 - redirect
 - 114 - protocol warning
 - 12x - no matching results
 - 120 - general message format warning
 - 122 - incomplete specification (best guess action/response applied)
 - 13x - security warning
 - 130 - general security warning
 - 132 - insecure request

- 134 - insufficient privileges (response was censored/action reduced in scope)
- 14x - content or action warning
 - 140 - general content/action warning
 - 142 - no content (server has processed the request but there is no data to be returned)
 - 144 - no action (no object to act upon)
 - 146 - partial content
 - 148 - partial action
- 15x - component defined
- 18x - application defined
- 2xx - wire protocol/network failure
 - 20x - protocol failure
 - 200 - general protocol/network failure
 - 21x - network failure
 - 210 - general network failure
 - 212 - cannot resolve host
 - 214 - cannot resolve port
 - 216 - cannot create socket
 - 218 - cannot bind socket
 - 22x - connection failure
 - 220 - general connection failure
 - 222 - cannot connect to service
 - 224 - cannot send data
 - 226 - cannot receive data
 - 23x - connection rejected
 - 230 - general connection failure
 - 232 - connection timed-out
 - 234 - connection rejected - too busy
 - 236 - connection rejected - message too big

- 24x - malformed framing
 - 240 - general framing failure
 - 242 - malformed framing protocol
 - 244 - invalid message size
 - 246 - unexpected end of file
- 25x - component defined
- 28x - application defined
- 3xx - messaging format error
 - 30x - general messaging format error
 - 300 - general messaging format error
 - 31x - malformed XML document
 - 310 - general malformed XML error
 - 32x - XML schema validation error
 - 320 - general XML schema validation
 - 33x - general syntax error in request
 - 330 - general syntax error in response
 - 332 - object incorrectly specified
 - 334 - action incorrectly specified
 - 336 - option/parameter incorrectly specified
 - 34x - general syntax error in response
 - 340 - general response syntax error
 - 342 - object incorrectly specified
 - 344 - action incorrectly specified
 - 346 - option/parameter incorrectly specified
 - 35x - synchronization failure
 - 350 - general synchronization failure
 - 352 - request identifier is not unique
 - 354 - request id values do not match
 - 356 - request id count does not match

- 4xx - security error occurred
 - 40x - authentication failure - client signature
 - 400 - general client signature failure
 - 402 - invalid authentication type
 - 404 - cannot generate security token key - inadequate information
 - 406 - cannot canonicalize request
 - 408 - cannot sign request
 - 41x - negotiation failure
 - 410 - general negotiation failure
 - 412 - negotiation request malformed
 - 414 - negotiation request not understood
 - 416 - negotiation request not supported
 - 42x - authentication failure
 - 420 - general authentication failure
 - 422 - client signature failure
 - 424 - server authentication failure
 - 426 - server signature failure
 - 428 - client authentication failure
 - 43x - encryption failure
 - 430 - general encryption failure
 - 432 - client encryption failure
 - 434 - server decryption failure
 - 436 - server encryption failure
 - 438 - client decryption failure
 - 44x - authorization failure
 - 440 - general authorization failure
 - 442 - client authorization failure
 - 444 - server authorization failure
 - 45x - component defined failure
 - 48x - application defined failure

- 5xx - event management request failure
 - 50x - reserved
 - 500 - reserved
- 6xx - reserved for future use
 - 60x - reserved
 - 600 - reserved
- 7xx - server side error occurred
 - 70x - server side error
 - 700 - general server side error
 - 71x - server does not support requested function
 - 710 - server does not support requested function
 - 72x - internal server error
 - 720 - general internal server error
 - 73x - resource unavailable
 - 730 - general resource unavailable error
 - 732 - software resource unavailable error
 - 734 - hardware resource unavailable error
 - 74x - request violates policy
 - 740 - general policy violation
 - 75x - component-defined failure
 - 78x - application-defined failure
- 8xx - client side error occurred
 - 80x - general client side error
 - 800 - general client side error
 - 81x - request not supported
 - 810 - request not supported
 - 82x - application specific failure
 - 820 - general application specific failure
- 9xx - miscellaneous
 - 90x - general miscellaneous error
 - 900 - general miscellaneous error

- 91x - general insufficient resources error
 - 910 - general insufficient resources error
- 99x - general unknown error
 - 999 - unknown error

[Moab Resource Manager Language Data Format](#)

[Managing Resources Directly with the Native Interface](#)

W.3 Moab RM Language Socket Protocol Description

Moab RM language is formerly known as WIKI. The Moab scheduler uses a simple protocol for socket connections to the user client and the resource manager as described below:

`<SIZE><CHAR>`

`CK=<CKSUM><WS>TS=<TIMESTAMP><WS>AUTH=<AUTH><WS>DT=<DATA>`

Attribute	Description
<SIZE>	8 character decimal ASCII representation of the size of the packet following ' <code><SIZE><CHAR></code> ' Leading zeroes must be used to pad this value to 8 characters if necessary.
<CHAR>	A single ASCII character
<CKSUM>	A 16 character hexadecimal ASCII DES-based checksum calculated using the algorithm below* and <code><SEED></code> selected and kept secret by the site admins. The checksum is performed on the line from <code>TS=</code> to the end of the message including <code><DATA></code> .
<WS>	a series of white space characters consisting of either tabs and/or space characters.
<TIMESTAMP>	ASCII representation of epoch time
<AUTH>	Identifier of user requesting service (i.e., <code>USERNAME</code>)
<DT>	Data to be sent

An example header follows:

`00001057 CK=cdf6d7a7ad45026f TS=922401962 AUTH=sched DT=<DATA>`

where `<DATA>` is replaced by actual message data.

W.3.1 Checksum Algorithm ('C' version)

```

#define MAX_CKSUM_ITERATION 4

int GetChecksum(
    char *Buf,
    int BufSize,
    char *Checksum,
    char *CSKey) /* Note: pass in secret key */
{
    unsigned int crc;
    unsigned int lword;
    unsigned int irword;
    int index;
    unsigned int Seed;
    Seed = (unsigned int)strtoul(CSKey,NULL,0);
    crc = 0;
    for (index = 0;index < BufSize;index++)
    {
        crc = (unsigned int)DoCRC((unsigned short)crc,Buf[index]);
    }
    lword = crc;
    irword = Seed;
    PSDES(&lword,&irword);
    sprintf(Checksum,"%08x%08x",
        lword,
        irword);
    return(SUCCESS);
}

unsigned short DoCRC(
    unsigned short crc,
    unsigned char onech)
{
    int index;
    unsigned int ans;
    ans = (crc ^ onech << 8);
    for (index = 0;index < 8;index++)
    {
        if (ans & 0x8000)
            ans = (ans <<= 1) ^ 4129;
        else
            ans <<= 1;
    }
    return((unsigned short)ans);
}

int PSDES(
    unsigned int *lword,
    unsigned int *irword)
{
    int index;
    unsigned int ia;
    unsigned int ib;
    unsigned int iswap;
    unsigned int itmph;
    unsigned int itmpl;
    static unsigned int c1[MAX_CKSUM_ITERATION] = {
        0xcba4e531, 0x537158eb, 0x145cdc3c, 0x0d3fdeb2 };
    static unsigned int c2[MAX_CKSUM_ITERATION] = {
        0x12be4590, 0xab54ce58, 0x6954c7a6, 0x15a2ca46 };
    itmph = 0;

```

```

itmpl = 0;
for (index = 0; index < MAX_CKSUM_ITERATION; index++)
{
    iswap = *irword;
    ia = iswap ^ c1[index];
    itmpl = ia & 0xffff;
    itmph = ia >> 16;
    ib = (itmpl * itmpl) + ~(itmph*itmph);
    ia = (ib >> 16) | ((ib & 0xffff) << 16);
    *irword = (*lword) ^ ((ia ^ c2[index]) + (itmpl * itmph));
    *lword = iswap;
}
return(SUCCESS);
}

```

W.3.2 Header Creation (PERL code)

(taken from PNNL's QBank client code)

```
#####
#
# subroutine wiki($COMMAND)
#
# Sends command to Moab server and returns the parsed result and status
#
#####
sub wiki
{
  my($COMMAND,$REQUEST,$result);
  my($sockaddr,$hostname);
  my($name,$aliases,$proto,$port,$type,$len,$thisaddr);
  my($thisport,$thatport,$response,$result);
  $COMMAND = shift;
  #
  # Establish socket connection
  #
  $sockaddr = 'S n a4 x8';
  chop ($hostname = `hostname`);
  ($name,$aliases,$proto)=getprotobyname('tcp');
  ($name,$aliases,$type,$len,$thisaddr)=gethostbyname($hostname);
  ($name,$aliases,$type,$len,$thataddr)=gethostbyname($BANKHOST);

    ($key,$value)=split(/=/,$_);
    $REQUEST{$key}=$value unless defined $REQUEST{$key};
}
$request =~ s/\s+CHECKSUM=.*//; # Strip off the checksum
print STDERR "REQUEST=$request\n";
chomp($checksum=`QSUM "$request"`);
$me=$REQUEST{AUTH};
$command=$REQUEST{COMMAND};
if (!grep($command eq $_,@VALIDCMDS))
{ $REPLY = "STATUSCODE=0 RESULT=$command is not a valid command\n";}
elsif ($checksum ne $REQUEST{CHECKSUM})
{ $REPLY = "STATUSCODE=0 RESULT=Invalid Checksum\n";}
else
{ $REPLY = do $command(@REQUEST); }
$len=sprintf("%08d",length($REPLY)-1);
$delim=' ';
$DEBUG && print STDERR "REPLY=${len}${delim}$REPLY\n";
$buf="$len"."$delim"."$REPLY";
syswrite(NS,$buf,length($buf));
close NS;

```

SCHEDCFG flags

Flag	Description
AGGREGATENODEFEATURES	<p><i>AGGREGATENODEFEATURES</i> causes Moab to aggregate features reported by the different RMs. For example, if you have two RMs reporting different features for the same node, Moab will add both features together (instead of one being overwritten by the other).</p> <p>In order to set features manually, you can use <code>mnodectl -m features</code> (for details, see mnodectl on page 306).</p>
ALLOWINFINITEJOBS	<p><i>ALLOWINFINITEJOBS</i> allows infinite wallclock times to be accepted. Previously, jobs with infinite job times were allowed by default.</p>

Flag	Description
ALLOWMULTICOMPUTE	<i>ALLOWMULTICOMPUTE</i> tells Moab how to resolve conflicting information from different resource managers. If <i>ALLOWMULTICOMPUTE</i> is specified, Moab will use the STATE and OS information from the resource manager that reports the node as online.
CANCELFAILEDDEPENDENCYJOBS	Automatically cancels dependency jobs that will never run because of an unmet requirement. For example, if you ran a job with both an afterok and afternotok job attached to it and that job was successful, the afterok job would run, leaving the afternotok job idle in the queue. If you set <i>CANCELFAILEDDEPENDENCYJOBS</i> , Moab will cancel the job with the failed dependency and remove it from the queue. For more information about job dependencies, see Job Dependencies on page 655 .
DISABLEPERJOBNODESETS	Disables a job's ability to override the system specified node set. See 13.3 Resource Manager Extensions for more information.
DISABLEPARTIALNODERESERVATIONS	Blocks partial node reservations.
ENABLEDYNAMICNODES	Enables the ability to automatically remove nodes from Moab that are no longer reported by the resource manager.
ENABLESLURMMEMPERCPU	By default Moab calls sbatch or srun with a --mem= request in a SLURM environment. When you set <i>ENABLESLURMMEMPERCPU</i> , Moab instead calls --mem-per-cpu=. This is to allow sites with policies that require the other parameter to use --mem-per-cpu.
ENFORCERESERVEDNODES	Without this flag Moab tries to optimize the reservation for a job before it starts, meaning a job may start on nodes that weren't part of its reservation. With this flag Moab tries to start jobs only on the nodes that were reserved.
ENFORCESAMENODESET	The same nodeset is not enforced across job requirements by default, rather each requirement is scheduled separately and the nodesets are determined on a per-req basis. To have Moab enforce the same nodeset across all job requirements set this flag.
EXTENDEDGROUPSUPPORT	Allows Moab to consider a user's secondary Linux groups when dealing with reservation ACLs .

Flag	Description
FASTGROUPLOOKUP	Moab will use the system call <code>getgrouplist</code> to gather group information. This can significantly improve performance on some LDAP systems.
FASTRVSTARTUP	<p>Speeds up start time if there are existing reservations.</p> <div>  FASTRVSTARTUP is incompatible with partial node reservations. </div> <p>On very large systems, if there is a reservation in the checkpoint file on all the nodes, it would take a really long time for Moab to start up. For every node in the reservation, Moab checks every other node. With this flag, Moab just uses the nodelist that was checkpointed to create the reservation. It speeds up the startup process because it doesn't have to check every node. Where Moab would take 8 - 10 minutes to start up with an 18,000 node reservation without the flag, Moab can start up in 2-3 minutes with the flag.</p> <p>With the flag you will see one difference in checknode. A reservation that uses all the procs on a node initially shows that all the procs are blocked. Without the flag, and as jobs fill on the node, the blocked resources will be configured - dedicated (ex. 5/6). With the flag, the blocked resources will always be what the reservation is blocking and won't change when jobs fill on the node.</p> <p>Without flag:</p> <pre>Reservations: brian.1x1 User -00:12:52 -> INFINITY (INFINITY) Blocked Resources@-00:00:02 Procs: 5/6 (83.33%) Mem: 0/5000 (0.00%) Blocked Resources@00:04:58 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%) m.2x1 Job:Running -00:00:02 -> 00:04:58 (00:05:00) Jobs: m.2</pre> <p>With flag:</p> <pre>Reservations: brian.1x1 User -00:00:15 -> INFINITY (INFINITY) Blocked Resources@-00:00:02 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%) Blocked Resources@00:04:58 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%) m.1x1 Job:Running -00:00:02 -> 00:04:58 (00:05:00) Jobs: m.1</pre> <div>  When you set the FASTRVSTARTUP flag, Moab will also set the DISABLEPARTIALNODERESERVATIONS flag. </div>

Flag	Description
<u>FILELOCKHA</u>	This is a <u>High Availability</u> feature. FILELOCKHA prevents scheduling conflicts between multiple Moab servers.
FREECOMPLETEDJOBSUBMITSTRING	Moab frees the job submit string for completed jobs, decreasing the amount of memory needed during operation. This is useful in environments with large job scripts that can create a large memory footprint.
IGNOREPIDFILELOCK	Moab will not fail if it cannot get a lock on the <code>.moab.pid</code> file. This is useful when Moab is running on a shared filesystem where file locking can be unpredictable.
JOBSUSERSVWALLTIME	Allows jobs submitted without a walltime request or default walltime received from a class or queue but with an <code>ADVRES:reservation</code> to inherit their walltime limit from the reservation instead of the Moab default. The job walltime limit is then the remaining time of the reservation to which the job was submitted.
NOCLASSUPDATE	While running against TORQUE, Moab will not update classes when it refreshes each iteration. Moab loads the classes at startup, but does not refresh them until the next time it is restarted.
NORMALIZETASKDEFINITIONS	<p>Instructs Moab to normalize all tasks that it receives via an <u>mshow -a</u> command. Moab normalizes the task definition to one processor and then changes the tasks requested to the number of processors requested. For example, when the following is received by Moab:</p> <pre>mshow -a -w mintasks=1@procs:4+mem:4096</pre> <p>It is changed to this:</p> <pre>mshow -a -w mintasks=4@procs:1+,mem:1024,tpn=4</pre>
NOVMDESTROYDEPENDENCIES	The destroy job a in cloud workflow does not have any dependencies, allowing it to run whenever you cancel the service. For more information about destroy jobs, see <u>DESTROYTEMPLATE</u> and <u>Creating a Cloud Workflow</u> .
OPTIMIZEDBACKFILL	On large systems that utilize system-wide reservations, backfill can take a considerable amount of time. This flag speeds up backfill scheduling by using an alternative BETA backfill algorithm. This flag will be the default in future versions of Moab.

Flag	Description
OUTOFBANDVMRSV	<p>Causes Moab to put reservations on untracked VMs (VMs that are created outside of Moab) so that the untracked VMs are visible when you use <code>checkjob</code>, <code>mshow</code>, <code>checknode</code>, etc. commands. These reservations are updated each new iteration, so if the VM is migrated or modified outside of Moab, the reservation will accordingly adjust automatically.</p> <p>The reservations are not checkpointed. The system re-creates them when you restart Moab (new reservation IDs, etc.). If a VM tracking job appears for the VM, then the reservation will be removed.</p> <div>  This scheduler flag is highly recommended for Cloud users. For more information, see Workload-Driven Cloud Services. </div>
PRIORITYPOLICYBLOCKING	<p>By default, a job that violates a policy is placed into the blocked queue. Jobs with a lower priority, but that do not violate the policy, will run. This can lead to situations in which small jobs starve out larger, higher priority jobs.</p> <p>When you set the PRIORITYPOLICYBLOCKING flag, Moab allows the job that violates the policy to continue consuming the policy slots while it remains blocked. With the policy slots consumed, the smaller, lower priority jobs will not run. The higher priority job will continue to consume the policy slots until it has consumed enough to actually run.</p> <p>Note that because the blocked job consumes policy slots, this will inevitably lead to lower system utilization.</p>
SHOWREQUESTEDPROCS	Shows requested processors regardless of NodeAccessPolicy in showq . When SINGLEJOB NODEACCESSPOLICY is used and the job requests one processor, <code>showq</code> displays the job with one processor.
SHOWUSERJOBONLY	Causes Moab, when a non-admin user runs <code>showq</code> , to return only that user's jobs. If an administrator runs <code>showq</code> when this flag is set, Moab returns the jobs of all users; no restrictions are placed on administrators.
STRICTSPOOLDIRPERMISSIONS	Enforces at least a 511 permission on the Moab spool directory.
UNMIGRATEONDEFER	Forces Moab to unmigrate a job in a grid if it enters a deferred state.

Moab Web Services

Moab Web Services Overview

Moab Web Services (MWS) is a component of Adaptive Computing Suites that enables programmatic interaction with Moab Workload Manager via a RESTful interface. MWS lets you create and interact with Moab objects and properties such as jobs, nodes, virtual machines, and reservations. MWS is the preferred method for those wishing to create custom user interfaces for Moab and is the primary method by which Moab Viewpoint communicates with Moab.

MWS communicates with the Moab Workload Manager (Moab) server using the same wire protocol as the Moab command-line interface. By publishing a standard interface into Moab's intelligence, MWS significantly reduces the amount of work required to integrate Moab into your solution.

This documentation is intended for developers performing such integrations. If you are a Moab administrator, and for conceptual information about Moab, see [Moab Workload Manager Overview on page 161](#).

Setup

Moab Web Services Setup

This section explains what you need to know in order to get MWS configured, and secured correctly. It contains the following topics:

- [Configuring Moab Web Services on page 1570](#)
- [Setting up MWS Security on page 1585](#)
- [Version and Build Information on page 1593](#)

Related Topics

- [Moab Web Services Overview on page 1569](#)
- [Access Control on page 1595](#)

Configuring Moab Web Services

This section describes the location of the MWS configuration files. It also shows some examples of how to configure logging.

i To see a full reference to all configuration and logging parameters available in MWS, see [Configuration](#) on page 2114.

This topic contains these sections:

- [Home Directory](#) on page 1570
- [Configuration Files](#) on page 1570
- [Logging Configuration Using mws-config.groovy](#) on page 1570
- [LDAP Configuration Using mws-config.groovy](#) on page 1576
- [Insight Database Configuration Using mws-config.groovy](#) on page 1580
- [PAM \(Pluggable Authentication Module\) Configuration Using mws-config.groovy](#) on page 1581
- [OAuth Configuration Using mws-config.groovy](#) on page 1582

Home Directory

The MWS home directory contains configuration files, log files, and files that serve features of MWS such as hooks and plugins. You should set the location of the MWS home directory using the **MWS_HOME** property. If you do not set **MWS_HOME** as a Java property or as an environment variable, then MWS will use `/opt/mws` as the default **MWS_HOME**.

Configuration Files

The primary configuration file is `MWS_HOME/etc/mws-config.groovy`. If this file is missing or contains errors, MWS will not start.

Configuration files can also be placed in the `MWS_HOME/etc/mws.d` directory. Any configuration files here get merged with `MWS_HOME/etc/mws-config.groovy`. In case of conflict, the configuration in `MWS_HOME/etc/mws.d` takes precedence.

If `MWS_HOME/etc/log4j.properties` exists, MWS will load it as well.

Logging Configuration Using mws-config.groovy

Shown below is an example that logs all error messages and fatal messages to `/opt/mws/log/mws.log` (For information about the format of the MWS logs, see "[Standard Log Format](#)" in the *Moab Workload Manager Administrator Guide*.). It also logs all stack traces to `/opt/mws/log/stacktrace.log`. Note

that this example is not configured to log events; for details on logging events, see [Configuring an Event Log on page 1571](#).

```
Minimal logging configuration
-----

log4j = {
  appenders {
    rollingFile name: 'stacktrace',
      file: '/opt/mws/log/stacktrace.log',
      maxFileSize: '1GB'
    rollingFile name: 'rootLog',
      file: '/opt/mws/log/mws.log',
      threshold: org.apache.log4j.Level.ERROR,
      maxFileSize: '1GB'
  }
  root {
    debug 'rootLog'
  }
}
```

Alternatively, you may configure a console appender instead of a rolling file, as shown below.

```
Console logging configuration
-----

log4j = {
  appenders {
    rollingFile name: 'stacktrace',
      file: '/opt/mws/log/stacktrace.log',
      maxFileSize: '1GB'
    console name: 'consoleLog',
      threshold: org.apache.log4j.Level.ERROR
  }
  root {
    debug 'consoleLog'
  }
}
```

i You may configure logging by using either `MWS_HOME/etc/mws-config.groovy` or `MWS_HOME/etc/log4j.properties`.

If you do not define any `log4j` configuration, MWS will write its log files to `java.io.tmpdir`. For Tomcat, `java.io.tmpdir` is generally set to `$CATALINA_BASE/temp` or `CATALINA_TMPDIR`.

Configuring an Event Log

Logging events to a flat file requires that you make a few changes to the configuration in the **log4j** section of the `mws-config.groovy` file so that events will be logged to the `events.log` file, and all other MWS logging information will be sent to the `mws.log` file.

Causing events.log to roll based on a time window

You can specify how often the `events.log` file rolls. The following example illustrates the configuration changes you will need make to `mws-config.groovy` to cause the `events.log` file to roll based on a time window. Note the following three examples:

- In this example, `mws-config.groovy` is configured so that `events.log` rolls daily at midnight.

```
Daily rolling events.log configuration in mws-config.groovy
-----
log4j = {
    def eventAppender = new org.apache.log4j.rolling.RollingFileAppender(name:
'events', layout: pattern(conversionPattern: "%m%n"))
    def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM-dd}', activeFileName:
'/tmp/events.log')
    rollingPolicy.activateOptions()
    eventAppender.setRollingPolicy(rollingPolicy)

    appenders {
        appender eventAppender

        rollingFile name: 'rootLog',
            file: '/tmp/mws.log',
            maxFileSize: '1GB'
    }

    root {
        warn 'rootLog'
    }

    trace additivity:false, events:'com.ace.mws.events.EventFlatFileWriter'
}
```

Note the **RollingFileAppender** and the **TimeBasedRollingPolicy** lines. These lines configure MWS to write the event log to the `events.log` file. Rolled log files will have a date appended to their name in this format: "yyyy-MM-dd" (for example, `events.log.2012-02-28`).

- If you want the event log file to roll at the beginning of each month, change the **fileNamePattern** `TimeBasedRollingPolicy` date format to `yyyy-MM`. For example:

```
Monthly event logs
-----
def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM}', activeFileName: '/tmp/events.log')
```

- If you want the event log file to roll at the beginning of each hour, change the date format to `yyyy-MM-dd_HH:00`. For example:

Hourly event logs

```
def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM-dd_HH:00}', activeFileName:
'/tmp/events.log')
```

[Configuring events.log to roll based on a file size threshold](#)

You can also configure the events.log file to roll when the log size exceeds a specified threshold. The following example illustrates the configuration changes you will need to make to `mws-config.groovy` to cause the events.log file to roll on a size threshold. (In this example, `mws-config.groovy` is configured so that events.log rolls when its size exceeds 50 MB.)

mws-config.groovy configuration that rolls events.log based on file size

```
log4j = {
  appenders {
    rollingFile name: 'events',
      file: '/tmp/events.log',
      maxFileSize: '50MB',
      maxBackupIndex: 10

    rollingFile name: 'rootLog',
      file: '/tmp/mws.log',
      maxFileSize: '1GB'
  }

  root {
    warn 'rootLog'
  }

  trace additivity: false, events: 'com.ace.mws.events.EventFlatFileWriter'
}
```

Note that **maxFileSize** is set to "50MB." This means that when the events.log file exceeds 50 MB, it will roll.

The name for the rolled log will be "events.log.1". When the *new* events.log file exceeds 50 MB, it will roll and be named "events.log.1", while the old "events.log.1" file will be renamed "events.log.2". This process will continue until the optional **maxBackupIndex** value is met. In the example above, **maxBackupIndex** is set to 10. This means that MWS will delete all but the ten most recent events.log files. Using this feature helps prevent hard drives from filling up.

[Additivity](#)

The **additivity** attribute of the EventFlatFileWriter logger can be either `true` or `false`. If you specify `true`, events will be logged to the events.log file *and* the mws.log file. If you specify `false`, events will be logged to the events.log file only. (All other MWS logging information will be logged to the mws.log file, as configured by the rootLog appender.)

To log events to the `mws.log` file in addition to the `events.log` file, make the `additivity:true` configuration. For example:

```
Logging events to both events.log and mws.log
-----
trace additivity:true, events:'com.ace.mws.events.EventFlatFileWriter'
```

For more configuration options, see [Apache Extras Companion for log4j](#).

Deleting old events

If your MongoDB server is version 2.2 or later, MongoDB will automatically delete events older than 30 days (by default). For more information, including how to change this default, see `mws.events.expireAfterSeconds` in [Configuration on page 2114](#).

If your MongoDB server is older than version 2.2, MongoDB will store event data indefinitely. However, if disk space is limited, you may want to regularly delete old, unneeded events from MongoDB. This section contains some examples of how you can do this.

Let's say that you want to delete events that are older than 90 days. (There are 86,400,000 milliseconds in a day, so in this example, 90×86400000 corresponds to 90 days in milliseconds.):

- You could run this script:

```
Delete events older than 90 days
-----
$ mongo
MongoDB shell version: 2.4.8
connecting to: test
> use mws
> db.event.remove({eventTime:{$lt:new Date(new Date().getTime()-90*86400000)}})
> exit
```

- To create a script to perform this task:

```
deleteOldEvents.sh
-----
#!/bin/bash
printf 'use mws_dev\ndb.event.remove({eventTime:{$lt:new Date(new Date().getTime()-90*86400000)}})\nexit' | mongo
```

- Now say that you want to set up a [cron job](#) (`$crontab -e`) so that old events are automatically deleted on a certain day of the week (for example, every Sunday at 2:00 a.m.), you would add an entry like this:

```
cron table entry to delete old events
-----
00 02 * * 0 /root/deleteOldEvents.sh
```

Configuring an Audit Trail Log

Audit logging enables you to track changes to [Permissions on page 1802](#), [Roles on page 1864](#), [Tenants on page 1970](#), and [Principals on page 1836](#).

```
mws-config.groovy configuration that enables audit logging
```

```
def auditAppender = new org.apache.log4j.RollingFileAppender(
    name: 'audit',
    layout: new com.ace.mws.logging.ACPatternLayout("%j\t\t\t%c{1}\t\t\t%m%n"))
def auditRollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy(
    fileNamePattern: '/opt/mws/log/audit.%d{yyyy-MM-dd}',
    activeFileName: '/opt/mws/log/audit.log')
auditRollingPolicy.activateOptions()
auditAppender.setRollingPolicy(auditRollingPolicy)

appenders {
    rollingFile name: 'stacktrace',
        file: '/opt/mws/log/stacktrace.log',
        maxFileSize: '100MB'
    rollingFile name: 'rootLog',
        file: '/opt/mws/log/mws.log',
        maxFileSize: '100MB', //The maximum file size for a single log file
        maxBackupIndex: 10, //Retain only the 10 most recent log files, delete
to save space
of each log entry
than this threshold
        layout: new com.ace.mws.logging.ACPatternLayout(), //Configures the o
        threshold: org.apache.log4j.Level.ERROR //Ignore any logging entries

    appender eventAppender
    appender auditAppender
}
```

You can customize audit logging in ways you can customize [event logging](#). For example, you can specify how often the `audit.log` file rolls. You can also configure the `audit.log` file to roll when the log size exceeds a specified threshold.

i Follow the same steps indicated in the previous section on [Configuring an Event Log on page 1571](#) for instruction on customizing audit logging; customization processes are the same for audit logging as for events logging.

audit.log file format

The default location to which the audit trail log is written is `/opt/mws/log/audit.log`. The log format is `yyyy-MM-dd HH:mm:ss resource username action data`. The following table offers a description for attributes included in the log format:

Parameter	Description
resource	The resource--permission, role, principal, or tenant--that changed.
username	The user's user name.
action	The type of change (create, update, or delete).
data	Dependent on what changed.

Sample `audit.log` format:

```
Audit trail log format
```

```
-----
2013-10-30 14:39:32,120 TENANT 'admin' updated resource named 'Engineering2' with
values:
  "name": "Engineering3",
  "attachedPrincipals": [{"name": "Engineering"}]
```

LDAP Configuration Using `mws-config.groovy`

Using a Supported LDAP Directory Type

To configure an MWS connection to an LDAP server, add the following parameters to `mws-config.groovy`:

i Throughout the following examples in this topic, you will see **dc=acme,dc=com**. "acme" is only used as an example to illustrate what you would use as your own domain controller if your domain name was "acme.com." You should replace any references to "acme" with your own organization's domain name.

Parameter	Description
ldap.server	The hostname or IP address of the LDAP server.
ldap.port	The port the LDAP server is listening on.
ldap.baseDNs	A list of distinguished names that are the root entries for LDAP searches.
ldap.bindUser	The distinguished name of the bind user.
ldap.password	The password of the ldap.bindUser.

Parameter	Description
ldap.directory.type	<p>The type of LDAP directory (e.g. "Microsoft Active Directory"). This parameter can have the following values:</p> <ul style="list-style-type: none"> • Microsoft Active Directory • OpenLDAP Using InetOrgPerson Schema • OpenLDAP Using NIS Schema • OpenLDAP Using Samba Schema

Here is a sample configuration for OpenLDAP.

i If you followed the Adaptive Computing tutorial [\[link\]"Setting up OpenLDAP on CentOS 6"](#) your **ldap.directory.type** should be set to "OpenLDAP Using InetOrgPerson Schema".

Sample OpenLDAP configuration

```
ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.directory.type = "OpenLDAP Using InetOrgPerson Schema"
```

Here is a sample configuration for Microsoft Active Directory.

Sample Active Directory configuration

```
ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["CN=Users,DC=acme,DC=com", "OU=Europe,DC=acme,DC=com"]
ldap.bindUser = "cn=Administrator,cn=Users,DC=acme,DC=com"
ldap.password = "*****"
ldap.directory.type = "Microsoft Active Directory"
```

i To see how to configure a secure connection to the LDAP server, see [Securing the LDAP Connection on page 1591](#).

Using an Unsupported LDAP Directory Type

If you are not using one of the supported directory types, you can explicitly configure MWS to work with your LDAP schema by using the following parameters:

Parameter	Description
ldap.user.objectClass	The name of the class used for the LDAP user object. For example: <ul style="list-style-type: none"> • user • person • inetOrgPerson • posixAccount
ldap.group.objectClass	The name of the class used for the LDAP group object. For example: <ul style="list-style-type: none"> • group • groupOfNames • posixGroup
ldap.ou.objectClass	The name of the class used for the LDAP organizational unit object. For example: <ul style="list-style-type: none"> • organizationalUnit
ldap.user.membership.attribute	The attribute field in a user entry to use when loading the user's groups (optional if ldap.group.membership.attribute is defined). For example: <ul style="list-style-type: none"> • memberOf
ldap.group.membership.attribute	The attribute field in a group entry to use when loading the group's members (optional if ldap.user.membership.attribute is defined). For example: <ul style="list-style-type: none"> • member • memberUid
ldap.user.name.attribute	The attribute field to use when loading the username. This field must uniquely identify a user. For example: <ul style="list-style-type: none"> • sAMAccountName • uid

For example:

Advanced Active Directory configuration

```

ldap.server = "myldaphostname"
ldap.port = 389
ldap.baseDNs = ["CN=Users,DC=acme,DC=com", "OU=Europe,DC=acme,DC=com"]
ldap.bindUser = "cn=Administrator,cn=Users,DC=acme,DC=com"
ldap.password = "*****"
ldap.user.objectClass = "person"
ldap.group.objectClass = "group"
ldap.ou.objectClass = "organizationalUnit"
ldap.user.membership.attribute = "memberof"
ldap.group.membership.attribute = "member"
ldap.user.name.attribute = "sAMAccountName"

```

Here is a similar example for OpenLDAP. Note there is no user membership attribute in the OpenLDAP InetOrgPerson schema and thus **ldap.user.membership.attribute** is set to null. This is allowable because the **ldap.group.membership.attribute** is set.

Advanced OpenLDAP configuration

```

ldap.server = "myldaphostname"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.user.objectClass = "inetOrgPerson"
ldap.group.objectClass = "groupOfNames"
ldap.ou.objectClass = "organizationalUnit"
ldap.user.membership.attribute = null
ldap.group.membership.attribute = "memberUid"
ldap.user.name.attribute = "uid"

```

Overriding Attributes in a Supported LDAP Directory Type

You can also override attributes in supported directory types. For example, say you are using OpenLDAP with an NIS Schema. The group objectClass for NIS defaults to "groupOfNames," but you want to use "groupOfUniqueNames" instead while retaining all other defaults for NIS. You can do this by setting **ldap.directory.type** to "OpenLDAP Using NIS Schema" and overriding the **ldap.group.objectClass** attribute as follows:

Advanced OpenLDAP configuration

```

ldap.directory.type = "OpenLDAP Using NIS Schema"
ldap.group.objectClass = "groupOfUniqueNames"

```

i LDAP is *not* currently used to authenticate users to MWS. LDAP is only used to map principals to roles, as explained in [Principals](#) on page 1836.

The user class in your LDAP schema must have an attribute that uniquely identifies a user (for example: "uid" or "sAMAccountName").

Insight Database Configuration Using `mws-config.groovy`

You will need to create and configure a read-only user that MWS will use to connect to the Insight database. It is recommended, but not required, that you configure an SSL connection to the Insight database.

To create a read-only PostgreSQL user

On the machine that contains the PostgreSQL service, run the following commands:

```
[root]# su - postgres
[postgres]$ psql -c "CREATE USER mws WITH PASSWORD 'changeme!'"
[postgres]$ psql -d moab_insight -U moab_insight -h 127.0.0.1 -c "GRANT SELECT
ON ALL TABLES IN SCHEMA public TO mws;"
[postgres]$ psql -d moab_insight -U moab_insight -h 127.0.0.1 -c "ALTER DEFAULT
PRIVILEGES IN SCHEMA public GRANT SELECT ON TABLES TO mws;"
```

To allow MWS to query the Moab Insight database

Add the following parameters to `mws-config.groovy`:

Parameter	Description
<code>dataSource_insight.url</code>	The JDBC URL for the Insight database.
<code>dataSource_insight.username</code>	The username used to log in to the Insight database.
<code>dataSource_insight.password</code>	The password for the username.

The following is an example configuration:

```
dataSource_insight.url = "jdbc:postgresql://localhost/moab_insight"
dataSource_insight.username = "mws"
dataSource_insight.password = "changeme!"
```

To configure connections to the Insight database over SSL

1. Ensure that your Java Runtime Environment (JRE) trusts the Insight database server's X.509 certificate. If the certificate was signed by a commercial certificate authority (CA), such as Verisign, then MWS should trust the certificate automatically. Otherwise, you must configure the JRE that MWS is using to trust this certificate explicitly. To do so, follow the steps described in the [PostgreSQL documentation](#) that describe how to use `keytool` to import the certificate.
2. Configure MWS to connect to the database over SSL by appending a URL parameter of `ssl=true` to your **`dataSource_insight.url`**.

```
dataSource_insight.url = "jdbc:postgresql://localhost/moab_insight?ssl=true"
```

PAM (Pluggable Authentication Module) Configuration Using `mws-config.groovy`

PAM functions as bridge to the underlying Unix authentication system. PAM treats the user as if it is local to the Unix machine doing the authenticating and uses whatever the Unix user is authenticating with, whether it be LDAP or NIS. PAM uses configuration files that specify the how, when, or what for authentication, session management, and account management. Each configuration file can be different. For example, `sudo` configuration file for the "sudo" command will handle authentication differently than the `login` configuration file. These configuration files are dynamically read for `/etc/pam.d`.

Requirements for PAM

In order to use PAM with MWS, the following is required:

- The PAM application package must be installed. For example:

```
yum install pam
```

- You must have a PAM configuration file in the `/etc/pam.d` directory. The following is an example of what a PAM configuration file might look like:

```

#%PAM-1.0
auth        required      pam_env.so
auth        sufficient    pam_unix.so nullok try_first_pass
auth        requisite     pam_succeed_if.so uid >= 1000 quiet_success
auth        required      pam_deny.so

account      required      pam_unix.so
account      sufficient    pam_localuser.so
account      sufficient    pam_succeed_if.so uid < 1000 quiet
account      required      pam_permit.so

password     requisite     pam_pwquality.so try_first_pass retry=3 authtok_type=
password     sufficient    pam_unix.so sha512 shadow nullok try_first_pass use_
authtok
password     required      pam_deny.so

session      optional     pam_keyinit.so revoke
session      required     pam_limits.so
-session     optional     pam_systemd.so
session      [success=1 default=ignore] pam_succeed_if.so service in crond quiet
use_uid
session      required     pam_unix.so

```

- (Optional) You must have PAM modules installed for your specific needs.

The PAM application comes with default modules—for example, **pam_unix.so**—that will check username and password credentials with Unix. You may have to install others for your distribution.

Configuring MWS to Use PAM

To configure an MWS connection to PAM, add the following parameter to `mws-config.groovy`:

Parameter	Description
pam.configuration.service	The name of the PAM configuration file located in <code>/etc/pam.d</code> . This parameter and specification tells MWS which PAM configuration file you want to use.

For example:

```
pam.configuration.service = "system-auth"
```

i You can configure only one authentication method in `mws-config.groovy`—LDAP or PAM, but not both. If you have configured both LDAP and PAM, MWS defaults to using LDAP.

If you need multiple authentication methods, you must add them to your local PAM configuration. See your distribution documentation for details.

⚠ There is a security risk when authenticating local users through your PAM configuration. This behavior is highly discouraged and not supported by Adaptive Computing.

For more information about PAM, please see the following [SLES](#) and [RedHat](#) documentation.

OAuth Configuration Using `mws-config.groovy`

OAuth is a security framework designed to simplify authentication in web technologies. In the case of MWS, OAuth allows trusted client applications to securely delegate authentication to MWS. Once MWS has authenticated a user by verifying the username and password in LDAP, PAM, or NIS, MWS returns an access token to the client. The client then presents this access token to MWS to access resources. OAuth is very flexible and allows MWS to work in many different scenarios by use of grant types. For more information on OAuth and grant types, please see the following [OAuth](#) documentation.

Example Using 'password' Grant Type

Terminology

Resource Owner: The person accessing and manipulating data. For MWS, this would be the person who logs into the client (the user).

Service Provider: The site or service where protected resources live. This can be (but is not necessarily) also the identify provider, where usernames and passwords are stored. This is the MWS service itself.

Client: The application that wants to access a resource. For MWS this is the user interface, potentially including APIs and command-line tools.

Protected Resource: The data for which protection is desired. For MWS this would be Moab itself, and interaction with Moab.

Access Token: Instead of user credentials, OAuth uses tokens to issue requests, and the tokens get signed to indicate authorization.

Register a Client in MWS

OAuth requires client registration. Its client credentials are used to validate that the client is allowed to authenticate on behalf of a resource owner. It involves giving the client its own credentials (username and password). MWS will first authenticate the client using a client id (username) and client secret (password), then will authenticate the resource owner.

Add the following line to `/opt/mws/etc/mws-config.groovy`:

```
grails.plugin.springsecurity.oauthProvider.clients = [
    [
        clientId:"THE_CLIENT_ID",
        clientSecret:"THE_CLIENT_SECRET",
        authorizedGrantTypes:["password"]
    ]
]
```

Replace `THE_CLIENT_ID` with client id (username). For example: `clientId:"iris"`. Also, replace `THE_CLIENT_SECRET` with client secret (password). For example: `clientSecret:"irisclientpassword"`, . Note that the values for `clientId` and `clientSecret` are case sensitive.

You can register more than one client. For example:

```
grails.plugin.springsecurity.oauthProvider.clients = [
    [
        clientId:"client_id_1",
        clientSecret:"client_secret_1",
        authorizedGrantTypes:["password"]
    ],
    [
        clientId:"client_id_2",
        clientSecret:"client_secret_1",
        authorizedGrantTypes:["password"]
    ]
]
```

Obtaining an Access Token from MWS for a Resource Owner (Logging In)

Before the client can access private data in MWS, the client must obtain an access token that grants access to the API. The token endpoint url is only used to gain an access token and log in a user.

Getting an access token:

```
POST http://localhost:8080/mws/rest/oauth/token?api-version=3
Adding header:
    "Content-Type: application/x-www-form-urlencoded"
Request body (String):
grant_type=password&client_id=THE_CLIENT_ID&client_secret=THE_CLIENT_SECRET&username=RESOURCE_OWNER_USERNAME&password=RESOURCE_OWNER_PASSWORD
```

Example using curl:

```
curl -X POST -H "Content-Type: application/x-www-form-urlencoded" -v -d 'grant_type=password&client_id=iris&client_secret=irisclientpassword&username=moab-admin&password=secret' 'http://localhost:8080/mws/oauth/token'
```

Produces the following response:

```
* About to connect() to localhost port 8080 (#0)
*   Trying 127.0.0.1... connected
* Connected to localhost (127.0.0.1) port 8080 (#0)
> POST /mws/oauth/token HTTP/1.1
> User-Agent: curl/7.19.7 (x86_64-redhat-linux-gnu) libcurl/7.19.7 NSS/3.14.0.0
zlib/1.2.3 libidn/1.18 libssh2/1.4.2
> Host: localhost:8080
> Accept: */*
> Content-Type: application/x-www-form-urlencoded
> Content-Length: 126
>
< HTTP/1.1 200 OK
< Server: Apache-Coyote/1.1
< Cache-Control: no-store
< Pragma: no-cache
< Set-Cookie: JSESSIONID=6CE8F9E7C454575FABCF3D156B153CFD; Path=/mws
< Content-Type: application/json; charset=UTF-8
< Transfer-Encoding: chunked
< Date: Fri, 18 May 2014 18:16:42 GMT
<
* Connection #0 to host localhost left intact
* Closing connection #0
{"access_token":"b693eec0-6c93-4540-8b2f-1e170be08046","token_type":"bearer","expires_in":43096}
```

Sending the Access Token to MWS When Requesting Protected Resource

After the client obtains an access token, it will send the access token to MWS in an HTTP authorization header for each rest call.

i The client is responsible for handling user sessions with each access token, meaning the client has to request a new access token when a new user logs in.

Requesting an MWS resource (getting list of all nodes for example):

```
GET http://localhost:8080/mws/rest/nodes?api-version=3&fields=name
Adding authorization header:
    "Authorization: Bearer ACCESS_TOKEN"
```

Example using curl:

```
curl -X GET -H "Authorization: Bearer b693eec0-6c93-4540-8b2f-1e170be08046" -v
'http://localhost:8080/mws/rest/nodes?api-version=3&fields=name'
```

Produces the following response:

```
* About to connect() to localhost port 8080 (#0)
* Trying 127.0.0.1... connected
* Connected to localhost (127.0.0.1) port 8080 (#0)
> GET /mws/rest/nodes?api-version=3&fields=name HTTP/1.1
> User-Agent: curl/7.19.7 (x86_64-redhat-linux-gnu) libcurl/7.19.7 NSS/3.14.0.0
zlib/1.2.3 libidn/1.18 libssh2/1.4.2
> Host: localhost:8080
> Accept: */*
> Authorization: Bearer b693eec0-6c93-4540-8b2f-1e170be08046
>
< HTTP/1.1 200 OK
< Server: Apache-Coyote/1.1
< Content-Type: application/json;charset=UTF-8
< Pragma: no-cache

Setting up MWS Security

When running MWS in production environments, security is a major concern. This section focuses on securing the connections with MWS:

- The connection between MWS and Moab Workload Manager (see [Securing the Connection with Moab on page 1586](#)).
- The connection between MWS and MongoDB (see [Securing the Connection with MongoDB on page 1586](#)).
- The connections between clients and MWS (see [Securing Client Connections to MWS on page 1587](#)).
- The connection between MWS and LDAP (see [Securing the LDAP Connection on page 1591](#)).
- The connection with the message queue (see [Securing the Connection with the Message Queue on page 1592](#)).

Related Topics

- [Configuring Moab Web Services on page 1570](#)
- [Version and Build Information on page 1593](#)

Securing the Connection with Moab

MWS communicates with Moab via the Moab Wire Protocol, which uses a direct connection between the two applications. The communication over this connection uses a shared secret key, which is discussed in the installation instructions (see "[Installing Moab Web Services on page 48](#)" in the installation documentation). However, the communication is not encrypted and is therefore susceptible to eavesdropping and replay attacks. For this reason, MWS is supported only when running on the same machine as Moab. This assures that any connections between the two applications occur internally on the server and are not exposed to external users.

Related Topics

- [Setting up MWS Security on page 1585](#)

Securing the Connection with MongoDB

By default, the connection between MWS and MongoDB is not authenticated. To enable authentication, follow the instructions below. For further reading, see the MongoDB tutorial "[Control Access to MongoDB Instances with Authentication](#)."

To enable an authenticated connection between MWS and MongoDB

1. Add an administrative user to the `admin` database.
2. Add an MWS user to the `mws` database.
3. To support MWS API version 2, add an MWS user with "read-only" rights to the `moab` database.

Here is an example of how to create all the required users. The users in the `moab` database are required only for MWS API version 2.

```
[root]# service mongod start
[root]# mongo
> use admin;
> db.addUser("admin_user", "secret1");
> use moab;
> db.addUser("moab_user", "secret2");
> db.addUser("mws_user", "secret3", true);
> use mws;
> db.addUser("mws_user", "secret3");
> exit;
```

i The passwords used here ("secret1," "secret2," and "secret3") are examples. Choose your own passwords for these users.

4. Add the MWS user credentials (the ones you just created) to the `mws-config.groovy` file. For example:

```
grails.mongo.username = "mws_user"
grails.mongo.password = "secret3"
```

5. Enable authentication in the MongoDB configuration file (called `/etc/mongodb.conf` on many Linux distributions). In that file, look for **#auth = true** and uncomment it.
6. Restart MongoDB.
7. Restart Tomcat.

If authentication is enabled in MongoDB, but the MWS user was not properly created or configured, MWS will not start. In this case, see the log file(s) for additional information.

- [Setting up MWS Security on page 1585](#)

Securing Client Connections to MWS

All connections to MWS, except those requesting the documentation or the main page, must be authenticated properly. MWS uses a single-trusted-user authentication model, meaning a single user exists that has access to all aspects of MWS. The username and password for this user are configured with the `auth.defaultUser` properties in the configuration file. For more information, see [Configuration on page 2114](#).

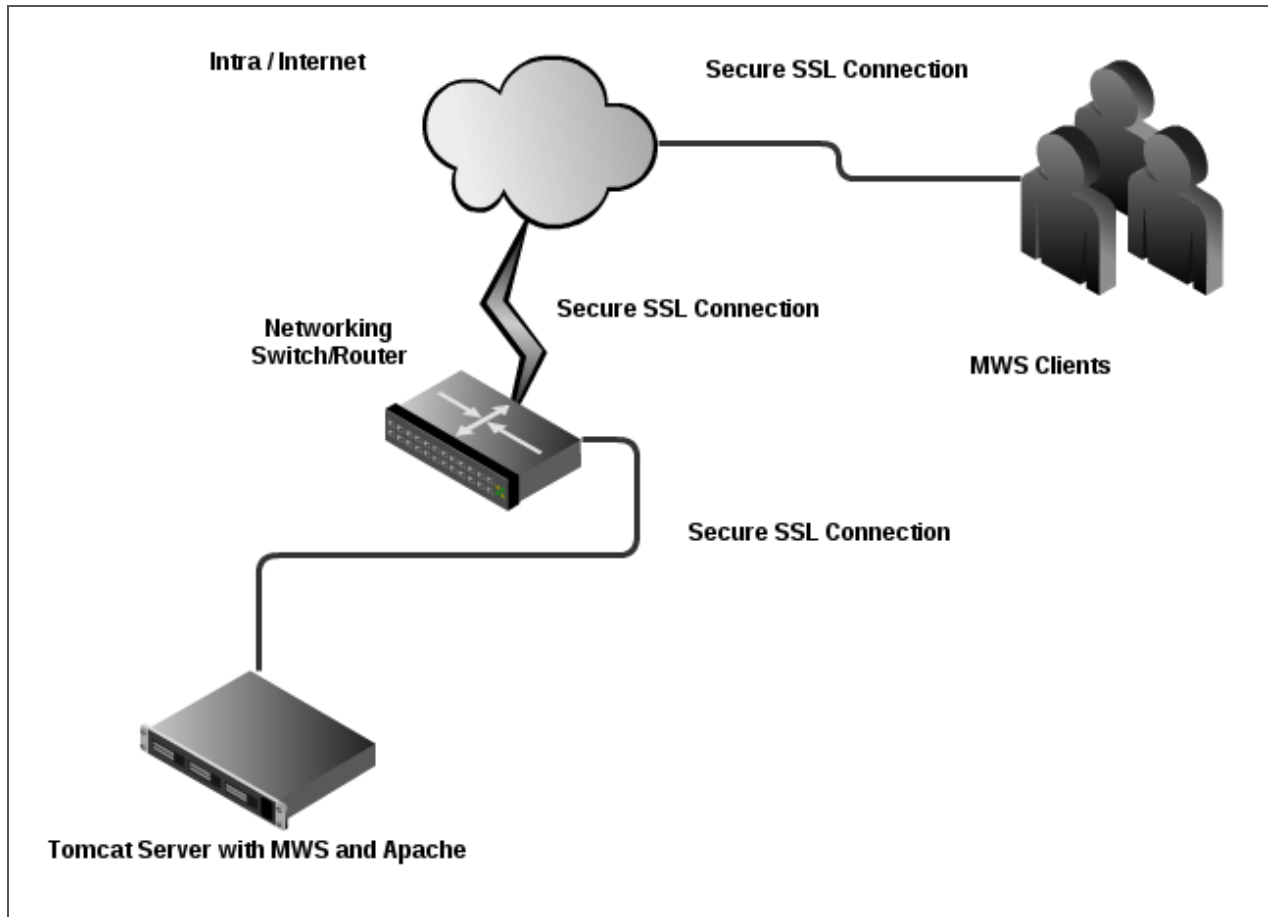

When using the MWS user interface in a browser, the user will be prompted for username and password. For information on how to authenticate requests when not using a browser, see [Authentication on page 1643](#).

i The username and password in the Basic Authentication header are encoded but not encrypted. Therefore, it is *strongly* recommended that MWS be run behind a proxy (like Apache) with SSL enabled. The instructions below provide an example of how to do this.

Encrypting Client Connections Using Apache and SSL

This section shows how to encrypt client connections to MWS using Apache and SSL. These instructions have been tested on CentOS™ 6.2 with the "Web Server" software set installed. The same ideas are applicable to other operating systems, but the details might be different. As shown in the diagram

below, these instructions assume that Tomcat and Apache are running on the same server.

To encrypt client connections using Apache and SSL

1. Create a self-signed certificate. (If desired, see <http://www.openssl.org/docs/HOWTO/certificates.txt> for more information.)

i Instead of creating a self-signed certificate, you can buy a certificate from a certificate vendor. If you do, then the vendor will provide instructions on how to configure Apache with your certificate.

2. Do the following:
 - a. Run these commands:

```
cd /etc/pki/tls/certs
cp -p make-dummy-cert make-dummy-cert.bak
cp -p localhost.crt localhost.crt.bak
```

- b. Edit `make-dummy-cert` and replace the **answers()** function with code similar to this:

```
answers() {
    echo US
    echo Utah
    echo Provo
    echo Adaptive Computing Enterprises, Inc.
    echo Engineering
    echo test1.adaptivecomputing.com
    echo
}
```

- c. Run this command:

```
./make-dummy-cert localhost.crt
```

3. Configure Apache to use the new certificate and to redirect MWS requests to Tomcat. To do so, edit `/etc/httpd/conf.d/ssl.conf`. Do the following"

- a. Comment out this line:

```
SSLCertificateKeyFile /etc/pki/tls/private/localhost.key
```

- b. Add these lines near the end, just above **</VirtualHost>**:

```
ProxyPass /mws http://127.0.0.1:8080/mws retry=5
ProxyPassReverse /mws http://127.0.0.1:8080/mws
```

4. Configure Apache to use SSL for all MWS requests. Add these lines to the end of `/etc/httpd/conf/httpd.conf`:

```
RewriteEngine On
RewriteCond %{HTTPS} off
RewriteRule (/mws.*) https://%{HTTP_HOST}%{REQUEST_URI}
```

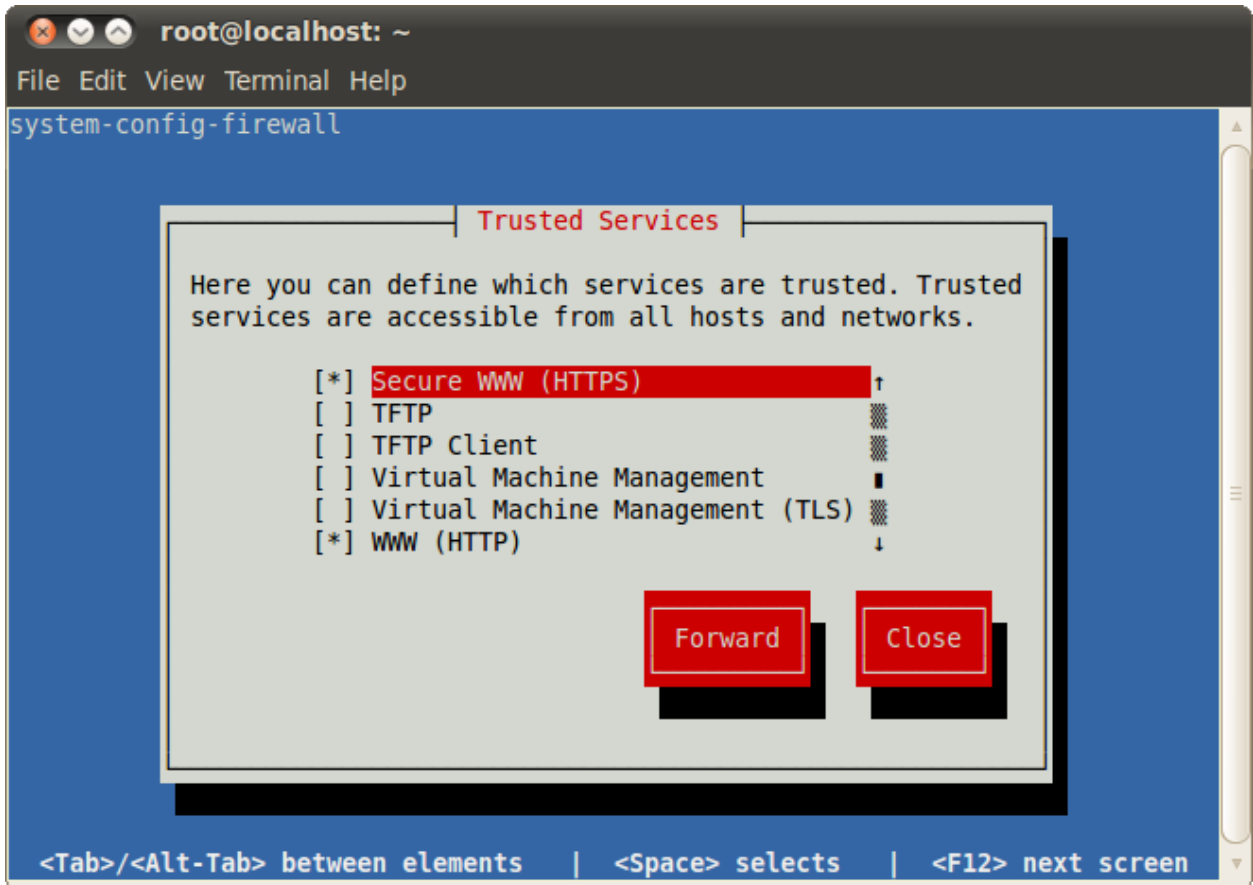

5. Give Apache permission to connect to Tomcat.

```
setsebool -P httpd_can_network_connect 1
```

6. Turn on Apache.

```
chkconfig httpd on
service httpd start
```

7. Using `system-config-firewall-tui`, enable "Secure WWW (HTTPS)" and "WWW (HTTP)" as trusted services.

Encrypting Client Connections Using Tomcat and SSL

This section shows how to encrypt client connections to MWS using Tomcat and SSL but without requiring the use of Apache. These instructions have been tested on CentOS™ 6.2 with Tomcat 6.0.

To encrypt client connections using Tomcat and SSL

1. First, you must generate a certificate. Do the following:
 - a. Use the keytool utility that is shipped with the Oracle Java Runtime Environment. As the Tomcat user, run the following:

```
keytool -genkey -alias tomcat -keyalg RSA
```
 - b. Specify a password value of "changeit". This will create a .keystore file that contains the new certificate in the user's home directory.
2. Enable the Tomcat SSL connector. Do the following:
 - a. Open the `server.xml` file, usually located in `$CATALINA_HOME/conf/` (`$CATALINA_HOME` represents the directory where Tomcat is installed).

- b. Verify the SSL HTTP/1.1 Connector entry is enabled. To do so locate the SSL HTTP/1.1 Connector entry and uncomment it.

```
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true" maxThreads="150"
scheme="https" secure="true" clientAuth="false" sslProtocol="TLS" />
```

i The code above enables SSL access on port 8443. The default for HTTPS is 443, but just as Tomcat uses 8080 instead of 80 to avoid conflicts, 8443 is used instead of 443.

- c. Save the `server.xml` file.
- d. Verify that `server.xml` is owned by the Tomcat user.

```
chown -R tomcat:tomcat server.xml
```

- e. Next modify the `MWSweb.xml` file. Add a security-constraint section to the `$CATALINA_HOME/webapps/mws/WEB-INF/web.xml` file found in your Tomcat directory.

```
<web-app>
...
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>MWS Secure URLs</web-resource-name>
      <url-pattern>/*</url-pattern>
    </web-resource-collection>
    <user-data-constraint>
      <transport-guarantee>CONFIDENTIAL</transport-guarantee>
    </user-data-constraint>
  </security-constraint>
</web-app>
```

- f. Now restart tomcat.

- [Setting up MWS Security on page 1585](#)

Securing the LDAP Connection

All connections from MWS to the LDAP server should be secured with SSL or StartTLS to ensure passwords and other sensitive information are encrypted as they pass to and from the LDAP server. If the LDAP server does not support SSL or StartTLS, the rest of this section is irrelevant.

Determine Whether the LDAP Server's Certificate is Trusted

If the LDAP server's X.509 certificate has been signed by a trusted certificate authority such as Verisign, Thawte, GeoTrust, and so on, Java will trust the certificate automatically and you won't need to add the certificate to Java's

keystore. Consult your IT department to determine whether the LDAP server certificate has been signed by a trusted certificate authority. If the LDAP server certificate is signed by a trusted certificate authority, skip ahead to [Configure MWS to Connect to LDAP Server Using SSL or StartTLS on page 1592](#). Otherwise, follow the instructions in [Trusting Servers in Java on page 130](#) to add the certificate to Java's keystore.

Configure MWS to Connect to LDAP Server Using SSL or StartTLS

To configure MWS to connect to LDAP using SSL/TLS

- 1. Update the `ldap.port` and `ldap.security.type` parameters in `/opt/mws/etc/mws-config.groovy`.

```
ldap.port = 636
ldap.security.type = "SSL"
```

To configure MWS to connect to LDAP using StartTLS

- 1. Update the `ldap.port` and `ldap.security.type` parameters in `/opt/mws/etc/mws-config.groovy`.

```
ldap.port = 389
ldap.security.type = "StartTLS"
```

The table below lists the possible values for `ldap.security.type`:

ldap.security.type	Default port	Notes
None	389	This is the default if no security type is configured. All data is sent in plain text.
SSL	636	Requires server certificate. All data is encrypted.
StartTLS	389	Starts as an insecure connection and is upgraded to an SSL/TLS connection. Requires server certificate. After upgrade all data is encrypted.

Securing the Connection with the Message Queue

MWS supports message queue security with AES. If the **moab.messageQueue.secretKey** property is set, then all messages MWS publishes on the message queue will be encrypted. Additionally, MWS can read messages from Moab Workload Manager that are encrypted with the same key using the **MESSAGEQUEUESECRETKEY** parameter. For more information, see [Configuration on page 2114](#).

Encryption is done with AES in CBC mode where inputs are padded with PKCS5 padding. Only 128-bit (16-byte) keys are supported. Keys should be encoded in [Base64](#).

For example:

```
moab.messageQueue.secretKey = "lr6RvfqJa6voezy5wAx0hw==" //must be a Base64-encoded
128-bit key
```

i Important: If MWS is configured to encrypt the message queue and Moab is not (or vice versa) then the messages from Moab will be ignored. Furthermore, all attempts to access the MWS service resource will fail.

Version and Build Information

To get detailed version information about MWS, use one of the following three methods:

- [Browser](#) on page 1593
- [REST Request](#) on page 1594
- [MANIFEST.MF File](#) on page 1594

Browser

Using a browser, visit the MWS home page (for example, <http://localhost:8080/mws/>). At the bottom of the page is the MWS version information. See the screenshot below:

Migrate a VM:

VM:

```
{"node": {"id": "hv1"}}
```

Moab Web Services 7.0.0-beta-3, Build 993 (2012-02-04_16-15-33), Revision 79f9da5b00e8a36e5cf40b5c96b61a04e9813fe9

REST Request

Using a REST client or other HTTP client software, send a GET request to the `rest/diag/about` resource. Here is an example:

```
curl -u username:password http://localhost:8080/mws/rest/diag/about?api-version=3
```

This resource is also described under [Diagnostics on page 1721](#).

MANIFEST.MF File

If MWS fails to start, version and build information can be found in the `META-INF/MANIFEST.MF` file inside the MWS WAR file. The version properties begin with **Implementation**. Below is an excerpt of a `MANIFEST.MF` file:

```
Implementation-Build: 26
Implementation-Build-Date: 2012-06-19_14-18-59
Implementation-Revision: 376079a5e5f552f2fe25e6070fd2e84c646a98fd

Name: Grails Application
Implementation-Title: mws
Implementation-Version: 7.1.0-rc2
Grails-Version: 2.0.3
```

Access Control

About Access Control

Access Control

This section describes how to manage access control in MWS. Applications are the consumers of MWS. They include Moab Viewpoint and other applications that need the resources provided by MWS. An application account consists of four editable fields and resource-specific access control settings:

Table 4-1: Field information

Field	Required	Default value	Value type	Maximum length	Description
Application Name	Yes	--	String	32	The name of the application. Must start with a letter and may contain letters, digits, underscores, periods, hyphens, apostrophes, and spaces.
Username	Yes	--	String	32	Used for authentication. Must start with a letter and may contain letters, digits, underscores, periods, and hyphens.
Description	No	--	String	1000	The description of the application.
Enabled	--	true	Boolean	--	Controls whether the application is allowed to access MWS.
Access Control Settings	Yes	All Permissions	--	--	The permissions granted to the application. This is controlled by selecting specific check boxes in a grid.

An application account also contains an auto-generated password that is visible only when creating the account or when resetting its password. Whenever an application sends a REST request to MWS, it needs to pass its credentials (username and password) in a Basic Authentication header. For more information, see [Authentication on page 1643](#).

The **Application Name** is a human-friendly way to identify an application account, but MWS does not use it during authentication (or at any other time, for that matter).

The **Enabled** field is set to true automatically when an application account is created. To change the value of this field, see [Modifying an Application Account on page 1598](#).

Here is an example of how you might set the fields when creating an application account:

- **Application Name:** Moab Viewpoint
- **Username:** viewpoint
- **Description:** This application account grants access to Moab Viewpoint for Moab Cloud Suite.

The permissions granted to an application account may be customized while creating or modifying the account. For more information, see [Creating an Application Account on page 1596](#) and [Modifying an Application Account on page 1598](#).

Managing Application Accounts

Application accounts are used to grant access to MWS. Every application with an application account must be granted at least one access control permission to a resource in MWS. To manage application accounts, see [Listing Application Accounts on page 1596](#).

Listing Application Accounts

To list all applications accounts, browse to the MWS home page (for example, <https://servername/mws>). Log in as the admin user, click **Admin** and then **Application Accounts**.

Each column (except **Password**) can be sorted in ascending or descending order by clicking on the column heading.

Creating an Application Account

To create an application account, go to the **Application List** page and click **Add Application**. The "Application Name" and "Username" are required fields. For more details, see [Field information on page 1595](#).

Access to specific resources and plugin custom web services is granted or revoked by checking or unchecking the check boxes in the respective resources or plugin web services access control sections. For each resource, access may be granted to a resource for each method supported by MWS, including GET, POST, PUT, and DELETE. See the figure below for an example.

<input type="checkbox"/> Select All	<input checked="" type="checkbox"/> GET	<input type="checkbox"/> POST	<input checked="" type="checkbox"/> PUT	<input checked="" type="checkbox"/> DELETE
<input checked="" type="checkbox"/> Access Control Lists			<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
<input checked="" type="checkbox"/> Accounts	<input checked="" type="checkbox"/>			
<input type="checkbox"/> Events	<input checked="" type="checkbox"/>	<input type="checkbox"/>		

In this example, the application has access to all available methods for the **Access Control Lists** and **Accounts** resources as well as to retrieve the **Events** resource through the GET method, but is denied the permission to create new events through the POST method.

Access may also be granted to each plugin type's custom web service(s). When new plugin types or plugin web services are added to MWS, applications must be updated with the new access control settings. See below for an example.

Plugin Type	<input checked="" type="checkbox"/> Can Access
<input checked="" type="checkbox"/> Test	
customService	<input checked="" type="checkbox"/>
unsecuredService (Unsecured)	

In this example, the application has access to all the custom web services defined for the **Test** plugin type. Note that though unsecured web services are listed, access to them cannot be denied (for more information, see [Exposing Web Services on page 2029](#)).

Displaying an Application Account

To show information about an application account, go to the **Application List** page and click the desired application name.

In addition to displaying the values for fields, grids are also displayed which represent the application's access control permissions defined for resources and plugin custom web services. Examples of the resources and the plugin web services access control displays are shown below:

	GET	POST	PUT	DELETE
Access Control Lists				
Accounts				
Events				

Plugin Type	Can Access
Test	
customService	
unsecuredService (Unsecured)	

Modifying an Application Account

To modify an application account, go to the **Application List** page, click the desired application name, and then click **Edit**. See [Creating an Application Account on page 1596](#) for more information on available fields and access control settings.

Resetting an Application Password

To reset an application password, go to the **Application List** page and click the **Reset** link for the desired application. Alternatively, go to the **Display Application** page for the desired application and click the **Reset** link.

Deleting an Application Account

To delete an application account, go to the **Application List** page, click the desired application name, and then click **Delete**. A confirmation message is shown. If the **OK** button is clicked, the application account is deleted from the system and cannot be recovered.

About Role-Based Access Control

Moab Web Services administrators use role-based access control to specify what operations each user can perform. They do this by assigning one or more roles to each user. Each role contains multiple permissions (such as *create service template*, *power on/off nodes*, and *view reservations*). By assigning a role to a user, an administrator grants each of that role's permissions to that user.

Example scenario

As part of his work, John needs to be able to create and manage services. The administrator therefore assigns John to the User role, which contains the *create service* and *view services* permissions.

Role-based access control is related to, but is not the same as, multi-tenancy. In order to function, Moab Web Services requires at least one tenant. By default, Moab Web Services creates a placeholder tenant named *Organization* when the system is installed or upgraded. If you do not need more than one tenant, this placeholder tenant is all you need. You will use this tenant to assign users to roles.

Image 4-1: Role-based access control model

Assigning Users to Roles

Before you assign users to roles, there are a number of things to consider and to verify are properly set up. Role-based access control will only work for users that have been added to an LDAP server. Additionally, you should determine whether there is a need for multi-tenancy in your environment.

Prerequisites:

1. Moab Web Services must be configured with an LDAP server. For more information, see [LDAP Configuration Using mws-config.groovy on page 1576](#).
2. Moab Web Services users must be added to the LDAP server. Optionally, users can be organized in LDAP groups or organizational units (OUs).

For the how-to, see [Setting Up and Provisioning a Tenant via the REST Interface or Provided Scripts on page 1607](#).

Whether or not your organization has a single tenant or multiple tenants, assigning users to roles works exactly the same. Just remember that if your organization only requires one tenant, you'll use the default tenant named

Organization for adding roles to users. If your organization includes multiple tenants, you'll need to create those tenants. (For more information, see [Modeling Your Organization with Tenants](#) on page 1604).

Considerations for Using or Not Using Multi-Tenancy

Why use multi-tenancy?

Multi-tenancy isolates each tenant's services, jobs, and virtual machines from other tenants, which makes it impossible for a given tenant's work to run on the same nodes as other tenants' work.

Why not use multi-tenancy?

The following points out consequences of choosing multi-tenancy and alternatives to multi-tenancy:

- There are good alternatives. Administrative reservations isolate work. Another option is to create a physically separate cluster, which does require additional administration overhead, but it absolutely guarantees that work from the isolated department or project will not intermix.
- Multi-tenancy essentially divides a node cluster into two or more mini-clusters, which may impact scheduling efficiency.
- Adding multiple tenants makes it more difficult for an administrator to manage the cluster. Reproducing and debugging problems are thus more challenging, and role and user management are more complicated.

Default Roles

Moab Web Services automatically creates default roles when it is installed or upgraded.

Cloud

Role	Description
User	Basic user, with permissions to start and view services.
PowerUser	Advanced user. In addition to starting and viewing services, can also create and manage service templates, and manage nodes.
Administrator	Has all permissions, including the ability to manage principals, roles, and permissions.

HPC

Role	Description
HPCAAdmin	Has all permissions. Can manage principals, roles, and permissions, and can view and manage all jobs and reservations.
HPCUser	Basic user, with permissions to start and view their own jobs.

CSA

Role	Description
Administrator	Has all permissions.

Custom Roles

If the default roles described above don't meet your needs, administrators have the ability to create their own custom roles. You can customize roles via the Moab Web Services REST interface. See [Editing an existing role](#) [Create Single Role on page 1868](#) in the MWS REST interface documentation.

The default roles can also be modified and even deleted. Care should be taken, however, when modifying these roles. Please consult Adaptive Computing Support or Professional Services for help.

Default Role Reset

If the default roles have been modified or deleted, a Moab Web Services administrator (moab-admin) can use the REST interface to reset these roles to their "factory" state.

```
POST /mws/rest/roles/reset-default?api-version=3
```

Resetting ensures that each of the default roles for the current suite have been created (or recreated), and that they contain all the default permissions they had when they were first created. This will not delete any roles or permissions, nor will it remove any permissions that may have been added to the default roles.

- [Access Control Lists \(ACLs\) on page 1648](#)

About Tenants

A tenant can represent an organization, department, or project. Tenants are used to isolate the work of a particular user or group from the work of everyone else in the cluster. Tenants effectively divide a cluster into smaller clusters. A tenant contains both resources and users. The users that belong to a tenant may only access the resources that belong to that tenant.

Example scenario

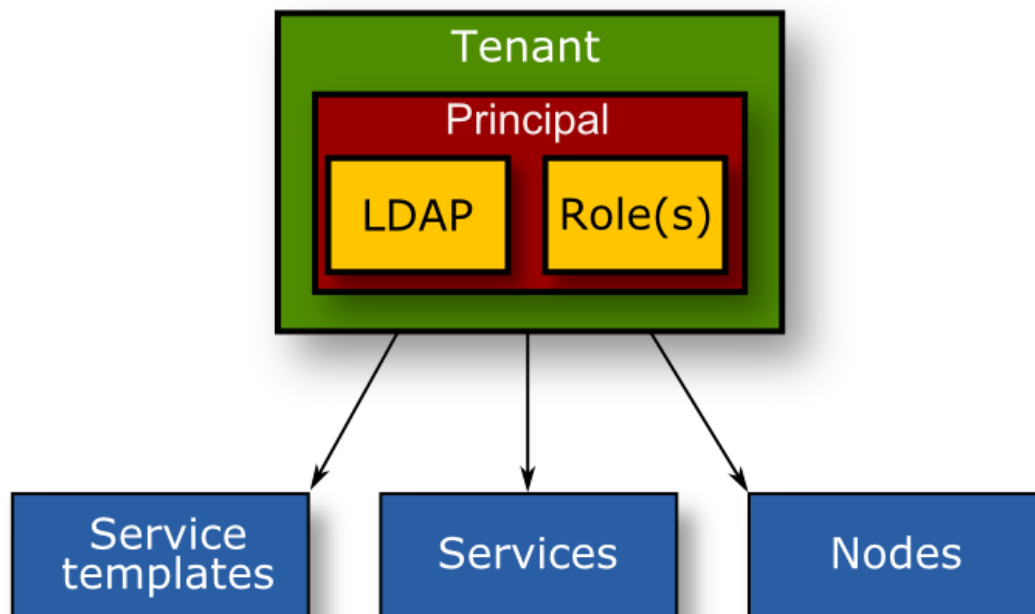

An administrator creates a tenant named "Research Labs" and assigns two nodes to it: blade01 and blade02. The administrator also assigns the user Shakespeare to "Research Labs". Whenever Shakespeare creates a service, Moab Web Services ensures that service only runs on node blade01 or blade02. Moab Web Services does not allow that service to run on any other node. Also, if a user that does not belong to "Research Labs" creates a service, Moab Web Services prevents that service from running on blade01 or blade02.

There are only certain types of resources that can be assigned to a tenant:

- Nodes
- Services
- Service templates

All other resource types (such as reservations, images, and policies) are global. Global resources cannot be assigned to individual tenants and instead are shared or ignored by all tenants. In addition, permissions, roles, principals, and even tenants themselves are considered global resources. Global resources are managed outside of tenants by administrators who have been given permission via global roles. Only an administrator with the correct role(s) can access, create, modify, or delete global resources.

Image 4-2: Tenant-owned resources

Using a Single Tenant

Most use cases will not require more than one tenant. By default, upon installation or upgrade, Moab Web Services creates a placeholder tenant named "Organization". This tenant can be renamed and modified to suit the needs of single-tenant systems. Users and resources can be added to it.

i Adaptive Computing recommends that those customers running Moab HPC Suite should not create more than a single tenant. To isolate the work of a particular user or group, first consider using administrative reservations.

Considerations for Using or Not Using Multi-Tenancy

Why use multi-tenancy?

Multi-tenancy isolates each tenant's services, jobs, and virtual machines from other tenants, which makes it impossible for a given tenant's work to run on the same nodes as other tenants' work.

Why not use multi-tenancy?

The following points out consequences of choosing multi-tenancy and alternatives to multi-tenancy:

- There are good alternatives. Administrative reservations isolate work. Another option is to create a physically separate cluster, which does require additional administration overhead, but it absolutely guarantees that work from the isolated department or project will not intermix.
- Multi-tenancy essentially divides a node cluster into two or more mini-clusters, which may impact scheduling efficiency.
- Adding multiple tenants makes it more difficult for an administrator to manage the cluster. Reproducing and debugging problems are thus more challenging, and role and user management are more complicated.

Next Steps

If you decide you don't need more than one tenant, please read the section on how to set up users and roles. If you decide you need more than one tenant, please see [Modeling Your Organization with Tenants on page 1604](#).

How-to

Modeling Your Organization with Tenants

The contents of this page apply to Cloud and CSA environments only; this content is not useful for modeling an HPC environment with tenants.

Context

The multi-tenancy model allows you to discretely control who has access to which resources. Usage of tenants is designed to subdivide your data center for such things as security and hardware ownership purposes. With tenants, you can allocate workload (services and VMs) and nodes that are available only to users assigned to a tenant.

The steps on this page explain how to organize your system of tenants and permissions.

Image 4-3: Multi-tenant model

i Creating subsections of nodes within a data center can have an impact on performance. The more tenants that are created, the greater the likelihood of impacting performance expectations.

To model your organization with tenants

1. Identify the tenants needed in your system. Tenants are groups of people collaborating across a common set of resources. They can represent a project, organization, or other type of group.

i Tenant resources are not shared, but users can belong to multiple tenants.

2. Identify the principals for each tenant and which roles will apply to those principals. Principals are one or more users—authenticated via LDAP and mapped to an LDAP user, group, or OU—who obtain access to the tenant's resources by being assigned one or more roles. In a cloud environment, the standard roles are Administrator, PowerUser, and User. Principals with the Administrator role have global privileges and access to all resources regardless of which tenants they belong to. Principals with the PowerUser and User roles have tenant privileges and can only access their assigned tenants' resources. A principal must be assigned to a single tenant, but a user or group may be assigned to multiple principals. This allows users to be assigned to multiple tenants, if desired. For more information about default and custom roles in cloud, HPC, and CSA environments, see [About Role-Based Access Control on page 1598](#).

i Fewer roles with minimal role overlap among principals is recommended.

3. Identify the nodes that each tenant will own, noting that a node can only be assigned to one tenant. Services created by a tenant's principals will run exclusively on nodes assigned to that tenant. Principals attached to the tenant that have the appropriate privileges may view and manage the nodes assigned to the tenant.

i Nodes are not required to be assigned to a tenant. Nodes that are not owned by a tenant are considered "tenantless" and can only be managed by principals with the Administrator role who therefore have global privileges. Unassigned nodes will not be used for placing or migrating services. In a single-tenant model, nodes are automatically assigned to the tenant.

4. Optionally (if applicable) identify services that should be migrated to the new tenant. Existing services may be re-assigned to the new tenant. Any container service can be migrated to any tenant if the current user has

either the update service privilege for both the old and new tenants or the global update service privilege. Migrating a container service moves the service, its child services, and any associated jobs, VMs, and PMs to the new tenant. Once it has been migrated, only users from that tenant and users with global rights will be able to access the service, its child services, and the associated jobs, VMs, or PMs.

i Services can be migrated to any tenant regardless of whether the new tenant has the necessary resources for running the service and its associated jobs. If the new tenant does not have the necessary resources, the service and associated jobs update to show they are moved, but the jobs, VMs, and PMs do not actually migrate and continue running on the old tenant's node(s). In such a case, Moab raises an event to alert the administrator.

5. Optionally (if applicable) identify service templates that should be copied to the new tenant. Service templates may be copied from tenant to tenant, and copying a container service template recursively copies all included service templates.

Setting Up and Provisioning a Tenant via the REST Interface or Provided Scripts

Context

The following procedure explains how to set up and provision a tenant through the REST interface or by running included command line scripts distributed with MWS. (See [Tenant Provisioning Scripts on page 1612](#) for more information.)

The procedure also offers an explanation for migrating a service to the new tenant and copying service templates to the new tenant, which can also be done through the REST interface or with the included command line scripts.

To provision tenants, you must meet the following prerequisites:

1. Follow the tenant setup instructions in [Modeling Your Organization with Tenants on page 1604](#).

2. Configure LDAP.
3. In LDAP, configure users, groups, and organizational units (OUs).

i Creating subsections of nodes within a data center can have an impact on performance. The more tenants that are created, the greater the likelihood of impacting performance expectations.

To set up and provision a tenant

1. Create the required principal(s). You can create a principal through the REST interface (see [Create Single Principal on page 1839](#)) or by running the `mprincipal` command line script shipped with MWS. See [The mprincipal Provisioning Script on page 1612](#) for information about syntax, commands, and options associated with this script.

```
> mprincipal -c ResearchUsers -g "cn=ResearchDept,ou=departments,dc=com" -r User -U moab-admin -P thePassword -H https://acme-mws:8080
```

The preceding `mprincipal` example creates a principal called `ResearchUsers` that maps to the `ResearchDept` group in LDAP, as identified by the supplied DN, and has the role of `User`. The script connects to MWS with the username `moab-admin`, the password `thePassword`, and the host name `https://acme-mws:8080`.

2. Create the required tenant(s). You can create a tenant through the REST interface (see [Create Single Tenant on page 1974](#)) or by running the `mtenant` command line script distributed with MWS. See [The mttenant Provisioning Script on page 1614](#) for information about syntax, commands, and options associated with this script.

```
> mttenant -c Research -U moab-admin -P thePassword -H https://localhost:8080
```

The preceding `mttenant` example creates a tenant called `Research`. The script connects to MWS with the user name `moab-admin`, the password `thePassword`, and the host name `https://localhost:8080`.

3. Attach the appropriate principals to the tenants. You can attach the principal(s) to the tenant(s) through the REST interface or by running the included `mttenant` command line script shipped with MWS. See [The mttenant Provisioning Script on page 1614](#) for information about syntax, commands, and options associated with this script.

```
> mttenant -p Research -U moab-admin -P thePassword -H http://localhost:8080
ResearchPowerUsers ResearchAdministrators
```

The preceding script adds the `ResearchAdministrators` principal to the `Research` tenant. The script connects to MWS with the user name `moab-admin`, the password `thePassword`, and the host name `https://localhost:8080`.

4. Assign the preferred node(s) to the tenant(s). You can assign the node(s) to the tenant(s) through the REST interface (see [Modify Single Tenant on page 1975](#)) or by running the included `mttenant` command line script shipped with MWS. See [The mttenant Provisioning Script on page 1614](#) for more

information about syntax, commands, and options associated with the script.

```
> mtenant -n Research -U moab-tenant -P thePassword -H https://localhost:8080 n001
n002 n003
```

The script above attaches nodes n001, n002, and n003 to the Research tenant. The script connects to MWS with the user name moab-tenant, the password thePassword, and the host name https://localhost:8080.

To migrate a service to a tenant

- If you want, you can migrate a service to the new tenant (if applicable). To migrate a service to the new tenant, [change the service's tenant field](#) to the new tenant and pass in the list of attached nodes (see [Modify Single Tenant on page 1975](#)) through the REST interface. You can also migrate a service to the new tenant using the included `msvc` command line script shipped with MWS. See [The msvc Provisioning Script on page 1618](#) for more information about syntax, commands, and options associated with the script.

```
> msvc -m Research -U moab-tenant -P thePassword -H https://localhost:8080
svc001 svc002 svc003
```

The script above migrates services svc001, svc002, and svc003 to the Research tenant. The script connects to MWS with the user name moab-tenant, the password thePassword, and the host name https://localhost:8080.

To copy service templates to a tenant

- If you want, you can copy service templates (if applicable) to a new tenant by first retrieving the service template(s), updating their name(s) to ensure they are unique, and updating the tenant field to the new tenant (see [Modify Service Template on page 1963](#)) through the REST interface. You can also copy service templates to a new tenant using the included `msvctempl` command line script shipped with MWS. See [The msvctempl Provisioning Script on page 1616](#) for more information about syntax, commands, and options associated with the script.

```
> msvctempl -c Research -U moab-tenant -P thePassword -H https://localhost:8080
lamp2container hcstorage
```

The script above copies the specified service template to the Research tenant and automatically selects a name for the new copy by appending an ordinal to the original name; for example, lamp2container becomes lamp2container-1. The script connects to MWS with the user name moab-tenant, the password thePassword, and the host name https://localhost:8080.

Removing a Tenant

 The following instructions are applicable to cloud, not HPC, environments.

Context

Removing a tenant is more than just deleting the tenant resource. Tenants are associated with nodes, services, service templates, jobs, vm's, and users. Before deleting the tenant, these other resources must be dealt with in order. The following procedure explains how to deprovision and remove a tenant. Some of the steps may be completed via Moab Viewpoint; other steps require that you use the REST interface or run included command line scripts distributed with MWS. (See [Tenant Provisioning Scripts on page 1612](#) for more information.)

To remove a tenant

1. Prevent service creation and migration from occurring on nodes assigned to the tenant you want to remove; to prevent such, you must do the following:
 - Delete principals associated with the tenant, which revokes the create service permission for the tenant for all users.
 - Create reservations on each of the tenant's nodes.

Deleting principals associated with the tenant prevents new services from being created on the tenant's nodes, but it does not stop existing services from migrating among those nodes. Creating reservations also prevents new services from being created, and it also prevents migration onto nodes; if users try to create new services, they will be unable to do so (an error results) because the reservation(s) prevent the requested services from being placed.

2. (Optional) Determine whether you want to delete or retain any service template(s) presently attached to the tenant you want to remove.
 - If you want to retain a service template, through the REST interface, [copy it to another tenant](#). You can also copy service templates to a new tenant using the included `msvctempl` command line script distributed with MWS. See [The msvctempl Provisioning Script on page 1616](#) for more information about syntax, commands, and options associated with the script.

Once you've copied all the service templates you want to keep, you should delete the remaining service templates from the tenant.

3. Migrate to another tenant, or delete, any service(s) assigned to the tenant

you want to remove. Only container services can be migrated, but when they are, they automatically migrate all their child services as well.

i If you have a lot of services assigned to the tenant you want to remove, consider migrating the services in smaller sets to avoid disruptions to data center performance.

- To migrate a container service to another tenant, [change the service's tenant field](#) to the other tenant (see [Modify single tenant](#)) through the REST interface. You can also migrate a service to another tenant using the included `msvc` command line script distributed with MWS. See [The msvc Provisioning Script on page 1618](#) for more information about syntax, commands, and options associated with the script.
- To delete a service, see [Delete Service on page 1922](#).

i It may take some time for all migrations and deletions to complete. Verify that all services have evacuated the tenant's nodes before allowing services from other tenants to use those nodes.

4. Once all services have cleared the tenant's nodes, you may reassign those nodes to other tenants. If the tenant's nodes are reassigned to other tenants before all services clear, services from different tenants may run simultaneously on those nodes.
 - Reassign the nodes presently assigned to the tenant you want to remove; for details on how to do so via the REST interface (see [Modify Single Tenant on page 1975](#)) or by running the included `mtenant` command line script distributed with MWS. See [The mtenant Provisioning Script on page 1614](#) for more information about syntax, commands, and options associated with the script.

i Moab may attempt to migrate services belonging to the tenant you want to remove to available nodes still owned by that tenant. However, the VMs should not have any eligible nodes to migrate to. Following these instructions should minimize the number of migrations, effectively eliminating the case where a VM needs to migrate off and then right back onto a node.

5. Delete the tenant you want to remove. To do so using the REST interface, see [Deleting Tenants on page 1977](#) for details.

Tenant Provisioning Scripts

Context

The tenant provisioning scripts assign ownership of nodes, service templates, VMs, and services to a specified tenant.

In order to provision tenants using this method, you must meet the following prerequisites:

1. MWS needs to be running `/opt/mws/check/basic-mws-diagnostics`. These are included in the RPM except for TORQUE.
2. LDAP is configured.
3. You have already configured your principals the way you want them.

The following tenant provisioning scripts are shipped with MWS:

- [The **mprincipal Provisioning Script** on page 1612](#)
- [The **mtenant Provisioning Script** on page 1614](#)
- [The **msvctempl Provisioning Script** on page 1616](#)
- [The **msvc Provisioning Script** on page 1618](#)

The mprincipal Provisioning Script

You can create, modify, or view principals in MWS using the `mprincipal` script.

mprincipal Syntax

```
mprincipal (-<shortCommand> <principalName>) | (--<longCommand>=<principalName>) [options...] [arg]
```

You may use either the short or long version of each command and option as long as you use the correct syntax as illustrated above.

Optional flags (`[options]`) are specified with the following syntax:

```
...(-<shortOption> <value>) | (--<longOption>=<value>) ...
```

Multiple options can be specified at the same time; they must be space-delimited.

An argument (`[arg]`) is name of the principal, and it is required to run the view and modify commands.

Commands for the mprincipal Script

The `mprincipal` commands are mutually exclusive and one is required.

Command	Short option	Long option	Description
Create	-c	--create	Lets you create a new principal.
Modify	-m	--modify	<p>Lets you modify an existing principal. You must specify the name of the principal to modify in the form of an argument as demonstrated in the syntax sample above.</p> <div>  When you modify a principal, you recreate a new principal with the same name. This means that, in addition to the desired modifications, you must re-specify the unchanging attributes that you wish to keep or else you will lose them. </div>
View	-v	--view	Lets you view an existing principal. You must specify the name of the principal to view in the form of an argument as demonstrated in the syntax sample above.

Options for the mprincipal Script

Option	Short option	Long option	Value	Description
Group	-g	--group	<i><groupName></i>	*Lets you specify the LDAP group distinguished name.
Help	-h	--help	---	Lets you view the usage.
Host	-H	--host	<i><hostName></i>	Lets you specify the MWS host to connect to while running this script. The default is <code>http://localhost:8080</code> .
LDAP user	-l	--ldapuser	<i><userName></i>	*Lets you specify the LDAP user name.
Organizational unit (OU)	-o	--ou	<i><ouName></i>	*Lets you specify the LDAP OU distinguished name.
Password	-P	--password	<i><password></i>	Lets you specify the MWS user's password with which to connect to MWS while running this script.

Option	Short option	Long option	Value	Description
Roles	-r	--roles	<roleName>	Lets you specify the MWS role names (separate multiple roles with commas)
User name	-U	--user	<userName>	Lets you specify the MWS user with which to connect to MWS while running this script. The default user is 'moab-admin'.

* The Group, LDAP user, and OU options are mutually exclusive. The LDAP user option takes precedence, then Group, and finally OU.

mprincipal Script Example

Both of the following examples will run the `mprincipal` script with user name "admin" and password "myPassword" to `https://smartuniversity-mws:8080`. The principal Biology will be modified to contain the BiologyDepartment LDAP group and the User role.

```
> mprincipal -m Biology -g "cn=BiologyDepartment,ou=departments,dc=com" -r User -U
admin -P myPassword -H https://smartuniversity-mws:8080
```

```
> mprincipal --modify=Biology --group="cn=BiologyDepartment,ou=departments,dc=com" --
roles=User --user=admin --password=myPassword --host=https://smartuniversity-mws:8080
```

The mtenant Provisioning Script

You can create, view, and attach nodes and principals to tenants using the `mtenant` provisioning script.

mtenant Syntax

Usage: `mtenant (-<shortCommand> <tenantName>) | (--<longCommand>=<tenantName>) [options] [args...]`

You may use either the short or long version of each command and option as long as you use the correct syntax as illustrated above.

Optional flags ([options]) are specified with the following syntax:

```
...(-<shortOption> <value>) | (--<longOption>=<value>) ...
```

Multiple options can be specified at the same time; they must be space-delimited.

An argument ([args]) is name of a principal or node by name or ID, which is required to attach a principal or node to the tenant, respectively. You can attach multiple principals or nodes to a tenant by delimiting them with a space.

Commands for the mtenant Script

The `mtenant` commands are mutually exclusive and one is required.

Command	Short option	Long option	Description
Create	-c	--create	Lets you create a new tenant.
Nodes	-n	--nodes	<p>Lets you attach nodes to the tenant. You must specify the name of the node to be attached in the form of an argument as demonstrated in the syntax sample above.</p> <div>  When you modify a tenant, you recreate a new tenant with the same name. This means that, in addition to the desired modifications, you must re-specify the unchanging attributes that you wish to keep or else you will lose them. </div>
Principals	-p	--principals	<p>Lets you attach principals to the tenant. Principal must have already been added in MWS. You must specify the name of the principal to be attached in the form of an argument as demonstrated in the syntax sample above.</p> <div>  When you modify a tenant, you recreate a new tenant with the same name. This means that, in addition to the desired modifications, you must re-specify the unchanging attributes that you wish to keep or else you will lose them. </div>
View	-v	--view	Lets you view a tenant.

Options for the mtenant Script

Option	Short option	Long option	Value format	Description
File	-f	--file	<fileName>	Lets you read data from file (instead of ARGS).
Help	-h	--help	---	Lets you view the usage.
Host	-H	--host	<hostName>	Lets you specify the MWS host to connect to while running this script. The default is <code>http://localhost:8080</code> .

Option	Short option	Long option	Value format	Description
Password	-P	--password	<password>	Lets you specify the MWS user password with which to connect to MWS while running this script.
User name	-U	--user	<userName>	Lets you specify the MWS username with which to connect to MWS while running this script. The default user is 'moab-admin'.

mtenant Script Example

Both of the following examples will run the `mtenant` script with user name "admin" and password "myPassword" to `https://smartuniversity-mws:8080`. The tenant Biology will be modified to own nodes n01, n02, and n03.

```
> mtenant -n Biology -U admin -P myPassword -H https://smartuniversity-mws:8080 n01 n02 n03
```

```
> mtenant --nodes=Biology --user=admin --password=myPassword --host=https://smartuniversity-mws:8080 n01 n02 n03
```

The msvctempl Provisioning Script

You can copy service templates to a tenant and view templates currently owned by a tenant with the `msvctempl` provisioning script.

msvctempl Syntax

```
msvctempl (-<shortOption> <value>) | (--<longOption>=<value>) ... [arg]
```

Multiple options can be specified at the same time; they must be space-delimited.

An argument (`[arg]`) is the name or ID of the service template if you are using the Copy option. You can attach multiple templates to a tenant by delimiting them with a space (for example, `msvctempl -c ... container1 container2 container3`).

Commands for the msvctempl Script

The `msvctempl` commands are mutually exclusive and one is required.

Command	Short option	Long option	Description
Copy	-c	--copy	Lets you copy container service templates to the tenant specified in your argument as demonstrated in the syntax sample above.
View	-v	--view	<tenantName>

Options for the msvctempl Script

Option	Short option	Long option		Description
File	-f	--file	<fileName>	Lets you specify the location of a file that contains additional template names or IDs. This is new line delimited.
Host	-H	--host	<hostName>	Lets you specify the name of the MWS host to connect while running this script. The default is <code>http://localhost:8080</code> .
Help	-h	--help	---	Lets you view the usage.
Password	-P	--password	<password>	Lets you specify the MWS password with which to connect to MWS while running this script. By default, you will be prompted for it.
User name	-U	--user	<userName>	Lets you specify the MWS username with which to connect to MWS while running this script. The default user is 'moab-admin'.

msvctempl Script Example

Both of the following examples will run the `msvctempl` script with user name "admin" and password "myPassword" to `https://smartuniversity-mws:8080`. The tenant Biology will be modified to own service templates st1, st2, and st3.

```
> msvctempl -c Biology -U admin -P myPassword -H https://smartuniversity-mws:8080 st1 st2 st3
```

```
> msvctempl --copy=Biology --user=admin --password=myPassword --host=https://smartuniversity-mws:8080 st1 st2 st3
```

The msvc Provisioning Script

You can move container services to a tenant and view top-level container services for the specified tenant with the `msvc` provisioning script.

The `msvc` provisioning script only works with services that run on a virtual machine, and there must be sufficient resources on the new tenant to accept the VMs or some services will not migrate to the new tenant. Also, any services with physical machine or storage components will not migrate and must be resolved outside of Moab. It is recommended that you copy the service template and launch the new service; that is, use the `msvctempl` provisioning script instead of the `msvc` provisioning script if possible.

msvc Syntax

`msvc (-<shortOption> <value>) | (--<longOption>=<value>) ... [arg]`

Multiple options can be specified at the same time; they must be space-delimited.

An argument (`[arg]`) is the name or ID of the service if you are using the Move option. You can move multiple services to a tenant by delimiting them with a space (for example, `msvc -m ... container1 container2 container3`).

Commands for the msvc Script

The `msvc` commands are mutually exclusive and one is required.

Command	Short option	Long option		Description
Move	-m	--move		Lets you move container services to the tenant specified in your argument as demonstrated in the syntax sample above.
View	-v	--view	<tenantName>	Shows container services for the specified tenant.

Options for the msvc Script

Option	Short option	Long option		Description
File	-f	--file	<fileName>	Lets you specify the location of a file that contains service names or IDs. This is new line delimited.

Option	Short option	Long option		Description
Host	-H	--host	<hostName>	Lets you specify the name of the MWS host to connect while running this script. The default is <code>http://localhost:8080</code> .
Help	-h	--help	---	Lets you view the usage.
Password	-P	--password	<password>	Lets you specify the MWS password with which to connect to MWS while running this script. By default, you will be prompted for it.
User name	-U	--user	<userName>	Lets you specify the MWS username with which to connect to MWS while running this script. The default user is 'moab-admin'.

msvc Script Example

Both of the following examples will run the `msvc` script with user name "admin" and password "myPassword" to `https://smartuniversity-mws:8080`. The tenant Biology will be modified to own services container1, container2, and container3.

```
> msvc -m Biology -U admin -P myPassword -H https://smartuniversity-mws:8080
container1 container2 container3
```

```
> msvc --move=Biology --user=admin --password=myPassword --
host=https://smartuniversity-mws:8080 container1 container2 container3
```

API Documentation

About the API

Moab Web Services provide a set of RESTful resources that can be used to create, read, update, and delete various objects in the Moab Workload Manager. This section describes how to use RESTful web services, explains the JSON data format used for all communications with MWS, describes global URL parameters used in MWS calls, and contains other helpful information for using the Moab Web Services API.

This section contains these topics:

- [RESTful Web Services on page 1620](#)
- [Data Format on page 1621](#)
- [Global URL Parameters on page 1622](#)
- [Requesting Specific API Versions on page 1626](#)
- [Responses and Return Codes on page 1626](#)
- [Error Messages on page 1631](#)
- [Pre- and Post-Processing Hooks on page 1633](#)
- [Authentication on page 1643](#)

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

RESTful Web Services

In order to understand how to use MWS, it is first necessary to give a brief introduction to REST. REST (Representational State Transfer) is a set of guidelines which utilizes the full HTTP (Hypertext Transfer Protocol) specification along with endpoint URLs that describe resources. The HTTP methods used in REST are comprised of the following:

Method	Description
GET	Query for a list or a single resource.
POST	Creating a resource.

Method	Description
PUT	Modifying a resource.
DELETE	Deleting a resource.

In comparison to other architectures of web services which use a single HTTP method and service endpoint to perform multiple types of operations (such as a POST operation to a URL), REST utilizes all of the available HTTP methods and URLs that directly correlate to resources. For example, RESTful web services for books in a library may expose many URL endpoints and the HTTP methods available for each such as GET, POST, PUT, and DELETE. The list below gives the methods, URLs, and descriptions for a sample set of services. The number 1 represents a unique identifier for books in each case.

Method	URL	Description
GET	/books	Retrieves a list of all books in the library.
POST	/books	Creates a new book.
GET	/books/1	Retrieves a single book.
PUT	/books/1	Modifies a single books.
DELETE	/books/1	Deletes a single book.

i Note that in the cases of the POST and PUT operations, additional information may be needed to describe the resource to be created or the fields that should be modified.

Moab Web Services provides RESTful web services for many resources. The methods and URLs available are documented in [Resources Introduction on page 1646](#).

- [About the API on page 1620](#)

Data Format

JSON (JavaScript Object Notation) is the data format used for all communication with MWS. This format makes use of two main structures:

collections of key/value pairs called *objects* and ordered lists of values called *arrays*. Objects are defined by using curly braces (`{}`), and arrays are defined by using square brackets (`[]`). A JSON object or array may contain several different types of values including numbers, booleans (`true/false`), strings, objects, arrays, or the keyword 'null' representing no value. For example, a simple JSON object might be defined as:

```
{
  "number": 1,
  "decimalNumber": 1.2,
  "boolean": true,
  "string": "Any string",
  "dateString": "2013-05-23 17:32:02 UTC",
  "object": {
    "key": "value"
  },
  "array": [
    "value1",
    "value2"
  ],
  "nullValue": null
}
```

Dates in MWS, for both input and output, use the pattern "`yyyy-MM-dd HH:mm:ss ZZZ`". For more details on that pattern, see [Joda-Time DateTimeFormat](#). For a list of valid time zone IDs, see [Joda-Time Available Time Zones](#).

For more information on JSON, see json.org.

The data format of MWS is defined as follows:

- Input for a POST or PUT must be in JSON format. Set the `Content-Type` header to `application/json`.
- Output is in JSON format and always consists of an object with zero or more key/value pairs.
- The output may also be "pretty-printed" or formatted for human viewing by sending a URL parameter. For more information, see [Global URL Parameters on page 1622](#).

Related Topics

- [About the API on page 1620](#)

Global URL Parameters

 All URL parameters are optional.

Parameter	Valid values	Description
api-version	Integer	Requests a specific API version
pretty	<i>true</i>	Controls pretty printing of output
fields	Comma-separated string	Includes only specified fields in output
exclude-fields	Comma-separated string	Excludes specified fields from output
max	Integer	The maximum number of items to return
offset	Integer	The index of the first item to return

API Version (api-version)

See [Requesting Specific API Versions on page 1626](#) for information on this parameter and how it should be used.

Pretty (pretty)

By default, the output is easy for a machine to read but difficult for humans to read. The **pretty** parameter formats the output so that it is easier to read.

Field Selection (fields)

The **fields** parameter will include *only* the specified fields in the output. For list queries, the field selection acts on the objects in **results** and not on the **totalCount** or **results** properties themselves.

The format of the **fields** parameter is a comma-separated list of properties that should be included, as in `id, state`. Using periods, sub-objects may also be specified, and fields of these objects may be included as well. This is done with the same syntax for both single sub-objects and lists of sub-objects, as in `id, requirements.requiredNodeCountMinimum, blockReason.message`.

Example 4-1: Example for a job query

Request

```
GET /rest/jobs?api-
version=3&fields=name,flags,requirements.taskCount,dates.createdDate
```

Response

```

{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "dates": {"createdDate": "2012-10-17 01:11:54 UTC"},
    "flags": ["GLOBALQUEUE"],
    "name": "Moab.24",
    "requirements": [{"taskCount": 1}]
  } ]
}

```

Field Exclusion (exclude-fields)

The **exclude-fields** parameter is the opposite of the **fields** parameter. All fields will be included in the output *except* those that are specified. For list queries, the field exclusion acts on the objects in **results** and not on the **totalCount** or **results** properties themselves.

The format of the **exclude-fields** parameter is a comma-separated list of properties that should be excluded from the output, as in `id,state`. Using periods, sub-objects may also be specified, and fields of these objects may be excluded as well. This is done with the same syntax for both single sub-objects and lists of sub-objects, as in

`id,requirements.requiredNodeCountMinimum,blockReason.message`.

Example 4-2:

Suppose a query returns the following JSON:

Request with No Field Exclusion

```
GET /objects
```

Response

```

{
  "id": "1",
  "listOfStrings": [
    "string1",
    "string2"
  ],
  "listOfObjects": [ {
    "item1": "value1",
    "item2": "value2"
  } ],
  "singleObject": {
    "id": "obj1",
    "field1": "value1"
  }
}

```

The same query with `exclude-fields` would return the following output:

Request with No Field Exclusion

```
GET /objects?exclude-fields=id,listOfObjects.item2,singleObject.field1,listOfStrings
```

Response

```
{
  "listOfObjects": [{"item1": "value1"}],
  "singleObject": {"id": "obj1"}
}
```

Sorting (sort)

[Services](#) on page 1871, [Service Templates](#) on page 1941, [Images](#) on page 1736, and [Events](#) on page 1728 support sorting based on [MongoDB syntax](#) by using the sort parameter. To sort in ascending order, specify a 1 for the sorting field. To sort in descending order, specify a -1. Objects can also be sorted on nested fields by using dot notation to separate the sub-fields, such as field.subfield1.subfield2.

Sorting examples

- To sort services in ascending order by account:

```
http://localhost:8080/mws/rest/services?api-version=3&sort={"account":1}
```

- To sort services in descending order by account:

```
http://localhost:8080/mws/rest/services?api-version=3&sort={"account":-1}
```

- To sort services in descending order by processors:

```
http://localhost:8080/mws/rest/services?api-version=3&sort=
{"attributes.moab.job.resources.procs":-1}
```

- To sort service templates in ascending order by name:

```
http://localhost:8080/mws/rest/service-templates?api-version=3&sort={"name":1}
```

- To sort service templates in descending order by name:

```
http://localhost:8080/mws/rest/service-templates?api-version=3&sort={"name":-1}
```

- To sort service templates in ascending order by the nested field template:

```
http://localhost:8080/mws/rest/service-templates?api-version=3&sort=
{"attributes.moab.job.template":1}
```

- [About the API](#) on page 1620

Requesting Specific API Versions

Because of significant changes in the API introduced in release version 7.2.0, MWS possesses a versioned API. The `api-version` URL parameter may be used to change the requested API version for any call to MWS. The current valid API versions with their corresponding MWS versions are shown in the table below:

API version	MWS version	Documentation	Additional notes
2 (deprecated)	7.2.x	7.2.x documentation on http://docs.adaptivecomputing.com/	As of the 8.1.0 release, API version 2 is officially deprecated and will be removed from Moab Web Services in the next major release.
3	8.0	Contained within this document	--
latest	Latest	Contained within this document	When the <code>latest</code> API version is requested, it resolves to the latest API version of MWS, such as <code>api-version=3</code> for MWS 8.1.0.

If no API version is specified, the request is rejected. An API version must be specified with every call in Moab Web Services 8.1.0 and later.

[Resources Introduction on page 1646](#) and [Resources reference on page 2124](#) contain information for the latest API version. For documentation of previous API versions, please see the table above.

Examples

```
GET http://localhost:8080/mws/rest/nodes?api-version=2
// Data returned uses API version 2

GET http://localhost:8080/mws/rest/nodes?api-version=latest
// Data returned uses API version 3
```

Responses and Return Codes

Various HTTP responses and return codes are generated from MWS operations. These are documented below according to the operation that they are associated with.

- [Listing and Showing Resources on page 1627](#)
- [Creating Resources on page 1627](#)
- [Modifying Resources on page 1629](#)
- [Deleting Resources on page 1630](#)
- [Moab Response Headers on page 1631](#)

Listing and Showing Resources

For any successful list or show operation (`GET`), a `200 OK` response code is always returned. No additional headers beyond those typical of a HTTP response are given in the response.

The body of this response consists of the results of the list or show operation. For a list operation, the results are wrapped in metadata giving total and result counts. The result count represents the number of resource records returned in the current request, and the total count represents the number of all records available. These differ when querying or the `max` and `offset` parameters are used. The following is an example of a list operation response:

JSON List Response Body

```
{
  "resultCount":1,
  "totalCount":5,
  "results":[
    {
      "id":"Moab.1",
      ...
    }
  ]
}
```

For a show operation, the result is given as a single object:

JSON Show Response Body

```
{
  "id":"Moab.1",
  ...
}
```

Creating Resources

A successful creation (`POST`) of a resource has two potential response codes:

- If the resource was created immediately, a `201 Created` response code is returned.
- If the resource is still being created, a `202 Accepted` response code is returned.

In either case, a `Location` header is added to the response with the full URL which can be used to get more information about the newly created resource or the task associated with creating the resource (if a `202` is returned).

Additionally, the body of the response will contain the unique identifier of the newly created resource or the unique identifier for the task associated with creating the resource (if a `202` is returned).

For example, during creation or submission of a job, a `201` response code is returned with the following response headers and body:

Job Creation Response Headers

```
HTTP/1.1 201 Created
Server: Apache-Coyote/1.1
Location: /mws/rest/jobs/Moab.21
X-Moab-Status: Success
X-Moab-Code: 000
Content-Type: application/json;charset=utf-8
Content-Length: 16
Date: Wed, 21 Dec 2011 23:04:47 GMT
```

Job Creation Response Body

```
{"id":"Moab.21"}
```

For another resource that is not immediately created, such as virtual machines, the response headers and body are shown below. In this case, a job is submitted to track the progress of the VM creation. This job contains information pertaining to the VM that is being created.

VM Creation Response Headers

```
HTTP/1.1 202 Accepted
Server: Apache-Coyote/1.1
Location: /mws/rest/jobs/vmcreate-1
X-Moab-Status: Success
X-Moab-Code: 000
Content-Type: application/json;charset=utf-8
Content-Length: 23
Date: Wed, 21 Dec 2011 23:12:50 GMT
```

VM Creation Response Body

```
{"jobId":"vmcreate-1"}
```

As can be seen, the body of the response contains only a job ID and not the ID of the virtual machine.

Modifying Resources

For any successful resource modification operation (`PUT`), a `200 OK` or `202 Accepted` response code is returned. A `200` response code signifies that the modification was immediately completed. No additional headers are returned in this case. A `202` response code is used again to signify that the modification is not yet complete and additional actions are taking place. In this case, a `Location` header is also returned with the full URL of the resource describing the additional actions.

In the case of a `200` response code, the body of this response typically consists of an object with a single `messages` property containing a list of statuses or results of the modification(s). However, a few exceptions to this rule exist as documented in [Resources Introduction on page 1646](#). In the case of a `202` response code, the format is the same as for a `202` during a creation operation, in that the body consists of an object with the unique identifier for the task associated with the additional action(s).

For example, when modifying a job, several messages may be returned as follows with the associated `200` response code.

Job Modification Response Headers

```
HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
X-Moab-Status: Success
X-Moab-Code: 000
X-Moab-Message:
Content-Type: application/json;charset=utf-8
Content-Length: ...
Date: Thu, 22 Dec 2011 16:49:43 GMT
```

JSON Modify Response Body

```
{
  "messages": [
    "gevent processed",
    "variables successfully modified"
  ]
}
```

When modifying a virtual machine, however, the action sometimes does not occur immediately, such as when migrating the VM to another hypervisor as described in [Migrate Virtual Machine on page 1992](#). In this case, the headers and response body are as follows:

VM Modification Response Headers

```

HTTP/1.1 202 Accepted
Server: Apache-Coyote/1.1
Location: /mws/rest/jobs/vmmigrate-1
X-Moab-Status: Success
X-Moab-Code: 000
Content-Type: application/json;charset=utf-8
Content-Length: 22
Date: Wed, 21 Dec 2011 23:12:50 GMT

```

VM Modification Response Body

```

{"jobId":"vmmigrate-1"}

```

Deleting Resources

For any successful resource deletion operation (`DELETE`), a `200 OK` or `202 Accepted` response code is returned. A `200` response code signifies that the deletion was immediately completed. No additional headers are returned in this case. A `202` response code is used again to signify that the deletion is not yet complete and additional actions are taking place. In this case, a `Location` header is also returned with the full URL of the resource describing the additional actions.

In the case of a `200` response code, the body of this response is empty. In the case of a `202` response code, the format is the same as for a `202` during a creation operation, in that the body consists of an object with the unique identifier for the task associated with the additional action(s).

For example, when deleting a job, a `200` response code is returned with an empty body as shown below.

Job Deletion Response

```

HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
X-Moab-Status: Success
X-Moab-Code: 000
X-Moab-Message:
Content-Type: application/json;charset=utf-8
Content-Length: 0
Date: Thu, 22 Dec 2011 16:49:43 GMT

```

When deleting a virtual machine, however, the action does not occur immediately. In this case, the headers and response body are as follows:

VM Deletion Response Headers

```

HTTP/1.1 202 Accepted
Server: Apache-Coyote/1.1
Location: /mws/rest/jobs/vmdestroy-1
X-Moab-Status: Success
X-Moab-Code: 000
Content-Type: application/json;charset=utf-8
Content-Length: 22
Date: Wed, 21 Dec 2011 23:12:50 GMT

```

VM Deletion Response Body

```

{"jobId":"vmdestroy-1"}

```

Moab Response Headers

In addition to the typical HTTP headers and the Location header described above, several headers are returned if the operations directly interact with Moab. These headers are described in the following table:

Name	Description
X-Moab-Status	One of Success, Warning, or Failure. Describes the overall status of the Moab request.
X-Moab-Code	A three digit code specifying the exact error encountered, used only in debugging.
X-Moab-Message	An optional message returned by Moab during the request.

Related Topics

- [About the API on page 1620](#)

Error Messages

Below is an explanation of what error message format to expect when an HTTP status code other than 20x is returned. All error codes have a response code of 400 or greater.

- [400 Bad Request on page 1632](#)
- [401 Unauthorized on page 1632](#)
- [403 Forbidden on page 1632](#)
- [404 Not Found on page 1632](#)

- [405 Method Not Allowed](#) on page 1633
- [500 Internal Server Error](#) on page 1633

400 Bad Request

This response code is returned when the request itself is at fault, such as when trying to modify a resource with an empty `PUT` request body or when trying to create a new resource with invalid parameters. The response body is as follows:

```
{
  "messages": [
    "Message describing error",
    "Possible prompt to take action"
  ]
}
```

401 Unauthorized

This response code is returned when authentication credentials are not supplied or are invalid. The response body is as follows:

```
{
  "messages": [
    "You must be authenticated to access this area"
  ]
}
```

403 Forbidden

This response code is returned when the credentials supplied are valid, but the permissions granted are insufficient for the operation. This occurs when using application accounts (see [Access Control on page 1595](#)) with limited access.

```
{
  "messages": [
    "You are not authorized to access this area"
  ]
}
```

404 Not Found

This response code is returned when the request specifies a resource that does not exist. The response body is as follows:

```
{
  "messages": [
    "The resource with id 'uniqueId' was not found"
  ]
}
```

405 Method Not Allowed

This response code is returned when a resource does not support the specified HTTP method as an operation. The response body is as follows:

```
{
  "messages": [
    "The specified HTTP method is not allowed for the requested resource"
  ]
}
```

500 Internal Server Error

This indicates that there was an internal server error while performing the request, or that an operation failed in an unexpected manner. These are the most serious errors returned by MWS. If additional information is needed, the MWS log may contain further error data. The response body is as follows:

```
{
  "messages": [
    "A problem occurred while processing the request",
    "A message describing the error"
  ]
}
```

Related Topics

- [About the API on page 1620](#)

Pre- and Post-Processing Hooks

MWS provides functionality to intercept and modify data sent to and returned from web services for all available resources. This is done by creating hooks in Groovy files located in a sub-directory of the `MWS_HOME` directory (by default, `/opt/mws/hooks`).

i Please see [Reference on page 1637](#) in this topic for the full reference for available hooks and methods available to them.

- [Configuring Hooks on page 1634](#)
- [Defining Hooks for a Resource on page 1634](#)
- [Before Hooks on page 1635](#)
- [After Hooks on page 1636](#)
- [Error Handling on page 1636](#)
- [Defining Common Hooks on page 1637](#)
- [Reference on page 1637](#)

Configuring Hooks

The directory of the `hooks` folder may be changed by providing a value for `mws.hooks.location` in the configuration file. If the directory starts with a path separator (ie `/path/to/hooks`), it will be treated as an absolute path. Otherwise, it will be used relative to the location of the MWS home directory (for more information, see [Configuring Moab Web Services on page 1570](#)).

For example, if the MWS home directory is set to `/opt/mws`, the hooks directory by default would be in `/opt/mws/hooks`. Changing the `mws.hooks.location` property to `myhooks` would result in the hooks directory being located at `/opt/mws/myhooks`. Due to the default location of the MWS home directory, the default directory of the `hooks` directory is `/opt/mws/hooks`.

On startup, if the `hooks` directory does not exist, it will be created with a simple `README.txt` file with instructions on how to create hooks, the objects available, and the hooks available. If the folder or file is unable to be created, a message will be printed on the log with the full location of a README file, copied into a temporary directory.

Defining Hooks for a Resource

Hooks are defined for resources by creating groovy class files in the hooks directory (`MWS_HOME/hooks` by default). Each groovy file must be named by the resource URL it is associated with and end in ".groovy". The following table shows some possible hook files that may be created. Notice that the virtual machines hook file is abbreviated as `vms`, just as the URL for virtual machines is `/rest/vms`. In most cases, the hook file names will exactly match the URLs. However, in cases of nested URLs—such as with "accounting/users"—the hook file name must replace slashes with periods. For example:

Resource	Hook filename
Jobs	<code>jobs.groovy</code>
Nodes	<code>nodes.groovy</code>
Virtual Machines	<code>vms.groovy</code>
Accounting Users	<code>accounting.users.groovy</code>
Accounting Funds Reports Statement	<code>accounting.funds.reports.statement.groovy</code>
Accounting Charge Rates	<code>accounting.charge-rates.groovy</code>
<i>url</i>	<i>url.groovy</i>

i `plugins.rm.groovy` is a valid hook filename. It works for the following URL: `/rest/plugins/<pluginID or all>/rm/<query or action>` (for example, `/rest/plugins/plugin1/rm/cluster-query`).

A complete example of a hook file is as follows:

Complete Hook File

```
-----
// Example before hook
def beforeList = {
    // Perform actions here
    // Return true to allow the API call to execute normally
    return true
}

def beforeShow = {
    // Perform actions here
    // Render messages to the user with a 405 Method Not Allowed
    // HTTP response code
    renderMessages("Custom message here", 405)
    // Return false to stop normal execution of the API call
    return false
}

// Example after hook
def afterList = { o ->
    if (!isSuccess()) {
        // Handle error here
        return false
    }
    // Perform actions here
    return o
}
```

i You must convert all actions or queries that are separated by dashes to a camel case. For example, the hooks called for "cluster-query" should be `beforeClusterQuery` and `afterClusterQuery`.

As the specific format for the hooks for `before` and `after` are different, each will be explained separately.

Before Hooks

As shown above, before hooks require no arguments. They can directly act on several properties, objects, and methods as described in [Reference on page 1637](#). The return value is one of the most important aspects of a `before` hook. If it is false, a `renderMessages`, `renderObject`, `renderList`, `render`, or `redirect` method *must* first be called. This signifies that the API call should be interrupted and the render or redirect action specified within the hook is to be completed immediately.

A return value of `true` signifies that the API call should continue normally. Parameters, session variables, request and response variables may all be modified within a `before` hook.

i If no return value is explicitly given, the result of the last statement in the `before` hook to be executed will be returned. This may cause unexpected behavior if the last statement resolves to `false`.

For all methods available to `before` hooks as well as specific examples, see [beforeSave on page 1638](#).

After Hooks

`After` hooks are always passed one argument: the object or list that is to be rendered as JSON. This may be modified as desired, but note that the object or list value is either a [JSONArray](#) or [JSONObject](#). Therefore, it may not be accessed and modified as a typical groovy Map.

Unlike `before` hooks, `after` hooks should not call the `render*` methods directly. This method will automatically be called on the resulting object or list returned. The `redirect` and `render` methods should also not be called at this point. Instead, if a custom object or list is desired to be used, the `serializeObject` and `serializeList` methods are available to create suitable results to return.

The return value of an `after` hook may be one of two possibilities:

- The potentially modified object or list passed as the first argument to the hook. In this case, this value will override the output object or list unless it is null.
- Null or false. In this case, the original, unmodified object or list will be used in the output.

i The return value of the `after` hook, if not null or false, *must* be the modified object passed into the hook or an object or list created with the `serialize*` methods.

For all methods available to `after` hooks as well as specific examples, see [afterSave on page 1638](#).

Error Handling

`After` hooks, unlike the `before` hooks, have the possibility of handling errors encountered during the course of the request. Handling errors is as simple as adding a one-line check to the hook as shown above or in the following code:

```
if (!isSuccess()) {
    // Handle error
    return false
}
```

It is recommended that each `after` hook contain at least these lines of code to prevent confusion on what the input object or list represents or should look like.

The `isSuccess()` function is false if and only if the HTTP response code is 400 or higher, such as a 404 Not Found, 400 Bad Request, or 500 Internal Server Error and the cause of the error state was not in the associated `before` hook. In other words, objects and lists rendered in the `before` hook with any HTTP response code will never run the associated `after` hook.

When handling errors, the passed in object will always contain a `messages` property containing a list of strings describing the error(s) encountered.

Defining Common Hooks

Sometimes it is beneficial to create hooks which are executed for all calls of a certain type, such as a `beforeList` hook that is executed during the course of listing any resource. These are possible using an `all.groovy` file. The format of this file is exactly the same as other hook files. The order of execution is as follows:

1. `Before` common hook executed.
2. `Before` resource-specific hook executed.
3. Normal API call executed.
4. `After` resource-specific hook executed.
5. `After` common hook executed.

Reference

This page gives specific examples and reference for implementing hooks in MWS.

[Available hooks](#)

The following table lists the available hooks for each resource with their associated HTTP method and description.

Name	HTTP method	Description
beforeList	GET	Runs before an API call that lists resources (for example, <code>GET /rest/jobs</code>).
afterList	GET	Runs after an API call that lists resources.

Name	HTTP method	Description
beforeShow	GET	Runs before an API call that returns a single resource (for example, GET /rest/jobs/job.1).
afterShow	GET	Runs after an API call that returns a single resource.
beforeSave	POST	Runs before an API call that saves a new resource (for example, POST /rest/-jobs).
afterSave	POST	Runs after an API call that returns a single resource.
beforeUpdate	PUT	Runs before an API call that returns a single resource (for example, PUT /rest/jobs/job.1).
afterUpdate	PUT	Runs after an API call that returns a single resource.
beforeDelete	DELETE	Runs before an API call that returns a single resource (for example, DELETE /rest/jobs/job.1).
afterDelete	DELETE	Runs after an API call that returns a single resource.

i If a resource does not support a certain operation, any hooks for that operation will simply be ignored—such as **beforeSave** and **afterSave** hooks for the Node resource, where saving is not supported.

Available properties

The following table lists the properties, objects, and methods available in all hooks. Note that although it is possible to directly call the `render*` methods in the `after` hooks, it is not recommended.

Name	Type	Description
params	Map	Contains all URL parameters as well as the body of the request as parsed JSON.
request	HttpServletRequest	Contains properties of the HTTP request.
response	HttpServletResponse	Contains properties of the HTTP response which can be modified directly.

Name	Type	Description
session	HttpSession	Contains the session parameters which can be modified directly.
flash	Map	Temporary storage that stores objects within the session for the next request only.
controllerName	String	The name of the controller responding to the request. Only available in before hooks.
actionName	String	The name of the action to be run on the controller. Only available in before hooks.
apiVersion	String	The API version for the current request (for example, 1 for 7.0 and 7.1, 2 for 7.2).

i The parsed JSON may be accessed in `before` hooks as a simple groovy Map with `params[controllerName]`.

In addition, several methods are available to the hooks. These are described in the following sections.

Redirect

The `redirect` method may be used to redirect the request to another API call or an arbitrary URL.

```
redirect(uri:'/rest/jobs')           // uri is used for internal redirection within MWS
redirect(url:'http://adaptivecomputing.com') // url is used for external redirection
redirect(uri:'http://adaptivecomputing.com', params:[lang:'en']) // params may be used
for URL parameters
```

i The `redirect` method will use the GET HTTP method for the resulting redirected request.

See the `redirect` method's [documentation](#) for more information.

Rendering objects, lists, or messages

There are several `render*` methods available to handle any case where objects or lists are desired to be rendered directly from the hook without continuing to the API call. Three different methods may be used depending on the desired output object type:

Render object

```

// Object that should be rendered as JSON
def objectToRender = ...
// HTTP response code (bad request)
def responseCode = 400
// Render a simple object
renderObject(objectToRender)
// Render a simple object with a custom response code
renderObject(objectToRender, responseCode)

```

Render list

```

// List that should be rendered as JSON
def listToRender = ...
// If the totalCount property differs from resultCount, use this value instead
def totalCount = ...
// HTTP response code (bad request)
def responseCode = 400
// Render a simple list
// Dynamically adds "resultCount" and "totalCount" properties based on the size of
the input list
renderList(listToRender)
// Render a simple list with a custom "totalCount"
renderList(listToRender, totalCount)
// Render a simple list without changing the "totalCount" but with a custom response
code
renderList(listToRender, null, responseCode)
// Render a simple list with a custom "totalCount" and response code
renderList(listToRender, totalCount, responseCode)

```

Render message(s)

```

// Messages
def messageToRender = "Single message"
def messagesListToRender = ["Message 1", "Message 2"]
// HTTP response code (bad request)
def responseCode = 400
// Render messages as an object with a property of "messages" containing a list of the
messages passed in
renderMessages(messageToRender)
renderMessages(messageToRender, responseCode)
// Supports either a single String or list of Strings
renderMessages(messagesListToRender)
renderMessages(messagesListToRender, responseCode)

```

i It is not recommended to call any of these methods from an `after` hook.

Render

Less commonly used, the `render` method is also available directly. This may be used to render text directly, change the content-type of the output, and many other functions. See the `render` method's [documentation](#) for more information.

i It is not recommended to call this method from an `after` hook.

Serialize objects

The `serializeObject` and `serializeList` methods may be used to convert a custom object or list respectively into a format usable for returning in the `after` hooks. Simply pass in the object or list and a serialized version will be returned from the method.

```
def afterShow = {
    def objectToRender = ...
    def serializedObject = serializeObject(objectToRender)
    return serializedObject
}
```

```
def afterShow = {
    def listToRender = [...]
    def serializedList = serializeList(listToRender)
    return serializedList
}
```

Error handling

Error handling is only available in `after` hooks by using the following check:

```
if (!isSuccess()) {
    // Handle error
    return ... // False or modified object/list to render
}
```

Usage examples

Override an API call

The following hook would serve to override an entire API call, the `list` call in this case, and return a `messages` list containing a single element of "Action is not supported" and a HTTP response code of 405 (Method Not Allowed):

```
def beforeList = {
    renderMessages("Action is not supported", 405)
    return false
}
```

To be even more specific and disallow the deletion of virtual machines, the following may be used as the `vms.groovy` file:

```
def beforeDelete = {
    renderMessages("Virtual Machine deletion is not allowed", 405)
    return false
}
```

Add an additional property during job creation

To add an additional property to a job definition during creation, create a `beforeSave` hook in the `jobs.groovy` file as follows:

```
def beforeSave = {
    // params[controllerName] is equivalent to params["job"] or params.job
    params[controllerName].user = "myuser"
}
```

This would cause the created job to have a user of `myuser`.

Redirect based on URL parameter

To redirect an API call if a certain URL parameter exists, create a `beforeSave` hook in the `jobs.groovy` file as follows:

```
def beforeSave = {
    if (params.external) {
        redirect(url:'http://example.com/create-job')
        return false; // Stop API call
    }
}
```

This would cause an API call of `PUT /rest/jobs?external=1` to redirect to `GET http://example.com/create-job`.

Remove a property from getting a single job

To remove a property from the output of getting a single job, create an `afterShow` hook in the `jobs.groovy` file as follows:

```
def afterShow = { o ->
    o.discard("group")
    return o
}
```

This will cause the resulting JSON to be missing the `group` property of the job resource. Note again that these calls must use the [JSONArray](#) and [JSONObject](#) classes as mentioned in [After Hooks on page 1636](#).

Filter list items

To filter the items in a list nodes request based on user provided query parameter in the URL, use the following in the `nodes.groovy` file. A sample request that would activate the filter is

`http://localhost:8080/mws/rest/nodes?api-version=3&filter-power=On.`

```
def afterList = { o ->
    // Do not filter if the user did not ask for it
    if (!params['filter-power'])
        return o
    // o = {resultCount: x, totalCount: x, results:[...]}

    // Using a built-in groovy method findAll to return all
    // list items that return true from the block
    def results = o.results.findAll { node ->
        // Includes the node only if the power equals the user input
        return params['filter-power'].equalsIgnoreCase(node.power)
    }

    // Sets the results on the return object and updates the counts
    o.element("results", results)
    o.element("resultCount", results.size())
    return o
}
```

To filter the items in a list nodes request based on values within the list itself, such as variable values, use the following in the `nodes.groovy` file.

```
def afterList = { o ->
    // o = {resultCount: x, totalCount: x, results:[...]}
    // Using a built-in groovy method findAll to return all
    // list items that return true from the block
    def results = o.results.findAll { node ->
        // Includes the node only if the variable "included" is set to "true"
        return node.variables?.included=="true"
    }

    // Sets the results on the return object and updates the counts
    o.element("results", results)
    o.element("resultCount", results.size())
    return o
}
```

Authentication

MWS uses Basic Authentication for all REST API requests. This means that a username and password must be provided for each call to resources. There are two types of accounts that can be granted access: **Users** and **Applications**.

- For instructions on how to set the credentials for the default **User** account, see [Setting up MWS Security on page 1585](#).
- For instructions on how to manage **Application** accounts, see [Access Control on page 1595](#).

To use Basic Authentication, each client request must contain a header that looks like this:

```
Authorization: Basic YWRhcHRpdmU6YzNVU3R1bkU=
```

The string after the word `Basic` is the base64 encoding of *username : password*. In the example above, `YWRhcHRpdmU6YzNVU3R1bkU=` is the base64 encoding of `adaptive:c3UStunE`. For more details, see section 2 of [RFC 2617](#).

i The username and password in the Basic Authentication header are encoded but not encrypted. Therefore, it is *strongly* recommended that MWS be run behind a proxy (like Apache) with SSL enabled. For more information, see [Setting up MWS Security on page 1585](#).

System Events

The broad category of system events may be broken down into two subcategories: events and notification conditions.

- [Events on page 1644](#)
- [Notification Conditions on page 1645](#)

Events

[Events on page 1728](#) are created by many components in the system, but most events originate from Moab Workload Manager and Moab Web Services. Events can be [created via the MWS interface](#) or by being placed on the message queue. The ZeroMQ™ message queue libraries were introduced in Moab and MWS 7.5.0. The message queue is critical to service lifecycle functionality (see "Service lifecycle" in the *Moab Cloud Suite Installation Guide*).

In a typical system, Moab will communicate events to MWS via a "private" message queue, and then MWS will replicate the events on the "public" message queue, or the message queue that is available to subscribers with the correct secret keys. In some cases, such as those related to the MWS service lifecycle, MWS uses events to determine activities or capabilities that are available.

A typical message on the message queue may look like the following (sent with a topic of `system.moab`):

Sample message on message queue

```
{
  "body" : {
    "associatedObjects" : [
      {
        "id" : "Moab",
        "type" : "scheduler"
      }
    ],
    "code" : 16777619,
    "eventDate" : "2014-02-28T10:57:21.000-0700",
    "message" : "A scheduler iteration is ending.",
    "origin" : "MSysMainLoop.c, MSysMainLoop, line 959"
  },
  "messageId" : "843269550",
  "messageType" : "event",
  "senderId" : "mwm@mwm-server",
  "sentDate" : "2014-02-28T10:57:21.000-0700",
  "ttl" : 3000
}
```

Notification Conditions

Notification Conditions on [page 1789](#) are related to an event, but differ in three distinct areas:

1. Notification conditions are a persistent condition of the system or a component rather than a single occurrence.
 - They are ongoing rather than reoccurring, which is why they are generated from NotificationConditions.
 - They may be observed many times, but the condition is always the same.
 - A good test for this is if something "is" wrong rather than something "went" wrong.
2. Notification conditions can be acted on to result in a resolved state, meaning the administrator or user can and must take actions to "fix" the condition or problem.
3. Notification conditions contain state information based on administrator or user input, meaning that they contain information about the condition (similar to events), but also contain the "status" of the administrator's view of the notification, whether it is currently open, dismissed, or ignored.

In general, questions may be asked to ascertain whether an event or a notification condition is the right fit for an occurrence. These questions, along with some sample situations, are provided below.

- Is the occurrence the root cause of a potentially ongoing condition?
 - A VM migration failed because the VM's state was unknown. The root cause was that the state was unknown, not that the VM migration

failed. Therefore, VM migration failed would be an event, while the unknown state would be a notification condition.

- A VM service provision fails because there are no hypervisors that satisfy the requirements. This would be an event. Note that there may be a notification related to this failure, such as a service template requires a feature that does not exist on any hypervisors in the system, but this would be distinctly detected and managed from the provision failure event.
- A request to MWS failed because the connection between Moab and MongoDB was misconfigured. The failed request may be represented as an event, but a notification condition should exist that the connection between Moab and MongoDB was down.
- Can an administrator or user affect the outcome of the occurrence?
 - The outcome of a VM migration failing is in the past and cannot be changed by the administrator. However, the outcome of a future VM migration may be changed when the administrator resolves the root problem (such as VM state is unknown).

Resources

Resources Introduction

The sections in this chapter show the MWS resources and the HTTP methods defined on them. The prefix for these resources depends on how the `mws.war` file is deployed. A typical prefix would be `http://localhost:8080/mws`. Using this example, one absolute resource URI would be `http://localhost:8080/mws/rest/jobs`.

This section only contains documentation for the latest API version. Please see the table in [Requesting Specific API Versions on page 1626](#) for links to documentation for previous versions.

Access Control Lists (ACLs)

This topic describes behavior of the ACL Rules (Access Control List Rules) object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Access Control Lists (ACLs)** reference contains the type and description of all fields in the **ACL Rules** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

i ACLs are not directly manipulated through a single URL, but with sub-URLs of the other objects such as Virtual Containers and Reservations.

Resource	GET	PUT	POST	DELETE
/rest/reservations/<rsvid>/acl-rules/<aclId>	--	Create or Update ACL	--	Delete ACL
/rest/vcs/<vcId>/acl-rules/<aclId>	--	Create or Update ACL	--	Delete ACL

This topic contains these sections:

- [Getting ACLs](#) on page 1649
- [Creating or Updating ACLs](#) on page 1649
 - [Create or Update ACL](#) on page 1649

- [Deleting ACLs on page 1650](#)
 - [Delete ACL on page 1651](#)

Getting ACLs

Although **ACL Rules** cannot be retrieved directly using the GET method on any of the `acl-rules` resources, **ACL Rules** are attached to supported objects when querying for them. Each supported object contains a field named `aclRules`, which is a collection of the **ACL Rules** defined on that object.

[Supported objects](#)

The following is a list of objects that will return **ACL Rules** when queried:

- [Reservations on page 1855](#)
- [Standing Reservations on page 1966](#)
- [Virtual Containers on page 1977](#)

Creating or Updating ACLs

The HTTP PUT method is used to create or update **ACL Rules**. The request body can contain one or more **ACL Rules**. If an **ACL Rule** with the same `type` and `value` exists, then it will be overwritten.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-version=3
PUT http://localhost:8080/mws/rest/vcs/<vcId>/acl-rules?api-version=3
```

Create or Update ACL

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-version=3
PUT http://localhost:8080/mws/rest/vcs/<vcId>/acl-rules?api-version=3
```

Parameter	Required	Type	Valid values	Description
<code>objectId</code>	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Request body](#)

The request body below shows all the fields that are available for the PUT method, along with some sample values.

JSON Request Body

```
{
  "aclRules": [
    {
      "affinity": "POSITIVE",
      "comparator": "LEXIGRAPHIC_EQUAL",
      "type": "USER",
      "value": "ted"
    }
  ]
}
```

Sample response

i This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON Request Body

```
{
  "messages": ["Virtual container 'vcl' Reservation 'rsvl' successfully modified"]
}
```

Samples

Create or update multiple ACLs on a single object:

CPUT <http://localhost:8080/mws/rest/reservations/system.21/acl-rules?api-version=3>

```
{
  "aclRules": [
    {
      "affinity": "POSITIVE",
      "comparator": "LESS_THAN_OR_EQUAL",
      "type": "DURATION",
      "value": "3600"
    },
    {
      "affinity": "POSITIVE",
      "comparator": "LEXIGRAPHIC_EQUAL",
      "type": "USER",
      "value": "ted"
    }
  ]
}
```

Restrictions

- **ACL Rules** cannot be added to or updated on **Standing Reservations**.
- The `affinity` and `comparator` fields are ignored for **Virtual Containers**.

Deleting ACLs

The HTTP DELETE method is used to remove **ACL Rules**.

[Quick reference](#)**i ACL Rules cannot be removed from Standing Reservations.**

```
DELETE http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-
version=3/<aclId>
DELETE http://localhost:8080/mws/rest/vcs/<vcId>/acl-rules?api-version=3/<aclId>
```

Delete ACL[URLs and parameters](#)

```
DELETE http://localhost:8080/mws/rest/reservations/<objectId>/acl-rules?api-
version=3/<aclId>
DELETE http://localhost:8080/mws/rest/vcs/<objectId>/acl-rules?api-version=3/<aclId>
```

Parameter	Required	Type	Valid values	Description
objectId	Yes	String	--	The unique identifier of the object from which to remove the ACL Rule .
aclId	Yes	String	--	A string representing the ACL Rule , with the format type:value.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

i This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON Response

```
{"messages":["Successfully modified virtual container 'vc1'Successfully modified
reservation 'rsv1'"]}
```

[Restrictions](#)

- **ACL Rules** cannot be removed from **Standing Reservations**.

[Related Topics](#)

- [Fields: Access Control Lists \(ACLs\) on page 2126](#)
- [Resources Introduction on page 1646](#)

Accounting

Accounting Accounts

This section describes the services available through Moab Web Services for interacting with the **Account** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

i The **Fields: Accounts** reference contains the type and description of the default fields for the **Accounts** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/accounting/accounts</code>	Get All Accounts	--	--	--
<code>/rest/accounting/accounts/<id></code>	Get Single Account	--	--	--

This topic contains these sections:

- [Getting Accounts](#) on page 1652
 - [Get All Accounts](#) on page 1652
 - [Get Single Account](#) on page 1654

Getting Accounts

The HTTP GET method is used to retrieve **Accounts** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3
GET http://localhost:8080/mws/rest/accounting/accounts/<id>?api-version=3
```

Get All Accounts

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3&proxy-user=<user>
[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]]&show-
all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	query={"organization":"sciences"}
fields	No	String	--	Comma-separated list of field names to display.	fields=id,organization
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	sort={"organization":1}

Parameter	Required	Type	Valid values	Description	Example
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3&proxy-user=amy&fields=id,organization&pretty=true
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "organization": "sciences",

    }
  ]
}
```

Get Single Account

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/accounts/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the object.	--
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
fields	No	String	--	Comma-separated list of field names to display.	fields=id,organization
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/accounts/chemistry?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": "chemistry",
  "active": true,

Accounting Allocations

This section describes the services available through Moab Web Services for interacting with the **Allocation** object in Moab Accounting Manager. It contains

the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

i The **Fields: Allocations** reference contains the type and description of the default fields for the **Allocation** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/accounting/allocations	Get All Allocations	--	--	--
/rest/accounting/allocations/<id>	Get Single Allocation	--	--	--

This topic contains these sections:

- [Getting Allocations on page 1656](#)
 - [Get All Allocations on page 1656](#)
 - [Get Single Allocation on page 1658](#)

Getting Allocations

The HTTP GET method is used to retrieve **Allocation** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3
GET http://localhost:8080/mws/rest/accounting/allocations/<id>?api-version=3
```

Get All Allocations

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]][&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	<code>query={"active":true}</code>
fields	No	String	--	Comma-separated list of field names to display.	<code>fields=id,fund,amount</code>
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	<code>sort={"fund":1}</code>
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "totalCount": 5,
  "resultCount": 5,

Accounting Charge rates

This section describes the services available through Moab Web Services for interacting with the **ChargeRate** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

i The **Fields: Charge Rates** reference contains the type and description of the default fields for the **ChargeRates** object.

Resource	GET	PUT	POST	DELETE
/rest/accounting/charge-rates	Get All Charge Rates	--	--	--
/rest/accounting/charge-rates/<name>/<value>	Get Single Charge Rate	--	--	--
/rest/accounting/charge-rates/<name>	Get Single Charge Rate	--	--	--

This topic contains these sections:

- [Getting Charge Rates](#) on page 1660
 - [Get All Charge Rates](#) on page 1660
 - [Get Single Charge Rate](#) on page 1662

Getting Charge Rates

The HTTP GET method is used to retrieve **ChargeRate** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3/<name>
[/<value>]
```

Get All Charge Rates

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=any

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	<code>query={"name":"QualityOfService"}</code>
fields	No	String	--	Comma-separated list of field names to display.	<code>fields=id,organization</code>
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	<code>sort={"organization":1}</code>

Parameter	Required	Type	Valid values	Description	Example
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3&proxy-user=moab&pretty=true
```

```
{
  "totalCount": 4,
  "resultCount": 4,
  "results": [
    {
      "name": "Processors",
      "value": "",
      "amount": "1/s",
      "description": "1 credit per processor-second"
    },
    {
      "name": "QualityOfService",
      "value": "high",
      "amount": "*2",
      "description": "Charge double for high QOS"
    },
    {
      "name": "QualityOfService",
      "value": "low",
      "amount": "*.5",
      "description": "Charge half for low QOS"
    },
    {
      "name": "QualityOfService",
      "value": "",
      "amount": "*1",
      "description": "No extra charge for \"normal\" QOSes"
    }
  ]
}
```

Get Single Charge Rate

i A regular charge rate is uniquely specified by both its name and its value. A default charge rate has a null value and is uniquely specified by only its name.

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3/<name>
[</value>]?proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
name	Yes	String	--	The name of the charge rate.	--
value	No	String	--	The value of the charge rate.	--
fields	No	String	--	Comma-separated list of field names to display.	fields=name,value,amount
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/charge-rates/QualityOfService/high?api-
version=3&proxy-user=moab&pretty=true
-----
{
  "name": "QualityOfService",
  "value": "high",
  "amount": "*2",
  "description": "Charge double for high QOS"
}
```

Accounting Funds

This section describes the services available through Moab Web Services for interacting with the **Fund** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

i The **Fields: Funds**, **Fields: Fund Balances**, **Fields: Fund Statements**, and **Fields: Fund Statement Summary** reference sections contain the type and description of the default fields in the **Fund** object as well as related objects and reports given in the URLs below.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/accounting/funds	Get All Funds	--	--	--
/rest/accounting/funds/<id>	Get Single Fund	--	--	--
/rest/accounting/funds/balances	Get All Fund Balances	--	--	--
/rest/accounting/funds/reports/statement	Get Fund Statement	--	--	--
/rest/accounting/funds/reports/statement/summary	Get Fund Statement Summary	--	--	--

This topic contains these sections:

- [Getting Funds on page 1664](#)
 - [Get All Funds on page 1665](#)
 - [Get Single Fund on page 1667](#)
 - [Get All Fund Balances on page 1669](#)
 - [Get Fund Statement on page 1671](#)
 - [Get Fund Statement Summary on page 1672](#)

Getting Funds

The HTTP GET method is used to retrieve **Fund** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/<id>?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/balances?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-version=3
```

Get All Funds

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3&proxy-user=<user>
[&active=true][&filter=<filter_options>[&filter-type=<filter_type>]][&query=<query_
conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]]&show-all=
(true|false)]
```

Parameter	Required	Type	Description	Example
proxy-user	Yes	String	Perform action as defined MAM user.	proxy-user=amy
active	No	Boolean	Lists only active or non-active allocations of the fund. The fund amount becomes the sum of the active/inactive allocations.	active=true
filter	No	JSON	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
filter-type	No	String	Query funds based on defined MAM filter type.	filter-type=NonExclusive

Parameter	Required	Type	Description	Example
query	No	JSON	<p>Results are restricted to those having the specified field values.</p> <div> The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</div>	<pre>query={"priority":"2","allocation.active":"false"}</pre>
fields	No	String	Comma-separated list of field names to display.	<pre>fields=id,name,amount</pre>
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	<pre>sort={"id":1}</pre>

Parameter	Required	Type	Description	Example
show-all	No	Boolean (true or false)	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3&proxy-user=amy&fields=id,name,amount&pretty=true
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "id": 1,
      "name": "biology",

Get Fund Statement

URLs and parameters

```

GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-
version=3&proxy-user=<user>[&filter=<filter_options>][&filter-type=<filter_type>]
[&start-time=<date_string>][&end-time=<date_string>][&context=<context>]

```

Parameter	Required	Type	Description	Example
proxy-user	Yes	String	Perform action as defined MAM user.	proxy-user=amy
filter	No	JSON	Query funds based on defined MAM filter.	filter={"account": "chemistry"}
filter-type	No	String	Query funds based on defined MAM filter type.	filter-type=NonExclusive
start-time	No	Date, -infinity, or now	Filter allocations and transaction after a start time.	start-time=2012-04-03 15:24:39 UTC
end-time	No	Date, -infinity, or now	Filter allocations and transactions before an end time.	end-time=2012-04-03 15:24:39 UTC
context	No	hpc or cloud	The context to use in Moab Accounting Manager. <div>  The context parameter overrides the default context set for MAM using the <code>mam.context</code> configuration parameter. For more information about this parameter, see Configuration on page 2114. </div>	context=hpc

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Sample response

The fund statement report provides a snapshot of the current funds. For more information, see [Fields: Fund Statements on page 2162](#).

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-version=3&proxy-user=amy&fields=startBalance,endBalance&pretty=true
```

```
{
  "startBalance":1234.01,
  "endBalance":1000
}
```

Get Fund Statement SummaryURLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-version=3&proxy-user=<user>[&filter=<filter_options>][&filter-type=<filter_type>][&start-time=<date_string>][&end-time=<date_string>]
```

Parameter	Required	Type	Description	Example
proxy-user	Yes	String	Perform action as defined MAM user.	proxy-user=amy
filter	No	JSON	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
filter-type	No	String	Query funds based on defined MAM filter type.	filter-type-e=NonExclusive
start-time	No	Date, -infinity, or now	Filter allocations and transaction after a start time.	start-time=2012-04-03 15:24:39 UTC
end-time	No	Date, -infinity, or now	Filter allocations and transactions before an end time.	end-time=2012-04-03 15:24:39 UTC

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

The fund statement summary is slightly different from the typical fund statement in that the transactions are provided as summaries grouped by object and action. For more information, see [Fields: Fund Statement Summary on page 2152](#).

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-
version=3&proxy-
user=amy&fields=totalCredits,totalDebits,transactions.action,transactions.amount,trans
actions.count&pretty=true
```

```
{
  "totalCredits":200.02,
  "totalDebits":-100,
  "transactions":[ {
    "action":"Deposit",
    "amount":200.02,
    "count":2
  }, {
    "action":"Charge",
    "amount":-100,
    "count":1
  }
]
```

```
GET http://localhost:8080/mws/rest/accounting/liens?api-version=3&proxy-user=<user>
[&active=true][&filter=<filter_options>[&filter-type=<filter_type>]][&query=<query_
conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=
(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
active	No	Boolean	--	Lists only active or non-active liens.	active=true
filter	No	JSON	--	Query funds based on defined MAM filter.	filter={"account": "chemistry"}
filter-type	No	String	--	Query funds based on defined MAM filter type.	filter-type=NonExclusive

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	<code>query={"allocations.fund":2}</code>
fields	No	String	--	Comma-separated list of field names to display.	<code>fields=id,instance,amount</code>
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	<code>sort={"instance":1}</code>
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/liens?api-version=3&proxy-user=amy&filter={"account":"chemistry"}&fields=instance,amount&active=true&pretty=true
-----
{
  "totalCount": 2,

 - [Get Single Organization on page 1679](#)

Getting Organizations

The HTTP GET method is used to retrieve **Organizations** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3
GET http://localhost:8080/mws/rest/accounting/organizations/<id>?api-version=3
```

Get All Organizations

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3&proxy-
user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_
sort>]][&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
query	No	JSON	--	Results are restricted to those having the specified field values. <div> The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</div>	query={"deleted":-false}
fields	No	String	--	Comma-separated list of field names to display.	fields=id
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	sort={"requestedId":-1}
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3&proxy-user=moab&fields=id,description&sort={"id":1}&pretty=true
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "description": "Arts College",
      "id": "arts"
    },
    {
      "description": "Sciences College",
      "id": "sciences"
    }
  ]
}
```

Get Single Organization

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/organizations/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the object.	--
fields	No	String	--	Comma-separated list of field names to display.	fields=id
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all-1=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/organizations/sciences?api-version=3&proxy-user=moab&pretty=true
```

```
{
  "description": "Sciences College",
  "id": "sciences"
}
```

Getting Quotes

The HTTP GET method is used to retrieve **Quote** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3
GET http://localhost:8080/mws/rest/accounting/quotes/<id>?api-version=3
```

Get All Quotes

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3&proxy-user=<user>
[&active=true][&filter=<filter_options>[&filter-type=<filter_type>]][&query=<query_
conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=
(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform actions as defined MAM user.	proxy-user=amy
active	No	Boolean	true or false	Lists only active or non-active quotes.	active=true
filter	No	JSON	--	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
filter-type	No	String	--	Query funds based on defined MAM filter type.	filter-type=NonExclusive
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	query={"instance":"-job.1"}
fields	No	String	--	Comma-separated list of field names to display.	fields=id,instance,amount

Parameter	Required	Type	Valid values	Description	Example
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	sort={"instance":1}
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3&proxy-user=amy&filter={"account":"chemistry"}
&fields=usageRecord,amount&active=true&pretty=true
```

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "usageRecord": 1,
    "amount": 57600
  } ]
}
```

Get Single Quote

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/quotes/<id>?api-version=3&proxy-user=<user>[&active=(true|false)][&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the object.	--

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
active	No	Boolean	true or false	Lists only active or non-active quotes.	active=true
fields	No	String	--	Comma-separated list of field names to display.	fields=id,name,amount
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/quotes/1?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": 1,
  "amount": 57600,
  "pinned": true,
  "instance": "",

Accounting Usage Records

This section describes the services available through Moab Web Services for interacting with the **Usage Record** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

 The **Fields: Usage Records** reference section contains the type and description of all fields in the **Usage Record** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/accounting/usage-records	Get All Usage Records	--	--	--
/rest/accounting/usage-records/<id>	Get Single Usage Record	--	--	--

Resource	GET	PUT	POST	DELETE
/rest/accounting/usage-records/quote	--	--	Obtain a Quote For Resource Usage	--

This topic contains these sections:

- [Getting Usage Records on page 1689](#)
 - [Get All Usage Records on page 1689](#)
 - [Get Single Usage Record on page 1692](#)
 - [Obtain a Quote For Resource Usage on page 1693](#)

Getting Usage Records

The HTTP GET method is used to retrieve **Usage Record** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3
GET http://localhost:8080/mws/rest/accounting/usage-records/<id>?api-version=3
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-version=3
```

Get All Usage Records

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>][&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	<pre>query={"account":"query"}</pre>
fields	No	String	--	Comma-separated list of field names to display.	<pre>field-s=id,instance,charge,user,account</pre>

Parameter	Required	Type	Valid values	Description	Example
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	sort={"user":1}
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3&proxy-user=amy&fields=id,instance,charge,user,account&pretty=true
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "id": 1,
      "instance": "job.1",
      "charge": 31,
      "user": "amy",
      "account": "chemistry"
    },
    {
      "id": 2,
      "instance": "job.2",
      "charge": 30,
      "user": "amy",
      "account": "biology"
    }
  ]
}
```

Get Single Usage Record

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/usage-records/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the object.	code
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
fields	No	String	--	Comma-separated list of field names to display.	field-s=id,instance,charge,user,account
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/usage-records/1?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": 1,
  "type": "Job",
  "instance": "job.1",
  "charge": 31,
  "stage": "Charge",
  "user": "amy",
  "group": "faculty",
  "account": "chemistry",
  "organization": "sciences",
  "qualityOfService": "",
  "machine": "colony",
  "nodes": "",
  "processors": 16,
  "memory": "",
  "disk": "",
  "network": "",
  "duration": 720,
  "startTime": "",
  "endTime": "",
  "description": ""
}
```

Obtain a Quote For Resource Usage

URLs and parameters

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-version=3&object-type=<object>&proxy-user=<user>&charge-duration=<seconds>
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
charge-duration	Yes	Integer	--	The quote duration of the job in seconds.	charge-duration=6400

Parameter	Required	Type	Valid values	Description	Example
object-type	Yes	String	--	The object to quote. It can be job or service.	object-type=job
itemize	No	Boolean	true or false	Returns the composite charge information in the response data.	itemize=true
rate	No	JSONArray	--	Uses the specified charge rates in the quote. The specified rates override the standard and quote rates. If the guarantee field is set to true, these charge rates will be saved and used when this quote is referenced in a charge action.	rate=[{"type":"VBR","name":"Memory","rate":1}, {"type":"VBR","name":"Processors","rate":1}]

Parameter	Required	Type	Valid values	Description	Example
guarantee	No	Boolean	true or false	Guarantees the quote and returns a quote id to secure the current charge rates. This results in the creation of a quote record and a permanent usage record. This parameter is mutually exclusive with the cost-only parameter.	guarantee=true

Parameter	Required	Type	Valid values	Description	Example
grace-duration	No	Integer	--	The guaranteed quote grace period in seconds. If the quote duration is specified but not the quote end time, the quote endtime will be calculated as the quote start time plus the quote duration plus the grace duration.	grace-duration=6400
cost-only	No	Integer	--	Returns the cost, ignoring all balance and validity checks. This parameter is mutually exclusive with the guarantee parameter.	cost-only=true

Parameter	Required	Type	Valid values	Description	Example
description	No	String	--	The guaranteed quote description.	description="ABC Coupon Rate"
start-time	No	Date	--	The guaranteed quote start time in the format yyyy-MM-dd HH:m-m:ss z,-Infinity,Infinity, or Now.	start-time="2012-04-09 13:49:40 UTC"
end-time	No	Date	--	The guaranteed quote end time in the format yyyy-MM-dd HH:m-m:ss z,-Infinity,Infinity, or Now.	end-time="2012-04-09 14:49:40 UTC"

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

The request body below shows all of the fields in a job that could affect the quote.

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-
version=3&object-type=job&charge-duration=300
```

```
{
  "id": "Moab.1",
  "user": "amy",
  "group": "group",
  "rmName": "machine1",
  "templateList": [
    "genericVm"
  ],
  "account": "biology",
  "qosRequested": "QOS1",
  "variables": {
    "imageName": "centos5.5-stateless",
    "topLevelServiceId": "myService.1",
    "serviceId": "vmService.1",
    "vmid": "VmService.1",
    "pmid": "VmService.1"
  },
  "requirements": [
    {
      "requiredProcessorsPerTask": 2,
      "genericResources": {
        "gold": 100,
        "os": 500
      },
      "requiredNodeCountMinimum": 1,
      "requiredMemoryPerTask": 1024,
      "requiredClass": "batch"
    }
  ]
}
```

The request body below shows all of the fields in a service that affect the quote in a default MAM installation.

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-
version=3&object-type=service&charge-duration=300
```

```
{
  "name": "service.1",
  "user": "amy",
  "account": "chemistry"
  "attributes": {
    "moab": {
      "job": {
        "resources": {
          "procs": 1,
          "mem": 2048,
          "OS": 500,
          "gold": 100
        },
        "variables": {
          "Var1": 1524
        },
        "image": "centos5.5-stateless",
        "template": "genericVM",
      }
    }
  }
}
```

Sample response

- If the quote is not guaranteed:

```
JSON response
```

```
{
  "instance": "Moab.1",
  "amount": 600
}
```

- If the quote is guaranteed:

```
JSON response
```

```
{
  "id": 1,
  "usageRecord": 2,
  "instance": "Moab.1",
  "amount": 600
}
```

- If the quote is guaranteed and itemized:

JSON response

```
{
  "details": [
    {
      "name": "Processors",
      "value": "2",
      "duration": 300,
      "rate": 1,
      "scalingFactor": 1,
      "amount": 600,
      "details": "2 [Processors] * 1 [ChargeRate{VBR}{Processors}] * 300 [Duration]"
    },
    {
      "name": "Memory",
      "value": "1024",
      "duration": 300,
      "rate": 1,
      "scalingFactor": 1,
      "amount": 307200,

Accounting Users

This section describes the services available through Moab Web Services for interacting with the User object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

 The **Fields: Users** reference contains the type and description of all fields in the **User** object.

Supported methods

Resource	GET	PUT	POST	DELETE
rest/accounting/users	Get All Users	--	--	--
rest/accounting/users/<id>	Get Single User	--	--	--

This topic contains these sections:

- [Getting Users on page 1703](#)
 - [Get All Users on page 1703](#)
 - [Get Single User on page 1705](#)

Getting Users

The HTTP GET method is used to retrieve **User** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3
GET http://localhost:8080/mws/rest/accounting/users/<id>?api-version=3
```

Get All Users

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3&proxy-user=<user>
[&query=<query_conditions>][&fields=<fields_to_display>][&sort=<fields_to_sort>]|&show-
all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
proxy-user	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
query	No	JSON	--	Results are restricted to those having the specified field values. <div>  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed. </div>	query={"active":true}

Parameter	Required	Type	Valid values	Description	Example
fields	No	String	--	Comma-separated list of field names to display.	fields=name,defaultAccount
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the fields parameter.	sort={"defaultAccount":1}
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3&proxy-user=moab&query={"active":true}&pretty=true
```

```
{
  "totalCount": 6,
  "resultCount": 4,
  "results": [
    {
      "active": true,
      "commonName": "",
      "phoneNumber": "",
      "emailAddress": "",
      "defaultAccount": "",
      "description": "Accounting Admin",
      "id": "scottmo"
    },
    {
      "active": true,
      "commonName": "Amy Miller",
      "phoneNumber": "(801) 555-1437",
      "emailAddress": "amy@hpc.com",
      "defaultAccount": "chemistry",
      "description": "",
      "id": "amy"
    },
    {
      "active": true,
      "commonName": "Robert Taylor",
      "phoneNumber": "(801) 555-1474",
      "emailAddress": "bob@hpc.com",
      "defaultAccount": "biology",
      "description": "",
      "id": "bob"
    },
    {
      "active": true,
      "commonName": "David Jones",
      "phoneNumber": "(801) 555-1436",
      "emailAddress": "dave@hpc.com",
      "defaultAccount": "film",
      "description": "",
      "id": "dave"
    }
  ]
}
```

Get Single User

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/users/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the object	--
fields	No	String	--	Comma-separated list of field names to display.	fields=name,defaultAccount
show-all	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/users/amy?api-version=3&proxy-user=moab&pretty=true
```

```
{
  "active": true,
  "commonName": "Amy Miller",
  "phoneNumber": "(801) 555-1437",
  "emailAddress": "amy@hpc.com",
  "defaultAccount": "chemistry",
  "description": "",
  "id": "amy"
}
```

Credentials

This section describes behavior of the **Credential** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Credential API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting Specific API Versions on page 1626](#).

The **Fields: Credentials** reference contains the type and description of all fields in the **Credential** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/credentials/accounts	Get All Account Credentials Get Single Account Credential	Modify Account Credentials on page 1719	--	--
/rest/credentials/classes	Get All Class Credentials Get Single Class Credential	Modify Class Credentials on page 1719	--	--
/rest/credentials/groups	Get All Group Credentials Get Single Group Credential	Modify Group Credentials on page 1720	--	--
/rest/credentials/qoses	Get All QoS Credentials Get Single QoS Credential	Modify QoS Credentials on page 1720	--	--
/rest/credentials/users	Get All User Credentials Get Single User Credential	Modify User Credentials on page 1720	--	--

Getting Credentials

The HTTP GET method is used to retrieve **Resource Type** information.

Quick reference

```
GET http://localhost:8080/mws/rest/credentials/accounts[/<name>]?api-version=3
GET http://localhost:8080/mws/rest/credentials/classes[/<name>]?api-version=3
GET http://localhost:8080/mws/rest/credentials/groups[/<name>]?api-version=3
GET http://localhost:8080/mws/rest/credentials/qoses[/<name>]?api-version=3
GET http://localhost:8080/mws/rest/credentials/users[/<name>]?api-version=3
```

Get All Account Credentials

URLs and parameters

```
GET http://localhost:8080/mws/rest/credentials/accounts?api-version=3
```

See **Global URL Parameters** on page 1622 for available URL parameters.

Sample response

GET http://localhost:8080/mws/rest/credentials/accounts?api-version=3

```

  "target": 18.43,
  "priority": 53,
  "max_job_duration_in_seconds": 234,
  "max_idle_jobs": 42,
  "max_jobs": 523,
  "max_processors": 4,
  "max_processor_seconds": 525,
  "max_nodes": 75,
  "email": "root@root.com"
}
```

Modifying Credentials

The HTTP PUT method is used to modify **credentials**.

Quick reference

```
PUT http://localhost:8080/mws/rest/credentials/accounts/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/classes/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/groups/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/qoses/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/users/<name>?api-version=3 [&change-
mode=<add|remove|set>]
```

URL parameters

URL parameters for modifying a credential.

Credentials parameter	Required	Type	Valid values	Description
change-mode	No	String	set (default) add remove	If set , replace existing list with the given one. If add , add the given field(s) to the existing list. If remove , remove the given field(s) from the existing list.

i Moab Workload Manager will automatically add SHARED and the value of default_partition to the partition_access_list.

Modify Account Credentials

URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/accounts/<name>?api-version=3[&change-mode=<add|remove|set>]
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample body

```
PUT http://localhost:8080/mws/rest/credentials/accounts/biology?api-version=3&change-mode=add

-----

{
  "qos_access_list": [
    "qos3",
    "qos4"
  ],
  "max_job_duration_in_seconds": 234
}
```

Modify Class Credentials

URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/classes/<name>?api-version=3[&change-mode=<add|remove|set>]
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample body

```
PUT http://localhost:8080/mws/rest/credentials/classes/highprio?api-version=3
-----
{
  "max_idle_jobs": 50,
  "max_jobs": 300
}
```

Modify Group CredentialsURLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/groups/<name>?api-version=3[&change-
mode=<add|remove|set>]
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample body

```
PUT http://localhost:8080/mws/rest/credentials/groups/students?api-version=3&change-
mode=set
-----
{
  "reservation": "system.2",
  "user_access_list": ["tom"]
}
```

Modify QoS CredentialsURLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/qoses/<name>?api-version=3[&change-
mode=<add|remove|set>]
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample body

```
PUT http://localhost:8080/mws/rest/credentials/qoses/special?api-version=3
-----
{
  "max_processors": 5,
  "max_processor_seconds": 500
}
```

Modify User CredentialsURLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/users/<name>?api-version=3[&change-
mode=<add|remove|set>]
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample body

```
PUT http://localhost:8080/mws/rest/credentials/users/tom?api-version=3
{
  "email": "tom@root.com"
}
```

Diagnostics

This section describes additional REST calls that are available for performing diagnostics on Moab Web Services.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/diag/about	Get Version Information	--	--	--
/rest/diag/auth	Diagnose Authentication	--	--	--
/rest/diag/health/summary	Get Health Summary	--	--	--
/rest/diag/health/detail	Get Health Detail	--	--	--

i [/rest/diag/ldap](#) is deprecated. All information that was available in that resource is now available in [/rest/diag/health/detail](#).

This topic contains these sections:

- [Get Version Information on page 1722](#)
- [Diagnose Authentication on page 1722](#)
- [Connection Health Information on page 1722](#)
 - [Get Health Summary on page 1723](#)
 - [Get Health Detail on page 1723](#)
- [Diagnostics on page 1721](#)

Get Version Information

The HTTP GET method is used to retrieve version and build information.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/diag/about?api-version=3
```

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/diag/about?api-version=3
```

[Sample response](#)

The response contains the application suite, version, build date, and revision.

```
{
  "suite": "CLOUD",
  "version": "7.2.2",
  "buildDate": "2013.03.15_13.12.45",
  "revision": "302238e24e327f4aa45ab4c91834216a7fc19d63"
}
```

Diagnose Authentication

The HTTP GET method is used to test for proper authentication. This resource is designed to be used as a simple validation of credentials and gives no output besides the response code.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/diag/auth?api-version=3
```

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/diag/auth?api-version=3
```

[Sample response](#)

 A successful result is indicated by the 200 response code while a failure is indicated by a 401 response code.

```
{}
```

Connection Health Information

The HTTP GET method is used to retrieve health or status information for connections to external systems or software. There are two available resources for health, one that returns simple summary information and another that returns detailed information.

Quick reference

```
GET http://localhost:8080/mws/rest/diag/health/summary?api-version=3
GET http://localhost:8080/mws/rest/diag/health/detail?api-version=3
```

Get Health Summary

URLs and parameters

```
GET http://localhost:8080/mws/rest/diag/health/summary?api-version=3
```

i If the MongoDB connection is down, authenticated resources are not available. While this resource does not possess much detail beyond that of simple connection information, it is still useful as it does not require authentication and therefore can be used to determine connection problems with MongoDB.

Sample response

The response contains the connection health for Moab Workload Manager (MWM), Moab Accounting Manager (MAM), MongoDB, LDAP, ZeroMQ, PAM, and the Insight database. A `true` response value indicates that the connection is healthy and available, and a `false` response indicates that the connection is currently down. Likewise, the `mongoConnected` property for Moab signifies the state of the Moab to MongoDB connection. The possible values of this state are `UP`, `DOWN`, `NOT_CONFIGURED` (when the MongoDB server is not configured in Moab), `NOT_SUPPORTED` (when Moab is not compiled with MongoDB support), and `UNKNOWN` (when MWS cannot communicate with Moab).

```
{
  "mam": {"connected": true},
  "mongo": {"connected": true},
  "mwm": {
    "connected": true,
    "mongoConnected": "UP",
    "zmqConnected": true
  },
  "ldap": {"connected": true},
  "pam": {"connected": true},
  "zmq": {"connected": true},
  "insight": {"connected": true}
}
```

Get Health Detail

URLs and parameters

```
GET http://localhost:8080/mws/rest/diag/health/detail?api-version=3
```

i If the MongoDB connection is down, authenticated resources such as this are not available. In this case, using the [Get Health Summary](#) instead may be required.

Sample response

The response contains the connection health and information for Moab Workload Manager (MWM), Moab Accounting Manager (MAM), MongoDB, LDAP, ZeroMQ, PAM, and the Insight database. A `"connected": true` response value indicates that the connection is healthy and available, and a `false` response indicates that the connection is currently down. Likewise, the `mongoConnected` property for Moab signifies the state of the Moab to MongoDB connection. The possible values of this state are `UP`, `DOWN`, `NOT_CONFIGURED` (when the MongoDB server is not configured in Moab), `NOT_SUPPORTED` (when Moab is not compiled with MongoDB support), and `UNKNOWN` (when MWS cannot communicate with Moab). A message is also present for all down connections except Moab to MongoDB giving a reason for the error state.

```

{
  "mam": {
    "connected": true,
    "adminUser": "root",
    "host": "mamhost",
    "port": 7741,
    "version": "7.5",
    "message": null
  },
  "mongo": {

}
```

Related Topics

- [Resources Introduction on page 1646](#)

Distinct

The **Distinct** resource enables clients to retrieve distinct (unique) values from another MWS resource. For example, a client can request the list of all featuresReported across all nodes like this:

```
GET http://localhost:8080/mws/rest/distinct/nodes/featuresReported/?api-version=3
```

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/distinct/<resource>/<field>	Get Distinct Values	--	--	--

This topic contains these sections:

- [Get Distinct Values on page 1727](#)

Get Distinct Values

The HTTP GET method is used to retrieve **distinct** values from another MWS resource.

URLs and parameters

```
GET http://localhost:8080/mws/rest/distinct/<resource>/<field>?api-version=3
```

Parameter	Required	Type	Valid values	Example
resource	Yes	String	The MWS resource to query.	nodes
field	Yes	String	The field for which to return the distinct values.	featuresReported
query	No	JSON	Determines the subset of objects from which to retrieve the distinct values.	query={"states.-powerState": "On"}

i The **Distinct** resource has no access control of its own. Rather, it depends on the access control of the MWS resource being queried.

For example, for a client to run a query like `/rest/distinct/nodes/featuresReported`, it must have GET rights on the `Nodes` resource. For more information, see [Access Control on page 1595](#).

Examples

Example 4-3: Get all featuresReported across all nodes

```
http://localhost:8080/mws/rest/distinct/nodes/featuresReported?api-version=3
```

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": ["vlan1"]
}
```

Example 4-4: Get all available operating system images across all nodes that are powered on

```
http://localhost:8080/mws/rest/distinct/nodes/operatingSystem.imagesAvailable?api-version=3&query={"states.powerState": "On"}
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    "linux",
    "windows"
  ]
}
```

Related Topics

- [Resources Introduction on page 1646](#)

Events

This section describes the URLs, request bodies, and responses delivered to and from Moab Web Services for handling events.

The Event API is new with API version 3. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting Specific API Versions on page 1626](#).

The **Fields: Events** reference contains the type and description of all fields in the **Event** object. It also contains details regarding which fields are valid during POST actions.

Important changes

- The following fields have been renamed in API version 3:

Name in version 1 & 2	Name in version 3
eventTime	eventDate
sourceComponent	origin
errorMessage.message	message
relatedObjects	associatedObjects

- The following fields have been removed in API version 3.

MWS will no longer report these fields, even if there are existing events in the database with these fields.

- eventCategory
 - status
 - facility
 - initiatedBy
 - primaryObject (Primary objects are now reported in associatedObjects.)
 - errorMessage.originator
 - errorMessage.errorCode
 - details
- The following fields are new in API version 3 (see [Fields: Events on page 2205](#)):
 - arguments
 - code

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/events	Get All Events	--	Create Event	--
/rest/events/<id>	Get Single Event	--	--	--

This topic contains these sections:

- [Getting Events on page 1730](#)
 - [Get All Events on page 1730](#)
 - [Get Single Event on page 1733](#)
- [Creating Events on page 1734](#)
 - [Create Event on page 1734](#)

Getting Events

The HTTP GET method is used to retrieve **Event** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/events?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
GET http://localhost:8080/mws/rest/events/<id>?api-version=3
```

Get All Events

URLs and parameters

```
GET http://localhost:8080/mws/rest/events?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
```

Parameter	Required	Type	Valid values	Example
query	No	JSON	Query for specific results. It is possible to query events by one or more fields based on MongoDB query syntax .	query={"severity":"ERROR"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"id":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/events?api-version=3
```

```
{
  "totalCount":2,
  "resultCount":2,
  "results":[
    {
      "arguments":[
        ],
      "associatedObjects":[
        {
          "type":"VM",
          "id":"vm1"
        }
      ],
      "tenant":
        {
          "id":"1234567890abcdef12345678",
          "name":"Research"
        },
      "code":234881023,
      "eventDate":"2013-06-10 17:13:31 UTC",
      "eventType":"VM Provision",
      "message":null,
      "origin":"CSA Plugin",
      "severity":"INFO",
      "id":"51b6093bc4aa708a5bebb6ae"
    },
    {
      "arguments":[
        "51b608ddc4aa708a5bebb684"
      ],
      "associatedObjects":[
        {
          "type":"Service",
          "id":"51b608ddc4aa708a5bebb684"
        }
      ],
      "tenant":
        {
          "id":"1234567890abcdef12345678",
          "name":"Research"
        },
      "code":33554944,
      "eventDate":"2013-06-10 17:11:59 UTC",
      "eventType":"Service Create",
      "message":"The service '51b608ddc4aa708a5bebb684' was created",
      "origin":"MWS/ServiceEvents/CREATE_1ID",
      "severity":"INFO",
      "id":"51b608dfc4aa708a5bebb686"
    }
  ]
}
```

Querying events

It is possible to query events by one or more fields based on [MongoDB query syntax](#). The following contains examples of simple and complex event queries

and event queries by date.

Simple queries:

- To see only events that are of type "Service Create":

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"Service Create"}
```

- To see only events of type "Service Create" with the severity of "INFO":

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"Service Create","severity":"INFO"}
```

- To see only events with a code of 33554946

```
http://localhost:8080/mws/rest/events?api-version=3&query={code:33554946}
```

More complex queries:

- You can query on embedded JSON objects within the event JSON. For example, to see events associated with service 51b608ddc4aa708a5bebb684:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"associatedObjects.id":"51b608ddc4aa708a5bebb684"}
```

- To see only events that are NOT associated with service 51b608ddc4aa708a5bebb684:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"associatedObjects.id":{"$ne":"51b608ddc4aa708a5bebb684"}}
```

- When the field values of the desired events are a finite set, you can use the \$in operator. For example, to see events that have a severity of either WARN or ERROR:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"severity":{"$in":["ERROR","WARN"]}}
```

Querying events by date

- To see events created before January 27, 2012 at 12:08 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$lt":"2012-01-27 12:08:00 UTC"}}
```

- To see events created before or on January 27, 2012 at 12:08 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$lte":"2012-01-27 12:08:00 UTC"}}
```

- To see all events created after January 27, 2012 at 12:04 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":
{"$gt":"2012-01-27 12:04:00 UTC"}}
```

- To see all events created after or on January 27, 2012 at 12:04 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":
{"$gte":"2012-01-27 12:04:00 UTC"}}
```

- To see events created between 12:04 a.m. and 12:08 a.m. UTC inclusive:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":
{"$gte":"2012-01-27 12:04:00 UTC", "$lte":"2012-01-27 12:08:00 UTC"}}
```

- To see events created between 12:04 a.m. and 12:08 a.m. UTC inclusive that have a severity of ERROR:

```
http://localhost:8080/mws/rest/events?api-version=3&query=
{"severity":"ERROR", "eventDate":{"$gte":"2012-01-27 12:04:00 UTC", "$lte":"2012-
01-27 12:08:00 UTC"}}
```

Sorting

See the sorting section of [Global URL Parameters on page 1622](#).

Limiting the number of results

- If you want to limit the number of results of events, you can use the `max` parameter. For example, to see only 10 "VM Provision" events:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"VM
Provision"}&sort={"eventDate":1}&max=10
```

- To see "VM Provision" events 51-60 when sorted by eventDate in descending order, you can combine `max` with `offset`, as follows:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"VM
Provision"}&sort={"eventDate":-1}&max=10&offset=50
```

Get Single Event

URLs and parameters

```
GET http://localhost:8080/mws/rest/events/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

GET http://localhost:8080/mws/rest/events/51b608dfc4aa708a5bebb686?api-version=3

```

{
  "arguments": ["51b608ddc4aa708a5bebb684"],
  "associatedObjects": [ {
    "type": "Service",
    "id": "51b608ddc4aa708a5bebb684"
  } ],
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "code": 33554944,
  "eventDate": "2013-06-10 17:11:59 UTC",
  "eventType": "Service Create",
  "message": "The service '51b608ddc4aa708a5bebb684' was created",
  "origin": "MWS/ServiceEvents/CREATE_1ID",
  "severity": "INFO",
  "id": "51b608dfc4aa708a5bebb686"
}

```

Creating Events

The HTTP POST method is used to create an **Event**.

Quick reference

POST http://localhost:8080/mws/rest/events?api-version=3

Create Event

URLs and parameters

POST http://localhost:8080/mws/rest/events?api-version=3

Request body

POST http://localhost:8080/mws/rest/events?api-version=3 Content-Type:application/json

```

{
  "arguments": ["vm1"],
  "associatedObjects": [ {
    "type": "VM",
    "id": "vm1"
  } ],
  "code": 234881023,
  "eventDate": "2013-06-10 17:13:31 UTC",
  "eventType": "VM Provision",
  "message": "The virtual machine \"vm1\" was provisioned",
  "origin": "CSA Plugin",
  "severity": "INFO"
}

```

i An event's `tenant` is automatically inherited from the `associatedObjects`.

Sample response

If the request was successful, the response will be an object with an **id** property containing the ID of the newly created events. On failure, the response is an error message.

JSON response

```
{
  "arguments": ["vm1"],
  "associatedObjects": [
    {
      "id": "vm1",
      "id": "vm1",
      "type": "VM",
      "version": 0
    }
  ],
  "code": 234881023,
  "eventDate": "2013-06-10 17:13:31 UTC",
  "eventType": "VM Provision",
  "id": "51b62046c4aa708a5bebc018",
  "message": "The virtual machine vm1 was provisioned",
  "origin": "CSA Plugin",
  "severity": "INFO",
  "version": 0
}
```

Below is an example of `events.log` output for a successful event request:

```
2013-06-10T11:13:31.000-06:00 severity="INFO" code="0x0dffffff" type="VM Provision"
origin="CSA Plugin" associatedObject.0.type="VM" associatedObject.0.id="vm1"
arguments=["vm1"] message="The virtual machine \"vm1\" was provisioned"
```

i Note that " (double quote) characters in the input have been replaced by \" characters in the output. (For other character restrictions, see [Restrictions on page 1735](#).)

Restrictions

Special characters—such as newline, carriage return, and " (double quote) characters—are encoded in the output of `events.log` to make `events.log` easy to parse with scripts and third party tools. For example, if the input XML contains:

```
<ErrorMessage>RM says, "Cannot provision vm21"</ErrorMessage>
```

Then the following will be output to `events.log`:

```
error.message="RM says, \"Cannot provision vm21\""
```

(Notice that " has been replaced with \".)

This table contains the most common encodings. (For more information, see [escape sequences for Java Strings](#).)

Character	Escape sequence
" (double quote)	\"

Character	Escape sequence
\ (backslash)	\\
newline	\n
carriage return	\r
tab	\t

Other restrictions include:

- **origin**, **eventType**, **associatedObject.id**, and **associatedObject.type** cannot contain single quotes (') or double quotes (").

Images

This section describes behavior of the **Image** object in Moab Web Services. An image resource is used to track the different types of operating systems and hypervisors available in the data center. It also tracks which virtual machines are available on the hypervisors. This section describes the URLs, request bodies, and responses delivered to and from MWS.

 The **Fields: Images** reference contains the type and description of all fields in the **Image** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/images	Get All Images	--	Create Single Image	--
/rest/images/<id>	Get Single Image	Modify Single Image	--	Delete Single Image
/rest/images/<name>	Get Single Image	Modify Single Image	--	Delete Single Image

This topic contains these sections:

Getting Images

The HTTP GET method is used to retrieve **Image** information. You can query all objects or a single object.

Quick reference

```
GET http://localhost:8080/mws/rest/images?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
GET http://localhost:8080/mws/rest/images/<id>?api-version=3
GET http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Get All Images

URLs and parameters

```
GET http://localhost:8080/mws/rest/images?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query images by one or more fields based on MongoDB query syntax .	query={"type":"stateful","osType":"linux"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/images?api-version=3&fields=id,name
```

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "4fa197e68ca30fc605dd1cf0",
    "name": "centos5-stateful"
  } ]
}
```

Sorting and querying

See the sorting and querying sections of [Global URL Parameters on page 1622](#).

Get Single Image

URLs and parameters

```
GET http://localhost:8080/mws/rest/images/<id>?api-version=3
GET http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Image.
name	Yes	String	--	The name of the Image.

i You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

Virtual machine image example:

```
GET http://localhost:8080/mws/rest/images/centos5-compute-stateful?api-version=3
```

```
{
  "active":true,
  "extensions":{
    "xcat":{
      "os":"centos",
      "architecture":"x86_64",
      "profile":"compute"
    }
  },
  "features":[],
  "hypervisor":false,
  "hypervisorType": null,
  "id":"4fa197e68ca30fc605dd1cf0",
  "name":"centos5-compute-stateful",
  "osType":"linux",
  "supportsPhysicalMachine":false,
  "supportsVirtualMachine":true,
  "templateName":null,
  "type":"stateful",
  "version":0,
  "virtualizedImages":[]
}
```

Hypervisor image example:

```
GET http://localhost:8080/mws/rest/images/esxi-4.1-stateful?api-version=3
```

```
{
  "active":true,
  "extensions":{
    "xcat":{
      "hvGroupName":"hvGroup",
      "vmGroupName":"vmGroup",
      "os":"esxi-4.1",
      "architecture":"x86_64",
      "profile":"hv"
    }
  },
  "features":[],
  "hypervisor":true,
  "hypervisorType":"ESX",
  "id":"4fa197e68ca30fc605dd1cf0",
  "name":"centos5-compute-stateful",
  "osType":"linux",
  "supportsPhysicalMachine":true,
  "supportsVirtualMachine":false,
  "templateName":null,
  "type":"stateful",
  "version":0,
  "virtualizedImages":[]
}
```

i The `version` field contains the current version of the database entry and does not reflect the version of the operating system. For more information, see [Modify Single Image](#) on page 1743.

Creating Images

The HTTP POST method is used to submit **Images**.

[Quick reference](#)

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

Create Single Image

[URLs and parameters](#)

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

See [Global URL Parameters](#) on page 1622 for available URL parameters.

[Request body](#)

Three fields are required to submit an image: **name**, **hypervisor**, and **osType**. Each image must also support provisioning to either a physical machine or a virtual machine by using the **supportsPhysicalMachine** or **supportsVirtualMachine** fields.

i The **name** field must contain only letters, digits, periods, dashes, and underscores.

The array of virtualized images are themselves objects that contain image IDs or names. For more information on available fields and types, see [Fields: Images on page 2211](#).

The following is an example of the most basic image that can be created:

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

```
{
  "name": "centos5-stateful",
  "osType": "linux",
  "hypervisor": false,
  "supportsVirtualMachine": true
}
```

Note that this example does not provide any information for a provisioning manager (such as xCAT) to actually provision the machine. In order to provide this, you must add an entry to the **extensions** field that contains provisioning manager-specific information. Each key in the extensions field corresponds to the provisioning manager, and certain properties are required based on this key. For example, the xCAT extension key must be named `xcat` and must contain certain fields. These extension keys are documented in [Fields: Images on page 2211](#). See the following examples of creating images with xCAT-specific provisioning information below.

[Sample response](#)

If the request was successful, the response body is the new image that was created exactly as shown in [Get Single Image](#). On failure, the response is an error message.

[Samples](#)

The **virtualizedImages** field only accepts input when the image is a hypervisor and expects an array of image IDs *or* names, as shown in the following example:

Example payload of hypervisor with 2 vms

```
{
  "hypervisor":true,
  "name":"esx5-stateful",
  "osType":"linux",
  "supportsPhysicalMachine":true,
  "type":"stateful",
  "hypervisorType":"ESX",
  "virtualizedImages": [
    {"id": "4fa197e68ca30fc605dd1cf0"},
    {"name": "centos5-stateful"}
  ]
}
```

The following example shows how to create an image that utilizes a cloned template for a virtual machine. (Note that the **type** must be set to **linkedclone** in order to set the **templateName** field.)

VM Utilizing a Cloned Template

```
{
  "active": true,
  "hypervisor": false,
  "name": "centos5-compute-stateful",
  "osType": "linux",
  "type": "linkedclone",
  "supportsVirtualMachine":true,
  "templateName":"centos5-compute"
}
```

The following are samples of a virtual machine and a hypervisor image that can be provisioned with xCAT:

xCAT Virtual Machine Image

```
{
  "active": true,
  "features": [],
  "hypervisor": false,
  "name": "centos5-compute-stateful",
  "osType": "linux",
  "type": "stateful",
  "supportsVirtualMachine":true,
  "extensions": {
    "xcat": {
      "os": "centos",
      "architecture": "x86_64",
      "profile": "compute"
    }
  }
}
```

xCAT Hypervisor Image

```

{
  "active": true,
  "features": [],
  "hypervisor": true,
  "name": "esxi5-base-stateless",
  "osType": "linux",
  "virtualizedImages": [
    { "name": "centos5-compute-stateless" }
  ],
  "type": "stateless",
  "hypervisorType": "ESX",
  "supportsPhysicalMachine": true,
  "extensions": {
    "xcat": {
      "os": "esxi5",
      "architecture": "x86_64",
      "profile": "base",
      "hvType": "esx",
      "hvGroupName": "esx5hv",
      "vmGroupName": "esx5vm"
    }
  }
}

```

Modifying Images

The HTTP PUT method is used to modify **Images**.

Quick reference

```

PUT http://localhost:8080/mws/rest/images/<id>?api-version=3
PUT http://localhost:8080/mws/rest/images/<name>?api-version=3

```

Modify Single Image

URLs and parameters

```

PUT http://localhost:8080/mws/rest/images/<id>?api-version=3
PUT http://localhost:8080/mws/rest/images/<name>?api-version=3

```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Image.
name	Yes	String	--	The name of the Image.

i You must specify either **id** or **name**, but you do not have to specify both. The **name** field must contain only letters, digits, periods, dashes, and underscores.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Example request

```
PUT http://localhost/mws/rest/images/centos5-stateful?api-version=3

{
  "name": "centos5-stateful",
  "type": "stateful",
  "hypervisor": false,
  "osType": "linux",
  "virtualizedImages": []
}
```

 The **version** field contains the current version of the database entry and does not reflect the version of the operating system. This field cannot be updated directly. However, if **version** is included in the modify request, it will be used to verify that another client did not update the object in between the time the data was retrieved and the modify request was delivered.

Sample response

If the request was successful, the response body is the modified image as shown in [Get Single Image](#). On failure, the response is an error message.

Deleting Images

The HTTP DELETE method is used to delete **Images**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/images/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Delete Single Image

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/images/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Image.
name	Yes	String	--	The name of the Image.

i Only one of **id** or **name** are required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON Response

```
{ }
```

Insight Database

This section describes the behavior of the Insight database query API in Moab Web Services. It contains the URLs and responses delivered to and from MWS.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/insight/priv/<view>	Get All Rows in a View	--	--	--
/rest/insight/user/<view>	Get All Rows the Current User Can See on page 1752	--	--	--

This topic contains these sections:

- [Getting Rows in a Relational Database View on page 1745](#)
 - [Get All Rows in a View on page 1751](#)
 - [Get All Rows the Current User Can See on page 1752](#)

Getting Rows in a Relational Database View

Queries with JSON operators

The HTTP GET method is used to retrieve rows in a view or table of the Insight database in JSON format. An array of JSON objects is returned. Each JSON object corresponds to a row in the view/table. The field name and values in each JSON object correspond the column names and values in the view/table. For example if view **myview1** in the Insight database contained the following data:

Table 4-2: "myview1"

column1	column2	column3	user_name
alpha	delta	1	wsmith
bravo	echo	2	tjones
charlie	echo	3	wsmith

Then you would query this data as follows:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3
```

The resulting JSON would look like this:

```
[
  {
    "column1": "alpha",
    "column2": "delta",
    "column3": 1,
    "user_name": "wsmith"
  },
  {
    "column1": "bravo",
    "column2": "echo",
    "column3": 2,
    "user_name": "tjones"
  },
  {
    "column1": "charlie",
    "column2": "echo",
    "column3": 3,
    "user_name": "wsmith"
  }
]
```

You can query using [MongoDB comparison and logical operators](#). For example:

- To query for all rows where column2 = echo:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column2": "echo"}
```

- To query for all rows where column2 = echo or column1 = bravo:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"$or": [{"column2": "echo"}, {"column1": "bravo"}]}
```

- To query for all rows where column3 >= 2:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column3": {"$gte": 2}}
```

Supported Mongo comparison operators include `$gt`, `$gte`, `$in`, `$lt`, `$lte`, `$ne`, and `$nin`. Supported logical operators include `$or`, `$and`, `$not`, and `$nor`.

Queries with dates and times

You can also query using date/time. For example:

- If `create_datetime` is a column in the "myview1" view and its data type is `TIMESTAMP`, then the following query is possible:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"create_datetime":{"$gte":"2014-03-08 4:00:00 EST"}}
```

This queries "myview1" for all rows whose value for create_datetime is greater than or equal to March 8, 2014 at 4:00:00 EST.

- To query for all rows where `create_date` is found in a date range, use `$and`, as follows:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"$and":[{"some_datetime":{"$gte":"2014-03-08 4:00:00 EST"}}, {"some_datetime":
{"$lte":"2014-03-08 7:00:00 EST"}}]}
```

Queries with wildcards

You can query for rows where a column value matches a specified pattern, instead of matching an exact string, by using the `$like` operator, which is similar to the SQL `LIKE` operator. `$like` allows the user of `"%"` as a wildcard that matches any substring. For example:

- To select all rows where `column3` starts with the letter "e" and ends with any substring:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column3":{"$like":"e%"}}
```

This matches rows where column3 is "echo," "excellent," "endeavor," etc.

- To query for all rows where `column3` ends with the letter, "o":

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column3":{"$like": "%o"}}
```

- To query for all rows where `column3` contains the substring "ch":

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column3":{"$like": "%ch%"}}
```

i When performing `$like` queries, you may need to replace `%` with the URL-encoded value of **%25**; otherwise, the meta-character may be interpreted as `%`.

You can also use "_" to substitute for any single character. For example, to query for all rows that start with any character and end in "cho":

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query=
{"column3":{"$like":"_cho"}}
```

This matches rows where column3 has the value "acho," "bcho," "ccho," "dcho," "echo," etc.

Privileged queries vs. user queries

The examples above show queries performed using the privileged query URL (/rest/insight/priv). The privileged query does not impose any additional conditions to what you specify in your query and max and offset parameters. By default only administrators have permission to use the privileged query URL. If you grant an unprivileged user access to the privileged query URL, the user could see data he should not be permitted to see.

If an unprivileged user needs to query the database view, he should only have permission to do so with the user query URL. This URL (/rest/insight/user) adds the implicit condition that the value for the user_name column must match that of the user that is currently logged in.

For example, the following two queries, the first a user query performed by user wsmith and the second a privileged query, are essentially the same:

```
GET http://localhost:8080/mws/rest/insight/user/myview1?api-version=3&query=
{"column2":"echo"}
```

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&query={$and":
[{"column2":"echo"}, {"user_name":"wsmith"}]}
```

Note that the user query URL can only access views that have a user_name column.

Field selection

To select which columns you want to see in the results, use the **fields** parameter. For example, to see only column1 and column2:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-
version=3&fields=column1,column2
```

Sorting

You can also sort the results by a one or more columns in ascending or descending order. Specifying additional sort columns provides an alternate value by which MWS will sort the rows if the values in the first column(s) match in multiple rows. There is no limit to the number of columns you can specify in your sort URL.

 All sort columns must be specified in the fields selection parameter.

To sort the results by a single column in ascending order:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&sort=
{"column1":1}
```

To sort the results by a single column in descending order:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&sort=
{"column1":-1}
```

To add a second sort column by which MWS will sort any rows with the same value in the first column:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&sort=
[{"column1":1}, {"column2":1}]
```

To add a third sort column by which MWS will sort any rows with the same values in the first column and the second column:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&sort=
[{"column1":1}, {"column2":1}, {"column3":1}]
```

Using aggregate functions, group by, and having clauses

You can use SQL aggregate functions like `count()`, `sum()`, and `avg()`. Aggregate functions perform an operation on a group of rows that have the same value with respect to an SQL 'GROUP BY' clauses. Aggregate functions are specified in the fields URL parameter.

Usage Scenario:

1. Assume you have the following data:

user_name	column1	column2
alice	3.0	alpha
alice	11.0	bravo
alice	4.0	charlie
bob	5.0	delta
bob	1.0	echo
dave	10.0	foxtrot

2. You want to get the sum of the column1 value for all rows corresponding to a user. For example you would like to know that the sum of column1 values for alice is $3 + 11 + 4 = 18$.

3. You would then use the `sum()` function and **group-by** clause as follows:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&fields=user_name,sum(column1)&group-by=user_name
```

Via SQL

```
SELECT user_name,SUM(column1) FROM myview1 GROUP BY user_name
```

It will return the following data:

```
[
  {
    "user_name":"alice",
    "sum":"18",
  },
  {
    "user_name":"bob",
    "sum":"6",
  },
  {
    "user_name":"dave",
    "sum":"10",
  },
]
```

4. Now try using the **having** clause to query only for rows where the results of an aggregate function meet some constraint. For example, to query only for users where the sum of column1 is greater than or equal to 10. Run the following:

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&fields=user_name,sum(column1)&group-by=user_name&having={"sum(column1)":{"$gte":10}}
```

Via SQL

```
SELECT user_name,SUM(column1) FROM myview1 GROUP BY user_name HAVING SUM(column1) >= 10
```

Having clauses have an identical syntax to query clauses except that query clauses constrain individual columns and having clauses constrain the results of aggregate functions over a set of rows that have been grouped together.

Other commonly used SQL aggregate functions include average and count. For example, to find out the

- average column1 value for each user.

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&fields=user_name,avg(column1)&group-by=user_name
```

- count of all rows associated with each user (use the count function with a parameter of 1).

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&fields=user_name,count(1)&group-by=user_name
```

- count of all rows associated with each user that has less than 3 rows.

```
GET http://localhost:8080/mws/rest/insight/priv/myview1?api-version=3&fields=user_name,count(1)&group-by=user_name&having={"count(1)":{"$lt":3}}
```

Quick reference

```
GET http://localhost:8080/mws/rest/insight/priv/<view>?api-version=3
GET http://localhost:8080/mws/rest/insight/user/<view>?api-version=3
```

Get All Rows in a View

URLs and parameters

```
GET http://localhost:8080/mws/rest/insight/priv/<view>?api-version=3
GET http://localhost:8080/mws/rest/insight/user/<view>?api-version=3
```

Parameter	Required	Type	Description	Example
fields	No	Comma-separated string	Includes only specified fields in output.	fields=name,type
group-by	No	Comma-separated-string	Used in conjunction with aggregate functions.	group-by=name
having	No	JSON	Queries for specific rows using results from aggregate functions.	having= {"sum(col1)":100}
max	No	Integer	The maximum number of items to return.	max=100
offset	No	Integer	The index of the first item to return.	offset=200
pretty	No	Boolean	true shows pretty printing of output. Default is false.	pretty=true
query	No	JSON	Queries for specific results. It is possible to query by one or more fields based on a subset of MongoDB query syntax. (See above.)	query= {"name":"node003"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

[Get all rows](#)

Queries performed with the privileged query URL (`/rest/insight/priv/<view>`) return all rows in a view that match that query.

[Sample response](#)

```
GET http://localhost:8080/mws/rest/insight/priv/node_management_view?api-version=3&pretty=true&fields=name,state,user_name
```

```
{
  "totalCount": 5,
  "resultCount": 5,
  "results": [
    {
      "job_name": "Moab.613",
      "job_state": "Running",
      "user_name": "wsmith"
    },
    {
      "job_name": "Moab.614",
      "job_state": "Running",
      "user_name": "tjones"
    },
    {
      "job_name": "Moab.615",
      "job_state": "Idle",
      "user_name": "wsmith"
    },
    {
      "job_name": "Moab.616",
      "job_state": "Running",
      "user_name": "tjones"
    },
    {
      "job_name": "Moab.617",
      "job_state": "Idle",
      "user_name": "tjones"
    }
  ]
}
```

Get All Rows the Current User Can See

Queries performed with the user query URL (`/rest/insight/user/<view>`) only return rows that the current user is authorized to see. The rows returned contain values in the `user_name` column that match that of the user who is currently logged in. For example, if `tjones` is logged in, then the user query URL will only return rows where `user_name` is equal to `"tjones"` and that match any other query submitted.

Note that you can only use the user query URL to query views with a `user_name` column.

Sample response

```
GET http://localhost:8080/mws/rest/insight/user/node_management_view?api-version=3&pretty=true&fields=name,state,user_name&query={"job_state":"Running"}
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "job_name": "Moab.614",
      "job_state": "Running",
      "user_name": "tjones"
    },
    {
      "job_name": "Moab.616",
      "job_state": "Running",
      "user_name": "tjones"
    }
  ]
}
```

Because tjones is currently logged in, MWS only returns information about running jobs submitted by tjones even though the query does not explicitly filter by user_name.

Job Arrays

This section describes behavior of the **Job Array** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Job Arrays** reference section contains the type and description of all fields in the **Job Array** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/job-arrays	--	--	Submit Job Array	--

This topic contains these sections:

- [Submitting Job Arrays on page 1753](#)
 - [Submit Job Array on page 1754](#)

Submitting Job Arrays

The HTTP POST method is used to submit **Job Arrays**.

Quick reference

```
POST http://localhost:8080/mws/rest/job-arrays?api-version=3[&proxy-user=<username>]
```

i While the `Job Array` resource only gives access to create job arrays, job arrays are retrieved using the operations in [Getting Job Information on page 1756](#).

Restrictions

All restrictions present for [Submitting Jobs](#) are present for job arrays. In addition, job arrays are *only* supported if the `ENABLEJOBARRAYS` parameter is set to `TRUE` in the `moab.cfg` file. For example:

```
ENABLEJOBARRAYS      TRUE
```

Submit Job Array

URLs and parameters

```
POST http://localhost:8080/mws/rest/job-arrays?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
proxy-user	No	String	--	Perform this action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

To submit a job array, only two fields are required: `jobPrototype` and one of `indexValues` or `indexRanges`. Both index ranges and values may be specified if desired.

The request body below shows all the fields that are available during job array submission, although the `jobPrototype` shown is a simple example and does not utilize all fields of a job submission.

i The `jobPrototype` field has the same properties as a typical job submission. Consequently the api-version of the job array will apply to the `jobPrototype` like it does when you submit jobs, so the api-version in the call must match the api-version of the job. Examples of this can be seen in [Submitting Jobs on page 1763](#).

JSON request body

```
{
  "name": "myarray",
  "indexRanges": [ {
    "startIndex": 11,
    "endIndex": 25,
    "increment": 2
  } ],
  "indexValues": [ 2, 4, 6, 8, 10 ],
  "slotLimit": 2,
  "cancellationPolicy": {
    "firstJob": "FAILURE",
    "anyJob": "SUCCESS"
  },
  "jobPrototype": {
    "commandFile": "/tmp/test.sh",
    "initialWorkingDirectory": "/tmp",
    "requirements": [{"taskCount": 4}]
  }
}
```

Sample response

The response of this task is the same as submitting a job (see [Submit Job on page 1764](#)).

Related Topics

Jobs

This section describes behavior of the **Job** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Job API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting Specific API Versions on page 1626](#).

The **Fields: Jobs** reference contains the type and description of all fields in the **Job** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/jobs	Get All Jobs	--	Submit Job	--
/rest/jobs/<name>	Get Single Job	Modify Job Attributes	--	Cancel Job
/rest/jobs/<name>/<modifyAction>	--	Perform Actions on Job	--	--

This topic contains these sections:

- [Getting Job Information](#) on page 1756
 - [Get All Jobs](#) on page 1756
 - [Get Single Job](#) on page 1758
- [Submitting Jobs](#) on page 1763
 - [Submit Job](#) on page 1764
- [Modifying Jobs](#) on page 1770
 - [Modify Job Attributes](#) on page 1770
 - [Generic Resources](#) on page 1773
 - [Perform Actions on Job](#) on page 1775
- [Deleting \(Canceling\) Jobs](#) on page 1776
 - [Cancel Job](#) on page 1776

Getting Job Information

The HTTP GET method is used to retrieve **Job** information.

Quick reference

```
GET http://localhost:8080/mws/rest/jobs/<name>?api-version=3
```

Get All Jobs

URLs and parameters

```
GET http://localhost:8080/mws/rest/jobs?api-version=3
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query by one or more fields based on MongoDB query syntax .	query={"isActive":true}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

How to get all jobs

```
GET http://localhost:8080/mws/rest/jobs?api-version=3&fields=name,flags&max=3
```

```
{
  "totalCount": 8,
  "resultCount": 3,
  "results": [
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.1"
    },
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.2"
    },
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.4"
    }
  ]
}
```

How to get a subset of jobs

```
Get active jobs
```

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"isActive":true}
```

```
Get completed jobs
```

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"isActive":false}
```

```
Get jobs owned by a particular user
```

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"credentials.user":"fred"}
```

[Known issues](#)

Some jobs are not returned if `DisplayFlags UseBlocking` is set in the `moab.cfg` file.

Get Single Job

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/jobs/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

i The `attributes` field is only applicable in API version 2 and later, and the `MOAB_TENANT` field only applies if the job is attached to a tenant.

```

Job arrays

- If a job is the master of a job array, the response will have some additional fields set as shown in the following example. The **name** field is chosen by the Moab, and the **customName** field comes from the [Fields: Job Arrays](#) name field.

```
Job array master
-----
{
  "name": "Moab.5",
  "customName": "myarray",
  "flags": [
    "ARRAYMASTER",
    "GLOBALQUEUE",
    "CANCELONFIRSTFAILURE",
    "CANCELONANYSUCCESS"
  ]
}
```

- If a job is a sub-job of an array, the response will have other fields set as shown in the following example.

```
Array sub-job
-----
{
  "name": "Moab.5[21]",
  "customName": "myarray",
  "arrayIndex": 21,
  "arrayMasterName": "Moab.5",
  "flags": [
    "ARRAYJOB",
    "GLOBALQUEUE",
    "CANCELONFIRSTFAILURE",
    "CANCELONANYSUCCESS"
  ]
}
```

Submitting Jobs

The HTTP POST method is used to submit **Jobs**.

Quick reference

```
POST http://localhost:8080/mws/rest/jobs?api-version=3 [&proxy-user=<username>]
```

Restrictions

- No more than one virtual container can be specified in the request. The virtual container must already exist.
- The `credentials.user` and `credentials.group` properties are used to submit a job as the specified user belonging to the specified group.

- Job variables have the following restrictions:
 - Variable names cannot contain equals (=), semicolon (;), colon (:), plus (+), question mark (?), caret (^), backslash (\), or white space.
 - Variable values cannot contain semicolon (;), colon (:), plus (+), or caret (^).
- When submitting jobs, the only supported hold type is User.
- The proxy-user parameter is ignored unless you set ENABLEPROXY=TRUE in the moab.cfg file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```
- When the JOBNODEMATCHPOLICY is set to EXACTNODE in Moab, avoid using requirements.tasksPerNode. Use requirements.resourcesPerTask.processors.dedicated instead.

Submit Job

URLs and parameters

```
POST http://localhost:8080/mws/rest/jobs?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

JSON request body (specified host list)

```
{

"standardErrorFilePath": "/tmp/error",

```

```

"standardOutputFilePath": "/tmp/out",
"submitHost": "admin-node",
"templates": [
  {"name": "template1"},
  {"name": "template2"}
],
"variables": {
  "var1": "val1",
  "var2": "val2"
},
"virtualContainers": [{"name": "vc1"}],
"vmUsagePolicy": "CREATEEVM"
}

```

[Sample response](#)

The response of this task is one of three possibilities:

- An object with a single **messages** property containing a list of error messages on failure.

```
{ "messages": ["Could not create job - invalid requirements"] }
```

- An object with a **name** property containing the name of the newly created job.

```
{ "name": "Moab.1" }
```

- An object with a **name** property and a **virtualContainers** list containing the name of the newly created virtual container.

```
{ "name": "Moab.1", "virtualContainers": [{"name": "vc1"}] }
```

i The virtual container will only be reported when a *new* virtual container has been created by Moab for the job.

[Examples of job submission](#)

This section includes some sample job submission requests.

Example 4-5: Submit job to run on node2 and node3

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/tmp",
  "nodesRequested": [
    {"name": "node2"},
    {"name": "node3"}
  ]
}
```

Example 4-6: Submit job that requires 20 processors

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/tmp",
  "requirements": [{"taskCount": 20}]
}
```

Example 4-7: Submit job to run after a certain time

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "dates": {"earliestRequestedStartDate": "2012-10-11 18:36:35 UTC"},
  "initialWorkingDirectory": "/tmp",
  "requirements": [{"taskCount": 20}]
}
```

Example 4-8: Submit job based on msub example

Given this **msub** command:

```
msub -l nodes=3:ppn=2,walltime=1:00:00,pmem=100 script2.pbs.cmd
```

Here is an equivalent MWS request:

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
```

```
{
  "duration": 3600,
  "commandFile": "/home/adaptive/script2.pbs.cmd",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/home/adaptive",
  "requirements": [ {
    "resourcesPerTask": {"memory": {"dedicated": 100}},
    "taskCount": 6,
    "tasksPerNode": 2
  } ]
}
```

i To emulate what `msub` does, make `commandFile` an absolute path, and add `credentials.user`, `credentials.group`, and `initialWorkingDirectory`.

As shown above, `nodes=3:ppn=2` is equivalent to setting `taskCount` to 6 and `tasksPerNode` to 2.

Example 4-9: Submit a job array

For information on how to submit a job array, see [Submitting Job Arrays on page 1753](#).

Modifying Jobs

The HTTP PUT method is used to modify **Jobs**.

Quick reference

```
PUT http://localhost:8080/mws/rest/jobs/<name>[/<modifyAction>]?api-version=3[&proxy-user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Modify Job Attributes

URLs and parameters

```
PUT http://localhost:8080/mws/rest/jobs/<name>?api-version=3[&proxy-user=<username>]
[&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Additional URL parameters

Parameter	Required	Valid values	Description
change-mode	No	set (default) add remove	If set , replace all fields with the fields specified. If add , add the specified fields to existing fields. If remove , remove the specified fields from existing fields.

Request body

The request body below shows all the fields that are available when modifying a job, along with some sample values.

JSON request body

```

{
  "credentials": {
    "account": "account",
    "jobClass": "BATCH",
    "qosRequested": "QOS1"
  },
  "customName": "custom name for job",

```

Sample response

i These messages may not match the messages returned from Moab exactly, but are given as an example of the structure of the response.

i Not all messages are shown for the above request body.

JSON response

```
{
  "messages": [
    "Account modified successfully",
    "Messages modified successfully",
    "Variables modified successfully"
  ]
}
```

Restrictions

- Old messages are not removed from jobs; only new messages are added.
- Job `variables` have the restrictions documented in [Submitting Jobs on page 1763](#).
- Although the client can modify `features` and `resourcesPerTask`, Moab only considers these elements when they appear in the first element of the `requirements` array. If the `requirements` array contains two or more elements, all elements but the first are silently ignored.

Generic Resources

Jobs can require configurable, site-specific consumable resources called generic resources. For example, some jobs may require a matlab license. Only one job at a time may legally consume this license. Matlab is not a standard resource and may only be available on some sites. Nevertheless Moab allows this to be configured and tracked as is explained in [Managing Consumable Generic Resources on page 701](#).

You must specify generic resources in the `requirements.resourcesPerTask` portion of the JSON document. Any resource in `requirement.resourcesPerTask` that is not a standard resource is considered a generic resource. Standard resources include disk, memory, processors, and swap. Assume a job has the following in `requirement.resourcesPerTask`:

```
{
  "resourcesPerTask":{
    "processors":{
      "dedicated":4,
      "utilized":0
    },
    "memory":{
      "dedicated":2048,
      "utilized":0
    },
    "disk":{
      "dedicated":4096,
      "utilized":0
    },
    "swap":{
      "dedicated":1024,
      "utilized":0
    },
    "tape":{
      "dedicated":1,
      "utilized":0
    },
    "matlab":{
      "dedicated":2,
      "utilized":0
    }
  }
}
```

The standard resources the job requires are:

- 4 processors
- 2048 MB of memory
- 4096 MB of disk
- 1024 MB of swap

The generic resources the job requires are

- 1 tape
- 2 matlab

To modify a job so that it requires 1 matlab license, run the following:

```
PUT http://localhost:8080/mws/rest/jobs/Moab.2?api-version=3
{
  "requirements":[
    {
      "resourcesPerTask":{
        "matlab":{
          "dedicated":1
        }
      }
    }
  ]
}
```

Perform Actions on Job

URLs and parameters

```
PUT http://localhost:8080/mws/rest/jobs/<name>/<modifyAction>?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
modifyAction	Yes	String	cancel checkpoint execute hold requeue rerun resume suspend unhold	<p>If cancel, attempts to cancel the job (equivalent to deleting a job).</p> <p>If checkpoint, attempts to checkpoint the job. Note that the OS must support checkpointing for this to work.</p> <p>If execute, executes the job (if possible).</p> <p>If hold, attempts to hold the job using the holds set in the request body.</p> <p>If requeue, attempts to requeue the job.</p> <p>If rerun, attempts to rerun the job.</p> <p>If resume, attempts to resume the job.</p> <p>If suspend, attempts to suspend the job.</p> <p>If unhold, attempts to release the holds set in the request body.</p>
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

Request bodies are only required for holding or unholding jobs. All other actions do not require request bodies of any kind.

JSON request body to add holds to a job

```
{"holds": ["User"]}
```

JSON request body to remove holds from a job

```
{"holds": ["User"]}
```

i If no holds are specified when unholding a job, all holds will be removed. This is equivalent to specifying `holds` as a list with a single element of `All`.

Sample response

i This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```
{"messages": ["Job modified successfully"]}
```

Deleting (Canceling) Jobs

The HTTP DELETE method is used to cancel **Jobs**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/jobs/<name>?api-version=3[&proxy-user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Cancel Job

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/jobs/<name>?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response for successful DELETE

```
{}
```

i Additional information about the DELETE can be found in the HTTP response header `X-MWS-Message`.

Job Templates

This section describes behavior of the **Job Template** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The [Fields: Job Templates](#) reference section contains the type and description of all fields in the **Job Template** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/job-templates</code>	Get All Job Templates	--	--	--
<code>/rest/job-templates/<id></code>	Get Single Job Template	--	--	--

This topic contains these sections:

- [Getting Job Templates on page 1777](#)
 - [Get All Job Templates on page 1778](#)
 - [Get Single Job Template on page 1778](#)

Getting Job Templates

The HTTP GET method is used to retrieve **Job Template** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/job-templates/<id>?api-version=3
```

Get All Job Templates

URLs and parameters

```
GET http://localhost:8080/mws/rest/job-templates?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/job-templates?api-version=3&fields=id
{
  "totalCount": 14,
  "resultCount": 14,
  "results": [
    {"id": "DEFAULT"},
    {"id": "genericVM"},
    {"id": "genericVM-setup"},
    {"id": "genericVM-destroy"},
    {"id": "genericVM-migrate"},
    {"id": "genericPM"},
    {"id": "genericPM-setup"},
    {"id": "genericPM-destroy"},
    {"id": "OSStorage"},
    {"id": "OSStorage-setup"},
    {"id": "OSStorage-destroy"},
    {"id": "extraStorage"},
    {"id": "extraStorage-setup"},
    {"id": "extraStorage-destroy"}
  ]
}
```

Get Single Job Template

URLs and parameters

```
GET http://localhost:8080/mws/rest/job-templates/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

Metric Types

This section describes behavior of the **Metric Type** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Metric Types** reference section contains the type and description of all fields in the **Metric Type** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/metric-types	Get All Metric Types	--	--	--

This topic contains these sections:

- [Getting Metric Types on page 1780](#)
 - [Get All Metric Types on page 1780](#)

Getting Metric Types

The HTTP GET method is used to retrieve **Metric Type** information.

Quick reference

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3
```

Get All Metric Types

URLs and parameters

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3&fields=id
{
  "totalCount": 9,
  "resultCount": 9,
  "results": [
    {"id": "vmcount"},

Nodes

This section describes behavior of the **Node** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

Nodes are tenant objects. If you have implemented a multi-tenant environment (see [About Tenants](#) on page 1602 for more information), and are logged in with an application account, you must include a `proxy-user` with each service call to limit the results to information that the user has permission to see. If you are logged in with an LDAP account, MWS will automatically limit the results to information that the LDAP user has permission to see. For more information, see [Roles](#) on page 1864.

The Node API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting Specific API Versions](#) on page 1626.

The **Fields: Nodes** reference contains the type and description of all fields in the **Node** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/nodes</code>	Get All Nodes	--	--	--
<code>/rest/nodes/<name></code>	Get Single Node	Modify Node	--	--

This topic contains these sections:

- [Getting Nodes](#) on page 1782
 - [Get All Nodes](#) on page 1782
 - [Get Single Node](#) on page 1782
- [Modifying Nodes](#) on page 1787
 - [Modify Node](#) on page 1788

Getting Nodes

The HTTP GET method is used to retrieve **Node** information.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/nodes/<name>?api-version=3
```

Get All Nodes

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/nodes?api-version=3
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query by one or more fields based on MongoDB query syntax .	query={"type":"-compute"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters](#) on page 1622 for available URL parameters.

i This query will not return the `DEFAULT` or `GLOBAL` nodes from Moab. However, the [Get Single Node](#) task may be used to retrieve them individually if desired.

[Sample response](#)

```
GET http://localhost:8080/mws/rest/nodes?api-version=3&fields=name
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"name": "node1"},
    {"name": "node2"},
    {"name": "node3"}
  ]
}
```

Get Single Node

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/nodes/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

The `attributes` field is only applicable in API version 2 and later, and the `MOAB_TENANT` field only applies if the node is attached to a tenant.

Sample response

JSON response

```
{
  "name": "l26.csa",
  "architecture": null,
  "classes": ["class1"],
  "attributes": {
    "MOAB_TENANT": {
      "value": "1234567890abcdef12345678",

Modifying Nodes

The HTTP PUT method is used to modify **Nodes**.

Quick reference

```
PUT http://localhost:8080/mws/rest/nodes/<name>?api-version=3 [&proxy-user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Modify Node

URLs and parameters

```
PUT http://localhost:8080/mws/rest/nodes/<name>?api-version=3[&proxy-user=<username>]
[&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Additional URL parameters

Parameter	Required	Valid values	Description
change-mode	No	set (default) add remove	If set , replace all features with the features specified. If add , add the specified features to existing features. If remove , remove the specified features from existing features.

Request body

The request body below shows all the fields that are available when modifying a node, along with some sample values.

```
Sample JSON request body to modify a node
-----
{
  "featuresCustom": ["feature1", "feature2"],
  "messages": [
    {"message": "Message one"},
    {"message": "Message two"}
  ],
  "metrics": {"pwatts": 211},
  "operatingSystem": {"image": "esx4.1"},
  "partition": "part1",
  "states": {
    "powerState": "On",
    "state": "Running"
  },
  "variables": {
    "key": "value",
    "arbitrary text key": "more value"
  }
}
```

Sample response

 This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```
{
  "messages": [
    "Successfully modified os to 'linux'",
    "Successfully powered node off"
  ]
}
```

Getting Notification Conditions

The HTTP GET method is used to retrieve **Notification Condition** information.

Quick reference

```
GET http://localhost:8080/mws/rest/notification-conditions?api-version=3
GET http://localhost:8080/mws/rest/notification-conditions/<id>?api-version=3
```

Get All Notification Conditions

URLs and parameters

```
GET http://localhost:8080/mws/rest/notification-conditions?api-version=3[&query=
{"escalationLevel":"ADMIN"}][&sort={"observedDate":-1}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Query for specific results. It is possible to query notifications by one or more fields based on MongoDB query syntax .	query={"escalationLevel":"ADMIN"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"observedDate":-1}

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/notification-conditions?api-version=3&query=
{"escalationLevel":"ADMIN"}&sort={"observedDate":-1}
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "createdDate": "2013-09-10 23:13:33 UTC",
      "details": {
        "pluginType": "NodeUtilizationReport",
        "pluginId": "node-report"
      },
      "escalationLevel": "ADMIN",
      "expirationDate": null,
      "expirationDuration": null,
      "message": "The node 'testnode' has not been updated since the last poll,
which is likely due to a misconfiguration.",
      "objectId": "testnode",
      "objectType": "Node",
      "observedDate": "2013-09-10 23:13:33 UTC",
      "origin": "MWS/plugins/NodeUtilizationReport/node-report",
      "tenant": {
        "id": "1234567890abcdef12345678",
        "name": "Research"
      },
      "id": "522fa79de4b0cafeaec6f83e"
    },
    {
      "createdDate": "2013-09-11 17:19:35 UTC",
      "details": {
        "pluginType": "VCenter",
        "pluginId": "vcenter42"
      },
      "escalationLevel": "ADMIN",
      "expirationDate": null,
      "expirationDuration": null,
      "message": "The node 'node1' does not have vcenter tools installed,
therefore the state is unknown and migrations may not work correctly",
      "objectId": null,
      "objectType": "System",
      "observedDate": "2013-09-11 17:19:35 UTC",
      "origin": "MWS/plugins/VCenter/vcenter42",
      "tenant": {
        "id": "1234567890abcdef12345678",
        "name": "Research"
      },
      "id": "5230a627e4b0d51bef490e86"
    }
  ]
}
```

i A notification's `tenant` is automatically inherited from the `objectId` and `objectType` fields. If no object is associated with the notification condition, the notification is visible to all tenants.

Get Single Notification Condition

URLs and parameters

```
GET http://localhost:8080/mws/rest/notification-conditions/<id>?api-version=3
```

Parameter	Required	Type	Description
id	Yes	String	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/notification-conditions/521a1f18e4b0e3f9031f47f5?api-version=3
-----
{
  "createdDate": "2013-09-10 23:13:33 UTC",
  "details": {
    "pluginType": "NodeUtilizationReport",
    "pluginId": "node-report"
  },
  "escalationLevel": "ADMIN",
  "expirationDate": null,
  "expirationDuration": null,
  "message": "The node 'testnode' has not been updated since the last poll, which is likely due to a misconfiguration.",
  "objectId": "testnode",
  "objectType": "Node",
  "observedDate": "2013-09-10 23:13:33 UTC",
  "origin": "MWS/plugins/NodeUtilizationReport/node-report",
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "id": "522fa79de4b0cafeaec6f83e"
}
```

i A notification's `tenant` is automatically inherited from the `objectId` and `objectType` fields. If no object is associated with the notification condition, the notification is visible to all tenants.

Updating Notification Conditions

The HTTP PUT method is used to update **Notification Condition** information. The PUT operation is idempotent, meaning that is used for both creating new notification conditions and updating existing ones. If the `escalationLevel`, `origin`, `message`, `objectType`, and `objectId` fields match an existing notification condition, it will be updated. Otherwise, a new condition will be created.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/notification-conditions?api-version=3
```

Update Notification Condition

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/notification-conditions?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Request body](#)

The request body below shows some fields that are available when updating a notification condition, along with some sample values.

Sample JSON request body to update a notification condition

```
{
  "details": {
    "pluginType": "NodeTester",
    "pluginId": "my-tester1"
  },
  "escalationLevel": "ADMIN",
  "expirationDuration": 30,
  "message": "Node 'node2' is powered off, please check your hardware.",
  "objectId": "node2",
  "objectType": "Node",
  "origin": "NodeTester/my-tester1/Test.groovy:141"
}
```

[Sample response](#)

JSON response

```
{
  "createdDate": "2013-09-10 23:13:33 UTC",
  "details": {
    "pluginType": "NodeTester",
    "pluginId": "my-tester1"
  },
  "escalationLevel": "ADMIN",
  "expirationDate": "2013-09-10 23:14:03 UTC",
  "expirationDuration": 30,
  "observedDate": "2013-09-10 23:13:33 UTC",
  "message": "Node 'node2' is powered off, please check your hardware.",
  "objectId": "node2",
  "objectType": "Node",
  "origin": "NodeTester/my-tester1/Test.groovy:141",
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "id": "5230a627e4b0d51bef490e86"
}
```

Notifications

This section describes behavior of the **Notifications** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Notifications API is new with *API version 3*, and is not available with older API versions. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.
For more information, see [Requesting Specific API Versions](#) on page 1626.

The [Fields: Notifications](#) reference contains the type and description of all fields in the **Notifications** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/notifications/	Get All Notifications	--	--	--
/rest/notifications/<id>	Get Single Notification	--	--	--
/rest/notifications/ignore	--	Ignore All Notifications	--	--

Resource	GET	PUT	POST	DELETE
/rest/notifications/<id>/ignore	--	Ignore Single Notification	--	--
/rest/notifications/unignore	--	Unignore All Notifications	--	--
/rest/notifications/<id>/unignore	--	Unignore Single Notification	--	--
/rest/notifications/dismiss	--	Dismiss All Notifications	--	--
/rest/notifications/<id>/dismiss	--	Dismiss Single Notification	--	--

Getting Notifications

The HTTP GET method is used to retrieve **Notification** information.

Quick reference

```
GET http://localhost:8080/mws/rest/notifications?api-version=3
GET http://localhost:8080/mws/rest/notifications/<id>?api-version=3
```

Get All Notifications

URLs and parameters

```
GET http://localhost:8080/mws/rest/notifications?api-version=3[&proxy-user=<username>]
[&query={"ignoredDate":null,"dismissedDate":null}][&sort={"observedDate":-1}]
```

Parameter	Required	Type	Description	Example
proxy-user	No	String	Perform the action as this user. <div>  Notifications cannot be created directly. Instead, they are automatically created for the current user or proxy-user specified in the request from non-expired notification conditions (see Notification Conditions on page 1789). This is true no matter the query specified. </div>	--
query	No	JSON	Query for specific results. It is possible to query notifications by one or more fields based on MongoDB query syntax . However, typically you will want to query on {"ignoredDate":null,"dismissedDate":null}.	query= {"ignoredDate":null,"dismissedDate":null}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"observedDate":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/notifications?api-version=3&proxy-
user=<username>&query={"ignoredDate":null,"dismissedDate":null}} [&sort=
{"observedDate":-1}

-----

{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {

  "observedDate": "2013-08-30 18:11:15 UTC",
  "origin": "MWS/HealthNotificationJob",
  "user": "admin",
  "id": "5230ed82e4b065347016d60d"
}
```

Ignoring Notifications

The HTTP PUT method is used to ignore **Notifications**.

Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/ignore?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/ignore?api-version=3
```

Ignore All Notifications

URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/ignore?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
JSON response
-----

{"messages":["Updated 10 Notification objects"]}
```

Ignore Single Notification

URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/ignore?api-version=3
```

Parameter	Required	Type	Description
id	Yes	String	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/ignore?api-version=3
```

```
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",
  "createdDate": "2013-08-25 15:13:28 UTC",
  "details": {},
  "dismissedDate": null,
  "ignoredDate": "2013-09-17 15:34:36 UTC",
  "message": "A health check failed for the 'LDAP' connection, please see the MWS health details page for more information.",
  "objectId": "ldap",

  "origin": "MWS/HealthNotificationJob",
  "user": "admin",
  "id": "5230ed82e4b065347016d60d"
}
```

Unignoring Notifications

The HTTP PUT method is used to unignore **Notifications**.

Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/unignore?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/unignore?api-version=3
```

Unignore All Notifications

URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/unignore?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{"messages":["Updated 10 Notification objects"]}
```

Unignore Single Notification

```
PUT
http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/unignore?api-version=3
```

Parameter	Required	Type	Description
id	Yes	String	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
PUT
http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/unignore?api-version=3
```

```
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",

  "user": "admin",
  "id": "5230ed82e4b065347016d60d"
}
```

Dismissing Notifications

The HTTP PUT method is used to dismiss **Notifications**.

Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/dismiss?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/dismiss?api-version=3
```

Dismiss All Notifications

URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/dismiss?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{"messages":["Updated 10 Notification objects"]}
```

Dismiss Single Notification

URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/dismiss?api-version=3
```

Parameter	Required	Type	Description
id	Yes	String	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/dismiss?api-version=3
```

```
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",

Permissions

This section describes behavior of the **Permissions** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: User's Permissions** reference section contains the type and description of fields that all **Permissions** have in common.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/permissions	Get All Permissions	--	Create Single Permission	--
/rest/permissions/<id>	Get Single Permission	--	--	Delete Single Permission
/rest/permissions/users/<id>	Get a User's Permissions	--	--	--
/rest/permissions/users	Get a Current User's Permissions	--	--	--

This topic contains these sections:

- [Getting Permissions](#) on page 1803
 - [Get All Permissions](#) on page 1803
 - [Get Single Permission](#) on page 1804
 - [Get a User's Permissions](#) on page 1804
 - [Get a Current User's Permissions](#) on page 1805
- [Creating Permissions](#) on page 1806
 - [Create Single Permission](#) on page 1806
- [Deleting Permissions](#) on page 1807
 - [Delete Single Permission](#) on page 1807

Getting Permissions

The HTTP GET method is used to retrieve **Permission** information. You can query all objects or a single object.

Quick reference

```
GET http://localhost:8080/mws/rest/permissions?api-version=3
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

Get All Permissions

URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query permissions by one or more fields based on MongoDB query syntax .	query={ "type": "CUSTOM" }
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name": -1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/permissions?api-
version=3&fields=resource,action,description
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [{
    "resource" : "chart",
    "action" : "read",
    "description" : "The permission to view all charts."
  } ]
}
```

Sorting and querying

See the sorting and querying sections of [Global URL Parameters on page 1622](#).

Get Single Permission

URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the permission.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

```
{
  "action" : "create",
  "description" : "The permission to create all charts.",
  "id" : "50296335e4b0011b0f8394ec",
  "label" : "Create Chart",
  "resource" : "chart",
  "resourceFilter" : null,
  "type" : "custom",
  "scope" : "NONE",
  "version" : 0
}
```

i For permissions with type "domain", scope must be GLOBAL or TENANT. All other permissions should have scope NONE.

Get a User's Permissions

URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions/users/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/permissions/users/bob?api-version=3
```

```
[
  {
    "action": "read",
    "description": "The permission to read all charts",
    "id": "5033b842e4b09cc61bedb818",
    "label": "",
    "resource": "chart",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "read",
    "description": "The permission to read all pages",
    "id": "5033b8a5e4b09cc61bedb82d",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "update",
    "description": "The permission to update all pages",
    "id": "5033b8a5e4b09cc61bedb82f",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  }
]
```

Get a Current User's Permissions

URLs and parameters

```
GET http://localhost/mws/rest/permissions/users/?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

GET http://localhost/mws/rest/permissions/users/?api-version=3

```
[
  {
    "action": "read",
    "description": "The permission to read all charts",
    "id": "5033b842e4b09cc61bedb818",
    "label": "",
    "resource": "chart",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "read",
    "description": "The permission to read all pages",
    "id": "5033b8a5e4b09cc61bedb82d",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "update",
    "description": "The permission to update all pages",
    "id": "5033b8a5e4b09cc61bedb82f",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  }
]
```

Creating Permissions

The HTTP POST method is used to create **Permissions**.

Quick reference

POST http://localhost:8080/mws/rest/permissions?api-version=3

Create Single Permission

URLs and parameters

POST http://localhost:8080/mws/rest/permissions?api-version=3

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

i The **resource**, **action**, and **type** are required on each permission.

Api permissions are permissions with the type 'api' and are the only permissions enforced by MWS.

Api permissions must map to a valid resource. For example, "services" is valid because there is a resource `/mws/rest/services`.

Api permissions must have `create`, `read`, `update`, or `delete` as the action.

The following is an example request body to create a permission:

```
POST http://localhost:8080/mws/rest/permissions?api-version=3
-----
{
    "resource" : "Chart",
    "action" : "read",
    "type" : "custom",
    "scope" : "NONE",
    "label" : "Read all charts",
    "description" : "The permissions to view all charts."
}
```

Sample response

If the request was successful, the response body is the new permission that was created exactly as shown in [Get Single Permission](#). On failure, the response is an error message.

Deleting Permissions

The HTTP DELETE method is used to delete **Permissions**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

Delete Single Permission

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/permission/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the permission.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

{}

Getting Plugins

The HTTP GET method is used to retrieve **Plugin** information. Queries for all objects, a single object, and query by reported object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/plugins?api-version=3
GET http://localhost:8080/mws/rest/plugins/<id>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-jobs/<jobName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/<nodeName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-vms/<vmName>?api-version=3
```

Get All Plugins

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/plugins?api-version=3&fields=id

{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "plugin1"},
    {"id": "plugin2"},
    {"id": "plugin3"}
  ]
}
```

Get All Plugins Reporting Object

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins/reporting-jobs/<jobName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/<nodeName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-vm/<vmName>?api-version=3
```

Parameter	Required	Type	Valid values	Description
jobName	Yes	String	--	The name of the job to query by.
nodeName	Yes	String	--	The name of the node to query by.
vmName	Yes	String	--	The name of the VM to query by.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

This built-in query returns the same information as [Get All Plugins](#), but filters the items to only plugins that are currently reporting the specified job, node, or VM (see [Reporting State Data on page 2031](#)). The list is sorted ascending by the `precedence` field. In other words, the most authoritative plugin for the report is listed first. For more information, see [Data Consolidation on page 2009](#).

```
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/node1?api-version=3&fields=id
```

```
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "plugin1"},
    {"id": "plugin2"},
    {"id": "plugin3"}
  ]
}
```

Get Single Plugin

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{
  "id": "plugin1",
  "pluginType": "Native",
  "pollInterval": 30,
  "autoStart": true,
  "config": {
    "getJobs": "exec:///opt/moab/tools/workload.query.pl"
  },
  "state": "STARTED",
  "nextPollDate": "2011-12-02 17:28:52 UTC",
  "lastPollDate": "2011-12-02 17:28:22 UTC"
}
```

Creating Plugins

The HTTP POST method is used to create **Plugins**.

Quick reference

```
POST http://localhost:8080/mws/rest/plugins?api-version=3
```

Create Plugin

URLs and parameters

```
POST http://localhost:8080/mws/rest/plugins?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

When creating a plugin, the `id` and `pluginType` fields are required. The request body below shows all fields that are available when creating a plugin, along with some sample values.

JSON request body

```
{
  "id": "plugin1",
  "pluginType": "Native",
  "pollInterval": 30,
  "autoStart": true,
  "config": {
    "getJobs": "exec:///opt/moab/tools/workload.query.pl"
  }
}
```

Sample response

JSON response for successful POST

```
{"id": "plugin1"}
```

Restrictions

While it is possible to create a plugin with arbitrary nested configuration, such as:

```
{
  "config": {
    "nestedObject": {
      "property1": "value1",
      "property2": "value2"
    },
    "nestedList": ["listItem1", "listItem2"]
  }
}
```

It is *not* recommended, because the user interface (see [Plugin Management on page 2078](#)) does not support editing or viewing any configuration data values other than strings.

Modifying Plugins

The HTTP PUT method is used to modify **Plugins**. Additionally, the POST method may be used to trigger an immediate poll of a **Plugin**.

Quick reference

```
PUT http://localhost:8080/mws/rest/plugins/<id>?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/poll?api-version=3
```

Modify Plugin

URLs and parameters

```
PUT http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

The request body below shows all the fields that are available when modifying a **Plugin**, along with some sample values.

```
JSON request body for plugin modification
-----
{
  "state":"STARTED",
  "pollInterval":30,
  "autoStart":true,
  "config":{
    "getJobs":"exec:///opt/moab/tools/workload.query.pl"
  },
  "state":"STARTED"
}
```

Sample response

```
JSON response
-----
{"messages":["Plugin plugin1 updated", "Started Plugin 'plugin1'"]}
```

Trigger Plugin Poll

URLs and parameters

```
POST http://localhost:8080/mws/rest/plugins/<id>/poll?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Trigger poll](#)

This resource call will trigger an immediate poll of the specified plugin. It is equivalent to the same operation on [Monitoring and Lifecycle Controls on page 2081](#).

[Request body](#)

No request body is required.

[Sample response](#)

JSON response

```
{"messages":["Polled Plugin with ID 'myPlugin'"]}
```

Deleting Plugins

The HTTP DELETE method is used to delete **Plugins**.

[Quick reference](#)

```
DELETE http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Delete Plugin

[URLs and parameters](#)

```
DELETE http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

JSON response for successful DELETE

```
{}
```

i Additional information about a successful DELETE can be found in the HTTP response header `X-MWS-Message`.

JSON response for an unsuccessful DELETE

```
{"messages":["Plugin plugin1 could not be deleted", "Error message describing the problem"]}
```

Accessing Plugin Web Services

All HTTP methods can be used to access **Plugin Web Services**. However, some services only support specific methods. Check the specific plugin type documentation for more information.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
PUT http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
DELETE http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
```

Access a Plugin Web Service

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
PUT http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
DELETE http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[/<objectId>]?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.
objectId	No	String	--	An arbitrary ID parameter that will be passed to the web service.
serviceName	Yes	String	--	The name of the web service, either in CamelCase or hyphenated.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Web service IDs

Translation is done to map [CamelCase](#) web service names to hyphenated names in the URL. For example, a web service method named `notifyEvent` on a plugin with a name of `notifications` may be called with the following URLs:

```
// CamelCase
/rest/plugins/notifications/services/notifyEvent

// Hyphenated
/rest/plugins/notifications/services/notify-event
```

HTTP method and request body

Because plugin custom web services do not need to distinguish which HTTP method is used (see [Custom Web Services on page 2007](#)), it is recommended to use GET and POST when making requests to access web services unless documented otherwise. The request body and output may vary for each web service called. See [Plugin Types on page 1816](#) for the requested plugin for available web services, request parameters, and expected output.

Plugin Types

This section describes behavior of the **Plugin Type** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

 The [Fields: Plugin Types](#) reference section contains the type and description of all fields in the **Plugin Type** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/plugin-types	Get All Plugin Types	Creating or Updating Plugin Types	--	--
/rest/plugin-types/<id>	Get Single Plugin Type	--	--	--

This topic contains these sections:

- [Getting Plugin Types](#) on page 1817
 - [Get All Plugin Types](#) on page 1817
 - [Get Single Plugin Type](#) on page 1817
- [Creating or Updating Plugin Types](#) on page 1818
 - [Update Plugin Type \(File\)](#) on page 1818
 - [Update Plugin Type \(JAR\)](#) on page 1820

Getting Plugin Types

The HTTP GET method is used to retrieve **Plugin Type** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/plugin-types/<id>?api-version=3
```

Get All Plugin Types

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugin-types?api-version=3
```

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/plugin-types?api-version=3&fields=id
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {"id": "vCenter"},
    {"id": "Native"}
  ]
}
```

Get Single Plugin Type

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugin-types/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{
  "author": "Adaptive Computing Enterprises, Inc.",
  "commonsVersion": "0.9.3 > *",
  "description": "Polls a VMware® vCenter™ Server for information on the hypervisors
and virtual machines it manages.",
  "documentationLink": "",
  "email": "",
  "eventComponent": 1,
  "realizedEventComponent": 513,
  "id": "VCenter",
  "initialPlugins": { },
  "instances": [
    { "id": "vcenter" }
  ],
  "issueManagementLink": "",
  "license": "APACHE",

  "pollMethod": true,
  "scmLink": "",
  "title": "VCenter",
  "version": "1.0",
  "webServices": [ ],
  "website": "http://www.adaptivecomputing.com"
}
```

Creating or Updating Plugin Types

The HTTP PUT method is used to create or update **Plugin Types**. The Content-Type HTTP header is used to determine if the request contains a single class file as plaintext or the binary data of a JAR file. Each request is explained in the following sections.

Quick reference

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3[&reload-plugins=false]
```

i There is a known issue with dynamically updating plugin types with typed field injection. For more information, see [Add or Update Plugin Types on page 2075](#).

Update Plugin Type (File)

URLs and parameters

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3[&reload-plugins=false]
```

Parameter	Required	Type	Valid values	Description
reload-plugins	No	String	true or false	Reloads all plugins of this type on successful update. Defaults to true.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

This function is idempotent, meaning it will create the **Plugin Type** if it does not exist or update it if it does. The request body is the actual contents of the class file to upload. This web service is an exception to most as it *requires* a content type of `application/x-groovy` or `text/plain`.

If the `application/x-groovy` or `text/plain` content types are not used in the request, it will be interpreted as JSON, resulting in a failure.

Plaintext upload

```
-----
package test

import com.adaptc.mws.plugins.*

class UploadPlugin {
    static author = "Adaptive Computing"
    static description = "A sample plugin class"
    String id

    public void configure() throws InvalidPluginConfigurationException {
        def myConfig = config
        def errors = []
        if (!myConfig.arbitraryKey)
            errors << "Missing arbitraryKey!"
        if (errors)
            throw new InvalidPluginConfigurationException(errors)
    }

    public def customService(Map params) {
        return params
    }
}
```

If using the `curl` library to perform plugin type uploading, the equivalent of the command-line option `--data-binary` must be used to send the request body. Otherwise compilation errors may be encountered when uploading the plugin type.

Sample response

The response of this task is the same as the [Get All Plugin Types](#) task. The reason that the return of this task is a list is to accommodate the possibility of

uploading multiple plugin types in a single JAR file as explained in the next section.

Update Plugin Type (JAR)

URLs and parameters

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3&jar-
filename=<filename.jar>[&reload-plugins=false]
```

Parameter	Required	Type	Valid values	Description
jar-file-name	Yes	String	--	The filename of the JAR file that is being uploaded.
reload-plugins	No	String	true or false	Reloads all plugins of this type on successful update. Defaults to true.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

This function is idempotent, meaning it will create the **Plugin Types** if they do not exist or update them if they do. The request body is the binary contents of the JAR file to upload. This web service is an exception to most as it *requires* a content type of `application/x-jar`.

If the `application/x-jar` content type is not used in the request, it will be interpreted as JSON, resulting in a failure.

If using the `curl` library to perform plugin type uploading, the equivalent of the command-line option `--data-binary` must be used to send the request body. Otherwise compilation errors may be encountered when uploading the plugin type.

Sample response

The response of this task is the same as the [Get All Plugin Types](#) task. Note that when using a JAR file, multiple plugin types may be uploaded in the same request.

Policies

This section describes behavior of the **Policies** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Policies** reference section contains the type and description of fields of all **Policies**.

Supported policies

Name	ID
Automatic VM Migration	auto-vm-migration
Fairshare	fairshare
Hypervisor Allocation Overcommit	hv-allocation-overcommit
Migration Exclusion List	migration-exclusion-list
Node Allocation	node-allocation

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/policies	Get All Policies	--	--	--
/rest/policies/<id>	Get Single Policy	Modify Policy	--	--

This topic contains these sections:

- **Getting Policies** on page 1821
 - [Get All Policies](#) on page 1822
 - [Get Single Policy](#) on page 1823
- **Modifying Policies** on page 1824
 - [Modify Policy](#) on page 1825

Getting Policies

The HTTP GET method is used to retrieve **Policies** information.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/policies?api-version=3
```

Get All Policies

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/policies?api-version=3
```

Parameter	Required	Type	Description	Example
query	No	JSON	Query for specific results.	query={"state":"DISABLED","-conflicted":"false"}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"id":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

```
GET http://localhost:8080/mws/rest/policies?api-version=3&fields=id,state,conflicted
```

```
{
  "totalCount": 4,
  "resultCount": 4,
  "results": [ {
    "conflicted": false,
    "state": "DISABLED",
    "id": "auto-vm-migration"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "hv-allocation-overcommit"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "node-allocation"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "migration-exclusion-list"
  } ]
}
```

Get Single Policy

URLs and parameters

```
GET http://localhost:8080/mws/rest/policies/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample responses

Auto VM Migration

```
{
  "conflicted": false,
  "description": "Controls how virtual machines are automatically migrated.",
  "id": "auto-vm-migration",
  "name": "Auto VM Migration",
  "potentialConflicts": [],
  "priority": 1,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "genericMetricThresholds": {
    "GMETRIC1": 1.3
  },
  "processorUtilizationThreshold": 0.5,
  "memoryUtilizationThreshold": 0.4
}
```

Fairshare

```
{
  "conflicted": false,
  "decayFactor": 0.44,
  "depth": 4,
  "description": "Control job feasibility and priority decisions based on system utilization targets for users, groups, accounts, classes, and QoS levels.",
  "intervalSeconds": 600,
  "name": "Fairshare",
  "potentialConflicts": [],
  "priority": 16,
  "state": "ENABLED",
  "tags": [],
  "types": [],
  "usageMetric": "DEDICATED_PROCESSOR_SECONDS_DELIVERED",
  "version": 3,
  "id": "fairshare"
}
```

Hypervisor Allocation Overcommit

```
{
  "conflicted": false,
  "description": "Controls how hypervisors are overallocated with regards to
processors and memory.",
  "id": "hv-allocation-overcommit",
  "name": "Hypervisor Allocation Overcommit",
  "potentialConflicts": [],
  "priority": 2,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "processorAllocationLimit": 29.5,
  "memoryAllocationLimit": 1.2
}
```

Migration Exclusion List

```
{
  "conflicted": false,
  "description": "Controls which machines are excluded from automatic live migration
operations.",
  "hvExclusionList": ["blade05", "blade02"],
  "name": "Migration Exclusion List",
  "potentialConflicts": [],
  "priority": 100,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 1,
  "vmExclusionList": ["vm1", "vm5"],
  "id": "migration-exclusion-list"
}
```

Node Allocation

```
{
  "conflicted": false,
  "description": "Controls how nodes are selected for workload placement.",
  "id": "node-allocation",
  "name": "Node Allocation",
  "potentialConflicts": [],
  "priority": 3,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "nodeAllocationAlgorithm": "CustomPriority",
  "customPriorityFunction": "-100*GMETRIC[vmcount]"
}
```

Modifying Policies

The HTTP PUT method is used to modify **Policies**.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/policies/<id>?api-version=3
```

Modify Policy

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/policies/<id>?api-version=3[&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Additional URL parameters](#)

URL parameters for modifying a Migration Exclusion Lists Policy.

Migration Exclusion Lists parameter	Required	Type	Valid values	Description
change-mode	No	String	set (default) add remove	If set , replace existing exclusion list(s) with the given one. If add , add the given VMs/HVs to the existing exclusion list(s). If remove , remove the given VMs/HVs from the existing exclusion list(s).

[Request body](#)

In general, the fields shown in the [Fields: Policies](#) reference section are *not* available for modification. However, the `state` field may be modified to a valid `PolicyState`. All other fields listed in the specific policy type sections (i.e. `AutoVMMigrationPolicy`) may be modified unless documented otherwise.

- The request body below shows all the fields that are available when modifying a Auto VM Migration Policy, along with some sample values.

```
JSON request body for Auto VM Migration Policy
```

```
{
  "genericMetricThresholds": {
    "GENERICTHRESHOLD": 5
  },
  "memoryUtilizationThreshold": 0.5,
  "processorUtilizationThreshold": 0.4
}
```

- The request body below shows all the fields that are available when modifying a Fairshare Policy, along with some sample values.

```
JSON request body for Fairshare Policy
-----
{
  "decayFactor": 0.44,
  "depth": 4,
  "intervalSeconds": 600,
  "usageMetric": "DEDICATED_PROCESSOR_SECONDS_DELIVERED",
}
```

- The request body below shows all the fields that are available when modifying a Hypervisor Allocation Overcommit Policy, along with some sample values.

```
JSON request body for Hypervisor Allocation Overcommit Policy
-----
{
  "processorAllocationLimit": 29.5,
  "memoryAllocationLimit": 1.2
}
```

- The request body below shows all the fields that are available when modifying a Migration Exclusion Lists Policy, along with some sample values.

```
JSON request body for Migration Exclusion Lists Policy
-----
{
  "vmExclusionList" : ["vm1", "vm3", "vm5"],
  "hvExclusionList" : ["hv2", "hv3", "hv6"]
}
```

- The request body below shows all the fields that are available when modifying a Node Allocation Policy, along with some sample values.

```
JSON request body for Node Allocation Policy
-----
{
  "nodeAllocationAlgorithm" : "CustomPriority",
  "customPriorityFunction" : "-100*GMETRIC[vmcount]"
}
```

Sample response

```
JSON response
-----
{
  "messages": ["Policy auto-vm-migration updated"]
}
```

Samples

Enable the Auto VM Migration Policy and set values.

```
PUT http://localhost:8080/mws/rest/policies/auto-vm-migration?api-version=3
```

```
{
  "state": "enabled",
  "migrationAlgorithmType": "overcommit",
  "processorUtilizationThreshold": 0.5,
  "memoryUtilizationThreshold": 0.4
}
```

i As noted in the [Fields: Policies](#) reference section documentation for AutoVMMigrationPolicy, if the state is set to ENABLED, then the migrationAlgorithmType must *not* be set to NONE.

Restrictions

All policies:

- Fields cannot be modified while the policy is disabled. Enable the policy to modify the field.

Auto VM Migration

- Arbitrary metrics can be added to **genericMetricThresholds**, but they cannot be removed once added.
- The **migrationAlgorithmType** field cannot be modified while the policy is disabled. Enable the policy to modify the field.
- Moab is configured with a default limit of 10 generic metrics. If this limit is reached, such as when arbitrary metrics are added to **genericMetricThresholds**, the metric will not be reported. To increase this limit, set the MAXGMETRIC property in the Moab configuration file.

Fairshare

- Updating the **usageMetric** field will clear all credential-based fairshare interval data.

Related Topics

- [Fairshare on page 1827](#)
- [Resources Introduction on page 1646](#)

Fairshare

This section describes behavior of the **Fairshare** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting Specific API Versions on page 1626](#).

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/policies/fairshare</code>	Get All Fairshare Interval Data on page 1829	--	--	--
<code>/rest/policies/fairshare/<credentialType></code>	Get all Fairshare Interval Data for a Single Credential Type on page 1832	--	--	--
<code>/rest/policies/fairshare/<credentialType>/<name></code>	Get all Fairshare Interval Data for a Single Credential on page 1835	--	--	--

This topic contains these sections:

- [Getting Credential-Based Fairshare Interval Data on page 1828](#)
 - [Get All Fairshare Interval Data on page 1829](#)
 - [Get all Fairshare Interval Data for a Single Credential Type on page 1832](#)
 - [Get all Fairshare Interval Data for a Single Credential on page 1835](#)

Getting Credential-Based Fairshare Interval Data

The HTTP GET method is used to retrieve **Policies** information.

Quick reference

```
GET http://localhost:8080/mws/rest/policies/fairshare/credentials?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/accounts?api-
version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/classes?api-
version=3

Principals

This section describes behavior of the **Principal** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Principals** reference contains the type and description of all fields in the **Principal** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/principals	Get All Principals	--	Create Single Principal	--
/rest/principals/<id>	Get Single Principal	Modify Single Principal	--	Delete Single Principal
/rest/principals/<name>	Get Single Principal	Modify Single Principal	--	Delete Single Principal

This topic contains these sections:

- [Getting Principals](#) on page 1836
 - [Get All Principals](#) on page 1837
 - [Get Single Principal](#) on page 1838
- [Creating Principals](#) on page 1839
 - [Create Single Principal](#) on page 1839
- [Modifying Principals](#) on page 1840
 - [Modify Single Principal](#) on page 1840
- [Deleting Principals](#) on page 1842
 - [Delete Single Principal](#) on page 1842

Getting Principals

The HTTP GET method is used to retrieve **Principal** information. You can query all objects or a single object.

Quick reference

```
GET http://localhost:8080/mws/rest/principals?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/principals/<id>?api-version=3
GET http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Get All Principals

URLs and parameters

```
GET http://localhost:8080/mws/rest/principals?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query principals by one or more fields based on MongoDB query syntax .	query= { "name": "Acme Principal" }
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={ "name": - 1 }

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/principals?api-version=3&fields=name,group
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "groups": [
        {
          "name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
          "type": "LDAPGROUP"
        }
      ],
      "name": "Engineering-Principal"
    },
    {
      "groups": [
        {
          "name": "CN=Marketing,CN=Users,DC=corp,DC=cloud,DC=dev",
          "type": "LDAPGROUP"
        }
      ],
      "name": "Marketing-Principal"
    }
  ]
}
```

Sorting and Querying

See the sorting and querying sections of [Global URL Parameters on page 1622](#).

Get Single Principal

URLs and parameters

```
GET http://localhost:8080/mws/rest/principals/<id>?api-version=3
GET http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the principal.
name	Yes	String	--	The name of the principal.

 You must specify either id or name, but you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

GET http://localhost:8080/mws/rest/principals/principal8?api-version=3

```

{
  "attachedRoles": [ {
    "description": "This is a role for normal users in the Acme BU Group.",
    "id": "5033b8eae4b09cc61bedb895",
    "name": "Acme-User-Role",
    "permissions": [
      {
        "action": "read",
        "description": "The permission to read all nodes",
        "id": "5033b842e4b09cc61bedb818",
        "label": "",
        "resource": "nodes",
        "resourceFilter": null,
        "type": "api",
        "version": 1
      }
    ],
    "version": 2
  } ],
  "description": "Principal 8",
  "groups": [ {
    "name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
    "type": "LDAPGROUP"
  } ],
  "id": "5033d33fe4b018b28745fecb",
  "name": "principal8",
  "users": [
    {
      "name": "jhammon",
      "type": "LDAP"
    },
    {
      "name": "bjones",
      "type": "LDAP"
    }
  ],
  "version": 0
}

```

Creating Principals

The HTTP POST method is used to submit **Principals**.

Quick reference

POST http://localhost:8080/mws/rest/principals?api-version=3

Create Single Principal

URLs and parameters

POST http://localhost:8080/mws/rest/principals?api-version=3

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

 The **name** field is required and must contain only letters, digits, periods, dashes, and underscores.
The **attachedRoles** field expects an array of Role IDs *or* names:

The following is an example request body to create a principal:

```
POST http://localhost:8080/mws/rest/principals?api-version=3

{
  "name" : "Acme-Principal",
  "attachedRoles" : [{"name":"Acme-User-Role"}],
  "description" : "A cool principal",
  "groups" : [{"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
"type":"LDAPGROUP"}],
  "users" : [{
    "name" : "john",
    "type" : "LDAP"
  } ]
}
```

Sample response

If the request was successful, the response body is the new principal that was created, exactly as shown in [Get Single Principal](#). On failure, the response is an error message.

Modifying Principals

The HTTP PUT method is used to modify **Principals**.

Quick reference

```
PUT http://localhost:8080/mws/rest/principals/<id>?api-version=3
PUT http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Modify Single Principal

URLs and parameters

```
PUT http://localhost:8080/mws/rest/principals/<id>?api-version=3
PUT http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Principal.

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the Principal. i The name field must contain only letters, digits, periods, dashes, and underscores.
change-mode	Yes	String	add remove set (default)	If add , add the given objects (ldapGroups, ldapOUs, etc.) to the objects that already exist. If remove , delete the given objects from the objects that already exist. If set , add the given objects (ldapGroups, ldapOUs, etc.) and remove the objects that already exist.

See [Global URL Parameters on page 1622](#) for available URL parameters.

i You must specify either **id** or **name**, but you do not have to specify both. The **attachedRoles** field expects an array of Role IDs *or* names:

Example request

```
PUT http://localhost/mws/rest/principals/Acme-Principal?api-version=3
{
  "groups" : [ {
    "name" : "CN=Marketing,CN=Users,DC=mycompany,DC=com",
    "type" : "LDAPGROUP"
  }, {
    "name" : "CN=Sales,CN=Users,DC=mycompany,DC=com",
    "type" : "LDAPGROUP"
  } ],
  "users" : [ {
    "name" : "jhammon",
    "type" : "LDAP"
  } ]
}
```

i The **version** field contains the current version of the database entry. This field cannot be updated directly. However, if **version** is included in the modify request, it will be used to verify that another client did not update the object between the time that the data was retrieved and the modify request was delivered.

Sample response

If the request was successful, the response body is the modified principal as shown in [Get Single Principal](#). On failure, the response is an error message.

Deleting Principals

The HTTP DELETE method is used to delete **Principals**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/principals/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Delete Single Principal

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/principals/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the principal.
name	Yes	String	--	The name of the principal.

See [Global URL Parameters on page 1622](#) for available URL parameters.

i You must specify either **id** or **name**, but you do not have to specify both.

Sample response

JSON response

```
{}
```

Getting Reports

The HTTP GET method is used to retrieve **Report** information. Queries for all reports with no attached data and a single report with associated data are available.

Quick reference

```
GET http://localhost:8080/mws/rest/reports?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<id>?api-version=3
GET http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

Get All Reports (No Data)

URLs and parameters

```
GET http://localhost:8080/mws/rest/reports?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Queries for specific results. It is possible to query reports by one or more fields based on MongoDB query syntax .	query={"reportSize":4}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "3efe5c670be86ba8560397ff",
    "name": "cpu-util"
  },
  ...
  ]
}
```

Samples

```
GET http://localhost:8080/mws/rest/reports?api-version=3&fields=id,name
```

```
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {
      "id": "3efe5c670be86ba8560397ff",
      "name": "cpu-util"
    },
    {
      "id": "3efe5c670be86ba856039800",
      "name": "cpu-temp"
    },
    {
      "id": "3efe5c670be86ba856039801",
      "name": "cpu-load"
    }
  ]
}
```

Get Single Report (With Data)

URLs and parameters

```
GET http://localhost:8080/mws/rest/reports/<id>?api-version=3
GET http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the report.
name	Yes	String	--	The name of the report.

 Only one of **id** or **name** are required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

In the example below, the first datapoint has a `null` data element, which means that the `minimumSampleSize` configured for the report was not met when consolidating the datapoint. The second datapoint contains actual data.

JSON response

```
{
  "consolidationFunction": "average",
  "datapointDuration": 15,
  "datapoints": [
    {
      "endDate": "2011-12-02 17:28:22 UTC",
      "startDate": "2011-12-02 17:28:22 UTC",
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null
    },
    {
      "endDate": "2011-12-02 17:28:23 UTC",
      "startDate": "2011-12-02 17:28:37 UTC",
      "firstSampleDate": "2011-12-02 17:28:23 UTC",
      "lastSampleDate": "2011-12-02 17:28:30 UTC",
      "data": {
        "utilization": 99.89,
        "time": 27.433333333333337
      }
    }
  ],
  "description": "Example of CPU utilization reporting",
  "id": "3efe5c670be86ba8560397ff",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 2
}
```

Get Datapoints for Single Report

URLs and parameters

```
GET http://localhost:8080/mws/rest/reports/<id>/datapoints?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/datapoints?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
id	Yes	String	The unique identifier of the report.	--
name	Yes	String	The name of the report.	--
query	No	JSON	Queries for specific results.	query={"reportSize":4}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

i Only one of **id** or **name** are required.

It is possible to query reports by one or more fields based on [MongoDB query syntax](#).

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

This function is exactly the same as [Get Single Report \(With Data\)](#). No report metadata (i.e. description, minimumSampleSize, etc.) is returned.

JSON response

```
{
  "resultCount":1,
  "totalCount":1,
  "results":[
    {
      "endDate": "2011-12-02 17:28:22 UTC",
      "startDate": "2011-12-02 17:28:22 UTC",
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null
    },
    {
      "endDate": "2011-12-02 17:28:37 UTC",
      "startDate": "2011-12-02 17:28:37 UTC",
      "firstSampleDate": "2011-12-02 17:28:23 UTC",
      "lastSampleDate": "2011-12-02 17:28:23 UTC",
      "data": {
        "utilization": 99.89,
        "time": 27.433333333333337
      }
    }
  ]
}
```

Getting Samples for Reports

The HTTP GET method is used to retrieve **Sample** information.

Quick reference

```
GET http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
```

Get Samples for Report

URLs and parameters

```
GET http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
id	Yes	String	The unique identifier of the report.	--
name	Yes	String	The name of the report.	--
query	No	JSON	Queries for specific results.	query={"reportSize":4}
sort	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

i Only one of **id** or **name** are required.

It is possible to query reports by one or more fields based on [MongoDB query syntax](#).

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
JSON response
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "timestamp": "2011-12-02 17:28:37 UTC"
    "data": {
      "cpu1": 2.3,
      "cpu2": 1.2,
      "cpu3": 0.0,
      "cpu4": 12.1
    },
    ...
  } ]
}
```

Creating Reports

The HTTP POST method is used to create **Reports**. Operations are available to create reports with or without historical datapoints.

[Quick reference](#)

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

Create Report

[URLs and parameters](#)

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Request body](#)

To create a report, several fields are required as documented in [Fields: Reports on page 2455](#).

The request body below shows all the fields that are available during report creation.

JSON request body

```
{
  "name": "cpu-util",
  "description": "An example report on cpu utilization",
  "consolidationFunction": "average",
  "datapointDuration": 15,
  "minimumSampleSize": 1,
  "reportSize": 2,
  "keepSamples": true,
  "reportDocumentSize": 1024,
  "datapoints": [
    {
      "startDate": "2011-12-01 19:16:57 UTC",
      "endDate": "2011-12-01 19:16:57 UTC",
      "data": {
        "time": 30,
        "util": 99.98
      }
    }
  ]
}
```

[Sample response](#)

```
{
  "messages": ["Report cpu-util created"],
  "id": "3efe5c670be86ba8560397ff",
  "name": "cpu-util"
}
```

Samples

```
POST http://localhost:8080/mws/rest/reports?api-version=3 (Minimal report without datapoints)
```

```
{
  "name": "cpu-util",
  "datapointDuration": 15,
  "reportSize": 2
}
```

Creating Samples

The HTTP POST method is used to create samples for **Reports**.

Quick reference

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

Create Samples for Report

URLs and parameters

```
POST http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3
POST http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the report.
name	Yes	String	--	The name of the report.

i Only one of **id** or **name** are required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

To create samples for a report, simply send data and an optional timestamp to the URL above. The request body below shows all the fields that are available during sample creation. Note that the `data` field can contain arbitrary JSON.

JSON request body

```
{
  "timestamp": "2011-12-01 19:16:57 UTC",
  "agent": "my agent",
  "data": {
    "cpu1": 2.3,
    "cpu2": 1.2,
    "cpu3": 0.0,
    "cpu4": 12.1
  }
}
```

Sample response

```
{"messages": ["1 sample(s) created for report cpu-util"]}
```

Deleting Reports

The HTTP DELETE method is used to delete **Reports**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/reports/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

Delete Report

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/reports/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the report.
name	Yes	String	--	The name of the report.

 Only one of **id** or **name** are required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{"messages": ["Report cpu-util deleted"]}
```

Getting Reservations

The HTTP GET method is used to retrieve **Reservation** information. Queries for all objects and a single object are available.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

[Restrictions](#)

Only admin or user reservations are returned with this call.

Get All Reservations

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/reservations?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

```
GET http://localhost:8080/mws/rest/reservations?api-version=3&fields=id
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "system.1"},
    {"id": "system.2"},
    {"id": "system.3"}
  ]
}
```

Get Single Reservation

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

Creating Reservations

The HTTP POST method is used to create **Reservations**.

Quick reference

```
POST http://localhost:8080/mws/rest/reservations?api-version=3
```

Create Reservation

URLs and parameters

```
POST http://localhost:8080/mws/rest/reservations?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

The request body below shows all the fields that are available when creating a **Reservation**, along with some sample values.

JSON request body

```
{
  "accountingAccount": "",
  "accountingGroup": "",
  "accountingQOS": "",
  "accountingUser": "root",
  "aclRules": [ {
    "affinity": "POSITIVE",
    "comparator": "LEXIGRAPHIC_EQUAL",

    "other2": 42
  },
  "startDate": "2011-11-14 20:15:50 UTC",
  "subType": "Other",
  "trigger": {
    "eventType": "START",
    "actionType": "EXEC",
    "action": "date"
  },
  "variables": {
```

```

    "var1": "val1",
    "var2": "val2"
  }
}

```

This example is to create a reservation if no conflicting reservations are found. (This is the equivalent to `mrsvctl -c -h node01 -E.`)

JSON request body

```

{
  "flags": [
    "DEDICATEDRESOURCE"
  ],
  "hostListExpression": "node01"
}

```

[Sample response](#)

JSON Response for successful POST

```

{"id": "system.44"}

```

Modifying Reservations

The HTTP PUT method is used to modify **Reservations**.

[Quick reference](#)

```

PUT http://localhost:8080/mws/rest/reservations/<id>?api-version=3&change-
mode=<add|remove|set>

```

Modify Reservation

[URLs and parameters](#)

```

PUT http://localhost:8080/mws/rest/reservations/<id>?api-version=3&change-
mode=<add|remove|set>

```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.
change-mode	Yes	String	add remove set	<p>If add, add the given variables to the variables that already exist.</p> <p>If remove, delete the given variables from the variables that already exist.</p> <p>If set, replace all existing variables with the given variables.</p>

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

The request body below shows all the fields that are available when modifying a **Reservation**, along with some sample values.

JSON request body for reservation modify

```
{
  "variables": {
    "var1": "val1",
    "var2": "val2"
  }
}
```

Sample response

 This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```
{"messages":["reservation 'system.43' attribute 'Variable' changed."]}
```

Restrictions

You can change the ACL Rules on a reservation, but not using this resource. See [Create or Update ACL on page 1649](#).

Releasing Reservations

The HTTP DELETE method is used to release **Reservations**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Release Reservation

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
JSON Response for successful DELETE
```

```
{}
```

Roles

This section describes behavior of the **Role** resource in Moab Web Services. The role resource is used to control access to MWS resources based on the proxy-user. Each role is attached to a principal and contains a list of proxy-user permissions that the group can use in MWS. This section describes the URLs, request bodies, and responses delivered to and from MWS.

 The **Fields: Roles** reference section contains the type and description of all fields in the **Role** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/roles	Get All Roles	--	Create Single Role	--
/rest/roles/<id>	Get Single Role	Modify Single Role	--	Deleting Roles
/rest/roles/<name>	Get Single Role	Modify Single Role	--	Delete Single Role

This topic contains these sections:

 - [Delete Single Role on page 1870](#)

Getting Roles

The HTTP GET method is used to retrieve **Role** information. You can query all objects or a single object.

Quick reference

```
GET http://localhost:8080/mws/rest/roles?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
GET http://localhost:8080/mws/rest/roles/<id>?api-version=3
GET http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Get All Roles

URLs and parameters

```
GET http://localhost:8080/mws/rest/roles?api-version=3[&query={"field":"value"}&sort=
{"field":<1|-1>}]
```

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	Queries for specific results. It is possible to query roles by one or more fields based on MongoDB query syntax .	query={ "name": "Acme-User-Role" }
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending.	sort={ "name": -1 }

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/roles?api-version=3&fields=id,name

{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "4fa197e68ca30fc605dd1cf0",
    "name": "Acme-User-Role"
  } ]
}
```

Sorting and querying

See the sorting and querying sections of [Global URL Parameters on page 1622](#).

Get Single Role

URLs and parameters

```
GET http://localhost:8080/mws/rest/roles/<id>?api-version=3
GET http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Role.
name	Yes	String	--	The name of the Role.

i You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/roles/Acme-User-Role?api-version=3
-----

{
  "description" : "This is a role for normal users in the Acme BU Group.",
  "id" : "5022e695e4b073f54e47c28d",
  "name" : "Acme-User-Role",
  "permissions" : [ {
    "action" : "create",
    "description" : "The permission to create all charts.",
    "id" : "5022e695e4b073f54e47c28e",
    "label" : "Create Chart",
    "resource" : "chart",
    "resourceFilter" : null,
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "read",
    "description" : "The permission to view all charts.",
    "id" : "5022e695e4b073f54e47c28f",
    "label" : "View Chart",
    "resource" : "chart",
    "resourceFilter" : null,
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "update",
    "description" : "The permission to modify the africa chart.",
    "id" : "5022e695e4b073f54e47c290",
    "label" : "Modify Africa Chart",
    "resource" : "chart",
    "resourceFilter" : {
      "name" : "africa"
    },
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "read",
    "description" : "The permissions to view John's services.",
    "id" : "5022e695e4b073f54e47c291",
    "label" : "Read John's services",
    "resource" : "services",
    "resourceFilter" : {
      "user": "john"
    },
    "type" : "api",
    "scope" : "GLOBAL",
    "version" : 0
  } ],
  "version" : 2
}
```

Creating Roles

The HTTP POST method is used to submit **Roles**.

[Quick reference](#)

```
POST http://localhost:8080/mws/rest/roles?api-version=3
```

Create Single Role

[URLs and parameters](#)

```
POST http://localhost:8080/mws/rest/roles?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Request body](#)

i The **name** field is required and must contain only letters, digits, periods, dashes, and underscores.

The following is an example of a request body to create a role:

```
POST http://localhost:8080/mws/rest/roles?api-version=3
-----
{
  "name" : "Acme-User-Role",
  "description" : "This is a role for normal users in the Acme BU Group.",
  "permissions" :
  [
    {
      "id" : "4fa197e68ca30fc605dd1cf0"
    },
    {
      "id" : "4fa197e68ca30fc605dd1df2"
    }
  ]
}
```

[Sample response](#)

If the request was successful, the response body is the new role that was created, exactly as shown in [Get Single Role](#). On failure, the response is an error message.

[Samples](#)

The **permissions** field only expects an array of permission IDs, as shown in the following example:

Example payload of role with 2 permissions

```
{
  "name" : "Acme-User-Role",
  "description" : "This is a role for normal users in the Acme BU Group.",
  "permissions" :
  [
    {
      "id" : "4fa197e68ca30fc605dd1cf0"
    }
  ]
}
```

Modifying Roles

The HTTP PUT method is used to modify **Roles**.

Quick reference

```
PUT http://localhost:8080/mws/rest/roles/<id>?api-version=3
PUT http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Modify Single Role

URLs and parameters

```
PUT http://localhost:8080/mws/rest/roles/<id>?api-version=3
PUT http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Role.
name	Yes	String	--	The name of the Role. <div> The name field must contain only letters, digits, periods, dashes, and underscores.</div>
change-mode	No	String	add remove set (default)	If add , adds the given permissions to the permissions that already exist. If remove , deletes the given permissions from the permissions that already exist. If set , adds the given permissions and deletes the permissions that already exist.

 You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Example request

```
PUT http://localhost/mws/rest/role/Acme-User-Role?change-mode=add?api-version=3
-----
{
    "permissions": [{"id": "4fa197e68ca30fc605dd1cf0"} ]
}
```

Sample response

If the request was successful, the response body is the modified role as shown in [Get Single Role](#). On failure, the response is an error message.

Deleting Roles

The HTTP DELETE method is used to delete **Roles**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/roles/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Delete Single Role

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/roles/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Role.
name	Yes	String	--	The name of the Role.

i You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```

Services

This section describes the behavior of a **Service** (an interdependent collection of workflows). It is possible for a **Service** to be composed of multiple Services. This section describes the URLs, request bodies, and responses delivered to and from Moab Web Services for each approach.

Services are tenant objects. If you have implemented a multi-tenant environment (see [About Tenants on page 1602](#) for more information) and are logged in with an application account, you must include a `proxy-user` with each service call to limit the results to information that the user has permission to see. If you are logged in with an LDAP account, MWS will automatically limit the results to information that the LDAP user has permission to see. For more information, see [Roles on page 1864](#).

i Moab Web Services reports a service's lifecycle, or a series of phases that a service goes through. The lifecycle allows you to follow the service's tracking job(s) in Moab as certain events occur. Services change phases as Moab enforces policies and as users request changes. For instance, you can choose to migrate, unblock, or terminate a service and trigger a phase change. Knowing a service's current phase lets you determine not only when a service has failed, but what might have caused it. For more information, see "" in the *Moab Cloud Suite 7.5.0 Installation Guide*.

The events that cause phase transitions to occur have a feature called phase hooks that you can use to run scripts during phase transitions. For instance, if you want to receive an email alert when a service becomes blocked, you can write a script that will send the email and attach it to an individual service, a service template, or globally on all services that will be created. You would then set the hook on the "block" event so that it runs whenever the service experiences this event. For more information, see the "[Creating Service Lifecycle Phase Hooks on page 1928](#)" section of this page.

i The [Fields: Services](#) reference section contains the type and description of all fields in the **Service** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/services	Services	--	Create Custom Service Create Service from Service Template	--
/rest/services/<id>	Get Single Service	Modify Service	--	Delete Service

Getting Service Information

The HTTP GET method is used to retrieve **Service** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/services?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}&[show-recursive-vc|show-vc]=true]]
GET http://localhost:8080/mws/rest/services/<id>?api-version=3[&[show-recursive-
vc|show-vc]=true&recursive=true]
GET http://localhost:8080/mws/rest/services/<name>?api-version=3[&[show-recursive-
vc|show-vc]=true&recursive=true]
GET http://localhost:8080/mws/rest/services/<id>/root?api-version=3[&[show-recursive-
vc|show-vc]=true&recursive=true]
GET http://localhost:8080/mws/rest/services/<name>/root?api-version=3[&[show-
recursive-vc|show-vc]=true&recursive=true]
GET http://localhost:8080/mws/rest/services/vms/<vmId>?api-version=3[&[show-recursive-
vc|show-vc]=true&recursive=true]
```

Get All Services

URLs and parameters

```
GET http://localhost:8080/mws/rest/services?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}&[show-recursive-vc|show-vc]=true]]
```

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	Query for specific results. It is possible to query services by one or more fields based on MongoDB query syntax .	<code>query={"type":"storage","label":"exlabel"}</code>
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending.	<code>sort={"account":-1}</code>
show-recursive-vc	No	Boolean	true or false	true shows extended details about the service's virtual container including nested virtual containers and nested jobs. Default is false.	<code>show-recursive-vc=true</code>
show-vc	No	Boolean	true or false	true shows details about the service's virtual container. Default is false.	<code>show-vc=true</code>

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/services?api-version=3&query={user:"bob"}
-----
```

      }
    },
    "id": "4edff0cc6852f709fa777828"
  }
]
}

```

Querying services

It is possible to query services by one or more fields based on [MongoDB query syntax](#).

Simple queries

- To see only services that are associated with the user "bob" you can use a query such as the following:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":"bob"}
```

- To see only services that are of type "vm":

```
http://localhost:8080/mws/rest/services?api-version=3&query={"type":"vm"}
```

- To see only bob's vm services:

```
http://localhost:8080/mws/rest/services?api-version=3&query={
  "user":"bob", "type":"vm"}
```

- To see only services that are NOT associated with bob:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":
{"$ne":"bob"}}
```

More complex queries

- When the field values of the desired services are a finite set, you can use the \$in operator. For example, to see services that belong to either bob, alice, or charlie, you can do the following:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":{"$in":
["alice","bob","charlie"]}}
```

- You can also query on embedded JSON objects within the service JSON. For example, to see services requesting 3 processors you can use:

```
http://localhost:8080/mws/rest/services?api-version=3&query=
{"attributes.moab.jobRequested.resources.procs":3}
```

Conditional operators

You can perform $<$, $<=$, $>$, $>=$ comparisons using the \$lt, \$lte, \$gt, \$gte operators.

Operator	Comparison
\$lt	<
\$lte	<=
\$gt	>
\$gte	>=

- To see services requesting < 2 processors:

```
http://localhost:8080/mws/rest/services?api-version=3&query=
{"attributes.moab.jobRequested.resources.procs":{"$lt":2}}
```

- To see services requesting >= 1024 memory:

```
http://localhost:8080/mws/rest/services?api-version=3&query=
{"attributes.moab.jobRequested.resources.mem":{"$gte":1024}}
```

Querying services by date

- To see all services created after February 8, 2012 at 1:00 PM Mountain Standard Time (MST):

```
http://localhost:8080/mws/rest/services?api-version=3&query={"dateCreated":
{"$gt":"2012-02-08 13:00:00 MST"}}
```

- To see services created before or on February 8, 2012 at 1:00 PM Pacific Standard Time (PST):

```
http://localhost:8080/mws/rest/services?api-version=3&query={"dateCreated":
{"$lte":"2012-02-08 13:00:00 PST"}}
```

- To see services created between 12:00 PM and 1:00 PM Eastern Standard Time (EST) on February 8, 2012:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"dateCreated":
{"$lte":"2012-02-08 13:00:00 EST","$gte":"2012-02-08 12:00:00 EST"}}
```

Querying services by containing service

Services can contain other services. When a service is contained within another service, you can find out what its container is by looking at the parent field. A service that is not contained in any other service is called a top level service. If you want to see only top level services you need to query for services with a null parent.

In MongoDB syntax you query for services whose parent field have a `$type` of **10** (with 10 representing null). The following query shows all of bob's top level services:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":"bob","parent":
{"$type":10}}
```

Once you have the top level service, you can find the direct child services:

```
http://localhost:8080/mws/rest/services?api-version=3&query=
{"user":"bob","parent":"bobService.1"}
```

Once you have the direct children, you can find the children of those children with a similar query.

Sorting

See the sorting section of [Global URL Parameters](#) on page 1622.

Limiting the number of results

- If you want to limit the number of results of services you can use the `max` parameter. For example, to see only 10 of bob's services:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":"bob"}&sort={"name":1}&max=10
```

- To see bob's services 91-100 when sorted by name in ascending order you can combine `max` with `offset` as follows:

```
http://localhost:8080/mws/rest/services?api-version=3&query={"user":"bob"}&sort={"name":1}&max=10&offset=90
```

Retrieving a subset of fields

To cause only certain fields to return for each service, use the `fields` parameter. For example, to show only the name field for each service:

```
http://localhost:8080/mws/rest/services?api-version=3&fields=name
```

This returns:

```
{
  "totalCount": 9,
  "resultCount": 3,
  "results": [
    {"name": "aliceService.1"},
    {"name": "machine0.1"},
    {"name": "OSStoremachine0.1"}
  ]
}
```

To show the name, type, and user:

```
http://localhost:8080/mws/rest/services?api-version=3&fields=name,type,user
```

This returns:

```
{
  "totalCount": 9,
  "resultCount": 3,
  "results": [
    {
      "name": "aliceService.1",
      "type": "container",
      "user": "alice"
    },
    {
      "name": "machine0.1",
      "type": "vm",
      "user": "alice"
    },
    {
      "name": "OSStoremachine0.1",
      "type": "storage",
      "user": "alice"
    }
  ]
}
```

Get Single Service

URLs and parameters

```
GET http://localhost:8080/mws/rest/services/<id>?api-version=3[&[show-recursive-vc|show-vc]=true]
GET http://localhost:8080/mws/rest/services/<name>?api-version=3[&[show-recursive-vc|show-vc]=true]
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the service. Must contain exactly 24 alphanumeric characters.	--
name	Yes	String	--	The name of the service.	--
show-recursive-vc	No	Boolean	true or false	true shows extended details about the service's virtual container including nested virtual containers and nested jobs. Default is false.	show-recursive-vc=true
show-vc	No	Boolean	true or false	true shows details about the service's virtual container. Default is false.	show-vc=true

Parameter	Required	Type	Valid values	Description	Example
recursive	No	Boolean	true or false	true shows details about all included services, including nested services. Default is false.	recursive=true

i Only one of **id** or **name** is required.

See [Global URL Parameters](#) on page 1622 for available URL parameters.

i If the service requested is a VM service and API version 2 is used, the full job and VM details will be returned in the `jobDetails` and `virtualMachineDetails` fields. The format of these fields match the full output of [Get Single Job](#) and [Get Single Virtual Machine](#). If Moab is not configured correctly to use API version 2, the request will fail just as it would with the **Job** and **Virtual Machine** resources if they were called directly.

These fields are also returned if a parent of a VM service is requested with the `recursive` flag set to true. This means that `children` services will also contain job and VM details if available.

Samples

- Typical service:

```
GET http://localhost:8080/mws/rest/services/bobService.1?api-version=3
```

```

```

- VM Service using API version 2:

i This output is using field selection for `id`, `name`, `attributes.moab.jobRequested.id`, `attributes.vmId`, `jobDetails.name`, and `virtualMachineDetails.name`—meaning not all of the output is shown. This example is simply to show the behavior of API version 2 with a VM service.

```
GET http://localhost:8080/mws/rest/services/vm3service.1?api-
version=3&fields=...
```

```
{
  "name": "vm3service",
  "attributes": {
    "moab": {
      "jobRequested": {
        "id": "Moab.9"
      }
    },
    "vmId": "vm3"
  },
  "id": "50f58eade4b03bfe59ca30c4",
  "jobDetails": {
    "name": "Moab.9"
  },
  "virtualMachineDetails": {
    "name": "vm3"
  }
}
```

Get Root Service

URLs and parameters

```
GET http://localhost:8080/mws/rest/services/<id>/root?api-version=3[&[show-recursive-
vc|show-vc]=true&recursive=true]
GET http://localhost:8080/mws/rest/services/<name>/root?api-version=3[&[show-
recursive-vc|show-vc]=true&recursive=true]
```

To see available URL parameters, see [Get Single Service](#) and [Global URL Parameters on page 1622](#).

Response

Returns the root service container for a specific service. The root service, sometimes referred to as the top level service, either directly or indirectly contains all other services in a service hierarchy.

For example, assume there are services **A**, **B**, **C**, **D**, **E**, **F**, and **G**. **A** contains **B** and **C**. **B** contains **D** and **E**. **C** contains **F** and **G**:

The root service of **A**, **B**, **C**, **D**, **E**, **F**, and **G** is **A**.

i In this example **A** is the root service of **A**.

Samples

```
GET http://localhost:8080/mws/rest/services/centos6Vm/root?api-
version=3&fields=name,type,includedServices
```

```
{
  "name": "centos6VmPlusStorage"
  "type": "container",
  "includedServices": [
    "centos6Vm",
    "centos6Storage"
  ]
}
```

Get Service for Virtual Machine

URLs and parameters

```
GET http://localhost:8080/mws/rest/services/vms/<vmId>?api-version=3 [&[show-recursive-
vc|show-vc]=true&recursive=true]
```

To see available URL parameters, see [Get Single Service](#) and [Global URL Parameters](#) on page 1622.

Response

Returns the service associated with a specific virtual machine. The service's `type` must be **vm** and the service's `attributes.vmId` must match the virtual machine's identifier (e.g "vm1").

i A maximum of one service should be associated with a virtual machine. If more than one service is associated with a virtual machine only one service will be displayed.

Samples

```
GET http://localhost:8080/mws/rest/services/vms/vm12?api-version=3&fields=name,type,attributes.vmId
```

```
{
  "name": "centos6Vm.12",
  "type": "vm",
  "attributes": {"vmId": "vm12"}
}
```

Creating Services

The HTTP POST method is used to create a **Service**.

Quick reference

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

i If you are logged in as an application account or LDAP user and submit a service without specifying the user, MWS considers the user as which you are logged in the user of the service.

Create Service from Service Template

URLs and parameters

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Simple case

i The **tenant** field is required and must contain only letters, digits, periods, dashes, and underscores. For POST and PUT actions, the tenant **name** or **ID**, or both the **name** and **ID** must be specified; if both the **name** and **ID** are specified, they must both refer to the same **tenant** or MWS returns an error.

- To create a service from the template named "Rhel54VmPlusStorage":

```
POST http://localhost:8080/mws/rest/services?api-version=3
-----
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "steve",
  "account": "cloud",
  "startDateRequested": "2013-07-19 13:18:47 MST",
  "durationRequested": 86400,
  "data": [
    {
      "label": "My RHEL 5.4 VM Plus Storage",
      "serviceTemplate": "Rhel54VmPlusStorage",
    }
  ]
}
```

Alternatively you can submit:

```
POST http://localhost:8080/mws/rest/services?api-version=3
-----
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "steve",
  "account": "cloud",
  "data": [
    {
      "label": "My RHEL 5.4 VM Plus Storage",
      "serviceTemplate": {
        "name": "Rhel54VmPlusStorage"
      }
    }
  ]
}
```

- To create a service based on the service template with id "4fbd2d90c4aa4996400bsa5m":

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "steve",
  "account": "cloud",
  "data": [
    {
      "label": "My RHEL 5.4 VM Plus Storage",
      "serviceTemplate": {
        "id": "4fbd2d90c4aa4996400bsa5m"
      }
    }
  ]
}
```

"name" and "label" fields

- The `name` field is deprecated in version 8.1.0. If it is set, it must be unique. However, if the `name` field is not set, a new UUID will be automatically generated for each service without a `name` value.
- The `label` field is required and must not be blank. However, if the `name` field is already specified by the client, it will be automatically used as the `label`.
- If neither `name` or `label` field is set during service creation, an error will occur.
- If the `label` field is not specified for a service, the `label` field from the service template will be inherited.

i Note that the `name` field must still be used for extending service templates and defining "included services."

Extending a service template

If you want to create a service from a service template, but wish to extend the service template with some additional variables or generic resources, you can use the `extends` field. Extending a service template is also helpful when you wish to override certain values, such as the amount of memory or processors the service requires.

To extend a service template, you will need to determine the `extends` path for the service you wish to override. The `extends` path is the name of the top level service, followed by one or more `localNames` as described in the `includedServices` field. All but the last **<localName>** are nested containers inside the top level container. For example:

```
<top_level_service_name>::<localName>[:<localName>]+
```

For example, suppose you want to create a new service from the "Rhel54VmPlusStorage" service template, and you want to name this new service "MyRhel54VmPlusStorage". In this example, "Rhel54VmPlusStorage" contains a service template named "SubContainer1". The `localName` for "SubContainer1" in the "Rhel54VmPlusStorage" `includedServices` field is "sc1".

```
Rhel54VmPlusStorage service template
-----
{
  "name":"Rhel54VmPlusStorage",
  "type":"container",
  ...
  "includedServices":[
    {
      "localName":"sc1",
      "serviceTemplate":"SubContainer1"
    }
  ]
}
```

The extends path for the instance of "SubContainer1" in your "MyRhel54VmPlusStorage" is:

```
MyRhel54VmPlusStorage::sc1
```

Let's say inside "SubContainer1" is another service template called "SubContainer2". The `localName` for "SubContainer2" as defined in the `includedServices` field for "SubContainer1" is "sc2".

```
SubContainer1 service template
-----
{
  "name":"SubContainer1",
  "type":"container",
  ...
  "includedServices":[
    {
      "localName":"sc2",
      "serviceTemplate":"SubContainer2"
    }
  ]
}
```

The extends path for the instance of "SubContainer2" in "MyRhel54VmPlusStorage" is:

```
MyRhel54VmPlusStorage::sc1:sc2
```

Now let's say that "SubContainer2" contains two service templates, "Rhel54Vm" and "OpsysStorage" with `localNames` "rvm" and "oss" respectively.

```
SubContainer1 service template
-----
{
  "name": "SubContainer2",
  "type": "container",
  ...
  "includedServices": [
    {
      "localName": "rvm",
      "serviceTemplate": "Rhel54Vm"
    },
    {
      "localName": "oss",
      "serviceTemplate": "OpSysStorage"
    }
  ]
}
```

The extends paths for the instances of "Rhel54Vm" and "OpSysStorage" in "MyRhel54VmPlusStorage" are:

```
MyRhel54VmPlusStorage::sc1:sc2:rvm
MyRhel54VmPlusStorage::sc1:sc2:oss
```

Now that we have the extends paths for all the services that will be created from the "Rhel54VmPlusStorage" template, we can add variables to these services that were not in the service templates.

i In the following example, the specified tenant must match the tenant in the corresponding service template.

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "steve",
  "account": "cloud",
  "data": [
    {
      "name": "MyRhel54VmPlusStorage",
      "serviceTemplate": "Rhel54VmPlusStorage",
      "attributes": {
        "sharedData": { "extraAttribute": "some attribute not in the
Rhel54VmPlusStorage template" }
      }
    },
    {
      "name": "MyRhel54Vm",
      "extends": "MyRhel54VmPlusStorage::sc1:sc2:rvm",
      "attributes": {
        "moab": { "job": { "variables": { "extraVar": "An additional variable not in
the Rhel54Vm template" } } },
        "sharedData": { "extraAttribute": "some attribute not in the Rhel54Vm
template" }
      }
    },
    {
      "name": "MyOsStorage",
      "extends": "MyRhel54VmPlusStorage::sc1:sc2:oss",
      "attributes": {
        "moab": { "job": { "variables": { "extraVar2": "An additional variable not in
the OpSysStorage template" } } },
        "sharedData": { "extraAttribute": "some attribute not in the OpSysStorage
template" }
      }
    }
  ]
}
```

When the "MyRhel54Vm" service is created, it will have a variable named "extraVar" even though this variable was not defined in the "Rhel54Vm" service template. Likewise, when the "MyOsStorage" service is created, it will have a variable named "extraVar2", even though no such variable was defined in the "OsStorage" service template. All three services will have an attribute named "extraAttribute" in their `attributes.sharedData` sections though "extraAttribute" does not appear in any service template.

Extending services and dependencies in a container service

To add a services to a container service that were not in the container's service template you first define the new services in the service request. Then you extend the `includedServices` field of the container with the newly defined services. This will add the new services to any that are already in the container as defined in the service template. It is only possible to add services to a

container. It is not possible to remove services from a container that were defined in the container's service template.

For example, say the CentosVmPlusStorage service template contains an OpSysStorage service template and a CentosVm service template.

```
CentosVmPlusStorage service template
-----
{
  "name": "CentosVmPlusStorage",
  "type": "container",
  ...
  "includedServices": [
    {
      "localName": "oss",
      "serviceTemplate": "OpSysStorage"
    },
    {
      "localName": "cvm",
      "serviceTemplate": "CentosVm"
    }
  ]
}
```

To add two storage services to the service created from the CentosVmPlusStorage service template submit the following service request:

```
POST http://localhost:8080/mws/rest/services?api-version=3
-----
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "bob",
  "account": "cloud",
  "data": [
    {
      "name": "BobsCentosVmPlusStorage",
      "serviceTemplate": "CentosVmPlusStorage",
      "includedServices": [
        "NewStorageToAdd1",
        "NewStorageToAdd2"
      ]
    },
    {
      "name": "NewStorageToAdd1",
      "serviceTemplate": "ExtraStorage"
    },
    {
      "name": "NewStorageToAdd2",
      "serviceTemplate": "ExtraStorage"
    }
  ]
}
```

The resulting service BobsCentosVmPlusStorage will contain NewStorageToAdd1, NewStorageToAdd2, a service created from the

OpSysStorage template, and a service created from the CentosVm template. To add a dependency such that the CentosVm service will not be able to start until both NewStorageToAdd1 and NewStorageToAdd2 have been set up:

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "bob",
  "account": "cloud",
  "data": [
    {
      "name": "BobsCentosVmPlusStorage",
      "serviceTemplate": "CentosVmPlusStorage",
      "includedServices": [
        "NewStorageToAdd1",
        "NewStorageToAdd2"
      ],
      "stepsCompleted": [],
      "hookDefinitions": [],
      "attributes": {
        "moab": {
          "dependencies": [
            {
              "service": "BobsCentosVm",
              "dependency": [
                "NewStorageToAdd1",
                "NewStorageToAdd2"
              ]
            }
          ]
        }
      }
    },
    {
      "name": "BobsCentosVm",
      "extends": "CentosVmPlusStorage:cvm"
    },
    {
      "name": "NewStorageToAdd1",
      "serviceTemplate": "ExtraStorage"
    },
    {
      "name": "NewStorageToAdd2",
      "serviceTemplate": "ExtraStorage"
    }
  ]
}
```

Extendable fields

You can only extend certain fields. Below is a table of fields that can be extended:

Extendable fields	Notes
attributes.moab.dependencies	Dependencies can be added but not removed. Only applicable to containers.
attributes.moab.job.features	Features can be added but not removed.
attributes.moab.job.nodeSet	Overrides the nodeSet from the service template.
attributes.moab.job.requestedHosts	Hosts can be added but not removed.
attributes.moab.job.resources	Including procs, mem, disk, and any generic resource.
attributes.moab.job.rules	Overrides all rules from the service template.
attributes.moab.job.variables	Can either change the value of variables in the template or add new variables.
attributes.sharedData	A place for arbitrary, site-specific data.
image	
includedServices	Services can be added but not removed. Only applicable to containers.
label	

Sample response

If the request was successful, the response includes the unique ID of the new **Service**. On failure, the response is an error message.

JSON response

```
{"name": "MyRhel54VmPlusStorage.1"}
```

Create Custom Service

URLs and parameters

```
POST http://localhost:8080/mws/rest/services
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

 The **tenant** field is required and must contain only letters, digits, periods, dashes, and underscores.

The payload below shows all the fields that are available during service submission.

```
POST http://localhost:8080/mws/rest/services?api-version=3
```

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "user": "adaptive",
  "account": "cloud",
  "startDateRequested": "2011-11-08 13:18:47 MST",
  "durationRequested": 86400,
  "data": [
    {
      "name": "myNewService",
      "type": "container",
      "label": "My New Service",
      "includedServices": [
        "myVmContainer",
        "myNetworkStorageWorkflow",
        "myPmContainer"
      ],
      "stepsCompleted": [],
      "hookDefinitions": []
    }
  ]
}
```

```

              "OS":2500
            }
          }
        }
      }
    },
    {
      "name":"myNetworkStorageWorkflow",
      "label":"My VM Container",
      "type":"storage",
      "includedServices":[

      ],
      "stepsCompleted": [],
      "hookDefinitions": [],
      "attributes":{
        "moab":{
          "job":{
            "template":"extraStorage",
            "resources":{
              "gold":500
            },
            "variables":{
              "mount":"/path/to/mount"
            }
          }
        }
      }
    },
    {
      "name":"myPmContainer",
      "label":"My PM Container",
      "type":"container",
      "includedServices":[
        "myPmWorkflow"
      ],
      "stepsCompleted": [],
      "hookDefinitions": []
    },
    {
      "name":"myPmWorkflow",
      "label":"My PM Workflow",
      "type":"pm",
      "includedServices":[

      ],
      "stepsCompleted": [],
      "hookDefinitions": [],

```

```

    "attributes":{
      "moab":{
        "job":{
          "resources":{
            "procs":2,
            "mem":2048,
            "disk":100
          },
          "variables":{
            "QOS":"Premium"
          },
          "image":"centos5.5-stateless",
          "template":"genericPM"
        }
      }
    }
  ]
}

```

i The `name` field must still be used when extending service templates and defining "included services." For more information, see ["name" and "label" fields on page 1900](#).

Sample response

If the request was successful, the response includes the unique ID of the new **Service**. On failure, the response is an error message.

JSON response

```
{"name":"myNewService.1"}
```

Service Inheritance

Child services can inherit certain attributes from parent (or grandparent) services. Inheritance happens when a child service's attribute is a null value and when one of its parent service's attribute is a non-null value. When a service is created from a service template, inheritance happens after any extensions. In other words, fields from the service template are overridden by corresponding fields in the service before inheritance occurs.

Currently, `attributes.moab.job.nodeSet` and `attributes.moab.job.rules` are the only attributes that support inheritance.

NodeSet inheritance

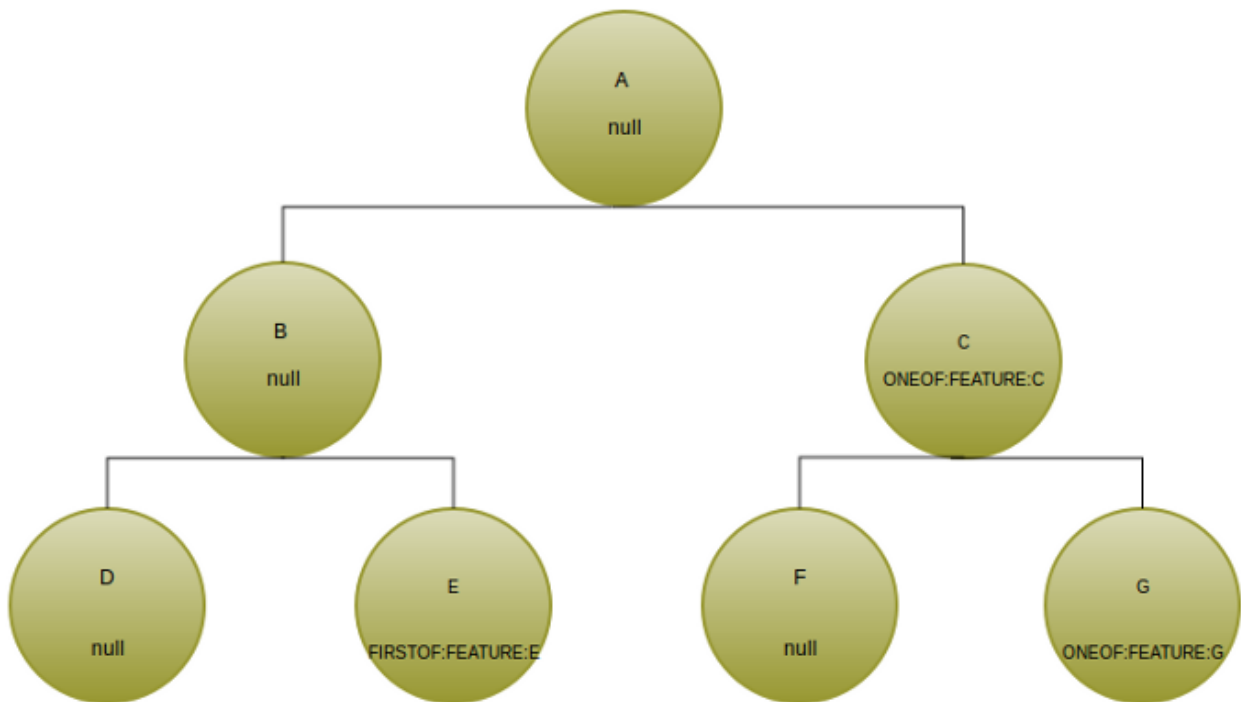

If a child service's `attributes.moab.job.nodeSet` field is null, it inherits the nodeSet values from its nearest parent that has a nodeSet value (anything non-null). This means that a child service will inherit a nodeSet value from its parent *if, and only if*, its nodeSet value is null, and the parent's nodeSet value is not null. If the parent service's value is also null, the child service will inherit the

nodeSet value from the grandparent service; if the grandparent's service value is null, the child service will inherit the nodeSet value from the great-grandparent service, and so on.

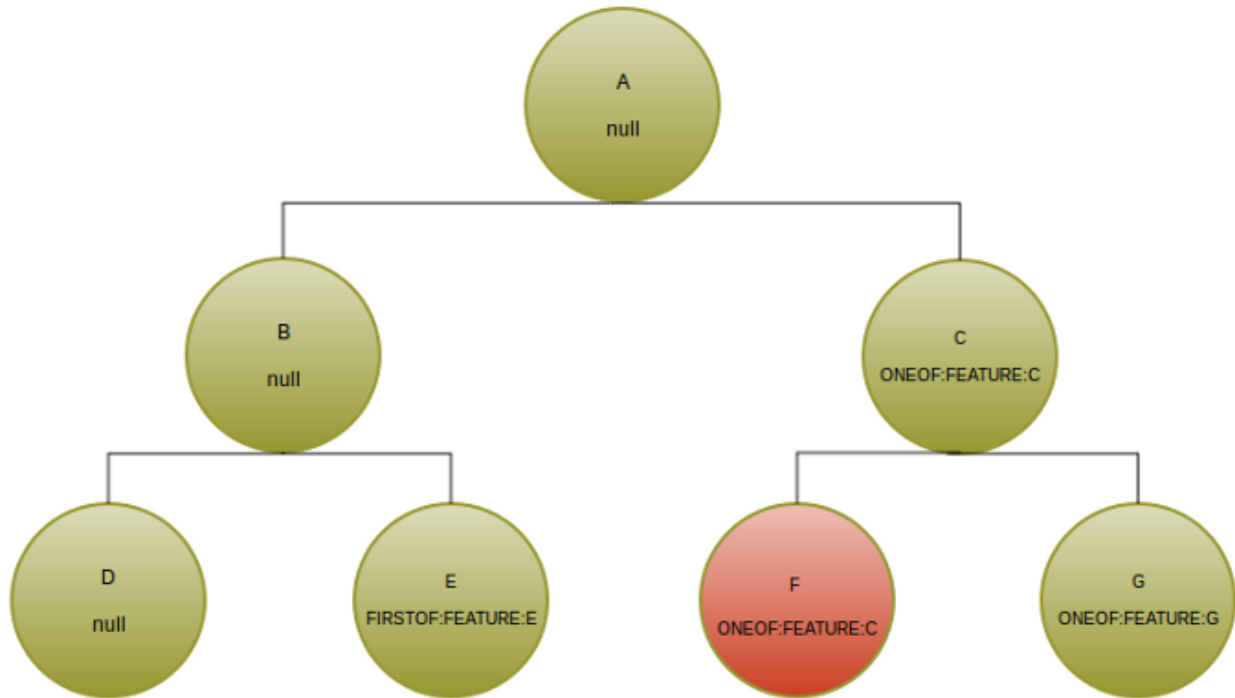

If all parent services have a null value, then the child service retains its null value (as there is nothing it can possibly inherit).

i It is possible for a nodeSet field to be an empty object. Even though the object is empty, it is considered to be a non-null value, and any child services with a null value will inherit the empty rules object from its parent service.

The following diagram shows a service hierarchy *before* any nodeSet values are inherited. Note that service **A**, the top-level or "grandparent" service, has a null nodeSet value.

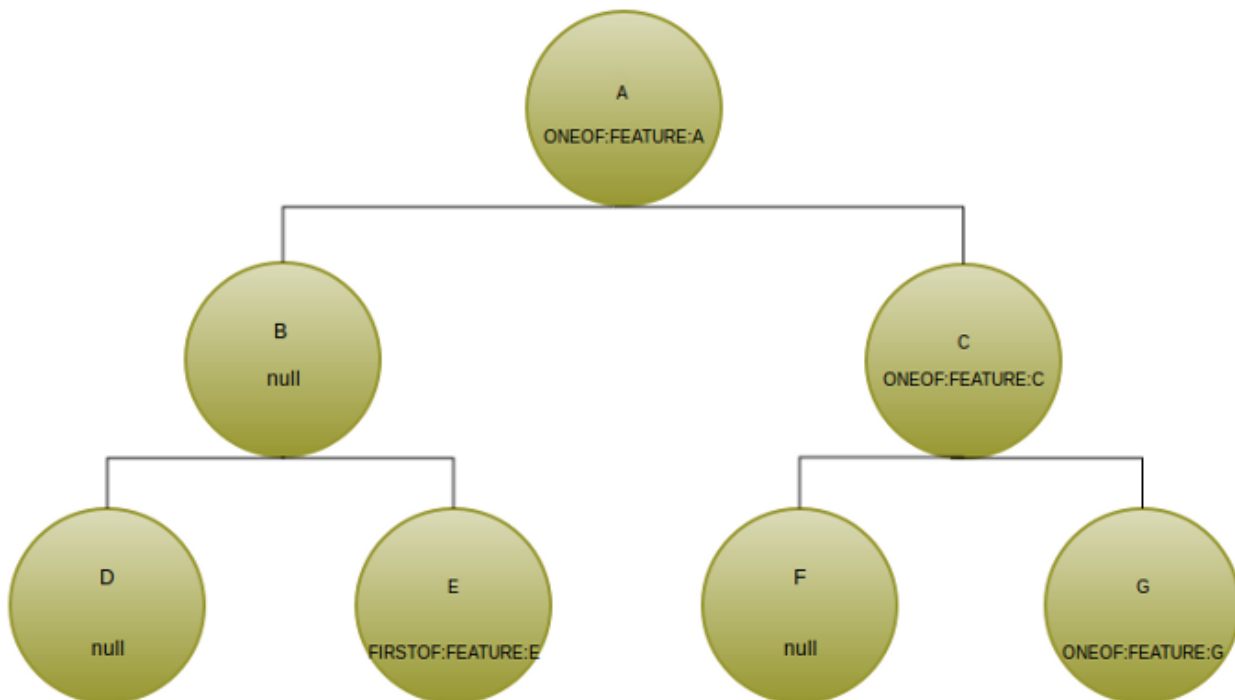

Once nodeSet values are inherited, the services will change as follows:

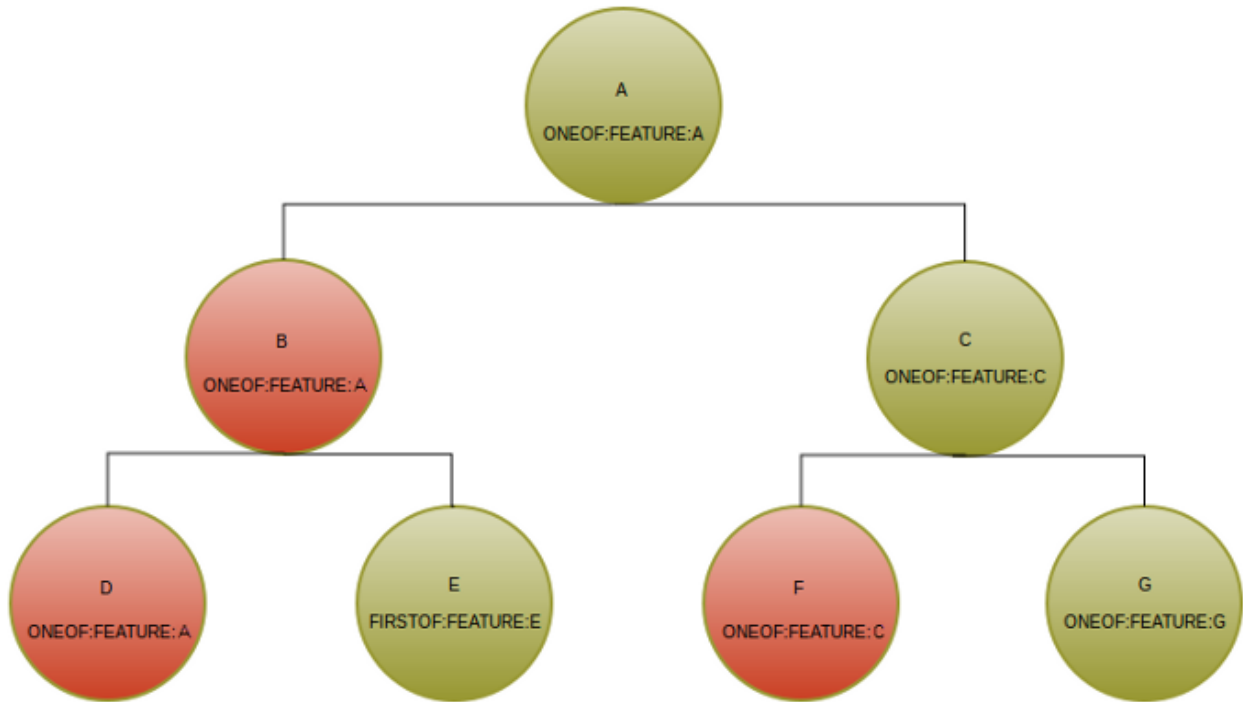

Services **B** and **D** remain unchanged, because they have no parent services with a non-null nodeSet value. However, note that service **F** has inherited service **C**'s nodeSet value. This is because service **F** previously had a null value, but its parent service, service **C**, had a non-null value (`ONEOF:FEATURE:C`).

Let's look at another example.

In this example, note that service **A**—the grandparent service—has a non-null nodeSet value (`ONEOF:FEATURE:A`).

Note that two things happened after inheritance occurred:

1. Service **B** inherited service **A**'s nodeSet value (`ONEOF:FEATURE:A`). Service **D** then inherited the same nodeSet value from service **B**.
2. Service **F** inherited service **C**'s nodeSet value (`ONEOF:FEATURE:C`). Note that it did not inherit service **A**'s nodeSet value. This is because a child service inherits the non-null nodeSet value from its nearest parent.

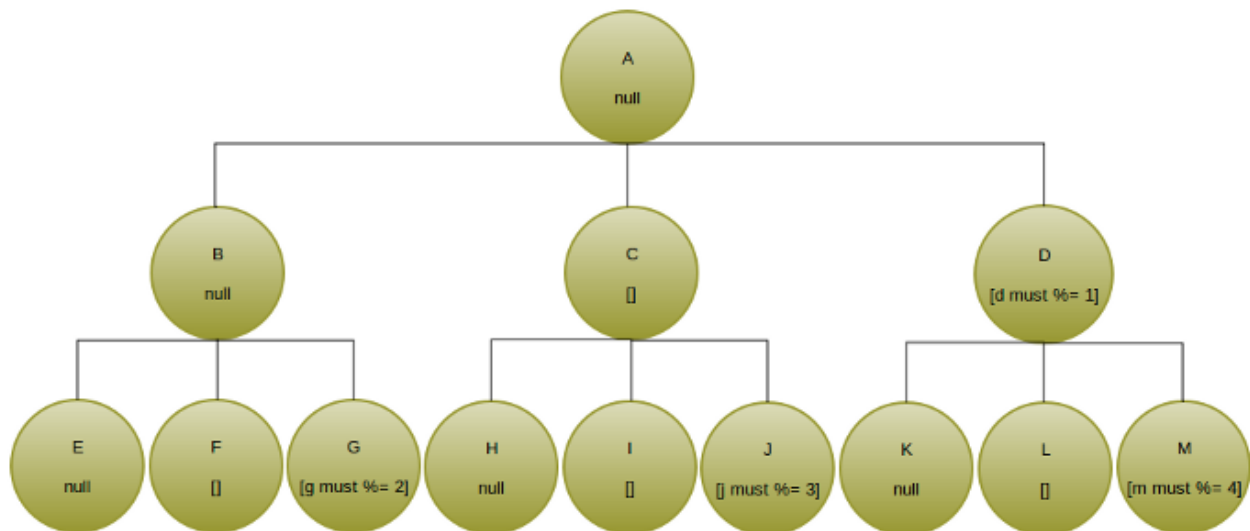

Rules inheritance

Similar to the way child services inherit nodeSet values, child services also inherit rules values. If a service's `attributes.moab.job.rules` field is null, it inherits the rules values from its nearest parent that has a rules value (i.e. a non-null value). This means that a child service will inherit a rules value from its parent *if, and only if*, its rules value is null, and the parent's rules value is not null.

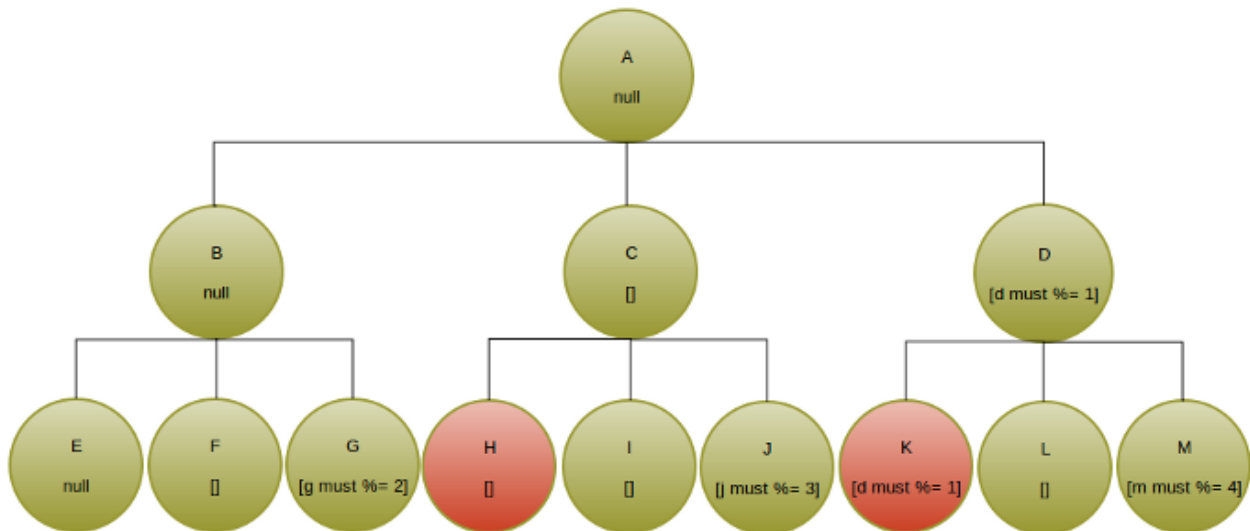

If all parent services have a null value, then the child service retains its null value (as there is nothing it can possibly inherit).

i It is possible for a rules field to be an empty object. Even though the object is empty, it is considered to be a non-null value, and any child services with a null value will inherit the empty rules object from its parent service.

The following diagram shows a service hierarchy *before* any rules values are inherited. Empty brackets (`[]`) indicate an empty rules object. Remember that an empty rules object is considered to be a non-null value.

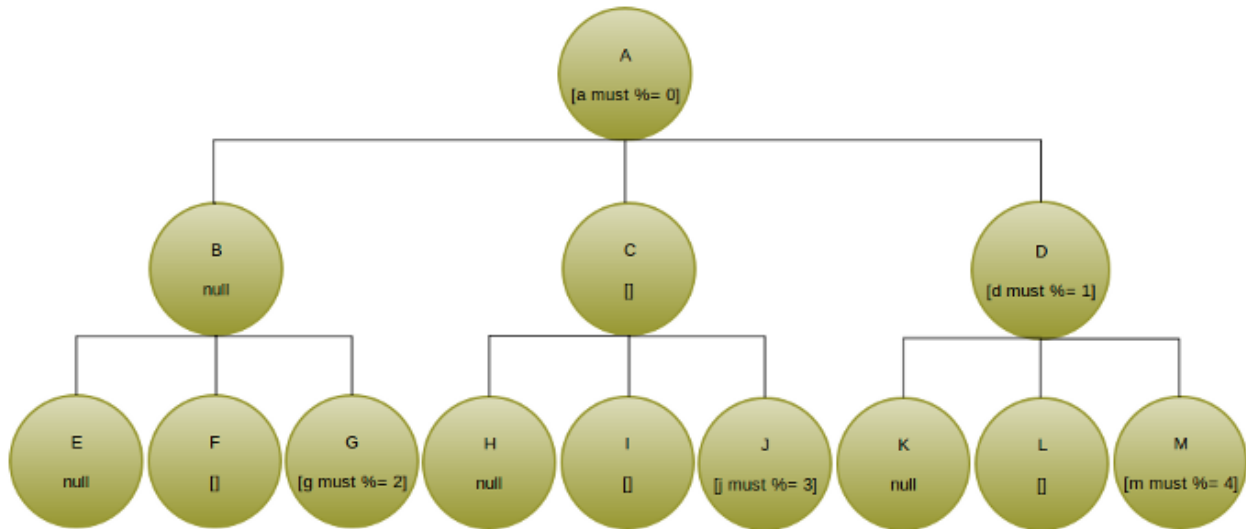

Once the rules values are inherited, the services change, as follows:

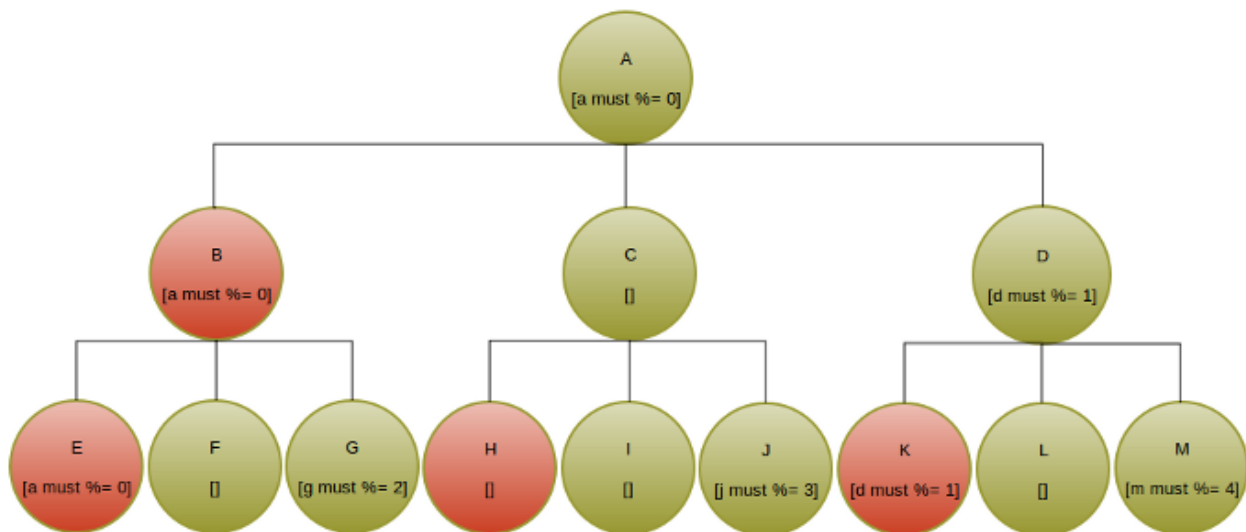

Three things of note occurred with inheritance:

1. Services **B** and **E** remain unchanged, because their parent (service **A**), has a null value.
2. Service **K** inherited the rules value from its parent, service **D**, (`[d must %= 1]`).
3. Service **H** inherited the empty list value from its parent, service **C**. This is because an empty object is still considered a non-null value.

Let's look at another example.

In this example, service **A** has a non-null rules value (`[a must %= 0]`). Once the rules values are inherited, the services change, as follows:

Two things of note occurred with inheritance:

1. Services **B** and **E** both inherit service **A**'s rules value.
2. Service **H** still inherited service **C**'s value, and service **K** still inherited service **D**'s value. This is because a child service inherits the non-null rules value from its nearest parent.

Modifying or Moving Services

The HTTP PUT method is used to modify **Services**.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/services/<id>?api-version=3&change-
mode=<add|remove|set>
PUT http://localhost:8080/mws/rest/services/<name>?api-version=3&change-
mode=<add|remove|set>
PUT http://localhost:8080/mws/rest/services/<id|name>/unblock?api-version=3
PUT http://localhost:8080/mws/rest/services/<id|name>/terminate?api-version=3
```

Modify Service

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/services/<id>?api-version=3&change-
mode=<add|remove|set>
PUT http://localhost:8080/mws/rest/services/<name>?api-version=3&change-
mode=<add|remove|set>
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the Service.
name	Yes	String	--	The name of the Service.
change-mode	No	String	add remove set	If add , add the specified steps or hook definitions to existing ones. If remove , remove the specified steps or hook definitions from existing ones. If set , replace all steps or hook definitions with the ones specified.

Only one of **id** or **name** is required.

The **change-mode** parameter only applies to the `stepsCompleted` and `hookDefinitions` fields.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Example request](#)

Only the `attributes`, `status`, `statusCode`, and `label` fields may be modified in services. Note that the `status` and `label` fields must be a valid string, and the `statusCode` field must be a valid number (long). Any arbitrary string and number may be used to represent the current state of the service through `status` and `statusCode` respectively.

```
PUT http://localhost:8080/mws/rest/services/myStorageService?api-version=3
```

```
{
  "label": "My Service",
  "status": "Done provisioning!",
  "statusCode": 200,
  "attributes": {
    "mount": "/mnt/myMount",
    "size": "2500",
    "sharedData": {
      "extraAttribute": "Some arbitrary value",
      "extraAttribute2": "Another arbitrary value"
    }
  }
}
```

i The `moab` element of attributes cannot be modified. An error will be returned if this is attempted.

}

```

Move Service

Moving a service is a matter of updating an existing service. The following requirements must be met to move a service:

1. The specified service must be a container service.
2. The destination tenant must exist.
3. The user requesting the move must have global update service permission or update service permissions for both the current tenant and the new tenant.

Moving a service moves that service and all its child services, plus all associated jobs and VMs. Jobs and VMs should automatically migrate to the new tenant's node(s) but may not due to resource availability, policies, and so forth.

i Services that contain storage or physical machines as part of the service will not move as intended and your service will not work as intended. Do not use this option on services that contain storage or physical machines.

Sample request

```
PUT http://localhost:8080/mws/rest/services/<serviced-id-or-name>?api-version=3
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "ResearchGroup"
  }
}
```

Unblock a Service

URLs and parameters

```
PUT http://localhost:8080/mws/rest/services/<id|name>/unblock?api-version=3
```

Response

Returns a list of actions Moab took to unblock the service.

Sample response

```
PUT http://localhost:8080/mws/rest/services/genericVM/unblock?api-version=3
[
  "requeued completed job 'Moab.3.genericVM-setup'"
]
```

i If a job in the service workflow cannot be requeued, MWS will return an error message to explain why it failed. If the service is not blocked when this call is made, MWS returns an error that says there is nothing to unblock.

Terminate a Service

URLs and parameters

```
PUT http://localhost:8080/mws/rest/services/<id|name>/terminate?api-version=3
```

Response

Ends a service's normal lifecycle but does not delete it.

Sample response

```
PUT http://localhost:8080/mws/rest/services/genericVM/terminate?api-version=3
[
  "terminated job 'Moab.1.genericVM-setup'",
  "terminated job 'Moab.2.genericVM-setup'",
  "terminated job 'Moab.4.genericVM-destroy'",
  "terminated job 'Moab.3.genericVM-setup'"
]
```

Deleting Services

The HTTP DELETE method is used to delete **Services**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/services/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/services/<name>?api-version=3
```

i If you delete a service without specifying who deleted it, MWS considers the deleter of the service the user as which you are logged in

Delete Service

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/services/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/services/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description	Example
force-delete	No	Boolean	true or false	If true MWS will not check service dependencies before deleting it.	--
id	Yes	String	--	The unique identifier of the Service.	--
name	Yes	String	--	The name of the Service.	--

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{}
```

Getting Service Lifecycle Phase Hook Information

The HTTP GET method is used to retrieve information about all global service hooks and all running service hooks (**global-definitions**, and **running**, respectively.). You may also query for all hooks on a single service (**definitions**).

Quick reference

```
GET http://localhost:8080/mws/rest/services/hooks/global-definitions?api-version=3
GET http://localhost:8080/mws/rest/services/hooks/running?api-version=3
GET http://localhost:8080/mws/rest/services/<id>|<name>/hooks/definitions?api-version=3
```

Get All Global Hook Definitions

URLs and parameters

See [Global URL Parameters on page 1622](#) for available URL parameters.

Response

Returns all configured global hook definitions.

Sample response

```
GET http://localhost:8080/mws/rest/services/hooks/global-definitions?api-version=3
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [
    {
      "id": "51f9395484aeed592c4d658e",
      "name": "auditHook",
      "type": "after",
      "includeServiceAsBody": true,
      "currentPhase": "analyzing",
      "transition": "accept",
      "nextPhase": "deploying",
      "url": "exec:///opt/mws/spool/hooks/audit.pl",
      "timeoutInSeconds": 3000
    },
    {
      "id": "12a8284373zddc481b3c547d",
      "name": "email",
      "type": "after",
      "includeServiceAsBody": false,
      "currentPhase": "analyzing",
      "transition": "accept",
      "nextPhase": "deploying",
      "url": "exec:///opt/mws/spool/hooks/serviceEmail.pl"
    }
  ]
}
```

Get All Hook Definitions on a Single Service

URLs and parameters

```
GET http://localhost:8080/mws/rest/services/<id>|<name>/hooks/definitions?api-version=3
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	---	The unique identifier of the service .	--
name	Yes	String	--	The unique name of the service.	--

 Only one of **id** or **name** is required.

To see available URL parameters, see [Global URL Parameters on page 1622](#).

Response

Returns a combination of all global (**global-definitions**) and service hook definitions.

Samples

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [
    {
      "id": "51f9395484aeed592c4d658e",
      "global": true,

      "type": "after",
      "includeServiceAsBody": true,
      "currentPhase": "analyzing",
      "transition": "accept",
      "nextPhase": "deploying",
      "url": "exec:///opt/mws/spool/hooks/script.pl",
      "timeoutInSeconds": 3000
    },
    {
      "id": "62g1416595ffe613d5e769f",
      "global": false,
      "name": "hookDefinitionName2",
      "type": "after",
      "includeServiceAsBody": false,
      "currentPhase": "",
      "transition": "migrate",
      "nextPhase": "",
      "url": "exec:///opt/mws/spool/hooks/script2.pl",
      "timeoutInSeconds": 900
    },
    {
      "id": "49e8284373zddc481b3c547d",
      "global": true,
      "name": "hookDefinitionName3",
      "type": "after",
      "includeServiceAsBody": true,
      "currentPhase": "",
      "transition": "",
      "nextPhase": "deployed",
      "url": "exec:///opt/mws/spool/hooks/script3.pl",
      "timeoutInSeconds": 900
    }
  ]
}
```

Get All Running Service Hooks

URLs and parameters

```
GET http://localhost:8080/mws/rest/services/hooks/running?api-version=3
```

To see available URL parameters, see [Global URL Parameters on page 1622](#).

Response

Returns all running service hooks.

Samples

```
GET http://localhost:8080/mws/rest/services/hooks/running?api-version=3
```

```

Creating Service Lifecycle Phase Hooks

The HTTP POST method is used to create a **global-definition** and service lifecycle phase hook on a service. The HTTP PUT method can also be used to create a service lifecycle phase hook on a service.

i The **Fields: Service Global Hook Definitions** on page 2666, **Fields: Service Running Hooks** on page 2664 reference sections contain the type and description of all fields in the **definitions**, **global-definitions**, and **running** objects. It also contains details regarding which fields are valid during PUT and POST actions.

Quick reference

```

POST http://localhost:8080/mws/rest/services/hooks/global-definitions?api-version=3
POST http://localhost:8080/mws/rest/services?api-version=3
PUT http://localhost:8080/mws/rest/services/<id|name>?api-version=3&change-mode=add

```

Create a Service Lifecycle Phase Hook

Service phase hooks execute scripts you have configured to run during transitional events between service lifecycle phases. For more information about the service lifecycle and its phases, see "" in the *Moab Cloud Suite Administrator Guide*. You can configure global hooks that will exist on all services and service hooks that only exist on a single service or on any service that derived from a template with the hook(s). Configuration options allow you to be as vague or specific as you want when you specify when the hook should execute; for instance, you might have the script run when the service leaves the **Analyzing** phase for any reason, or you might have the script run only when the service leaving **Analyzing** is entering the **Blocked** phase.

[URLs and parameters](#)**Service phase hook attributes**

Parameter	Required	Type	Valid values	Description	Example
id	No	String	--	The unique identifier of the service, generated on POST.	--
currentPhase	Yes	String	analyzing, blocked, cleaning, defining, deploying, deployed, migrating, rejected, reserved, terminated See Services on page 1871 for more information about each phase.	When your service transitions from this phase to another, the hook executes. currentPhase can be used with nextPhase or with both nextPhase and transition to attach the hook to a more specific event.	currentPhase=submit
global	No	Boolean	--	Indicates whether the phase hook is global or belongs to a specific service. It is false by default.	global=true

Parameter	Required	Type	Valid values	Description	Example
includeServiceAsBody	Yes	Boolean	--	If true, MWS passes the full service JSON into the service's stdin.	<code>includeServiceAsBody=true</code>
name	Yes	String	--	The name of the hook. Because hooks run alphabetically, the name determines the run order in relation to other scripts. When you give a service hook the same name as a global hook, the service hook overrides the global hook.	<code>name=myHook</code>

Parameter	Required	Type	Valid values	Description	Example
nextPhase	Yes	String	analyzing, blocked, cleaning, deleted, deploying, deployed, migrating, rejected, reserved, terminated See Services on page 1871 for more information about each service lifecycle phase.	When your service transitions to this phase from another, the hook runs. nex-tPhase can be used with currentPhase or with both currentPhase and transition to attach the hook to a specific event.	nex-tPhase=analyzing
timeoutInSeconds	No	Integer	--	The number of seconds that the hook will run before it times out. When a service hook times out, the service continues to run, but an error message is generated. The default is 900 seconds.	timeoutInSeconds=3000

Parameter	Required	Type	Valid values	Description	Example
transition	Yes	String	accept, automigrate, block, clean, deploy, expire, migrate, migrateaccept, migratefail, migratesuccess, purge, reject, reserve, submit, terminate, unblock See Services on page 1871 for more information about each service lifecycle phase transitions.	The event that causes the hook to execute. The services will not pause its transition to wait for the hooks to run, so the scripts must be short-run executions. transition can be used with currentPhase and nextPhase to attach the hook to a specific event.	transition=submit
type	Yes	String	"after"	The type of hook you are creating. The only valid type at present is after.	type=after

Parameter	Required	Type	Valid values	Description	Example
url	Yes	Path	<code>exec:///<path>[?<field>=<variable>[&<field>=<variable>]</code>	The location of the script that will run when the hook executes. You can include a list of variables from the service or hook to pass into the script. Because MWS does not pause the service transition for the hook, your script should be simple. If the script takes too long to run, the service could become unsynchronized with the associated Moab job.	<code>url= =exec:///myScript- .pl</code>

i Only one of **currentPhase**, **nextPhase**, or **transition** is required; however, you can also choose to use both **currentPhase** and **nextPhase** together or all three parameters.

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Service hook status

If you would like to view the status of script after its execution, make sure that your script prints the following statuses to stdout. See step 3 in the instructions below for an example.

Status	Description
failed	The script failed. This could be due to a corrupt script, an improperly configured status, the script's running past the specified timeoutInSeconds , or other reasons. If the hook fails, MWS generates an error message and the service continues to run normally.
succeeded	The script executed and completed successfully without exceeding the specified timeoutInSeconds .
waiting	The script is currently running. The status will change to either failed or succeeded once the script finishes, but you may also change the status manually. When you manually change a running hook's status from waiting to succeeded, MWS assumes the script succeeded, regardless of what actually happened or if the script has finished running.

To create a service with a service hook

1. Verify that the `/opt/mws/spool` directory exists in your system and that tomcat has read and write access to it.
2. Create a new directory inside `/opt/mws/spool` for your scripts.

```
> mkdir /opt/mws/spool/hooks
```

3. Write a script executable by tomcat called `/opt/mws/spool/hooks/helloWorld.sh` that performs the action that should occur when the hook's service phase transition begins.

```
1 #!/bin/sh
2
3 is_succeeded=true
4 if $is_succeeded ; then
5   echo '{"output":"hello world!", "status":"succeeded"}'
6 else
7   echo '{"status":"failed"}'
8 fi
```

4. Create a service with the hook definition, making sure that the URL references the script you made.

```

http://localhost:8080/mws/rest/services?api-version=3
-----
{
  "name": "vm1",
  "type": "vm",
  "tenant": {
    "name": "Gryffindor"
  },
  "hookDefinitions": [
    {
      "name": "myHook",
      "transition": "submit",
      "type": "after",
      "url": "exec:///opt/mws/spool/hooks/helloWorld.sh"
    }
  ],
  "attributes": {
    "moab": {
      "job": {
        "resources": {
          "procs": "2",
          "mem": "1028"
        },
        "image": "centos5.5-stateless",
        "template": "genericVM"
      }
    }
  }
}

```

5. Create a container service that will hold the new VM.

```

http://localhost:8080/mws/rest/services?api-version=3
-----
{
  "includedServices": [
    {
      "localName": "vm1"
    }
  ],
  "type": "container",
  "user": "rweasley",
  "account": "cloud",
  "tenant": {"name": "Gryffindor"},
  "data": [
    {
      "name": "vmGreat",
    }
  ],
  "hookDefinitions": []
}

```

6. Query `/services/<id>/hooks/definitions` to see both your global and local hooks for the service.

i You can override global hook descriptions by giving a service hook definition the same name as the global hook.

Once your service runs, you can find it when you query the running hooks (`/services/hooks/running`).

Sample response

Modifying Service Lifecycle Phase Hooks

The HTTP PUT method is used to modify service lifecycle phase hooks on **Services**.

i The **Fields: Service Global Hook Definitions** on page 2666, **Fields: Service Running Hooks** on page 2664 reference sections contain the type and description of all fields in the **definitions**, **global-definitions**, and **running** objects. It also contains details regarding which fields are valid during PUT and POST actions.

Quick reference

```
PUT http://localhost:8080/mws/rest/services/<id>?api-version=3&change-mode=<add|remove|set>
PUT http://localhost:8080/mws/rest/services/<name>?api-version=3&change-mode=<add|remove|set>
```

Modify a Service Lifecycle Phase Hook

URLs and parameters

```
PUT http://localhost:8080/mws/rest/services/hooks/<id>/global-definitions?api-version=3
PUT http://localhost:8080/mws/rest/services/hooks/<name>/global-definitions?api-version=3
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String		The unique identifier of the hook.	--
name	Yes	String		The name of the hook.	--
change-mode	Yes	String	One of add , remove , or set .	Whether you are replacing certain settings of the hook (add), removing certain settings of the hook (remove), or replacing the hook entirely (set). <div><p>i The change-mode parameter is used to delete a service phase hook. See Delete a Service Lifecycle Phase Hook on page 1938 for more information.</p></div>	change-mode=set

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

```
-----
```

Changing the Status of a Running Service Hook

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/services/hooks/running/<id>/?change-mode=set?api-version=3
```

Parameter	Required	Type	Valid values	Description	Example
change-mode	Yes	String	set	Lets you change the current status of the service hook (see Service hook status on page 1934 for valid statuses). When you manually change a hook from waiting to succeeded, MWS assumes that the script did succeed, regardless of what actually happened or whether the script is still running. i You can only modify the status field of a running hook.	change-mode=set
id	Yes	String	--	The unique identifier of the service hook.	
name	Yes	String	--	The name of the service hook.	

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

```
PUT http://localhost:8080/mws/rest/services/hooks/running?change-mode=set?api-version=3
{
  "status": "succeeded"
}
```

Deleting Service Lifecycle Phase Hooks

The HTTP DELETE method is used to delete service lifecycle phase hooks from **Services**. Deleting a service (see [Deleting Services on page 1922](#) for more information) deletes all hooks attached to it.

Quick reference

```
DELETE http://localhost:8080/mws/rest/services/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/services/<name>?api-version=3
```

Delete a Service Lifecycle Phase Hook

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/services/hooks/global-definitions/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/services/hooks/global-definitions/<name>?api-version=3
PUT http://localhost:8080/mws/rest/services?api-version=3&change-mode=remove
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String		The unique identifier of the hook.	
name	Yes	String		The name of the hook.	

 Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
PUT http://localhost:8080/mws/rest/services?api-version=3&change-mode=remove
{
  "hookDefinitions":
  [
    {
      "id": "23423h2132kl23kk12"
    }
  ]
}
```

Getting stepsCompleted Information

The HTTP GET method is used to get stepsCompleted information.

Quick reference

```
GET http://localhost:8080/mws/rest/services/<id|name>?api-version=3&fields=stepsCompleted
```

i For information about using the stepsCompleted field in the Moab Cloud Suite, see "" in the *Moab Cloud Suite Installation Guide*.

Get Steps Completed InformationURLs and parameters

```
GET http://localhost:8080/mws/rest/services/<id|name>?api-version=3&fields=stepsCompleted
```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the Service.	--
name	Yes	String	--	The name of the Service.	--

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
stepsCompleted: ["step1, step2"]
```

Modifying stepsCompleted

The HTTP GET method is used to modify the stepsCompleted.

Quick reference

```
PUT http://localhost:8080/mws/rest/services/<id|name>?api-version=3&change-mode=add
```

i For information about using the stepsCompleted field in the Moab Cloud Suite, see "" in the *Moab Cloud Suite Installation Guide*.

Modify stepsCompleted

URLs and parameters

```
PUT http://localhost:8080/mws/rest/services/<id|name>?api-version=3&change-mode=add
```

Parameter	Required	Type	Valid values	Description	Example
change-mode	Yes	String	One of add , remove , or set .	Whether you are adding steps (add), removing steps (remove), or replacing the steps entirely (set).	change-mode=set
id	Yes	String	--	The unique identifier of the Service.	--
name	Yes	String	--	The name of the Service.	--

 Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
PUT http://localhost:8080/mws/rest/services/<id|name>?api-version=3&change-mode=add
{stepsCompleted=>["step1"]}
```

```

Service Templates

This section describes the behavior of the **Service Template** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

Service templates are tenant objects. If you have implemented a multi-tenant environment (for more information, see [About Tenants on page 1602](#)), and are logged in with an application account, you must include a `proxy-user` with each service call to limit the results to information that the user has permission to see. If you are logged in with an LDAP account, MWS will automatically limit the results to information that the LDAP user has permission to see. For more information, see [Roles on page 1864](#).

i The **Fields: Service Templates** reference section contains the type and description of all fields in the **ServiceTemplate** object. It also contains details regarding which fields are valid during PUT and POST actions.

i See [Create Service from Service Template on page 1898](#) to create services from service templates.

The **Service Template** name has the following constraints:

- It must contain only letters, digits, spaces, and these special characters: underscore, comma, hyphen, period, question mark, at sign, tilde, pound sign, square brackets, angle brackets, vertical bar, equals sign, ampersand, parentheses, asterisk, curly braces, grave accent, and dollar sign.
- It cannot have the same form as a MongoDB ID (24 characters of 0-9 and a-f)
- It must be unique in the database.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>rest/service-templates</code>	Get All Service Templates	--	Create Service Template	--
<code>/rest/service-templates/<id> or <name></code>	Get Single Service Template	Modify Service Template	--	Cancel Service Template

This topic contains these sections:

 - [Get All Service Templates on page 1943](#)
 - [Get Single Service Template on page 1949](#)
- [Creating Service Templates on page 1955](#)
 - [Create Service Template on page 1955](#)

- [Modifying Service Templates on page 1962](#)
 - [Modify Service Template on page 1963](#)
- [Deleting \(Canceling\) Service Templates on page 1965](#)
 - [Cancel Service Template on page 1965](#)

Getting Service Templates

The HTTP GET method is used to retrieve **<name>** information.

Quick reference

```
GET http://localhost:8080/mws/rest/service-templates?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/service-templates/<id>?api-version=3
GET http://localhost:8080/mws/rest/service-templates/<name>?api-version=3
```

Get All Service Templates

URLs and parameters

```
GET http://localhost:8080/mws/rest/service-templates?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	Query for specific results.	query={"type":"vm","createdBy":"name"}
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

Querying service templates

It is possible to query service templates by one or more fields based on the [MongoDB query syntax](#).

i For example queries, see [Querying services](#) on page 1879. In the query URL, be sure to replace "services" with "service-templates."

Sorting

See the sorting section of [Global URL Parameters](#) on page 1622.

Limiting the number of results

i For examples of limiting the number of results, see [Limiting the number of results](#) on page 1882. In the URL, be sure to replace "services" with "service-templates."

Retrieving a subset of fields

i For examples of retrieving a subset of fields, see [Retrieving a subset of fields](#) on page 1882. In the URL, be sure to replace "services" with "service-templates."

Get Single Service Template

URLs and parameters

```

GET http://localhost:8080/mws/rest/service-templates/<id>?api-version=3
[&recursive=true]
GET http://localhost:8080/mws/rest/service-templates/<name>?api-version=3
[&recursive=true]

```

Parameter	Required	Type	Valid values	Description	Example
id	Yes	String	--	The unique identifier of the service template. Must contain exactly 24 alphanumeric characters.	--
name	Yes	String	--	The name of the service template.	--
recursive	No	Boolean	true or false	true shows details about all included templates, including nested templates. Default is false .	recursive=true

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Response

```
GET http://localhost:8080/mws/rest/service-templates/Centos55Vm?api-version=3
```

Creating Service Templates

The HTTP POST method is used to create **Service Templates**.

Quick reference

```
POST http://localhost:8080/mws/rest/service-templates?api-version=3
```

i If you are logged in as an application account or LDAP user and submit a service template without specifying the user, MWS considers the user as which you are logged in the user of the service template.

Create Service Template

URLs and parameters

```
POST http://localhost:8080/mws/rest/service-templates?api-version=3
```

See **Global URL Parameters** on page 1622 for available URL parameters.

Request body

i The **tenant** field is required and must contain only letters, digits, periods, dashes, and underscores. For POST and PUT actions, the tenant **name** or **ID**, or both the **name** and **ID** must be specified; if both the **name** and **ID** are specified, they must both refer to the same **tenant** or MWS returns an error.

- The request body below shows some of the fields that are available when creating a **Service Template**, along with some sample values.

JSON request body

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "name": "Centos55Vm",
  "label": "Centos 5.5 VM",
  "type": "vm",
  "createdBy": "bob",
  "tags": ["tag1", "tag2", "tag3"],
  "attributes": {
    "moab": {
      "job": {
        "image": "centos5.5-stateless",
        "resources": {
          "procs": 1,
          "mem": 1024,
          "disk": 20480
        },
        "template": "genericVM",
        "variables": {
          "var1": "variable to be attached to tracking job",
        }
      }
    },
    "sharedData": {
      "custom1": "Custom data to be attached to service",
      "custom2": "More custom data to be attached to service"
    }
  }
}
```

- The following payload is an example of a **Service Template** that can be used to create an OS storage service.

OS storage JSON payload

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "name": "OpSysStorage",
  "label": "Operating System Storage",
  "type": "storage",
  "createdBy": "bob",
  "tags": ["tag1", "tag2", "tag3"],
  "attributes": {
    "moab": {
      "job": {
        "resources": {
          "OS": 100
        },
        "template": "OSStorage",
        "variables": {
          "var1": "variable to be attached to tracking job"
        }
      }
    },
    "sharedData": {
      "custom1": "Custom data to be attached to service",
      "custom2": "More custom data to be attached to service"
    }
  }
}
```

- The following payload is an example of a **Service Template** that can be used to create an extra storage service.

Extra storage JSON payload

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "name": "NetworkStorage",
  "label": "Network Storage",
  "type": "storage",
  "createdBy": "bob",
  "tags": ["tag1", "tag2", "tag3"],
  "attributes": {
    "moab": {
      "job": {
        "resources": {
          "gold": 100
        },
        "template": "extraStorage",
        "variables": {
          "var1": "variable to be attached to tracking job"
        }
      }
    },
    "sharedData": {
      "custom1": "Custom data to be attached to service",
      "custom2": "More custom data to be attached to service"
    }
  }
}
```

- The following payload is an example of a **Service Template** that can be used to create a container service that contains a vm service, an OS storage service, and an extra storage service.

Container JSON payload

```
{
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "name": "Centos55VmPlusStorage",
  "label": "Centos 5.5 VM Plus OS and Network Storage",
  "type": "container",
  "createdBy": "bob",
  "tags": ["tag1", "tag2", "tag3"],
  "includedServices": [
    {
      "localName": "cvm",
      "serviceTemplate": "Centos55Vm"
    },
    {
      "localName": "oss",
      "serviceTemplate": "OpSysStorage"
    },
    {
      "localName": "ns",
      "serviceTemplate": "NetworkStorage"
    }
  ]
},
```

```

    "hookDefinitions": [],
    "attributes": {
      "moab": {
        "dependencies": [
          {
            "dependency": [
              "oss", "ns"
            ],
            "localName": "cvm"
          }
        ],
        "job": {
          "rules": {
            "MOAB_DATACENTER": [
              {
                "value": "datacenter2",
                "restriction": "must",
                "comparator": "%="
              }
            ]
          },
          "nodeSet": {
            "selection": "FIRSTOF",
            "type": "VARATTR",
            "name": "MOAB_DATACENTER",
            "values": ["vcenter-datacenter-416"]
          }
        }
      },
      "sharedData": {
        "custom1": "Custom data to be attached to service",
        "custom2": "More custom data to be attached to service"
      }
    }
  }
}

```

i **includedServices** is a key-value pair of the internal service name and the serviceTemplate. The service name is unique for each service container.

i The `name` field is deprecated in version 8.1.0. If it is set, it must be unique. However, if the `name` field is not set, a new UUID will be automatically generated for each service without a `name` value.

The `label` field is required and must not be blank. However, if the `name` field is already specified by the client, it will be automatically used as the `label`.

If neither `name` or `label` field is set during service creation, an error will occur.

i For information about configuring service lifecycle phase hooks on a service template, see [Creating Service Lifecycle Phase Hooks on page 1928](#) on the Services resource page.

Sample response

JSON response for successful POST

```
{"id":"4f06111184ae2bbfa31fa4c7"}
```

- If the **Service Template** name is not unique:

JSON response

```
{
  "messages": [
    "Service template RHEL54Vm could not be created",
    "Request has a non-unique service template name 'RHEL54Vm'",
    "Please correct the request and try again"
  ]
}
```

- If the **Service Template** included service local name is not unique to this service template:

JSON response

```
{
  "messages": [
    "Service template CentOS5 could not be created",
    "Service template request has a non-unique included service template local name ([SQLServ05])",
    "Please correct the request and try again"
  ]
}
```

- If the **Service Template** depends on a non-existent included service:

JSON response

```
{
  "messages": [
    "Service template NSSstor34 could not be created",
    "Service template requires service template(s) [NewRHEL54Vm] which do not exist",
    "Please correct the request and try again"
  ]
}
```

- If the **Service Template** depends on more than one non-existent included service:

JSON response

```
{
  "messages": [
    "Service template NSStor34 could not be created",
    "Service template requires service template(s) [NewRhel54Vm, Storage003]
which do not exist",
    "Please correct the request and try again"
  ]
}
```

- If the **Service Template** name contains a colon:

JSON response

```
{
{
  "messages": [
    "Service template Rhel54Vm:C could not be created",
    "Request contains a colon (:) in the service template name
'Rhel54Vm:C'",
    "Please correct the request and try again"
  ]
}
```

- If the **Service Template** name has the same format as a MongoDB ID (Service Template ID):

JSON response

```
{
  "messages": [
    "Service template 4f2049a684ae6e1d4f09bd71 could not be created",
    "Request has a MongoDB Object ID format for the service template name
'4f2049a684ae6e1d4f09bd71'",
    "Please correct the request and try again"
  ]
}
```

Modifying Service Templates

The HTTP PUT method is used to modify **Service Templates**.

The `modified` field is not automatically updated. It will need to be changed by the user.

Quick reference

```
PUT http://localhost:8080/mws/rest/service-templates/<id>?api-version=3
PUT http://localhost:8080/mws/rest/service-templates/<name>?api-version=3
```

Modify Service Template

URLs and parameters

```
PUT http://localhost:8080/mws/rest/service-templates/<id>
PUT http://localhost:8080/mws/rest/service-templates/<name>
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	(24 alphanumeric characters)	The unique identifier of the service template.
name	Yes	String	--	The name of the service template.

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

This is similar to create, except you change the request body to what you need modified.

The request body below shows some of the fields that are available when modifying a **Service Template**, along with some sample values.

```
PUT http://localhost:8080/mws/rest/service-templates/Centos55Vm?api-version=3
```

```
{
  "label": "Centos 5.5 VM (updated)",
  "createdBy": "newUser",
  "tags": ["newTag", "newTag2"],
  "attributes": {
    "moab": {
      "job": {
        "image": "centos5.5-stateful",
        "resources": {
          "procs": 2,
          "mem": 2048,
          "disk": 22480
        },
        "template": "genericVM",
        "variables": {
          "newVar": "variable to be attached to tracking job",
        }
      }
    },
    "sharedData": {
      "custom3": "Custom data to be attached to service",
      "custom4": "More custom data to be attached to service"
    }
  }
}
```

Sample response

JSON response for successful PUT

```

{
  "attributes":{
    "moab":{
      "job":{
        "image":"centos5.5-stateful",
        "resources":{
          "procs":2,
          "mem":2048,
          "disk":22480
        },
        "template":"genericVM",
        "variables":{
          "newVar":"variable to be attached to tracking job"
        }
      }
    },
    "sharedData":{
      "custom3":"Custom data to be attached to service",
      "custom4":"More custom data to be attached to service"
    }
  },
  "createdBy":"newUser",
  "id":"50d4de6bc4aa6ca84bbe9be4",
  "includedServices":[
  ],
  "hookDefinitions":[],
  "label":"Centos 5.5 VM (updated)",
  "modified":"2012-12-21 15:12:01 MST",
  "name":"Centos55Vm",
  "tags":[
    "newTag",
    "newTag2"
  ],
  "type":"vm",
  "version":0
}

```

- If the **Service Template** depends on a non-existent included service:

JSON response

```

{
  "messages": [
    "Service template NewR could not be updated",
    "Service template requires service template(s) [RhOs045] which do not exist",
    "Please correct the request and try again"
  ]
}

```

- If the **Service Template** depends on more than one non-existent included service:

JSON response

```
{
  "messages": [
    "Service template NewR could not be updated",
    "Service template requires service template(s) [Stor45, Stor12] which do not exist",
    "Please correct the request and try again"
  ]
}
```

- An attempt to modify the **Service Template** name to an existing template name:

JSON response

```
{
  "messages": [
    "Service template NewR could not be updated",
    "Request has a non-unique service template name 'Stor44'"
  ]
}
```

Deleting (Canceling) Service Templates

The HTTP DELETE method is used to delete **Service Templates**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/service-templates/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/service-templates/<name>?api-version=3
```

Cancel Service Template

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/service-templates/<id|name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	(24 alphanumeric characters)	The unique identifier of the service template.
name	Yes	String	--	The name of the service template.

i Only one of **id** or **name** is required.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Response

- A successful deletion:

JSON response

```
{}
```

- If the **Service Template** ID does not exist:

JSON response

```
{
  "messages": [
    "Service template not found with ID '4f2049a684ae6e1d4f09bd71'"
  ]
}
```

- If the **Service Template** name does not exist:

JSON response

```
{
  "messages": [
    "Service template not found with ID 'Stor44'"
  ]
}
```

- If other **Service Templates** depend on the one being deleted:

JSON response

```
{
  "messages": [
    "Service template Cent5 could not be deleted",
    "Service template 'Cent5' cannot be deleted because Service template '[Cent5]' depends on it "
  ]
}
```

Standing Reservations

This section describes behavior of the **Standing Reservation** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Standing Reservations** reference section contains the type and description of all fields in the **Standing Reservation** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/standing-reservations</code>	Get All Standing Reservations	--	--	--
<code>/rest/standing-reservations/<id></code>	Get Single Standing Reservation	--	--	--

This topic contains these sections:

- [Getting Standing Reservations on page 1967](#)
 - [Get All Standing Reservations on page 1967](#)
 - [Get Single Standing Reservation on page 1968](#)

Getting Standing Reservations

The HTTP GET method is used to retrieve **Standing Reservation** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/standing-reservations/<id>?api-version=3
```

Get All Standing Reservations

URLs and parameters

```
GET http://localhost:8080/mws/rest/standing-reservations?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/standing-reservations?api-version=3&fields=id

{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "sr1"},
    {"id": "sr2"},
    {"id": "sr3"}
  ]
}
```

Get Single Standing Reservation

URLs and parameters

```
GET http://localhost:8080/mws/rest/standing-reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

Tenants

This section describes behavior of the **Tenants** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Tenants** reference contains the type and description of all fields in the **Tenants** object.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/tenants	Get All Tenants	--	Create Single Tenant	--
/rest/tenants/<id>	Get Single Tenant	Modify Single Tenant	--	Delete Single Tenant
/rest/tenants/<name>	Get Single Tenant	Modify Single Tenant	--	Delete Single Tenant
/rest/tenants/users/<username>	Get a User's Tenants	--	--	--

This topic contains these sections:

- [Getting Tenants](#) on page 1971
 - [Get All Tenants](#) on page 1971
 - [Get Single Tenant](#) on page 1972

 - [Modify Single Tenant on page 1975](#)
- [Deleting Tenants on page 1977](#)
 - [Delete Single Tenant on page 1977](#)

Getting Tenants

The HTTP GET method is used to retrieve Tenant information. You can query all tenants or a single tenant.

[Quick reference](#)

```
GET http://localhost:8080/mws/rest/tenants?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/tenants/<id>?api-version=3
GET http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Get All Tenants

[URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/tenants?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
query	No	JSON	Filter results. It is possible to query tenants by one or more fields based on MongoDB query syntax.	query={"name":"TenantX"}
sort	No	JSON	Sort the results by field. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/tenants?api-version=3&field=name,description

{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "description": "Research personnel",
      "name": "ResearchDept"
    },
    {
      "description": "Programmers, testers, and product owners",
      "name": "DevDept"
    }
  ]
}
```

Sorting and querying

See the sorting and querying sections of [Global URL Parameters on page 1622](#).

Get Single Tenant

URLs and parameters

```
GET http://localhost:8080/mws/rest/tenants/<id>?api-version=3
GET http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the tenant.
name	Yes	String	--	The name of the tenant.

i You must specify either **id** or **name**; you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

GET http://localhost:8080/mws/rest/tenants/ResearchDept?api-version=3

```

{
  "attachedNodes": [
    "node01",
    "node02",
    "node43"
  ],
  "attachedPrincipals": [
    {
      "attachedRoles": [

      "type": "LDAPGROUP"
    }
  ],
  "id": "51cb4c3b84ae4c8a6829812d",
  "name": "Research",
  "users": [ ],
  "version": 1
},
{
  "description": "Research personnel",
  "id": "51ca256f84ae4c8a6828f8e9",
  "name": "ResearchDept",
  "version": 0
}
}

```

Get a User's Tenants

URLs and parameters

```

GET http://localhost:8080/mws/rest/tenants/users/<username>/<resource>/<action>?api-version=3

```

Parameter	Required	Type	Valid values	Description
username	No	String	--	User's user name.
resource	No	String	Any resource a user has permission for and that is assigned to a tenant.	An MWS resource .
action	No	String	create, read, update, delete	CRUD

See [Global URL Parameters on page 1622](#) for available URL parameters.

i If **username** is unspecified, the current user's tenants are listed; if the user is not an RBAC user, all tenants are listed.

Sample response

```
GET http://localhost:8080/mws/rest/tenants/users/msmith?api-version=3
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "id": "51ffd9b1e4b027c0f94e65cf",
      "name": "ResearchDiv"
    },
    {
      "id": "51abcdef12345fedcba99978",
      "name": "ResearchFaculty"
    }
  ]
}
```

Creating Tenants

The HTTP POST method is used to submit **Tenants**.

Quick reference

```
POST http://localhost:8080/mws/tenants?api-version=3
```

Create Single Tenant

URLs and parameters

```
POST http://localhost:8080/mws/tenants?api-version=3
```

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

- i** The **name** field is required and must contain only letters, digits, periods, dashes, and underscores.
- The **attachedPrincipals** field expects an array of tenant IDs or names.
- The **attachedNodes** field expects an array of node IDs (api-version 1) *or* names (api-version 2).

The following is an example request body to create a tenant:

```
POST http://localhost:8080/mws/rest/tenants?api-version=3
-----
{
  "name": "ResearchDept",
  "description": "Research personnel, assistants, and admins",
  "attachedPrincipals": [
    {"name": "ResearchAdmin"},
    {"name": "ResearchLeader"},
    {"name": "Research"}
  ],
  "attachedNodes": [
    "node01",
    "node02",
    "node43"
  ]
}
```

Sample response

If the request was successful, the response body is the new tenant, exactly as shown in [Get Single Tenant](#). On failure, the response is an error message.

Modifying Tenants

The HTTP PUT method is used to modify **Tenants**.

Quick reference

```
PUT http://localhost:8080/mws/rest/tenants/<id>?api-version=3
PUT http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Modify Single Tenant

The HTTP PUT method is used to modify tenants.

URLs and parameters

```
PUT http://localhost:8080/mws/rest/tenants/<id>?api-version=3
PUT http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the tenant.
name	Yes	String	--	The name of the tenant. <div> The name field must contain only letters, digits, periods, dashes, and underscores.</div>
change-mode	Yes	String	add remove set (default)	If add , add the given objects (attachedNodes, attachedPrincipals) to the objects that already exist. If remove , delete the given objects from the objects that already exist. If set , replace existing objects with those specified

 You must specify either **id** or **name**; you do not have to specify both.
The **attachedPrincipals** field expects an array of tenant IDs *or* names.
The **attachedNodes** field expects an array of node IDs (api-version 1) or names (api-version 2).

See [Global URL Parameters on page 1622](#) for available URL parameters.

Example request

```
PUT http://localhost:8080/mws/rest/tenants/ResearchDept?api-version=3
```

```
{
  attachedNodes: [
    "node01",
    "node03",
    "node43",
    "node44"
  ],
  attachedPrincipals: [
    {name: "ResearchAdmin"},
    {name: "ResearchLeader"},
    {name: "Research"}
  ]
}
```

 The **version** field contains the current version of the database entry. This field cannot be updated directly. However, if version is included in the modify request, it will be used to verify that another client did not update the object between the time that the data was retrieved and the modify request was delivered.

[Sample response](#)

If the request was successful, the response body is the modified tenant as shown in [Get Single Tenant](#). On failure, the response is an error message.

Deleting Tenants

The HTTP DELETE method is used to delete tenants.

[Quick reference](#)

```
DELETE http://localhost:8080/mws/rest/tenants/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Delete Single Tenant

[URLs and parameters](#)

```
DELETE http://localhost:8080/mws/rest/tenants/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/tenants/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the tenant.
name	Yes	String	--	The name of the tenant.

i You must specify either **id** or **name**; you do not have to specify both.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Virtual Containers

This section describes behavior of the **Virtual Container** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

i The **Fields: Virtual Containers** reference section contains the type and description of all fields in the **Virtual Container** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/vcs	Get All Virtual Containers	--	Create Virtual Container	--
/rest/vcs/<id>	Get Single Virtual Container	Modifying Virtual Containers	--	Destroy Virtual Container

This topic contains these sections:

- [Getting Virtual Containers](#) on page 1978
 - [Get All Virtual Containers](#) on page 1978
 - [Get Single Virtual Container](#) on page 1979
- [Creating Virtual Containers](#) on page 1980
 - [Create Virtual Container](#) on page 1981
- [Modifying Virtual Containers](#) on page 1982
 - [Modify Virtual Container](#) on page 1982
- [Destroying Virtual Containers](#) on page 1984
 - [Destroy Virtual Container](#) on page 1985

Getting Virtual Containers

The HTTP GET method is used to retrieve **Virtual Container** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/vcs/<id>?api-version=3
```

Get All Virtual Containers

URLs and parameters

```
GET http://localhost:8080/mws/rest/vcs?api-version=3
```

See [Global URL Parameters](#) on page 1622 for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/vcs?api-version=3&fields=id
```

```
{
  "totalCount": 5,
  "resultCount": 5,
  "results": [
    {"id": "vc3"},
    {"id": "vc1"},
    {"id": "vc4"},
    {"id": "vc5"},
    {"id": "vc2"}
  ]
}
```

Get Single Virtual Container

URLs and parameters

```
GET http://localhost:8080/mws/rest/vcs/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response

```
{
  "aclRules": [ {
    "affinity": "POSITIVE",
    "comparator": "LEXIGRAPHIC_EQUAL",
    "type": "USER",
    "value": "root"
  } ],
  "createDate": "2011-11-15 14:01:40 UTC",
  "creator": "root",
  "description": "vc2",
  "flags": ["DESTROYWHENEMPTY"],
  "id": "vc2",
  "jobs": [
    { "id": "Moab.1" }
  ],
  "nodes": [
    { "id": "node1" }
  ],
  "owner": {
    "name": "root",
    "type": "USER"
  },
  "reservations": [
    { "id": "system.1" }
  ],
  "variables": {
    "a": "b",
    "c": "d"
  },
  "virtualContainers": [
    { "id": "vc3" }
  ],
  "virtualMachines": [
    { "id": "vm1" }
  ]
}
```

Creating Virtual Containers

The HTTP POST method is used to create **Virtual Containers**.

Quick reference

```
POST http://localhost:8080/mws/rest/vcs?api-version=3[&proxy-user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Create Virtual Container

URLs and parameters

```
POST http://localhost:8080/mws/rest/vcs?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

The request body below shows all the fields that are available when creating a **Virtual Container**, along with some sample values.

JSON request body

```
{
  "description": "ted's vc",
  "owner": {
    "name": "ted",
    "type": "USER"
  },
  "requiredStartDate": "2012-11-08 13:18:47 MST",
  "flags": ["HOLDJOBS"],
  "virtualContainers": [
    {"id": "vc93"},
    {"id": "vc94"}
  ],
}
```

Sample response

JSON response for successful POST

```
{"id": "vc8"}
```

Restrictions

- When creating a **Virtual Container**, the `creator` field is set to the value of **proxy-user** (if set) or `owner.name` (if set). However, setting the `creator` field works only if you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. Example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

- You can set the **creator** field (as shown above), but you can never change it.

Modifying Virtual Containers

The HTTP PUT method is used to modify **Virtual Containers**.

Quick reference

```
PUT http://localhost:8080/mws/rest/vcs/<id>?api-version=3&change-mode=<add|remove|set>
[&proxy-user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Modify Virtual Container

URLs and parameters

```
PUT http://localhost:8080/mws/rest/vcs/<id>?api-version=3&change-mode=<add|remove|set>
[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object
change-mode	Yes	String	add remove set	If add , add the given objects (jobs, VMs, etc) to the objects that already exist. If remove , modify the attributes of the virtual container itself and not the associated objects. If set , perform the action as this user.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

Here are three examples of Virtual Container updates: add objects, remove objects, and update attributes. In each case, the examples below show all the fields that are available, along with some sample values.

```
Add objects with /rest/vcs/vc1?change-mode=add
{
  "jobs": [
```

```

    {"id": "Moab.37"},
    {"id": "Moab.38"}
  ],
  "nodes": [
    {"id": "node1"},
    {"id": "node2"}
  ],
  "reservations": [
    {"id": "system.48"},
    {"id": "system.49"}
  ],
  "virtualContainers": [
    {"id": "vc93"},
    {"id": "vc94"}
  ],
  "virtualMachines": [
    {"id": "vm2"},
    {"id": "vm4"}
  ]
}

```

Remove objects with /rest/vcs/vcl?change-mode=remove

```

{
  "jobs": [
    {"id": "Moab.37"},
    {"id": "Moab.38"}
  ],
  "nodes": [
    {"id": "node1"},
    {"id": "node2"}
  ],
  "reservations": [
    {"id": "system.48"},
    {"id": "system.49"}
  ],
  "virtualContainers": [
    {"id": "vc93"},
    {"id": "vc94"}
  ],
  "virtualMachines": [
    {"id": "vm2"},
    {"id": "vm4"}
  ]
}

```

Modify VC attributes with `/rest/vcs/vc1?change-mode=set`

```
{
  "description": "This is a new description.",
  "flags": ["HOLDJOBS"],
  "owner": {
    "name": "ted",
    "type": "USER"
  },
  "variables": {
    "a": "b",
    "c": "d"
  }
}
```

Sample responses

i These messages may not match the messages returned from Moab exactly, but they are given as examples of the structure of the responses.

JSON response for adding objects

```
{
  "messages": [
    "job '147' added to VC 'vc3'",
    "job 'Moab.1' added to VC 'vc3'"
  ]
}
```

JSON response for removing objects

```
{
  "messages": [
    "job '147' removed from VC 'vc3'",
    "job 'Moab.1' removed from VC 'vc3'"
  ]
}
```

JSON response for updating attributes

```
{"messages":["VC 'vc3' successfully modified"]}
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Destroying Virtual Containers

The HTTP GET method is used to retrieve **<name>** information.

[Quick reference](#)

```
DELETE http://localhost:8080/mws/rest/vcs/<id>?api-version=3[&proxy-user=<username>]
```

[Restrictions](#)

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Destroy Virtual Container

[URLs and parameters](#)

```
DELETE http://localhost:8080/mws/rest/vcs/<id>?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Sample response](#)

```
JSON response for successful DELETE
-----
{}

```

Virtual Machines

This section describes behavior of the **Virtual Machine** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Virtual Machine API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

In order to access documentation for previous API versions, see [Requesting Specific API Versions](#) on page 1626.

The **Fields: Virtual Machines** reference section contains the type and description of all fields in the **Virtual Machine** object. It also contains details regarding which fields are valid during PUT actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/vms</code>	Get All Virtual Machines	--	--	--
<code>/rest/vms/<name></code>	Get Single Virtual Machine	Modify Virtual Machine	--	Destroy Virtual Machine

This topic contains these sections:

- [Getting Virtual Machines](#) on page 1986
 - [Get All Virtual Machines](#) on page 1987
 - [Get Single Virtual Machine](#) on page 1987
- [Modifying Virtual Machines](#) on page 1991
 - [Modify Virtual Machine](#) on page 1991
 - [Migrate Virtual Machine](#) on page 1992
- [Destroying Virtual Machines](#) on page 1993
 - [Destroy Virtual Machine](#) on page 1993

Getting Virtual Machines

The HTTP GET method is used to retrieve **Virtual Machine** information.

Quick reference

```
GET http://localhost:8080/mws/rest/vms/<name>?api-version=3
```

Get All Virtual Machines

URLs and parameters

```
GET http://localhost:8080/mws/rest/vms?api-version=3
```

Parameter	Required	Type	Valid values	Description	Example
query	No	JSON	--	Queries for specific results. <div>  It is possible to query by one or more fields based on MongoDB query syntax. </div>	query={"migrationDisabled":true}
sort	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/vms?api-version=3&fields=name
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"name": "vm1"},
    {"name": "vm2"},
    {"name": "vm3"}
  ]
}
```

Get Single Virtual Machine

URLs and parameters

```
GET http://localhost:8080/mws/rest/vms/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.

See [Global URL Parameters on page 1622](#) for available URL parameters.

 The `attributes` field is only applicable in API version 2 and later, and the `MOAB_TENANT` field only applies if the VM is attached to a tenant.

Sample response

JSON response

```
{
  "name": "vm3",
  "attributes": {
    "MOAB_TENANT": [
      {
        "value": "1234567890aabbccddeeff00",
        "displayValue": "ResearchGroup"
      }
    ],
    "description": null,
    "host": {"name": "hv2"},
    "hostnames": [],
    "ipAddress": "10.0.0.5",
    "migrationDisabled": false,
    "lastUpdatedDate": "2012-10-11 17:46:32 UTC",
    "startDate": "2012-09-25 18:12:23 UTC",
    "trackingJob": null,
    "metrics": {"watts": 200},
    "variables": {},
    "resourceManagers": [
      {
        "name": "msm",
        "isMaster": true,
        "stateReported": "Active"
      }
    ],
    "operatingSystem": {
      "image": "stateless1",
      "imageExpected": null,
      "imageLastUpdatedDate": null,
      "imagesAvailable": []
    },
    "states": {
      "powerState": "On",
      "powerStateExpected": null,
      "powerStateLastUpdatedDate": null,
      "state": "Idle",
      "stateLastUpdatedDate": "2012-10-11 17:15:01 UTC",
      "subState": null,
      "subStateLast": null,
      "subStateLastUpdatedDate": null
    },
    "resources": {
      "processors": {
        "configured": 1,
        "dedicated": 0,
        "available": 1
      },
      "memory": {
        "configured": 512,
        "dedicated": 0,
        "available": 512
      },
      "disk": {
        "configured": 1024,
        "dedicated": 0,
        "available": 1024
      },
      "swap": {
        "configured": 0,
        "dedicated": 0,
        "available": 0
      }
    }
  }
}
```

```

    },
    "triggers": [],
    "virtualContainers": []
  }

```

Modifying Virtual Machines

The HTTP PUT method is used to modify **Virtual Machines**.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/vms/<name>?api-version=3[&proxy-user=<username>]
```

[Restrictions](#)

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

Modify Virtual Machine

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/vms/<name>?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

[Request body](#)

The request body below shows all the fields that are available when modifying a **Virtual Machine**, along with some sample values.

```
JSON request body for VM modify
-----
{
  "metrics": {"pwatts": 211},
  "migrationDisabled": true,
  "operatingSystem": {"image": "esx4.1"},
  "states": {
    "powerState": "On",
    "state": "Running"
  },
  "triggers": [{"name": "trigger_id"}],
  "variables": {
    "key": "value",
    "arbitrary text key": "more value"
  }
}
```

Sample response

i This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

```
JSON response
-----
{"messages":["successfully updated VM variables"]}
```

Migrate Virtual Machine

URLs and parameters

```
PUT http://localhost:8080/mws/rest/vms/<name>?api-version=3[&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Request body

- The request body below shows how to migrate a **Virtual Machine** to a host (hypervisor) with name "hv2".

```
JSON request body for VM Migrate to a specific host
-----
{"host": {"name": "hv2"}}
```

- The request body below shows how to migrate a **Virtual Machine** to any available host by using the destination name of `ANY`, which for this operation is a reserved word.

JSON request body for VM Migrate to any available host

```
{"host": {"name": "ANY"}}
```

Sample response

i The HTTP response code for this operation is 202 Accepted. See the [Responses and Return Codes on page 1626](#) section for more information.

JSON response

```
{"jobId": "vm-migrate1"}
```

Restrictions

If a migration is requested by setting the host as shown in the above examples, any other properties in the same request body will be ignored.

Destroying Virtual Machines

The HTTP GET method is used to retrieve **<name>** information.

Quick reference

```
DELETE http://localhost:8080/mws/rest/vms/<name>?api-version=3[&proxy-user=<username>]
```

Destroy Virtual Machine

URLs and parameters

Code example (replace with your own content)

Parameter	Required	Type	Valid values	Description
name	Yes	String	--	The name of the object.
proxy-user	No	String	--	Perform the action as this user.

See [Global URL Parameters on page 1622](#) for available URL parameters.

Sample response

JSON response for successful DELETE

```
{"jobId": "vmdestroy-26"}
```

i The **jobId** in the response identifies the job that will destroy the virtual machine.

Reporting Framework

Overview of Reporting Framework

The reporting framework is a set of tools to make time-based reports from numerical data. The following sections will (1) provide an overview of the framework and the concepts related to it, and (2) work through an example report (CPU Utilization) with details regarding which web services to use and with what data.

The REST API reference is located in the Report resource section (see [Reports on page 1845](#)).

Concepts

The reporting framework uses 3 core concepts: reports, datapoints, and samples.

- Reports (see [Fields: Reports on page 2455](#)): A report is a time-based view of numerical data.
- Report Datapoints (see [Fields: Report Datapoints on page 2453](#)): A datapoint is a consolidated set of data for a certain time period.
- Report Samples (see [Fields: Report Samples on page 2511](#)): A sample is a snapshot of a certain set of data at a particular point in time.

To illustrate, consider the memory utilization of a virtual machine: at any given point in time, you can get the memory utilization by using your operating system's performance utilities (top for Linux, Task Manager for Windows):

2400/12040MB

By recording the memory utilization and time constantly for 1 minute, you could gather the following data:

Time	Memory utilization
3:53:55 PM	2400/12040 MB
3:54:13 PM	2410/12040 MB
3:54:27 PM	2406/12040 MB
3:54:39 PM	2402/12040 MB
3:54:50 PM	2409/12040 MB

Each of the rows in the table above represent a **sample** of data. By averaging the rows we can consolidate them into one or more **datapoints**:

Start time	End time	Memory utilization
3:53:30 PM	3:54:00 PM	2400/12040 MB
3:54:00 PM	3:54:30 PM	2408/12040 MB
3:54:30 PM	3:55:00 PM	2406/12040 MB

i Note that each datapoint covers exactly the same amount of time, and averages all samples within that period of time.

A **report**, then, is simply a list of datapoints with some additional configuration information:

Field	Value
Name	Memory Utilization Report
Datapoint Duration	30 seconds
Report Size	3 datapoints

Datapoints:

Start time	End time	Memory utilization
3:53:30 PM	3:54:00 PM	2400/12040 MB
3:54:00 PM	3:54:30 PM	2408/12040 MB
3:54:30 PM	3:55:00 PM	2406/12040 MB

Capabilities

While storing simple information like memory utilization is nice, the reporting framework is built to automatically handle much more complex information.

Consolidating Samples

Samples are JSON documents which are pushed into the report using the Samples API (see [Creating Samples on page 1853](#)). Samples are then stored until the consolidation operation creates a datapoint out of them. The table below shows how different data types are handled in this operation:

Type	Consolidation function handling
Numbers	Numerical data is averaged.
Strings	Strings are aggregated into an array.
Objects	The consolidation function recursively consolidates sub-objects.
Lists	Lists are combined into a single flat list containing all elements.
Mixed	If samples have different types of data for the same field, the values are aggregated into an array.
Null	These values will be ignored unless all values for a sample field are set to null, resulting in a null result.

 If the mixed data types contains at least one number, it will be treated as numerical data. The non-numerical data will be ignored and the result will be averaged.

Below is an example of how the consolidation function works:

- Samples:

Time	NumberEx	StringEx	ListEx	MixedEx	MixedNumberEx
3:53:55 PM	2400	"str1"	["elem1"]	"str1"	"str1"
3:54:13 PM	2410	"str2"	["elem2", "elem3"]	["elem1"]	["elem1"]
3:54:27 PM	2405	"str3"	["elem4"]	null	5

- Resulting Datapoint after consolidation:

Time	NumberEx	StringEx	ListEx	MixedEx	MixedNumberEx
3:55:00 PM	2405	["str1", "str2", "str3"]	["elem1", "elem2", "elem3", "elem4"]	["str1", "elem1"]	5

Minimum number of samples

If your dataset is highly variable (i.e. values contained in samples are not very close together), converting a single sample into a datapoint may provide misleading information. It may be better to have a datapoint with an "Unknown" value. This can be accomplished by setting the minimum number of samples for a datapoint in the report.

The `minimumSampleSize` field in the Reports reference section (see [Reports on page 1845](#)) explains that if the specified size of samples is not met when the consolidation function is performed, the datapoint is considered "null" and no data is available for it. When this occurs, the sample data is discarded and the `data` field of the datapoint is set to "null".

For information on how to set this option, see the REST API Report Resource section (see [Reports on page 1845](#)).

Report size

Reports have a predetermined number of datapoints, or size, which sets a limit on the amount of data that can be stored. After the report size has been reached, as newly created datapoints are pushed into the report, the oldest datapoints will automatically be deleted. This is to aid in managing the storage capacity of the server hosting MWS.

On report creation, a Mongo collection will be initialized that is the configured report document size multiplied by the report size. Be careful in setting a large report size or report document size as this may quickly allocate the entire disk. See the `reportDocumentSize` and `reportSize` fields in [Fields: Reports on page 2455](#) for more information.

Related Topics

- [Example Report \(CPU Utilization\) on page 1998](#)

Example Report (CPU Utilization)

To understand how the behavior and usage of the reporting framework, a sample report covering CPU Utilization will be shown in this section. It will not cover how to gather or display data for reports, but will cover some basic operations that are available with Moab Web Services to facilitate reporting.

Creating a Report

Before any data is sent to Moab Web Services, a report must first be created. A JSON request body with a HTTP method of POST must be used to do this.

```
POST /rest/reports
-----
{
  "name": "cpu-util",
  "description": "An example report for cpu utilization",
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "reportSize": 288
}
```

This will result in a report being created which can then be retrieved by sending a GET request to `/rest/reports/cpu-util`. The `datapointDuration` of 600 signifies that the datapoint consolidation should occur once every 10 minutes, while the `reportSize` (i.e. number of the datapoints) shows that the report will retain up to 2 days worth of the latest datapoints.

```
GET /rest/reports/cpu-util
```

```
{
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "datapoints": [],
  "description": "An example report for cpu utilization",
  "id": "aef6f6a3a0bz7bf6449537c9d",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 288,
  "version": 0
}
```

(Note that an ID has been automatically generated and that no datapoints are associated with the report.)

Adding Samples

Until samples are added and associated with the report, datapoint consolidation will generate datapoints with a `data` field equal to `null`. Once samples are added, however, they will be averaged and inserted into the next datapoint.

Create samples for the `cpu-util` by sending a POST request as follows:

```
POST /rest/reports/cpu-util/samples
```

```
[
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:00:00 UTC",
    "data": {
      "minutes1": 0.5,
      "minutes5": 0,
      "minutes15": 0
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:01:00 UTC",
    "data": {
      "minutes1": 1,
      "minutes5": 0.5,
      "minutes15": 0.05
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:02:00 UTC",
    "data": {
      "minutes1": 1,
      "minutes5": 0.5,
      "minutes15": 0.1
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:03:00 UTC",
    "data": {
      "minutes1": 0.75,
      "minutes5": 1,
      "minutes15": 0.25
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:04:00 UTC",
    "data": {
      "minutes1": 0,
      "minutes5": 1,
      "minutes15": 0.85
    }
  }
]
```

This sample data contains average load for the last 1, 5, and 15 minute intervals. The samples were recorded at one-minute intervals starting at noon on January 1st, 2012.

Consolidating Data

A consolidation function must run to generate datapoints from the given samples. This scheduled consolidation will occur at intervals of `datapointDuration` seconds. For each field in the `data` object in samples, all

values will be averaged. If non-numeric values are included, the following strategies will be followed:

1. All fields which contain a single numeric value in any included sample will be averaged and the non-numeric or null values will be ignored.
2. All fields which contain a list will be consolidated into a single, flat list.
3. All fields which contain only non-numeric or null values will be consolidated into a single, flat list.

If no historical datapoints are provided in the creation of a report as in this example, the next consolidation will be scheduled for the current time plus the `datapointDuration`. In this example, the scheduled consolidation is at 10 minutes from the creation date. If historical datapoints are included in the report creation, the latest datapoint's `endDate` plus the `datapointDuration` will be used as the scheduled time. If this date was in the past, the next scheduled consolidation will occur at the appropriate interval from the last `endDate`.

Retrieving Report Data

To retrieve the consolidated datapoints, simply perform a GET request on the report once again. Alternatively, the GET for a report's datapoints (see [Get Datapoints for Single Report on page 1849](#)) may be used.

```
GET /rest/reports/cpu-util
```

```
{
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "datapoints": [
    {
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null,
      "startDate": "2012-01-01 11:49:00 UTC",
      "endDate": "2012-01-01 11:59:00 UTC"
    },
    {
      "firstSampleDate": "2012-01-01 12:00:00 UTC",
      "lastSampleDate": "2012-01-01 12:04:00 UTC",
      "data": {
        "minutes1": 0.65,
        "minutes15": 0.25,
        "minutes5": 0.6
      },
      "startDate": "2012-01-01 11:59:00 UTC",
      "endDate": "2012-01-01 12:09:00 UTC"
    }
  ],
  "description": "An example report for cpu utilization",
  "id": "aef6f6a3a0bz7bf6449537c9d",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 288,
  "version": 0
}
```

Note that of the two datapoints above, only the second actually contains data, while the other is set to `null`. Only samples lying within the datapoint's duration, or from the `startDate` to the `endDate`, are included in the consolidation. Therefore the first datapoint, which covered the 10 minute period just before the samples' recorded timestamps, contained no data. The second, which covers the 10 minute period matching that of the samples, contains the averaged sample data. This data could be used to display consolidated report data in a custom interface.

Possible Configurations

Configuration options may be changed to affect the process of report generation. These are documented in [Fields: Reports on page 2455](#) and [Fields: Report Samples on page 2511](#).

About Moab Web Services Plugins

This chapter describes MWS plugins, their use, and their creation in Moab Workload Manager. The sections in this chapter provide you with the following information:

- An introduction to the concept of MWS plugins (see [Plugin Introduction on page 2004](#)).
- A description of the plugin lifecycle (see [Lifecycle States on page 2006](#)).
- How plugins are driven by events ([Handling Events on page 2046](#)).
- How to expose web services from a plugin ([Exposing Web Services on page 2029](#)).
- How plugin utility services may be used ([Utility Services on page 2008](#)).
- How data report collisions between plugins are consolidated ([Data Consolidation on page 2009](#)).
- How calls from Moab are routed to MWS plugins ([Routing on page 2010](#)).

It contains the following sections:

- [Plugin Overview on page 2003](#)
- [Plugin Developer's Guide on page 2011](#)
- [Plugin Type Management on page 2073](#)
- [Plugin Management on page 2078](#)
- [Plugin Services on page 2084](#)

Related Topics

- [Configuring Moab Web Services on page 1570](#)

Plugin Overview

This section provides an overview of the plugin layer in web services. It contains these topics:

- [Plugin Introduction on page 2004](#)
- [Lifecycle States on page 2006](#)
- [Events on page 2007](#)
- [Custom Web Services on page 2007](#)

- [Utility Services on page 2008](#)
- [Data Consolidation on page 2009](#)
- [Routing on page 2010](#)

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

Plugin Introduction

Moab Web Services plugins provide a highly extensible interface to interact with Moab, MWS, and external resources. Plugins can perform some of the same functions as Moab resource managers (RMs), while also providing many other features not available to RMs. This section will discuss the main features of plugins, some basic terminology, and how MWS plugins can interact with Moab.

[Features](#)

Plugins can:

- Be created, modified, and deleted without restarting Moab Workload Manager or MWS.
- Be defined in Groovy and uploaded to MWS without restarting.
- Have individual data storage space and configuration.
- Access MWS configuration and RESTful web services.
- Log to a standard location configured in MWS.
- Be polled at a regular interval (configured on a per-plugin basis).
- Be informed of important system events.
- Be individually stopped, started, paused, and resumed.
- Expose secured and unsecured custom web services for external use.
- Be manipulated via a full RESTful API (for more information, see [Resources Introduction on page 1646](#)).
- Be manipulated via a full user interface in a web browser.

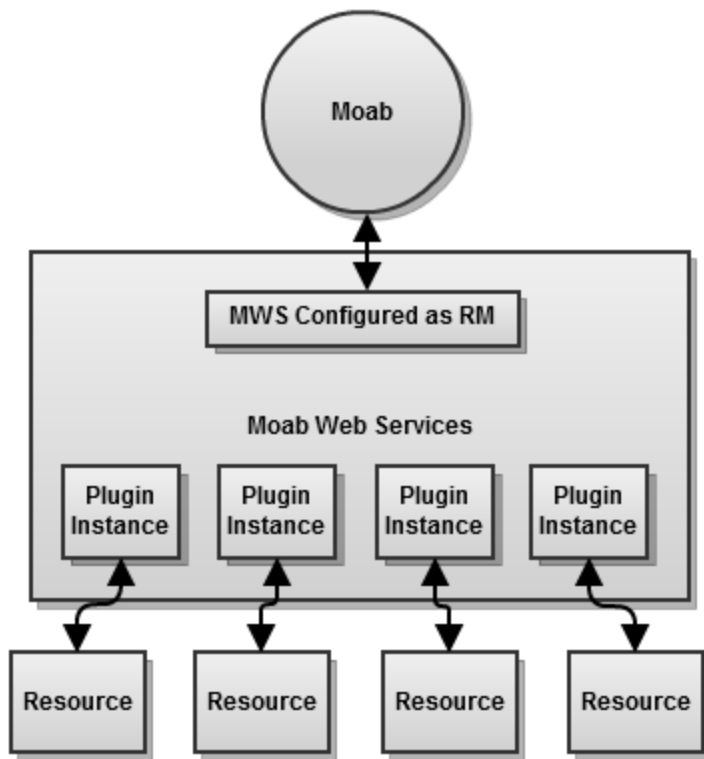

[Terminology](#)

There are two distinct terms in the plugin layer: [plugin types](#) and [plugins \(instances\)](#).

Term	Description
plugin types	<p>Plugin types can be considered plugin templates with built-in logic. In object-oriented programming languages, this relates to the concept of a class. They possess certain abilities, or methods, that can be called by Moab Web Services to query or update information about certain resources. They also can define methods which will be exposed to external clients as web services. They do not contain any configuration or current data, but they are often tied to a <i>type</i> of component, such as components that communicate with Moab's WIKI Protocol, or those that are built on a certain product.</p> <p>They can define several types of methods:</p> <ul style="list-style-type: none"> • Instance methods that return information about the current plugin, such as <code>getState</code>. (While these are defined in the plugin type, the plugin type itself does not have a state.) • The poll event method that is called at a configured interval. • Lifecycle event methods of plugins created from the plugin type, such as <code>beforeStart</code> and <code>afterStart</code>. • RM event methods that are called by Moab when certain events occur. • Web service methods that expose custom functionality as public web services. <p>Some examples of plugin types include the Native and vCenter plugin types.</p>
plugins (instances)	<p>Plugins (also called plugin instances) are created from plugin types. They contain current data or configuration and use the plugin type methods to interact with resources.</p>

[Interactions with Moab as a resource manager](#)

The plugin layer in MWS is integrated with Moab Workload Manager via the Native Resource Manager (RM) interface. When utilizing plugins, MWS is configured as a RM in Moab, as explained in the next section. Events from Moab are pushed through the RM interface to MWS, which is then pushed to each plugin in turn. The relationship between MWS, Moab, and plugins is shown in the following image:

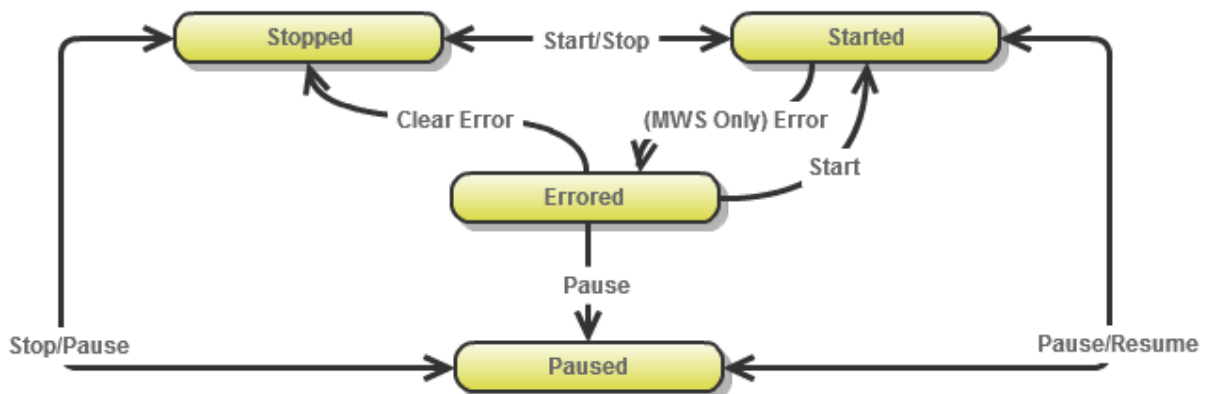

For more information, see [Data Consolidation on page 2009](#) and [Reporting State Data on page 2031](#).

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

Lifecycle States

During the course of a plugin's use, the state of the plugin may change many times. Plugins have four possible states: **Stopped**, **Started**, **Paused**, and **Errored**. For the descriptions of each state, see the [Fields: Plugins](#) reference section. The flow of a plugin through the states is shown in the following image:

i You can see [Handling Events](#) on page 2046 for information about the events that occur during lifecycle state changes.

Related Topics

- [Plugin Introduction](#) on page 2004

Events

Plugins use an event-based model, meaning that methods are called on the plugin when certain criteria are met or situations arise. Events currently exist for polling, lifecycle state changes, and RM events from Moab. For more information, see [Handling Events](#) on page 2046.

Related Topics

- [Handling Events](#) on page 2046
- [Plugin Introduction](#) on page 2004

Custom Web Services

Although the events interface typically serves most cases, there are some instances where an event is not supported that is desired. This is especially true when an external resource is the source of the event. To address these issues, plugins can expose custom web services to external resources. These web services may be named freely and do anything they wish within the plugin framework.

For example, suppose a resource needs to notify a plugin that provisioning of a virtual machine has been completed. Instead of having the plugin poll the resource to verify that the provisioning was finished, the plugin could expose a custom web service to handle notification from the resource itself.

```

Sample custom web service
-----

def vmProvisionFinished(Map params) {
    // Handle event
    return [messages:["Event successfully processed"]]
}

```

Additionally, plugin types may define web services which are unsecured, meaning that a user or application account is not required to access it. A full explanation of the syntax and creation of custom secured and unsecured web services may be seen on [Exposing Web Services on page 2029](#).

For information how resources can access plugin web services, see [Accessing Plugin Web Services on page 1815](#).

Related Topics

- [Plugin Introduction on page 2004](#)

Utility Services

Several features of plugins are only available by utilizing bundled services. These include:

- Accessing the individual datastore (see [Individual Datastore on page 2027](#)).
- Reporting state data to Moab through the Resource Manager interface (see [Reporting State Data on page 2031](#)).
- Manipulating other plugins and controlling their lifecycle (see [Controlling Lifecycle on page 2035](#)).
- Accessing REST resources from Moab Web Services ([Accessing MWS REST Resources on page 2036](#)).

It may also be necessary or desired to create additional utility services when creating new plugin types. The easiest way to do this is to create a utility service which is called by convention a translator (see [Using Translators on page 2051](#)), because it can typically "translate" from a specific resource or API to data which can be used by the plugin type.

Finally, custom components (see [Registering Custom Components on page 2052](#)) may be used to fulfill use cases not covered by bundled services or custom translators.

Related Topics

- [Plugin Introduction on page 2004](#)

Data Consolidation

At times, plugins can report differing or even contradictory data for nodes, virtual machines, and jobs. This is called a data "collision". The act of resolving these collisions is called "Consolidation." Plugins also have the concept of "precedence," where the plugins with the lowest precedence value are considered more authoritative than the greater precedence values plugins. For example, a plugin with a precedence value of 1 has a higher precedence and is considered more authoritative than a plugin with a precedence value of 5. If no precedence is provided when creating plugins, the plugin is automatically assigned to the lowest precedence, or 1 greater than the highest precedence value. The precedence value may not be less than 1.

When data from one plugin "collides" with another, the data from the highest precedence plugin will be considered the authoritative source for information. If multiple sets of data (reports) are provided by the same plugin, the latest set of data will take precedence. Additionally, MWS supports the concept of treating node and virtual machine data with state information **optimistically**, **pessimistically**, or **neither**. This is configured using the `plugins.stateConsolidationPolicy` configuration property in the MWS configuration file. If this property is set to `optimistic` and *any* plugin reports the state for a node or VM as "Up," the consolidated state will be "Up." Inversely, if the property is set to `pessimistic` and *any* plugin reports the state as "Down," the consolidated state will be "Down." If it is set to `null` (neither), consolidation will occur for the state field just as with any other field, with higher precedence and later reports being considered authoritative.

i When MWS is upgraded to a version that supports plugin precedence from an older version, existing plugins will not have the precedence field set. The administrator should assign precedence to each plugin manually through the API (see [Modifying Plugins on page 1812](#)) or through the user interface (see [Modifying a Plugin on page 2080](#)) to ensure that the consolidation will occur as expected. By default, data from a plugin without a precedence defaults to a precedence of 1, or the highest precedence.

Consolidation examples

Suppose two plugins exist, `pluginA` and `pluginB`. Plugin "A" has a precedence of 1, and plugin "B" has a precedence of 2, meaning that plugin "A" is more authoritative. These plugins both report data for a node with an ID of `node1`. However, each reports a different node power state. Plugin "A" reports the power as `ON`, while plugin "B" reports the power as `OFF`. The data collision that occurs due to these two contradictory reports is resolved by the precedence of the plugins. Since plugin A has a higher precedence (lower number), it is considered authoritative and the node will be reported as `ON`.

Now suppose that the plugins also report differing node state for `node1`. In this case, the node state would depend on the `plugins.stateConsolidationPolicy` property. The different combinations

of report values compared to the state consolidation policy and the final reported state are shown in the table below.

Plugin "A" node state	Plugin "B" node state	State consolidation policy	Consolidated node state
ON	OFF	null (neither)	ON
OFF	ON	null (neither)	OFF
ON	OFF	optimistic	ON
OFF	ON	optimistic	ON
ON	OFF	pessimistic	OFF
OFF	ON	pessimistic	OFF

In general, it is recommended that no two plugins report the same resource or that they report different properties of the same resource. For example, if plugin "A" only modified the power state and plugin "B" only modified the available disk resource, these two plugins would work in harmony to provide a consistent view of the node resource.

For more information, see [Reporting State Data on page 2031](#) and [Resource Manager Queries on page 2071](#).

- [Plugin Introduction on page 2004](#)

Routing

i Plugin routing is currently in *Beta*. Interfaces may change significantly in future releases.

Because Moab Web Services is configured as a Resource Manager (RM) in Moab Workload Manager, events are sometimes triggered by Moab through the RM interface. These actions could be migrating a virtual machine, starting a job, submitting a job, modifying a node, and so forth. The decisions regarding which plugins are affected and notified is termed **routing**.

Currently all plugins receive all commands from Moab. This means that each plugin will receive the command to start a job if sent from Moab, even if that plugin does not handle the job. This means that plugins must ensure they handle actions or commands only for resources which they report or handle.

Plugin Developer's Guide

Plugin types comprise the methods by which Moab may communicate with resource managers or other external components. They define all operations that can be performed for a "type" or "class" of plugins, hence the name "plugin type."

Several plugin types are provided with Moab Web Services, but it is easy to create additional plugin types and add their functionality to web services. This involves using [Groovy](#), which is based on the [Java](#) programming language. This section describes the general guidelines and specifics of implementing new plugin types.

[API classes and interfaces](#)

There are several packages and classes available to assist in creating plugin types. These can all be found in the [API documentation](#).

This section contains these topics:

- [Requirements on page 2012](#)
- [Dynamic Methods on page 2013](#)
- [Logging on page 2013](#)
- [i18n Messaging on page 2014](#)
- [Configuration on page 2016](#)
- [Configuration Constraints on page 2018](#)
- [Individual Datastore on page 2027](#)
- [Exposing Web Services on page 2029](#)
- [Reporting State Data on page 2031](#)
- [Controlling Lifecycle on page 2035](#)

- [Utilizing Services or Custom "Helper" Classes on page 2050](#)

- [Packaging Plugins on page 2055](#)
- [Example Plugin Types on page 2065](#)

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

Requirements

This section discusses the requirements to create a basic functional plugin. The `com.adaptec.mws.plugins` package contains the abstract class [AbstractPlugin](#) that should form the basis of any new plugin type. However, this class need not be extended to create a functional plugin type. Only two requirements must be fulfilled for this:

1. The class name must end in `Plugin`.
2. There must exist `id` field getter and setter methods:

```
* public String getId();
* public void setId(String id);
```

The `id` field may be stored in whichever way desired as long as the getter and setter are available as shown above, but will most likely be implemented as follows:

```
class BasicPlugin {
    String id
}
```

In this case, `String id` will be expanded by the Groovy compiler to the full getter and setter method definitions given above. In other words, no explicit method definitions are actually needed. Note that the `BasicPlugin` shown above is able to be uploaded as a plugin type to MWS, but does not actually do anything.

It must also be noted that the `AbstractPlugin` class already implements an `id` field. Therefore, a plugin type that extends this class does not need to define the field as shown in the following example.

```
import com.adaptec.mws.plugins.AbstractPlugin

class BasicPlugin extends AbstractPlugin {
    // No ID field is needed since it exists in AbstractPlugin
}
```

Related Topics

- [Plugin Developer's Guide on page 2011](#)

Dynamic Methods

i These methods are currently in *Beta*. Interfaces may change significantly in future releases.

Several methods are dynamically inserted onto each plugin. These methods do not need to be included in the plugin class, and will be overwritten if included. Additionally, a logger is inserted into each plugin as discussed in the next section. The inserted methods are shown below (full definitions can be found in [AbstractPlugin](#) and [AbstractPluginInfo](#)):

- `public void start() throws PluginStartException;` (Equivalent to the start method in the [Plugin Control Service on page 2087](#).)
- `public void stop() throws PluginStopException;` (Equivalent to the stop method in the [Plugin Control Service on page 2087](#).)
- `public Log getLog();` (See [Logging on page 2013](#).)
- `public ConfigObject getAppConfig();` (See [Configuration on page 2016](#).)
- `public String message(Map parameters);` (See [i18n Messaging on page 2014](#).)
- `public String getPluginType();`
- `public PluginState getState();`
- `public Integer getPollInterval();`
- `public Boolean getAutoStart();`
- `public Map<String, Object> getConfig();` (See [Configuration on page 2016](#).)

Many of these methods are provided for convenience and are discussed in the linked pages or the following sections.

Related Topics

- [Plugin Developer's Guide on page 2011](#)

Logging

Logging in plugin types uses the [Apache Commons Logging](#) and [log4j](#) libraries. Each plugin is injected with a method called `getLog` which can be used to access the configured logger. It returns an instance of [org.apache.commons.logging.Log](#). Examples of using the logger are shown below.

The logger may used to register messages to the MWS log at several levels (in order of severity):

1. trace
2. debug
3. info
4. warn
5. error
6. fatal

Each of these levels is available as a method on the logger, for example:

```
public void poll() {
    getLog().debug("getLog() is equivalent to just using 'log' in Groovy")
    log.debug("This is a debug message and is used for debugging purposes only")
    log.info("This is a informational message")
    log.warn("This is a warning")
    log.error("This is an error message")
}
```

Logger name

Each logger in the MWS logging configuration has a name. In the case of plugins, it is comprised of the full class name, including the package, prepended by "plugins.". For example, a plugin class of "example.LoggingPlugin" will have access to a logger configured as `plugins.example.LoggingPlugin`.

Logging configuration

The logging configuration is done through the MWS configuration file. For more information on configuring loggers, see [Configuring Moab Web Services on page 1570](#). A good configuration for developing plugin types may be to add "plugins" at the debug level. Be sure to set the log level threshold down for the desired appender.

```
log4j = {
    ...
    // Appender configuration
    ...
    debug "plugins"
}
```

Related Topics

- [Plugin Developer's Guide on page 2011](#)

i18n Messaging

Plugins, translators, and custom components all have access to [i18n](#) messages. Utilizing messages requires the two following steps:

1. Including a file (or multiple files) that ends in "messages.properties" in the plugin JAR file.
2. Using the `message` method on a plugin type, translator, or custom component.

Including messages in plugin JAR file

Messages are defined using property files. These may be named anything as long as they end with "messages.properties" and must be placed at the root or top level of the plugin JAR file. If they are present, they will be loaded automatically. Multiple property files may be used within a single plugin JAR file.

Each property file consists of an arbitrary amount of lines that define a message property (also called a code) with letters, numbers, and periods, associated with a human-readable message that can span multiple lines, have quotes, or contain arguments. These are demonstrated in the following example.

```
first.message.code=This is the first message
second.message=This message can span multiple lines, \\
    and will not show the linebreaks when retrieved
message.with.arguments=This message has arguments: first - {0}, second - {1}, third - {2}, etc.
message.with.quotes=This message uses single quotes around 'this phrase'.
```

It is recommended to namespace the messages by using the property definitions and multiple property files if necessary. For example, suppose a plugin JAR existed which actually contained two plugin types: `Message1Plugin` and `Message2Plugin`. The first suggestion is to namespace the messages for each plugin by the property definition, such as the following:

```
message1Plugin.first.message=This is a message for Message1Plugin
message2Plugin.first.message=This is a message for Message2Plugin
```

These messages could be stored in a file named "messages.properties" in the root of the plugin JAR file. If there are many messages contained for each plugin type, it may be necessary to split each plugin type's messages into a separate file, such as "message1-messages.properties" and "message2-messages.properties". Note that it is essential that each property file ends with "messages.properties" so that it is registered correctly.

It is important that no two message codes are identical within a single plugin JAR file, even if they are defined in separate property files. If this is done, a conflict will exist with the messages and behavior is undefined.

Using the message method

Each plugin, translator, and custom component is injected with a method named `message`. This method takes a `Map` as its parameter, which can contain one or several of the following properties:

Parameter	Type	Description
code	String	The message property definition (everything before the equals sign in the property file for a single message), for example, <code>first.message.code</code> .
args	List<Object>	A list of arguments to insert into the message.
default	String	A default message to be used when the message code cannot be resolved.
error	org.springframework.context.MessageSourceResolvable	An object that represents a hierarchy of message codes. This is typically used to display errors.

The most utilized parameters are `code` and `args`, as these combined provide great flexibility in generating messages. If a message cannot be resolved, or in other words the message definition does not exist, the code will simply be returned as the resolved message. Below are several examples of messages resolved using the property files given above. While these are contained in the polling method, the `message` may be used anywhere within a plugin type.

```
package example
import com.adaptc.mws.plugins.AbstractPlugin

class MessagingPlugin extends AbstractPlugin {
  def poll() {
    assert message(code:"first.message.code")=="This is the first message"
    assert message(code:"message.with.arguments", args:[
      "1st", 2, true
    ])=="This message has arguments: first - 1st, second - 2, third - true, etc."
    assert message(code:"message.with.quotes")=="This message uses single quotes around
'this phrase'."
    assert message(code:"invalid.message.code")=="invalid.message.code"
  }
}
```

Related Topics

- [Plugin Developer's Guide on page 2011](#)

Configuration

Plugin types can access two different kinds of configuration: an individual plugin's configuration, and the global MWS application configuration.

[Individual plugin configuration](#)

The individual plugin configuration is separate for each instance of a plugin. This may be used to store current configuration information such as access information for linked resources. It should not be used to store cached information or non-configuration related data. The individual datastore should be used instead for these cases (for more information, see [Individual Datastore on page 2027](#)).

It is accessed by using the `getConfig` method discussed in [Dynamic Methods on page 2013](#).

```
public void poll() {
    def configFromMethod = getConfig()
    // OR an even simpler method...
    def configFromMethod = config
}
```

A common case is to retrieve the configuration in the `configure` method, verify that it matches predetermined criteria, and utilize it perform initial setup of the plugin (e.g. initialize libraries needed to communicate with external resources). For example, to verify that the configuration contains the keys "username" and "password," the following code may be used.

```
public void configure() throws InvalidPluginConfigurationException {
    def myConfig = config
    // This checks to make sure the key exists in the configuration Map and that the
    // value is not empty or null
    if (!myConfig.containsKey("username") || !myConfig.username)
        throw new InvalidPluginConfigurationException("The username configuration parameter
        must be provided")
    if (!myConfig.containsKey("password") || !myConfig.password)
        throw new InvalidPluginConfigurationException("The password configuration
        parameter must be provided")
}
```

[Access MWS configuration](#)

The MWS application configuration can also be accessed in plugin types. This configuration is global for the entire application and can be modified by the administrator as shown in [Configuring Moab Web Services on page 1570](#).

It is accessed by using the `getAppConfig` method discussed in [Dynamic Methods on page 2013](#). This is demonstrated below:

```
public void poll() {
    // Retrieve the current MWS_HOME location
    def mwsHome = appConfig.mws.home.location
    // OR an even simpler method...
    def mwsHome = getAppConfig().mws.home.location
}
```

Any of the properties shown in the [Configuration](#) reference may be accessed. Custom properties may also be registered and accessed:

```
mws-config.groovy
-----
plugins.custom.property = "This is my custom property"
```

```
CustomAppPropertyPlugin
-----
public void poll() {
    assert appConfig.plugins.custom.property=="This is my custom property"
}
```

Configuration Constraints

Plugin types can optionally define validation constraints for the polling interval and plugin configuration. These parameters are then checked against the defined constraints during the creation of a new plugin. If the validation fails, meaning the configuration provided does not pass the constraints defined by the plugin type, the plugin will fail to be created with error messages based on the parameters and constraints defined.

Defining constraints

To define constraints for a plugin type and therefore for all plugins created using it, use the following syntax:

```
import com.adaptc.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
    static constraints = {
        // Set plugin's default polling interval
        pollInterval defaultValue:60
        // The "myParam" configuration parameter is automatically required and cannot be
blank
        myParam blank:false
        // The "myEnum" configuration parameter is not required and must set to one of the
values in the list
        myEnum required:false, inList:["val1", "val2", "val3"]
        // Insert additional constraints here...
    }
}
```

In the table below, all available constraints are shown, as well as the expected value type, an example, the default message code, and the message suffix. The message columns are described in greater detail in the [Messaging](#) section below.

Con- strai- nt	D- ef- au- lt va- lu- e	T- y- p- e	Exam- ple value	Default mes- sage code	Message suffix	Description
blank	--	Bo- ol- ea- n	true	default.b- lank.message	blank	If false, the parameter (if present) cannot be a blank string.
cred- itCar- d	--	Bo- ol- ea- n	true	default.in- val- id.creditCard.message	cred- itCard.invalid	If true , uses <code>org.apache.commons.validator.CreditCardValidator</code> to determine if the parameter (if present) is a valid credit card number.
defau- ltVal- ue	--	O- bj- ec- t or Cl- os- ur- e	60	--	--	If the parameter is not present, it will be set to this default value. Does not return any error mes- sages. See Default value below for more information.
email	--	Bo- ol- ea- n	true	default.in- val- id.email.message	email.invalid	If true , the parameter (if present) must be a valid email address.
inList	--	Li- st	["fir- st", "seco- nd"]	default.not.in- list.message	not.inList	The parameter (if present) must be set to one of the values spe- cified.
matc- hes	--	St- ri- ng	"[a-z] [A-Z] +"	default.- does- nt.match.message	matches.in- valid	The parameter (if present) must match the specified regular expres- sion.

Con- strai- nt	D- ef- au- lt va- lu- e	T- y- p- e	Exa- m- ple value	Default mes- sage code	Message suffix	Description
max	--	In- te- ge- r	10	default.in- valid.max.message	max.exceeded	The parameter (if present) must not be greater than the defined value.
*max- Size	--	In- te- ge- r	10	default.in- val- id.max.size.message	maxS- ize.exceeded	The parameter's (if present) size must not be greater than the defined value.
min	--	In- te- ge- r	1	default.in- valid.min.message	min.notmet	The parameter (if present) must not be less than the defined value.
*min- Size	--	In- te- ge- r	1	default.in- val- id.min.size.message	minS- ize.notmet	The parameter's (if present) size must not be less than the defined value.
notEq- ual	--	O- bj- ec- t	"Inva- lid Value"	default.notequal- message	notEqual	The parameter (if present) must <i>not</i> be set to the defined value.
nul- lable	tru- e	Bo- ol- ea- n	false	default.null.mes- sage	nullable	If true , the parameter (if present) must be non-null value. See required for how to enforce the parameter to be present.
pass- word	--	Bo- ol- ea- n	true	--	--	If true , the parameter (if present) is hidden from the user both on input and display when managing plugin configuration. It is not, how- ever, hidden in the REST API. Does not return any error messages.

Con- strai- nt	D- ef- au- lt va- lu- e	T- y- p- e	Exam- ple value	Default mes- sage code	Message suffix	Description
range	--	Ran- ge	1..10	default.in- val- id.range.message	range.toos- mall/range.to- obig	Uses a groovy range to validate that the value is within a specified range.
requi- red	true	Bo- ol- ea- n	false	default.re- quired.message	required	If true , the parameter must be present and non-null for the plugin to be created successfully. Implies the <code>nullable:false</code> constraint.
scale	--	In- te- ge- r	2	--	--	Only valid for Double parameters. Rounds the parameter (if present) to the specified number of digits. Does not return any error mes- sages.
*size	--	Ran- ge	2	default.in- valid.size.message	size.toos- mall/s- ize.toobig	Uses a groovy range to restrict the size of a collection, string, or a num- ber.
*type	--	Cl- as- s	Integ- er,- class	typeMismatch	typeMismatch	See Type inferencing and con- version below.
url	--	Bo- ol- ea- n	true	default.in- valid.url.message	url.invalid	If true , uses <code>org.apache.commons.validator.UrlValidator</code> to determine if the parameter (if present) is a valid URL. Does not support <code>exec</code> or <code>file</code> scheme URLs.
scrip- table- Url	--	Bo- ol- ea- n	true	default.in- val- id.scriptable.url.mess	script- ableUrl.in- valid	Identical to the url validator, but adds support for <code>exec</code> and <code>file</code> scheme URLs.

Constraint	Default value	Type	Example value	Default message code	Message suffix	Description
validator	--	Closure	(See Custom validator)	default.invalid.validator.message	validator.error	See Custom validator below.
widget	--	String	"textarea"	--	--	By default, all strings render as a text field when creating or editing plugins. Setting this to "textarea" causes it to render as a text area with multi-line support. This is only valid for string configuration parameters.

* The user interface (see [Plugin Management on page 2078](#)) does not support parameters whose type is a subclass of Collection (a List, for example). Such parameters are therefore not recommended.

 The polling interval constraints must always apply to Integer types. If this specification is violated, the plugin type cannot be added or updated.

Messaging

When defined constraints are violated for a plugin, error messages are retrieved based on the configuration parameters and the applied constraints using i18n Messaging codes (see [i18n Messaging on page 2014](#)). First, the most specific error message will be attempted to be resolved from a message code generated from the plugin type name, the configuration parameter, and the constraint. This code takes the format of

`pluginTypeName.parameterName.suffix` where the plugin type's name has a lowercase first letter and the suffix is shown in the table above. If this message code is not defined, the default message code (as shown in the table above) will be used.

For example, if the [url](#) constraint validation failed for the "ExamplePlugin" plugin type's "endpoint" configuration parameter, the following message codes would be resolved in order:

- `examplePlugin.endpoint.url.invalid`
- `default.invalid.url.message`

i Plugin types that have two or more uppercase letters at the start of the name will not be converted to have a lowercase first letter for error message codes. In other words, for the example just given using "VCenterPlugin" instead of "ExamplePlugin", the following message codes would be resolved in order:

```
VCenterPlugin.endpoint.url.invalid  
default.invalid.url.message
```

Default messages

Default messages may be contained in any `messages.properties` file included in the plugin JAR file as explained in [i18n Messaging \(see **i18n Messaging on page 2014**\)](#). Arguments for each constraint vary, but they always include these argument indices:

- `{0}`: The configuration parameter name (for example, `endpoint`).
- `{1}`: The plugin type class name (for example, `my.package.ExamplePlugin`).
- `{2}`: The value of the configuration parameter.

If default messages are not defined in the plugin project, the following messages will be used:

```

default.doesnt.match.message=The ''{0}'' configuration parameter value ({2}) does not
match the required pattern ''{3}''
default.invalid.url.message=The ''{0}'' configuration parameter value ({2}) is not a
valid URL
default.invalid.scriptable.url.message=The ''{0}'' configuration parameter value ({2})
is not a valid scriptable URL
default.invalid.creditCard.message=The ''{0}'' configuration parameter value ({2}) is
not a valid credit card number
default.invalid.email.message=The ''{0}'' configuration parameter value ({2}) is not a
valid e-mail address
default.invalid.range.message=The ''{0}'' configuration parameter value ({2}) does not
fall within the valid range from {3} to {4}
default.invalid.size.message=The ''{0}'' configuration parameter value ({2}) does not
fall within the valid size range from {3} to {4}
default.invalid.max.message=The ''{0}'' configuration parameter value ({2}) is greater
than the maximum value of {3}
default.invalid.min.message=The ''{0}'' configuration parameter value ({2}) is less
than the minimum value of {3}
default.invalid.max.size.message=The ''{0}'' configuration parameter value ({2})
exceeds the maximum size of {3}
default.invalid.min.size.message=The ''{0}'' configuration parameter value ({2}) is
less than the minimum size of {3}
default.invalid.validator.message=The ''{0}'' configuration parameter value ({2}) does
not pass custom validation
default.not.inlist.message=The ''{0}'' configuration parameter value ({2}) is not
contained within the list [{3}]
default.blank.message=The ''{0}'' configuration parameter cannot be blank
default.not.equal.message=The ''{0}'' configuration parameter value ({2}) cannot be
equal to ''{3}''
default.null.message=The ''{0}'' configuration parameter cannot be null
default.required.message=The ''{0}'' configuration parameter is required and cannot be
null
typeMismatch=The ''{0}'' configuration parameter value ({2}) does not match the
required type ''{3}''

```

Labels and help messages

Message codes may also be provided for configuration parameters to aid the admin user with human readable property labels and help messages. Similar to the validation error message codes, labels and help message codes may be defined using the `pluginTypeName.parameterName.label` and `pluginTypeName.parameterName.help` message codes. These values are used only in plugin type management (see [Plugin Type Management on page 2073](#)) and are not exposed through the REST API.

Type inferencing and conversion

Due to the dynamic nature of configuration parameters, the expected type or class of values for each parameter are inferred from constraints. The following rules govern how type is inferred, in priority order:

- If the ***type** constraint is applied to a parameter, the constraint value will be used as the expected type.

i Only the `String`, `Date`, `Double`, `Integer`, and `Boolean` classes are supported for the **`*type`** constraint. If `Float` or `Long` is desired, use `Double` and `Integer` respectively as the type.

- If the **`inList`** or **`range`** constraints are applied to a parameter, the class of the first element in the constraint value array is used as the expected type.
- If the **`*minSize`** or **`*maxSize`** constraints are applied to a parameter, `java.lang.Collection` is used as the expected type.
- If the **`max`**, **`min`**, or **`notEqual`** constraints are applied to a parameter, the class of the constraint value is used as the expected type.
- If none of the above apply, `java.lang.String` is used as the expected type.

If the configuration parameter values can be converted to the expected types, this will occur automatically. Otherwise, the **`*type`** constraint is violated and the applicable error messages will be generated.

Custom validator

In cases where the built-in constraints prove inadequate for validation, custom validators may be used. The **`validator`** constraint expects a Groovy Closure parameter which has one or (optionally) two arguments: the value of the configuration parameter and the plugin object. With these parameters, complex validation logic may be defined. Additionally, custom message codes and arguments may be defined by validator constraints and these will be used in generating error messages when validation fails.

For example, suppose that the parameter "user" cannot be set to the same value as parameter "creator." Additionally, the "creator" parameter must not be equal to either "bob" or "joe." The existing constraints are inadequate to fulfill this use case, but the following code using validators would perform exactly as expected:

```
import com.adaptec.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
    static constraints = {
        user validator:{ val, obj ->
            if (val==obj.config.creator)
                return "invalid.equal.to.creator"
        }
        creator validator:{ val ->
            if ("val"=="joe")
                return ["invalid.equal", "joe"]
            if (val=="bob")
                return ["invalid.equal", "bob"]
        }
    }
}
```

In the examples above, the message codes and output on validation failure is shown below:

Message codes

```
constrainedPlugin.user.invalid.equal.to.creator=The user configuration parameter value
({2}) must not be equal to the creator parameter.
constrainedPlugin.creator.invalid.equal=The creator configuration parameter must not
be equal to {3}.
```

Output error messages

```
For user = "jill", creator = "jill"
"The user configuration parameter value (jill) must not be equal to the creator
parameter."
For user = "jill", creator = "bob"
"The creator configuration parameter must not be equal to bob."

For user = "jill", creator = "joe"
"The creator configuration parameter must not be equal to joe."
```

The validator Closure may return:

- `Nothing` (`null`) or `true` if the validation succeeded without errors.
- `false` if a validation error occurred (in this case the default validator message suffix would be used).
- A string which will be used as the message code suffix in the `pluginTypeName.propertyName.suffix` format.
- A list with the first element being the message code suffix, and all other elements being arguments for the message indexed starting at 3 (as shown in the example above).

All validator constraints automatically have the `appConfig` property available, which contains the application configuration as discussed in the Configuration section (see [Configuration on page 2016](#)). The `suite` property contains the value of the configured MWS suite. Additionally, services may be retrieved as explained in the next section.

[Retrieving services](#)

At times it may be necessary to use Bundled Services in custom validators. A method named `getService` which takes a single string parameter of the name of the service (as used during injection) is provided to be used in these cases. For example, if a plugin needs a valid server certificate file, the SSL Service may be used as follows:

```
import com.adaptec.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
  static constraints = {
    certificateFile validator:{ val ->
      ISslService sslService = getService("sslService")
      try {
        sslService.getSocketFactory(val)
      } catch (Exception e) {
        // Certificate file is invalid, return an error
        return ["invalid", e.message]
      }
    }
  }
}
```

i The `getService` method does not work with [translators](#), [custom components](#), [RM services](#), or the [Individual Datastore on page 2027](#).

Default value

The default value for a configuration parameter might depend on the MWS configuration or other properties. Therefore, the [defaultValue](#) constraint can be set to a closure. The `defaultValue` closure does not take any parameters and must return the object to be used as the default value.

For example, if the default value of a parameter must be true if and only if MWS is configured for the Cloud suite, then the following constraints would satisfy these conditions:

```
import com.adaptec.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
  static constraints = {
    myParameter required: true, type: Boolean, defaultValue: {
      return suite == Suite.CLOUD
    }
  }
}
```

As with [validator](#) closures, `defaultValue` closures have access to `appConfig`, `suite`, and `getService`.

Individual Datastore

Each plugin has access to an individual, persistent datastore which may be used for a variety of reasons. The datastore is not designed to store Moab data such as nodes, jobs, or virtual machines, but custom, arbitrary data pertinent only to the individual plugin. This may include storing objects in a persistent cache, state information for currently running processes, or any other arbitrary data. The individual datastore has the following properties:

- Data is persisted to the Mongo database and will be available even if the plugin or MWS is restarted.
- The data must be stored in groups of data called **collections**. These correspond directly to MongoDB collections.
- Each plugin may have an arbitrary number of collections.
- Collections are guaranteed not to collide if there are identically named collections between two plugin types or even two plugin instances.
- Each collection contains multiple objects or **entries**. These correspond directly to MongoDB documents.
- The values of entries may be any object which can be serialized to MongoDB: simple types (int or Integer), Maps, and Lists.
- A collection is automatically created whenever an entry is added to it, it does not need to be specifically initialized.

To utilize the datastore, the [Plugin Datastore Service](#) must be used. Operations are provided to add, query, and remove data from each collection.

i Simple key/value storage is not currently provided with the datastore. It may easily be done, however, by storing data in the format of `{name:"key", value:"value"}` and then retrieving this entry later by querying on name equals "key."

Example

The example below demonstrates two web services (see [Exposing Web Services on page 2029](#)). The first adds multiple entries containing various types of data to an arbitrarily named collection. The second retrieves the data and returns it to the user.

```
package example
import com.adaptc.mws.plugins.*

class DatastorePlugin extends AbstractPlugin {
  IPluginDatastoreService pluginDatastoreService

  def storeData(Map params) {
    def collectionName = params.collectionName
    def data = [[boolVal:true], [stringVal:"String"], [intVal:1], [nullVal:null]]
    if (pluginDatastoreService.addData(collectionName, data))
      log.info("Data successfully added")
    else
      log.info("There was an error adding the data")
    return [success:true]
  }

  def retrieveData(Map params) {
    def collectionName = params.collectionName
    return pluginDatastoreService.getCollection(collectionName)
  }
}
```

Exposing Web Services

Any number of methods may be exposed as public, custom web services by satisfying several criteria:

- The method must declare that it returns `Object` or `def`.
- The method must define a single argument of type `Map`.
- The method must actually return a `List` or `Map`.
- The method must not be declared as private or protected; only public or unscoped methods will be recognized as web services.

[Parameters and request body](#)

The `Map` argument will contain all parameters passed into the web service by the client. See [Accessing Plugin Web Services on page 1815](#) for additional details.

Parameters may be passed into the web service call as normal URL parameters such as `?param=value¶m2=value2`, as key-value pairs in the POST body of a request, or as JSON in the body.

For the first two cases, the parameters will be available on the `Map` argument passed into the web service call as key value pairs matching those of the request. Note that in these cases all keys and values will be interpreted as strings. However, the parameters object has several helper methods to convert from Strings to simple types, such as Booleans, integers, doubles, floats, and lists. If the value is not a valid simple type, null is returned.

Finally, note that the client may optionally include an `objectId` as the last part of the URL. When this is done, the **id** field will be set to this value in the `Map` argument to the web service.

```
GET <webServiceUrl>?key=value&key2=true&key3=5&list=1&list=2

def serviceMethod(Map params) {
    assert params.key=="value"
    assert params.key2=="true"
    assert params.bool('key2')==true
    assert params.key3=="5"
    assert params.int('key3')==5
    assert params.list('list')==[1, 2]

    // Null is returned if the conversion is invalid
    assert params.int('key')==null
}
```

When the body possesses JSON, the parsed JSON object or array will be available within a parameter called **body** in the `Map` argument. In this scenario, the types of the values are preserved by the JSON format.

```
POST <webServiceUrl> with JSON body of
{"key": "value", "key2": true, "key3": 5}
```

```
def serviceMethod(Map params) {
    assert params.body.key=="value"
    assert params.body.key2==true
    assert params.body.key3==5
}
```

Unsecured web services

There are times when it is desirable to create a plugin with a publicly available web service that does not require a valid application account in order to access it (for details, see [Access Control on page 1595](#)). In these cases, the [Unsecured](#) annotation may be used on the plugin web service method. No authentication will be performed on Unsecured web services. An example of using the annotation is given below.

Sample unsecured custom web service

```
@Unsecured
def retrievePublicData(Map params) {
    return [data:["data item 1", "data item 2"]]
}
```

Be cautious in using this annotation as it may potentially present a security risk if sensitive data is returned from the web service.

Returning errors

In order to signify an error occurred or invalid data was provided, the [WebServiceException](#) class may be thrown from any custom web service. This exception contains constructors and fields for a list of messages and a HTTP response code. For example, suppose that the user provided inadequate information. The web service could use the following code to notify the user and prompt them to take action with custom messages.

```
def service(Map params) {
    // Handle invalid input
    if (!params.int('a'))
        throw new WebServiceException("Invalid parameter 'a' specified, please specify an
integer!", 400)
    // Use params.a correctly ...
}
```

For the example above, a 400 response code (bad request) would be returned with a response body as follows:

```
{
  "messages": [
    "Invalid parameter 'a' specified, please specify an integer!"
  ]
}
```

If any other exception is thrown from a web service (ie Exception, IllegalArgumentException, etc.), a 500 response code will be returned with the following response body:

```
{
  "messages": [
    "A problem occurred while processing the request",
    "Message provided in the exception constructor"
  ]
}
```

See [Responses and Return Codes on page 1626](#) for more information on error formats in MWS.

[Accessing the HTTP Request Method](#)

The HTTP method used for the request is available from the Map parameters argument. The key used to access it is stored as a static field in [PluginConstants](#) called `WEB_SERVICES_METHOD`. The value is a string which can be GET, POST, PUT, or DELETE. The following example demonstrates how this could be used with the `WebServiceException` to create a REST API with a plugin.

```
def serviceMethod(Map params) {
  // Check to make sure that this request used the HTTP GET method
  // Throw a 405 error (method not supported) if not
  if (params[PluginConstants.WEB_SERVICES_METHOD] != "GET")
    throw new WebServiceException("Method is not supported", 405)
}
```

Reporting State Data

As long as Moab Workload Manager is configured with MWS as a Resource Manager (RM), plugins may report state information on jobs, nodes, storage, and virtual machines to Moab. This is done through **Reports** that are generated by the plugin and passed to the bundled RM services ([Job RM Service](#), [Node RM Service](#), [Storage RM Service](#), and [Virtual Machine RM Service](#)). Each report is for a specific type of object: job, node, storage, or virtual machine. Each contains current state information on the specific attributes of the type it is for.

i Note that storage is a sub-type of node, meaning that it is a specialized node.

[Generating reports](#)

To generate a report, simply create a new instance of a report depending on the type of object to be reported:

Object type	Report type
Job	JobReport
Node	NodeReport
Storage	StorageReport
Virtual Machine	VirtualMachineReport

Each report has a single required parameter for creating a new instance—the ID of the object which is being reported. Once the report instance has been created, any property may be modified as shown in the API documentation links in the table above. The following example shows the creation of a simple node report and modification of a few properties:

```
public void poll() {
    NodeReport node = new NodeReport("node1")
    node.timestamp = new Date()
    node.image = "centos-5.4-stateless"
    ... // Set other properties and persist the report
}
```

[Master and slave reports](#)

At times, you may want to report some additional attributes on objects *only if* the objects are being reported by other plugins. For example, you may want to report the power state of a VM, but sometimes the plugin reporting this data can receive data even after the VM has been destroyed. In this case, you can set the `slaveReport` field on any report to `true`, signifying that the report should only be used if another plugin is reporting on the same object (in other words, creating "master" reports).

i If all reports for an object are "slave" reports, and no "master" reports exist, then the object will not report to Moab Workload Manager.

[Special cases in field values](#)

All complex types, such as Lists, Maps, and objects (not including Enumerated values such as [NodeReportState](#) and [JobReportState](#)) have default values set for them and are not required to be instantiated before use. For example, the metrics property of a node report may be modified as follows:

```
public void poll() {
    NodeReport node = new NodeReport("node1")
    // The following assignments are equivalent in their functionality
    node.features.add("FEAT1")
    node.features << "FEAT2"
    // The following assignments are equivalent in their functionality
    node.metrics.METRIC1 = 4d
    node.metrics["METRIC2"] = 125.5
    ... // Set other properties and persist the report
}
```

For the `resources` and `requirements` (jobs only) properties, assignments may be made easily without checking for previously existing values or null objects. For example, `resources` may be added to the `resources` property simply by accessing it as a Map:

```
public void poll() {
    NodeReport node = new NodeReport("node1")
    node.resources.RES1.total = 10
    node.resources.RES1.available = 3
    node.resources["RES2"].total = 10
    node.resources["RES2"].available = 10
    ... // Set other properties and persist the report
}
```

The job report's `requirements` property has some additional handling to allow it to be accessed as a single [JobReportRequirement](#) object, such as in the following example:

```
public void poll() {
    JobReport job = new JobReport("job.1")
    job.nodeCountMinimum = 4
    job.processorCountMinimum = 2
    job.requiredNodeFeatures << "FEAT1"
    job.preferredNodeFeatures << "FEAT2"
    ... // Set other properties and persist the report
}
```

i Although multiple requirements may be added to the `requirements` list to provide consistency with the MWS Job resource (see [Jobs on page 1755](#)), only the first requirement object's properties will be reported to Moab through the RM interface.

Managing images for nodes

In order to have Moab Workload Manager recognize a node as a virtual machine hypervisor, it must have a valid associated Image (see [Images on page 1736](#)). In particular, the `image` property on a node report must set to a valid image name. The image's `hypervisorType` and `virtualizedImages` properties are then used to report the correct hypervisor type and supported virtual machine images to Moab.

If the `image` is invalid, it will be ignored and the node will not be recognized as a hypervisor. If the `image` is valid, but no `hypervisorType` value is present, the `extensions.xcat.hvType` field value will be used. If that is also not present,

the configuration parameter for default hypervisor type (see [Configuration on page 2114](#)) will be used instead.

Persisting a Report

After a report has been generated and all desired fields have been updated, the report must be sent to one of the three bundled RM services for persisting. If this is not done, the report will be discarded and will not be considered when reporting state information to Moab. The RM services are shown below according to the object type that they handle:

Object type	RM service
Job	Job RM Service
Node	Node RM Service
Storage	Storage RM Service
Virtual Machine	Virtual Machine RM Service

Each service has two methods: `save` and `update`. The difference between these is that the `save` method first removes all previous reports from the plugin calling the method, and then persists the new reports, thereby only persisting the latest reports, while the `update` method does not remove any reports before persisting the new reports. Typically, the `save` method will be used while a plugin is being polled, while the `update` method will be used in incremental event based reporting. An example of using the `save` method is shown below.

```
INodeRMService nodeRMService

public void poll() {
    NodeReport node = new NodeReport("node1")
    // Change the state
    node.state = NodeReportState.BUSY
    // Persist
    nodeRMService.save([node])
}
```

Once this is done, the reports will be persisted to MongoDB and will be included in RM queries (see [Resource Manager Queries on page 2071](#)) from Moab Workload Manager or users.

Controlling Lifecycle

i Plugin control is currently in Beta. Interfaces may change significantly in future releases.

At times a plugin developer may wish to modify the current state of a plugin or even create plugins programatically. This may be done with the [Plugin Control Service](#). Operations exist on the service to:

- create plugin instances dynamically with specific configuration.
- retrieve plugin instances by ID or based on configuration properties.
- start or stop plugin instances.
- verify plugin instance configuration.

[Creating plugins](#)

Several methods are provided to allow on-the-fly creation of new plugins. Generally, they allow a plugin with a specific ID and plugin type (as a string or as a Groovy Class) to be created with optional configuration properties. These properties should match the fields in [Plugins on page 1808](#).

If any configuration properties are omitted, the defaults will be used as described in [Setting Default Plugin Configuration on page 2083](#). A boolean value is also returned indicating whether the creation succeeded or not.

Note that the `createPlugin` methods will initialize the plugin for retrieval or usage and attempt to start the plugin if the `autoStart` property is true.

[Retrieving plugins](#)

Plugins may be retrieved by using an ID, querying by plugin type, or even querying based on configuration parameters. Several methods are provided to perform these functions as shown on [Plugin Control Service on page 2087](#).

[Starting and stopping plugins](#)

Plugins may also be started or stopped on demand. These two methods are exposed directly as `start` and `stop` on the plugin control service. Although each method does not return any data, exceptions are thrown if errors are encountered.

[Verifying plugin configuration](#)

Finally, the plugin control service may be used to verify plugin configuration at any point instead of just when the plugin is started or modified. This may be useful to attempt to modify plugin configuration directly through the `setConfig` dynamic method (see [Dynamic Methods on page 2013](#)) and then verify that the new configuration is valid for the plugin. Exceptions are thrown if the plugin or the configuration is invalid.

Examples

If an error state is detected it may be necessary to stop the current plugin instance until corrective action can be taken. This may be done using the following code:

```
package example

import com.adaptc.mws.plugins.*

class ErrorPlugin {
    IPluginControlService pluginControlService

    public void poll() {
        // Error is detected, stop plugin instance!
        try {
            log.warn("An error was detected, trying to stop the plugin ${id}")
            pluginControlService.stop(id)
            log.warn("The plugin was successfully stopped")
        } catch (PluginStopException e) {
            log.error("Plugin instance ${id} could not be stopped", e)
        }
    }
}
```

- [Plugin Developer's Guide on page 2011](#)

Accessing MWS REST Resources

Often a plugin type may need to access existing MWS REST Resources in order to extend or complement default MWS functionality. This may be done with the **Moab REST Service**, which allows a plugin type developer to utilize the existing Resources documentation see [Resources Introduction on page 1646](#)) to perform these tasks.

All accesses to resources require a HTTP method to use (such as GET, POST, PUT, or DELETE) and a relative URL (such as `/rest/jobs`). Although it mimics the REST resource interface, no actual requests are made and no data is transmitted through the network.

Authentication

All resources are available to the Moab REST Service, and no authentication or Application Accounts are needed.

i Caution must be used when developing plugin types, as there are no restrictions to what may be done with the Moab REST Service. This is especially true when not utilizing hooks as discussed below.

Hooks

If pre and post-processing hooks are utilized in MWS (**Pre- and Post-Processing Hooks on page 1633**), the plugin type developer may choose

whether or not they are executed when performing a "request" through the Moab REST service. This is done through the hooks option as documented in [Moab REST Service on page 2085](#).

Verifying API version support

The Moab REST Service provides a method for easily determining which API versions are supported by the current version of MWS. This method includes checks to make sure that the API version will work as expected, including verifying any configuration or external services are running.

```
moabRestService.isAPIVersionSupported(1)
moabRestService.isAPIVersionSupported(2)
```

Converting string dates

Because the Moab REST Service returns data exactly as given to an external consumer of MWS, including dates converted to strings, the service provides a method for converting MWS date strings to actual Date objects.

```
moabRestService.convertDateString("2011-11-08 13:18:47 MST")
```

URL parameters

URL parameters, such as `query`, `sort`, `proxy-user`, and others should be not be appended directly to the URL. Instead, these may be specified with the `params` option:

```
// Query images that are hypervisors
moabRestService.get("/rest/images", params:[query:'{"hypervisor":true}'])
// Sort images by osType
moabRestService.get("/rest/images", params:[sort:'{"osType":1}'])
```

Examples

This code retrieves a list of all nodes, and is equivalent to the [Get All Nodes](#) task.

```

package example

import com.adaptc.mws.plugins.*
import net.sf.json.*

class RestPlugin {
    IMoabRestService moabRestService

    public void poll() {
        def result = moabRestService.get("/rest/nodes")
        // OR with the hook enabled...
        def result = moabRestService.get("/rest/nodes", hooks:true)

        assert result instanceof MoabRestResponse
        assert nodes instanceof List

        log.debug("Nodes list:")
        nodes.each { JSON node ->
            log.debug(node.id)
        }
    }
}

```

This code adds a flag to a job, and is equivalent to the **Modify Job Attributes** task. This request also enables the hook (if one is configured) for the "request" and uses a URL parameter. This is the equivalent of making a call to `/rest/jobs/job.1?proxy-user=adaptive`.

```

package example

import com.adaptc.mws.plugins.*
import net.sf.json.*

class RestPlugin {
    IMoabRestService moabRestService

    public void poll() {
        def jobId = "job.1"
        def result = moabRestService.put("/rest/jobs/"+jobId, hooks:true, params:['proxy-
user':'adaptive']) {
            [flags:["RESTARTABLE"]]
        }
        assert result.isSuccess()
    }
}

```

- [Plugin Developer's Guide on page 2011](#)

Creating Events and Notifications

Plugins may easily create new events and create or update notification conditions using the **Plugin Event Service**. Previously, this was only possible by utilizing the MWS REST resources. The event service eases this burden from plugin developers. There are several operations that are available using the service:

- Create an event with or without specifying an event date.
- Create an event from an enumeration annotated with `EventEnumeration` (see [Plugin Event Service on page 2092](#)) with or without specifying an event date.
- Create or update a notification condition with or without specifying an observed date or expiration duration.

Creating Events

Events are composed of several properties such as arguments, associated objects, origin, message, severity, escalation level, and a unique event code. The plugin event service removes the need for magic strings such as those for event severity ("INFO", "WARN", "FATAL") and also handles creating unique event codes. In other words, no bitwise manipulation is required to create new events.

The event code is comprised of several elements:

Code element	Description
Severity	If the event is informational, a warning, an error, or fatal.
Escalation level	Who cares about the event, or who should act on the event.
Component code	Internally made up of the MWS component code (stored internally) and the plugin event component code (see Plugin event component code on page 2039).
Entry code	The code representing a unique event for the component (for each plugin event component code).

The plugin event service handles the severity, escalation level, and entry code portions of the code by the values passed as parameters to the `createEvent` method. The plugin event component code is described in the next section.

[Plugin event component code](#)

The plugin event component code should be a unique number across all plugin types or projects from 1–254. This number is combined with the MWS component code to represent each plugin as a unique component code across all Adaptive Computing products. 0 is reserved for MWS itself and should not be used. 255 is reserved for plugin types that do not define an event component code and represents an "unknown" plugin component. Additionally, codes 1–150 are reserved for Adaptive Computing plugins, while 151–254 are reserved for Professional Services and/or customer-specific plugins.

This code may be specified by setting an `eventComponent` property (see [Fields: Plugin Types on page 2414](#)) on the plugin project file or as a static property on the plugin type. As with all other project properties, the plugin type value overrides the project value. For example:

```
class MyExampleProject {
    ...
    Integer eventComponent = 2
    ...
}
ExamplePlugin {
    static final eventComponent = 1
    ...
}
Example2Plugin {
    // no eventComponent property
    ...
}
```

In this case, the plugin type `ExamplePlugin` has a plugin event component code of 1, while the `Example2Plugin` has a code of 2 since it inherits it from the project properties.

[Origin suffix](#)

The origin of an event created through the plugin event service is automatically set by the plugin framework to `MWS/plugins/<plugin type>/<plugin id>`. For example, an event created by the plugin created from the "ExamplePlugin" plugin type with an ID of "plugin1" would generate events with an origin of `MWS/plugins/Example/plugin1`.

While this origin is sufficient for an administrator to determine the plugin where the event came from, the plugin developer may want this to be more specific to a class name or method name. This may be done using the optional `originSuffix` parameter to the `createEvent` method. The origin suffix, as its name implies, is appended to the end of the generated origin. For the example above, suppose the plugin developer passed `myMethod/switch1` as the origin suffix parameter when creating a new event. The event would then have an origin of `MWS/plugins/Example/plugin1/myMethod/switch1`.

[Event enumerations](#)

While creating events using the plugin event service is quite simple, often there are related events that have properties in common, such as the event type prefix or the origin suffix. Additionally, i18n messages (see [i18n Messaging on page 2014](#)) are typically used for the event's message. Using the `EventEnumeration` annotation (see [Plugin Event Service on page 2092](#)) in combination with an enumeration simplifies this process. When this is done, each message is pulled from the `messages.properties` files using a standard convention, and the event type prefix and the origin suffix may optionally added as static properties on the enumeration. Using `EventEnumeration` requires:

- The annotated element is an `enum`, not a `class` or `interface`.
- Each enumeration value must use the constructor with three arguments: the event name, the severity, and the escalation level.
- If an event type prefix is specified, it must be defined as `"static String EVENT_TYPE_PREFIX = ..."`, otherwise the property should not be defined.
- If an origin suffix is specified, it must be defined as `"static String ORIGIN_SUFFIX = ..."`, otherwise the property should not be defined.

If any of these conditions are not fulfilled, using the `EventEnumeration` annotation will result in compilation errors.

Enumeration values are automatically marked as implementing the `IPluginEvent` interface and may be used as the first parameter of the `createEvent` method on the plugin event service. For example:

```
package example

import com.adaptec.mws.plugins.EventEnumeration
import com.adaptec.mws.plugins.IPluginEventService.AssociatedObject
import static com.adaptec.mws.plugins.IPluginEventService.Severity.*
import static com.adaptec.mws.plugins.IPluginEventService.EscalationLevel.*

public class ExamplePlugin {
    void poll() {
        // Event 1 takes no arguments
        pluginEventService.createEvent(ExampleEvents.EVENT1, null, null)
        // Event 2 takes one argument and has an associated object
        pluginEventService.createEvent(ExampleEvents.EVENT2, ["arg1"], [new AssociatedObject
(type:"type1", id:"id1")])
    }
}

@EventEnumeration
enum ExampleEvents {
    EVENT1("Example One", INFO, USER), // Entry code is 0
    EVENT2("Example Two", INFO, USER) // Entry code is 1
}
```

It may be noted that several key properties of events are missing from the enumeration definition and create event call parameters:

- Message: retrieved automatically from i18n messages (see [Messages for event enumerations on page 2042](#))
- Event type: generated from the enumeration constructor and optional event type prefix property (see [Event type for event enumerations on page 2042](#))
- Entry code: generated from the return value of `ordinal()` on the enumeration value; in other words, this is generated from the order of the enumeration values

Messages for event enumerations

The message for events created from enumerations is generated using i18n messages (see [i18n Messaging on page 2014](#)) with codes in the following format:

- `<enumeration type name>.<enumeration value name>.message`
- `<enumeration type name>.<enumeration value name>.comment`

Considering the example in the section above, the message for `ExampleEvents.EVENT1` would be generated using the argument list passed to the `createEvent` method with the `"ExampleEvents.EVENT1.message"` message from `messages.properties`. This message should contain arguments if needed, such as "My example with ID {0} was created" and is used as the "message" property in the created event. The comment, on the other hand, is not persisted with the event and should be text (typically in paragraph format) describing why the event typically occurs or what actions should be taken when it does occur. Consider the message to contain instance specific information for the event (passed as arguments to the message) and the comment to be general documentation concerning the event.

As a best practice, name event enumeration values using the number and short name of each argument to the message. This makes it easy for the consumer to know which arguments are expected and what each means. For example, if an event is for connection errors and needs two arguments to the message, the URL and the error message, the enumeration value should be named `"CONNECT_FAILURE_1URL_2ERROR"` or even `"CONNECT_TO_1URL_FAILURE_2ERROR"`. In this way, the consumer knows that the first argument represents the URL and the second is the error message.

Event type for event enumerations

As described above, the static string field `EVENT_TYPE_PREFIX` may be defined on the enumeration. This value is optional and, when present, is prepended with a space to the event name parameter from the constructor to generate the event type. For example, consider the following enumeration:

```
package example

import com.adaptec.mws.plugins.EventEnumeration
import static com.adaptec.mws.plugins.IPluginEventService.Severity.*
import static com.adaptec.mws.plugins.IPluginEventService.EscalationLevel.*

@EventEnumeration
enum MyPluginEvents {
    CONNECT("Connect", INFO, ADMIN),
    DISCONNECT("Disconnect", INFO, ADMIN)

    static String EVENT_TYPE_PREFIX = "My Plugin"
}
```

If `MyPluginEvents.CONNECT` and `MyPluginEvents.DISCONNECT` were used with the plugin event service, the generated event types would be "My Plugin Connect" and "My Plugin Disconnect" respectively.

Origin for event enumerations

The origin for event enumeration values automatically contains more information than those for non-enumerated events, such as those described above. The enumeration type name and value are appended to the origin. For example, consider the following enumeration and plugin fragment:

```
...
class ExamplePlugin {
    ...
    assert id=="example1"    // plugin ID is example1
    pluginEventService.createEvent(ExampleEvents.EVENT1, null, null)
    ...
}
...
@EventEnumeration
enum ExampleEvents {
    EVENT1("Event One", INFO, ADMIN)
    ...
}
```

The origin generated for the created event would be `MWS/plugins/Example/example1/ExampleEvents/EVENT1`. The static string field `ORIGIN_SUFFIX` may also be defined on the enumeration. This value is optional and, when present, is appended to the end of the generated origin as described above with the origin suffix parameter to the `createEvent` method.

Example

In order to understand all interactions when event enumerations are used, the following is a complete example.

```
Plugin type
-----

package example
import com.adaptec.mws.plugins.*

class ConnectPlugin extends AbstractPlugin {
    static eventComponent = 1

    IPluginEventService pluginEventService

    void poll() {
        def errorMessage = connect()
        if (errorMessage)
            pluginEventService.createEvent(ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR,
[config.url, errorMessage], null)
        else
            pluginEventService.createEvent(ConnectEvents.CONNECT_SUCCESS, null, null)
    }

    // Returns the error message or null/empty on success
    private String connect() {
        String errorMessage
        ...
        return errorMessage
    }
}
```

Event enumeration

```

package example
import com.adaptc.mws.plugins.EventEnumeration
import static com.adaptc.mws.plugins.IPluginEventService.Severity.*
import static com.adaptc.mws.plugins.IPluginEventService.EscalationLevel.*

@EventEnumeration
enum ConnectEvents {
    CONNECT_SUCCESS("Success", INFO, ADMIN),
    CONNECT_TO_1URL_FAILURE_2ERROR("Failure", ERROR, ADMIN)

    static String EVENT_TYPE_PREFIX = "Connect"
}

```

messages.properties

```

ConnectEvents.CONNECT_SUCCESS.message=The plugin was successfully connected!
ConnectEvents.CONNECT_SUCCESS.comment=This occurs when the plugin successfully
connects to the configured URL and
    is informational only.
ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR.message=The plugin failed to connect to
{0}: {1}
ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR.comment=This occurs when the plugin fails
to connect to the configured
    URL for any reason. The most common reason is that the service is not running and
needs to be started.

```

The following are examples of the events created in MWS:

Created events

```

{"totalCount": 2, "resultCount": 2, "results": [
  {
    "arguments": ["http://localhost:1000", "The service is not running!"],

    "associatedObjects": []
  }
]}

```

Unique event codes

The last topic that must be covered in creating events from plugins is that all efforts should be made to make sure that event codes are unique throughout all Adaptive Computing product suites. Additionally, the codes should be static, meaning they do not change once established. In order to do this, adhere the following recommendations:

- Use a unique (across all plugin types) plugin event component code for each plugin type.
- Follow the guidelines for plugin event component codes established above (see [Plugin event component code on page 2039](#)) and ensure it is a number 1-254.
- Use event enumerations where possible, otherwise ensure (through testing if possible) that all entry codes are unique for each plugin type.
- Ensure (through testing if possible) that the ordinal value of the event enumeration values do not change.

Creating or Updating Notification Conditions

The plugin event service also makes it easy to create or update notification conditions. Simply use the `updateNotificationCondition` method. Just as the MWS notification condition resource, this is an idempotent operation, meaning it can be called multiple times with the same result. If the notification condition does not exist, it will be created automatically. If it does exist, the observed date and details will be updated accordingly.

Examples

Examples are available on [Plugin Event Service on page 2092](#).

Related Topics

- [Resources Introduction on page 1646](#)
- [Events on page 1728](#)
- [Notifications on page 1794](#)
- [Notification Conditions on page 1789](#)
- [Plugin Developer's Guide on page 2011](#)
- [Fields: Events on page 2205](#)
- [Plugin Event Service on page 2092](#)
- [Handling Events on page 2046](#)
- [System Events on page 1644](#)
- [Securing the Connection with the Message Queue on page 1592](#)

Handling Events

i Plugin events (excepting the poll event) are currently in Beta. Interfaces may change significantly in future releases.

Plugin types may handle specific events by containing methods defined by the conventions below. All events are optional.

The polling event

To maintain current information, each plugin is polled at a specified time interval. The following method definition is required to utilize the polling event.

```
void poll() { ... }
```

Typically this polling method is used to report node and virtual machine information. By default, the polling interval is set to 30 seconds, but can be modified for all or individual plugins as explained in [Plugin Management on page 2078](#).

When a polling event occurs, the `poll` method on the target plugin is called. This method may perform any function desired and should typically make calls to the [Node RM Service](#), the [Virtual Machine RM Service](#), and the [Job RM Service](#) services to report the current state of nodes and virtual machines. For example, the `poll` method in the Native plugin type is implemented as follows:

i This is an extremely simplified version of what is actually implemented in the Native plugin type.

```
INodeRMService nodeRMService;
IVirtualMachineRMService virtualMachineRMService;

public void poll() {
    nodeRMService.save(getNodes());
    virtualMachineRMService.save(getVirtualMachines());
}
```

This simple poll method calls two other helper methods called `getNodes` and `getVirtualMachines` to retrieve node and virtual machine reports. These reports are then sent to the appropriate RM service. See [Reporting State Data on page 2031](#) for more information on the RM services; however, the objective of this example is to demonstrate one possible use of the poll event handler. Other plugin types, on the other hand, may use the poll event to update internal data from pertinent resources or make calls to external APIs.

Lifecycle events

Events are also triggered for certain lifecycle state changes. The following method definitions are required to receive lifecycle events.

```

public void configure() throws InvalidPluginConfigurationException { ... }
public void beforeStart() { ... }
public void afterStart() { ... }
public void beforeStop() { ... }
public void afterStop() { ... }

```

Each event is described in the table below with the associated state change when the event is triggered.

State change	Event	Description
configure	Configure	Triggered before <code>beforeStart</code> and after the plugin has been configured. May be used to verify configuration and perform any setup needed any time configuration is loaded or modified.
beforeStart	Start	Triggered just before starting a plugin.
afterStart	Start	Triggered just after a plugin has been started.
beforeStop	Stop	Triggered just before stopping a plugin.
afterStop	Stop	Triggered just after stopping a plugin.

Currently, no events are triggered for pausing, resuming, erroring, or clearing errors for plugins.

RM events

When MWS is configured as a Moab Resource Manager (see [Moab Workload Manager Resource Manager Integration on page 2066](#), and more specifically, [Configuring Moab Workload Manager on page 2067](#)), RM events are sent from Moab to each plugin according to the routing specification (see [Routing on page 2010](#)). The following method definitions are required to receive these events.

```

public boolean jobCancel(String jobName) { ... }
public boolean jobModify(String jobName, Map<String, Object> attributes, ModifyMode modifyMode) { ... }
public boolean jobRequeue(String jobName) { ... }
public boolean jobResume(String jobName) { ... }
public boolean jobStart(String jobName, List<String> nodes, String username) { ... }
public boolean jobSubmit(Map<String, Object> job, String submissionString, String submissionFlags) { ... }
public boolean jobSuspend(String jobName) { ... }
public boolean nodeModify(List<String> nodes, Map<String, String> attributes, ModifyMode modifyMode) { ... }
public boolean nodePower(List<String> nodes, NodeReportPower state) { ... }
public boolean virtualMachinePower(List<String> virtualMachines, NodeReportPower state) { ... }

```

Handling Exceptions

i Plugin exceptions are currently in Beta. Interfaces may change significantly in future releases.

The `com.adaptc.mws.plugins` package contains several exceptions that may be used and in some cases, should be caught. All exceptions end with "Exception", as in [PluginStartException](#).

There are several specific cases where Exceptions should or can be used:

- The `reload` method on the [Plugin Control Service](#) can throw the [InvalidPluginConfigurationException](#) to signify that the configuration contains errors.
- Various methods on the [Plugin Control Service](#) throw plugin exceptions which must be caught to diagnose errors when creating plugin types.
- Any exception (including the Exception class) can be thrown from a custom web service to display a 500 Internal Server Error to the client requesting the service with the given error message.

Managing SSL Connections

At times it is desirable to load and use self-signed certificates, certificates generated from a single trusted certificate authority (CA), or even simple server certificates. It may also be necessary to use client certificates to communicate with external resources. To ease this process, the [SSL Service](#) may be utilized. This service provides methods to load client and server certificates from the filesystem. Methods are also present to aid in creating connections which automatically trust all server certificates and connections.

Several points should be noted when using the SSL Service:

- Certificate files may be in the PEM file format and do not need to be in the DER format (as is typical of Java security).
- Each method returns an instance of `SSLConnectionFactory`, which may then be used to create simple sockets or, in combination with another client library of choice, create a connection.
- If the client certificate password is non-null, it will be used to decrypt the protected client certificate.
- This service is *not* needed when performing SSL communications with trusted certificates, such as those for HTTPS enabled websites that do not have a self-signed certificate.
- If the file name of the certificate file (client or server) is relative (no leading '/' character), it will be loaded from the `mws.certificates.location` configuration parameter (see [Configuration on page 2114](#)).
 - The default value of `mws.certificates.location` is `MWS_HOME/etc/ssl.crt`.
- Both the client certificate alias and password may be `null`. In this case, the client certificate must not be encrypted and the client certificate's default alias (the first subject CN) will be used.
- The lenient socket factory and hostname verifier automatically trust all server certificates. Because of this, they present a large security hole. Only use these methods in development or in fully trusted environments.

Example

To create a socket to a server that requires a client certificate, the following code may be used.

```
package example

import com.adaptc.mws.plugins.*

class SSLConnectionPlugin extends AbstractPlugin {
  ISslService sslService

  public void poll() {
    // This certificate is not encrypted and will be the only certificate presented to
    the
    // connecting end of the socket.
    // This file will be loaded from MWS_HOME + mws.certificates.location + my-cert.pem.
    String clientCert = "my-cert.pem"

    def socketFactory = sslService.getSocketFactory(clientCert, null, null)
    def socket = socketFactory.createSocket("hostname.com", 443)
    // Write and read from the socket as desired...
  }
}
```

To create a HTTPS URL connection to a server that has a self-signed certificate, the following code may be used. Note that this is very typical of client libraries –

they have a method to set the SSL socket factory used when creating connections.

```
package example

import com.adaptec.mws.plugins.*

class SSLConnectionPlugin extends AbstractPlugin {
    ISslService sslService

    public void poll() {
        // This certificate represents either the server public certificate or the CA's
        // certificate.
        // Since the path is absolute it will not be loaded from the MWS_HOME directory.
        String serverCert = "/etc/ssl/certs/server-cert.pem"

        def socketFactory = sslService.getSocketFactory(serverCert)

        // Open connection to URL
        HttpURLConnection conn = "https://hostname.com:443/test".toURL().openConnection()
        conn.setSSLSocketFactory(socketFactory)

        // Retrieve page content and do with as desired...
        def pageContent = conn.getInputStream().text
    }
}
```

Utilizing Services or Custom "Helper" Classes

There are three general types of services available for use in plugins:

- Bundled services such as the [Moab REST Service](#).
- Custom built translators loaded by convention of their name.
- Other custom built helper classes registered with Annotations.

These will each be described in this section.

Bundled Services

Bundled services are utility classes that are included and injected by default onto all plugin types. It is not required to use any of these services, but they enable several core features of plugin types as discussed in [Utility Services on page 2008](#).

More information may be found on each bundled service in [Plugin Services on page 2084](#).

Using Translators

Often a plugin type class file becomes so complex that it is desirable to split some of its logic into separate utility service classes. The most typical use case for this is to split out the logic for "translating" from a specific resource API to a format of data that the plugin type can natively understand and utilize. For this reason, there is a convention defined to easily add these helper classes called "Translators."

Simply end any class name with "Translator," and it will be automatically injected just as bundled services onto plugin types, other translators, or even custom registered components. The injection occurs only if a field exists on the class matching the name of the translator with the first letter lower-cased. For example, a translator class called "MyTranslator" would be injected on plugin types, other translators, and custom components that define a field called "myTranslator" as `def myTranslator or MyTranslator myTranslator`.

 Do not use two upper-case letters to start the class name of a Translator. Doing this may cause injection to work improperly. For example, use `RmTranslator` instead of `RMTranslator` as the class name.

 Be careful not to declare translator and custom component injection such that a cyclic dependency is created.

Logging in translators

All translators automatically have a "getLog" method injected on them which can be used to access the configured logger. It returns an instance of org.apache.commons.logging.Log.

```
package example

class ExampleTranslator {
    public void myMethod() {
        // log will be translated to getLog() by the groovy compiler
        log.info("Starting my method")
    }
}
```

See [Logging on page 2013](#) for more information on logging configuration and usage.

Example

Suppose that a translator needs to be created to handle a connection to access an external REST resource. The translator could be defined as follows:

```
package example

class ExampleTranslator {
    public int getExternalNumber() {
        def number = ... // Make call to external resource
        return number
    }
}
```

A plugin type can then use the translator by defining a field called "exampleTranslator". Note that an instance does not need to be explicitly created.

```
package example

class ExamplePlugin {
    def exampleTranslator
    // OR ...
    //ExampleTranslator exampleTranslator

    public void poll() {
        // Use the translator
        log.info("The current number is "+exampleTranslator.getExternalNumber())
    }
}
```

To extend the example, the translator may also be injected into another translator:

```
package example

class AnotherTranslator {
    def exampleTranslator

    public int modifyNumber(int number) {
        return number + exampleTranslator.getExternalNumber()
    }
}
```

This translator may be used in the plugin type just as the other translator.

Registering Custom Components

There are cases where the concept of a "Translator" does not fit the desired use of a utility class. In these cases, it is possible to register any arbitrary class as a component to be injected just as a translator would be. This is done using the Spring Framework's annotation

`org.springframework.stereotype.Component`. When this annotation is used, the class is automatically registered to be injected just as translators onto plugin types and translators.

i All annotations are available in the dependencies declared by the plugins-commons artifact.

i Do not use two upper-case letters to start the class name of a custom component. Doing this may cause injection to work improperly. For example, use `RmUtility` instead of `RMUtility` as the class name.

Changing scope

By default, when a custom component is injected, only a single instance is created for all classes which inject it. This is referred to as the 'singleton' scope. Another scope that is available is 'prototype', which creates a new instance every time it is injected. This is useful when the class contains state data or fields that are modified by multiple methods. To change the scope, use the `org.springframework.context.annotation.Scope` on the class with a single String parameter specifying "singleton" or "prototype."

Injecting translators or components

The need may arise to inject translators or other custom components onto custom components. This is done using the `org.springframework.beans.factory.annotation.Autowired` or `javax.annotation.Resource` annotations. The `Autowired` annotation is used to inject class instances by the type (i.e. `MyTranslator myTranslator`) while the `Resource` annotation is used to inject class instances by the name (i.e. `def myTranslator`). Add the desired annotation to the field that needs to be injected.

i Note that using the `Autowired` annotation does injection by type which differs from translator and plugin type injection. These are done by name just as the `Resource` annotation allows. Due to this fact, a type of "def" cannot be used when doing injection onto custom components using the `Autowired` annotation. See the example below.

Injection of custom components *onto* translators and plugin types are still done by name, only fields injected using the `Autowired` annotation are affected.

⚠ Be careful not to declare translator and custom component injection such that a cyclic dependency is created.

Logging in custom components

Unlike plugins and translators, custom components do *not* automatically have a "getLog" method injected on them. In order to log with custom components, you must use the Apache Commons Logging classes to retrieve a new log. The `PluginConstants` class contains the value of the logger prefix that is used for all plugins and translators. The following is an example of how to retrieve and use a logger correctly in a custom component.

```
package example

import com.adaptc.mws.plugins.PluginConstants
import org.apache.commons.logging.Log
import org.apache.commons.logging.LogFactory
import org.springframework.stereotype.Component

@Component
class ExampleComponent {
    private static final Log log = LogFactory.getLog(PluginConstants.LOGGER_
PREFIX+this.name)

    public void myMethod() {
        log.info("Starting my method")
    }
}
```

See [Logging on page 2013](#) for more information on logging configuration and usage.

Example

Suppose that a custom utility class is needed to perform complex logic. A custom component could be defined as follows (notice the optional use of the `Scope` annotation):

```
package example

import org.springframework.stereotype.Component
import org.springframework.context.annotation.Scope

@Component
@Scope("prototype")
class ComplexLogicHandler {
    def handleLogic() {
        ... // Perform complex logic and return
    }
}
```

A plugin type or translator could then be defined to inject this component:

```
package example

class CustomPlugin {
    def complexLogicHandler

    public void poll() {
        complexLogicHandler.handleLogic()
    }
}
```

Now suppose another custom component needs to use the `ComplexLogicHandler` in its code. It can inject it using the `Autowired` annotation:

```

package example

import org.springframework.stereotype.Component
import org.springframework.beans.factory.annotation.Autowired

@Component
class AnotherHandler {
    // Note that this is injected by type, so 'def' may not be used
    @Autowired
    ComplexLogicHandler complexLogicHandler

    def wrapLogic() {
        complexLogicHandler.handleLogic()
    }
}

```

To perform the same injection but by name (as translators and plugin types are injected), use the `Resource` annotation:

```

package example

import org.springframework.stereotype.Component
import javax.annotation.Resource

@Component
class AnotherHandler {
    // Note that this is injected by name based solely on the name defined in
    // the annotation. The name of the field itself does not affect the injection.
    @Resource(name="complexLogicHandler")
    def complexLogicHandler

    def wrapLogic() {
        complexLogicHandler.handleLogic()
    }
}

```

Packaging Plugins

Plugin types may be packaged in two different ways to upload to MWS:

- A simple Groovy file containing a single plugin type definition.
- A JAR file containing one or more plugin types, translators, and custom components.

While each may be uploaded to MWS using the REST API or the User Interface as described in [Add or Update Plugin Types on page 2075](#), using a JAR file is recommended. Using a simple Groovy file is useful for testing and generating proof of concept work, but does not allow the use of several features of plugins.

The principles of packaging a plugin type or set of plugin types in a JAR file are very simple. Simply compile the classes and package in a typical JAR file. All classes ending in "Plugin" are automatically attempted to be loaded as a plugin type, all classes ending in "Translator" are attempted to be loaded as a

translator, and all classes annotated as a custom component will be attempted to be loaded. It is recommended that a build framework is used to help with compiling and packaging the JAR file, such as [Gradle](#). This makes it easy to declare a dependency on the necessary JAR files used in plugin development and to debug, compile, and test plugin code.

In addition to using utility services such as translators, packaging plugin types in JAR files allows the creation of a single project for multiple related plugin types and bundling of external dependencies. These two features are discussed in the following sections.

Plugin Projects and Metadata

Each plugin type has information attached to it, called metadata, which describes the origin and purpose of the plugin type. Additionally, a JAR file may also contain a project file which defines default metadata attributes for all plugin types in the JAR. Initial plugins, or plugins that will be created on loading of the JAR file if they do not exist, are also able to be defined on a project file. In all cases, metadata declared on a plugin type will override the metadata defined on the project file.

To define a project file, simply add a class to JAR file that ends in "Project." This file will attempted to be loaded as the project file. Every field on a project file, and even the file itself, is optional. All available fields are shown in the example below.

```

class SampleProject {
    // Plugin information
    String title = "Sample"
    String description = "Sample plugin types"
    String author = "Our Company."
    String website = "http://example.com"
    String email = "sample@example.com"
    Integer eventComponent = 1
    // Versioning properties
    String version = "0.1"
    String mwsVersion = "7.1 > *"
    String commonsVersion = "0.9 > *"
    String license = "APACHE"

    // Documentation properties
    String issueManagementLink = "http://example.com/ticket-system/sample-plugins"
    String documentationLink = "http://example.com/docs/sample-plugins"
    String scmLink = "http://example.com/git/sample-plugins"

    // Plugins that are to be created with these properties only when they do NOT exist
    // This does not override any existing plugin instance configuration
    def initialPlugins = {
        /*
        // Multiple instances of plugins may be defined here.
        // In this case, 'sample' is the id of the plugin
        sample {
            pluginType = "Sample"
            // All properties except for "pluginType" are optional
            pollInterval = 30
            autoStart = true
            // Although it is possible to set plugin precedence, it is not recommended
            // may already be taken and plugin creation will fail in this case
            precedence = 5
            config {
                configParam = "value"
            }
        }
        // Another plugin with an ID of 'sample2'
        sample2 {
            ...
        }
        */
    }
}

```

As can be seen, metadata information about the plugin type(s), versions, and documentation are available. These are displayed when viewing plugin information in the User Interface or through the REST API.

Any of these properties except for `initialPlugins`, `mwsVersion`, and `commonsVersion` may be overwritten by the plugin type class itself by using static properties. A simple example is shown below.

```

package example

class SamplePlugin {
    // Properties may be typed, untyped, final, or otherwise,
    // but they MUST be static
    static version = "0.2"
    static title = "Sample plugin"
    static description = "This sample plugin is used to demonstrate metadata information"
    static author = "Separate Division"
    static eventComponent = 1

    ... // Rest of the plugin type definition
}

```

Event component

The `eventComponent` field is explored in [Creating Events and Notifications on page 2038](#).

MWS and commons versions

The `mwsVersion` and `commonsVersion` fields are used to restrict the versions of MWS and plugin framework with which the plugin project may be used. Each field is of the format `FIRST VERSION > LAST VERSION`, where `FIRST VERSION` is the first supported MWS or plugin framework version (inclusive), and `LAST VERSION` is the last supported MWS or plugin framework version (inclusive). Each version must take the format of `#. #` or `#. #. #`, as in 7.1, or 7.1.2. An asterisk (*) is used to denote any version, and may be used for the first or the last version.

Although support for restricting both the MWS and commons versions are provided, it is recommended to use the commons version restriction always and the MWS version restriction where necessary. Restrictions on the commons version prevent plugin loading errors while restrictions on the MWS version prevent runtime errors such as missing support for certain MWS API versions.

Typically the `mwsVersion` and `commonsVersion` fields are set as shown above, with the first version set to a specific number, and the last version set to any (an asterisk). This is the recommended approach for setting both fields. It is not recommended to use any version (asterisk) for the first version. Some examples of `mwsVersion` and `commonsVersion` values are shown below with explanations of how they behave.

```
String mwsVersion = "7.1 > *" // Any MWS version 7.1.0 and greater is supported
(including 7.2, etc)
String mwsVersion = "7.1.3 > *" // Any MWS version 7.1.3 and greater is supported
(including 7.2, etc)
String mwsVersion = "7.1 > 7.1.3" // Any MWS version between 7.1.0 and 7.1.3 is
supported
String mwsVersion = "*" > *" // Any MWS version is supported (not recommended!)
String mwsVersion = "*" > 7.2" // Any MWS version up to 7.2 is supported (not
recommended!)

String commonsVersion = "0.9 > *" // Any framework version 0.9.0 and greater is
supported (including 1.0, etc)
String commonsVersion = "0.9.3 > *" // Any framework version 0.9.3 and greater is
supported (including 1.0, etc)
String commonsVersion = "0.9 > 0.9.3" // Any framework version between 0.9.0 and 0.9.3
is supported
String commonsVersion = "*" > *" // Any framework version is supported (not
recommended!)
String commonsVersion = "*" > 1.0" // Any framework version up to 1.0 is supported (not
recommended!)
```

If the `mwsVersion` or `commonsVersion` fields are formatted incorrectly, the plugin project will fail to load. If a plugin project is uploaded to MWS and the version check fails, the project will fail to load with an error message about the `mwsVersion` or `commonsVersion`.

i The `mwsVersion` and `commonsVersion` fields cannot be overridden by a single plugin type, but can be set only at the plugin project level. This prevents mixing of MWS and commons version requirements within a single project.

Initial plugins

The initial plugins closure provides the flexibility to insert plugin instances when the JAR is loaded. This occurs at two points: when the plugin JAR is first uploaded to MWS, and when MWS is restarted. As shown in the example above, the ID, pluginType, and other properties may be configured for multiple plugins.

The nature of Groovy closures means that programmatic definition of initial plugins is possible. This may even be based on the MWS application configuration. Two properties are automatically available in the `initialPlugins` closure:

- `appConfig` – Contains the MWS application configuration. Any configuration parameter is available for access as documented on [Configuration on page 2114](#).
- `suite` – Contains the currently configured suite that MWS is running in. This is equivalent to the `mws.suite` configuration parameter, and is an instance of [Suite](#).

Native plugin case study

The Native JAR file utilizes many of the features discussed above. In the root of the JAR file, a compiled class called `NativeProject` exists which defines all of the metadata fields, including `initialPlugins`. Trying to create an initial plugin presents two distinct problems:

- The plugin should be initialized only if the suite is CLOUD.
- The plugin type configuration must contain an entry referencing the configured `mws.home.location` parameter, or the configured `MWS_HOME` location.

The `initialPlugins` closure is defined as follows:

```
import com.adaptec.mws.plugins.Suite

class NativeProject {
  ... // Metadata fields

  def initialPlugins = {
    // Initialize the cloud-native plugin only if the suite is CLOUD
    if (suite==Suite.CLOUD) {
      'cloud-native' {
        pluginType = "Native"
        pollInterval = 30
        config {
          // Use the appConfig property to retrieve the current MWS_HOME
          getCluster = "file://${appConfig.mws.home.location}/etc/nodes.t
        }
      }
    }
  }
}
```

Managing External Dependencies

External dependencies (e.g. JAR files) may be included and referenced in JAR files. Certain rules must also be followed in order to have the dependencies loaded from the JAR file correctly:

The plugin type must bundle all external dependency JARs in the root of the plugin type JAR file.

An entry must be included in the `MANIFEST.MF` file that references each of these bundled JAR files as a space separated list:

```
Class-Path: dependency1.jar dependency2.jar dependency3.jar
```

Assuming that these rules are followed and that the plugin type is uploaded using the REST API or the User Interface, the dependent JARs will first be loaded and then the new plugin type and associated files will be loaded.

Documenting Plugin Types

Documentation may also be included in JAR files by placing one or more [Markdown](#) formatted files in the root of the project JAR file. These files will be processed dynamically by MWS and presented as documentation pages for the respective plugin types within the MWS plugin user interface pages. Markdown is a simple text-to-HTML format used in some of the most popular open-source repositories such as [GitHub](#) and [BitBucket](#). To help provide plugin developers use a single place or file for documentation, the conventional use of "README.md" as documentation was followed within MWS.

[Documentation file naming](#)

Each documentation filename must start with "README" and end with ".md". If only one documentation file is needed for bundled plugin type(s), it is recommended to call the file "README.md". For multiple plugin types, the file name must contain the plugin type name without the "Plugin" suffix in the format of "README-<PluginName>.md". For example, if a plugin project JAR file contained the plugin type classes "MyPlugin", "ABTestPlugin", and "ImportantPlugin", the documentation files would be located in the root of the JAR file and would be called "README-My.md", "README-ABTest.md", and "README-Important.md" respectively. If a "README" file does not exist for a certain plugin type, the main "README.md" file (if provided) will be used as documentation for that plugin type.

[Markdown syntax](#)

The Markdown syntax supported by MWS is very close to [GitHub Flavored Markdown](#). Internally, the [pegdown](#) Markdown processor is used to generate the HTML with the `TABLES`, `ABBREVIATIONS`, `FENCED_CODE_BLOCKS`, `SMARTYPANTS`, `DEFINITIONS`, and `QUOTES` extensions enabled. HTML tags may also be used directly in order to create more refined formatting of the documentation, but this is discouraged with the exception of inserting the configuration reference table discussed below.

For example, the `TABLES` extension may be used to easily create HTML tables:

Name	Notes
Bob	Knows how to use MWS plugins but has never created one
George	Writes MWS plugins in his spare time

The only main difference from standard Markdown processors is that block quotes (marked by lines prepended with '> ') are shown as highlighted information boxes when displayed in MWS. This may be used to draw more attention to informational or warning messages without writing custom HTML.

```
> **Warning:** The use of this plugin type requires that MWS and MWM are configured
correctly as described in
> the MWS user guide.
```

[Configuration reference table](#)

A table of available configuration parameters is often constructed in documentation for each plugin type. To ease the burden on the plugin developer of maintaining this documentation and the constraints on the plugin type, a table generated from the constraints (see [Configuration Constraints on page 2018](#)) and included messages is available by using the following HTML in the README file(s):

```
<div class="configuration-table">This section will be replaced by MWS with the
configuration parameters table</div>
```

The text within the `div` container may be anything, but should state something helpful such as that it is placeholder in cases where the documentation may be viewed within other contexts such as on GitHub.

The generated table includes the following columns for each configuration parameter listed in the constraints: name, key, required, type, description. The "name" and "description" values are retrieved from the "help" and "label" messages bundled in the plugin JAR (see the labels and help messages section in [Configuration Constraints on page 2018](#) for more information).

[Web services reference sections](#)

Documentation for exposed web services (see [Exposing Web Services on page 2029](#)) is also able to be generated automatically. Instead of a single table as done with configuration parameters, a section with several tables (possible URL access points, URL parameters, and response fields) and additional information is generated for each exposed web service. This is available by using the following HTML in the README file(s):

```
<div class="webservice-sections">This section will be replaced by MWS with the web
service documentation</div>
```

The text within the `div` container may be anything, but should state something helpful such as that it is placeholder in cases where the documentation may be viewed within other contexts such as on GitHub.

[Changing heading sizes](#)

The generated sections each begin with an `<h2>` heading with the name of the web service. If a different heading size (`h3`, `h4`, etc.) is desired, this may be done with the following HTML:

```
<div class="webservice-sections" data-level="3">This section will be replaced by MWS
with the web service documentation</div>
```

Notice the `data-level` attribute, which contains the number used in the HTML `h` tag.

Message codes

Just as with the configuration table, the data for the content is generated automatically from the web service method name and from i18n messages (see [i18n Messaging on page 2014](#)) bundled in the plugin JAR file. Message codes are available to customize the label and description of the web service. Codes are also available to define an arbitrary number of URL parameters and response fields. These do not need to be defined, but are helpful. The following table defines each message used in generating the documentation for web services.

Name	Message code	Description
Web Service Label	<pluginType>.webServices.<webServiceMethod>.label	The label used as the heading for the section, defaults to the naturally capitalized method name if not present.
Web Service Description	<pluginType>.webServices.<webServiceMethod>.help	Paragraph text describing the web service and its functionality, outputs, etc.
Parameter Key	<pluginType>.webServices.<webServiceMethod>.parameter<n>.key	The nth URL parameter, starting at 1 (example: id).
Parameter Label	<pluginType>.webServices.<webServiceMethod>.parameter<n>.label	The label for the nth URL parameter, defaults to the naturally capitalized key if not present.
Parameter Type	<pluginType>.webServices.<webServiceMethod>.parameter<n>.type	The type for the nth URL parameter, defaults to String if not present.
Parameter Description	<pluginType>.webServices.<webServiceMethod>.parameter<n>.help	The description or help text for the nth URL parameter.
Response Field Key	<pluginType>.webServices.<webServiceMethod>.return<n>.key	The nth response field, starting at 1 (example: success).

Name	Message code	Description
Response Field Label	<code><pluginType>.webServices.<webServiceMethod>.return<n>.label</code>	The label for the <i>n</i> th response field, defaults to the naturally capitalized key if not present.
Response Field Type	<code><pluginType>.webServices.<webServiceMethod>.return<n>.type</code>	The type for the <i>n</i> th response field, defaults to <code>String</code> if not present.
Response Field Description	<code><pluginType>.webServices.<webServiceMethod>.return<n>.help</code>	The description or help text for the <i>n</i> th response field.

As an example, suppose that a web service method called "doSomething" exists on a plugin type named "MyExamplePlugin". This web service expects two URL parameters: `id`, an integer, and `action`, a string. The response body consists of a JSON object with two fields: `success`, a boolean value, and `messages`, a list of strings. The following messages would serve to generate helpful documentation:

```

messages.properties
-----

# web service messages
myExamplePlugin.webServices.doSomething.label=Do Something Important
myExamplePlugin.webServices.doSomething.help=This web service does something important
with the input parameters.
# parameters
myExamplePlugin.webServices.doSomething.parameter1.key=id
myExamplePlugin.webServices.doSomething.parameter1.label=ID
myExamplePlugin.webServices.doSomething.parameter1.type=Integer
myExamplePlugin.webServices.doSomething.parameter1.help=The identifier of an object
myExamplePlugin.webServices.doSomething.parameter2.key=action
myExamplePlugin.webServices.doSomething.parameter2.label=Action # same as the default
would be
myExamplePlugin.webServices.doSomething.parameter2.type=String # same as the default
would be
myExamplePlugin.webServices.doSomething.parameter2.help=The action to perform

# response fields
myExamplePlugin.webServices.doSomething.return1.key=success
myExamplePlugin.webServices.doSomething.return1.label=Success # same as the default
would be
myExamplePlugin.webServices.doSomething.return1.type=Boolean
myExamplePlugin.webServices.doSomething.return1.help=True if the request succeeded,
false otherwise
myExamplePlugin.webServices.doSomething.return1.key=messages
myExamplePlugin.webServices.doSomething.return1.label=Error Messages
myExamplePlugin.webServices.doSomething.return1.type=List of Strings
myExamplePlugin.webServices.doSomething.return1.help=Error messages describing the
reason why success is false.

```

Note that if the *first* URL parameter key is `id`, the listed resource URLs will include the optional URL with the `id` parameter inline, such as `/rest/plugins/<pluginId>/services/<webService>/<id>`. Therefore, it is recommended to use `id` as parameter 1 if the web service expects a parameter with that key.

Example Plugin Types

Several plugin types are provided by Adaptive Computing for use in Moab Web Services. Examples of these include the Native and vCenter plugin types.

A sample plugin type in Groovy would resemble the following:

```

package sample

import com.adaptc.mws.plugins.*

class SamplePlugin extends AbstractPlugin {
    static author = "Adaptive Computing"
    static description = "A simple plugin in groovy"
    static version = "0.1"

    INodeRMService nodeRMService

    public void configure() throws InvalidPluginConfigurationException {
        def myConfig = config // "config" is equivalent to getConfig() in groovy
        def errors = []
        if (!myConfig.arbitraryKey)
            errors << "Missing arbitraryKey!"
        if (errors)
            throw new InvalidPluginConfigurationException(errors)
    }

    public void poll() {
        NodeReport node = new NodeReport("node1")
        node.resources.RES1.total = 5
        node.resources.RES1.available = 5
        node.state = NodeReportState.IDLE
        nodeRMService.save([node])
    }

Moab Workload Manager Resource Manager Integration

Moab Workload Manager possesses the concept of Resource Managers (RMs). While plugins can be related to RMs, they often provide greater functionality and serve more purposes than a typical RM. MWS must be represented in Moab as a RM to enable certain plugin features such as state reporting and handling RM events. This section describes the process of configuring Moab and additional details of its queries to MWS. It includes the following topics:

- [Configuring Moab Workload Manager on page 2067](#)
- [Resource Manager Queries on page 2071](#)

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

Configuring Moab Workload Manager

During each iteration of Moab Workload Manager's cycle, it will query MWS through the RM interface to access current node, virtual machine, and job information. At this point, all reports are loaded from the database and consolidated into a single report of each object as explained in [Data Consolidation on page 2009](#).

i All unset (or null) values for properties on reports are ignored.

In some cases it may be desired to query MWS directly for the current consolidated node, storage, virtual machine, and job reports. This may be done using the following URLs which return data in a format that is a subset of the API version 3 interface for each object (i.e. `/rest/nodes?api-version=3`, `/rest/vms?api-version=3`, `/rest/jobs?api-version=3`).

Query	Description
<code>/rest/plugins/all/rm/cluster-query?api-version=3</code>	Retrieves consolidated node, storage, and virtual machine reports from all plugins.
<code>/rest/plugins/<ID>/rm/cluster-query?api-version=3</code>	Retrieves consolidated node, storage, and virtual machine reports for the specified plugin ID.
<code>/rest/plugins/all/rm/workload-query?api-version=3</code>	Retrieves consolidated job reports from all plugins.
<code>/rest/plugins/<ID>/rm/workload-query?api-version=3</code>	Retrieves consolidated job reports for the specified plugin ID.

These queries have no effect on the data itself. In other words, reports are not removed or manipulated when RM queries are performed. These are manipulated only the RM services as described in [Reporting State Data on page 2031](#).

Examples

The following example uses cURL (see [curl Samples on page 2113](#)) to perform the query.

```
$ curl -u moab-admin:changeme! http://localhost:8080/mws/rest/plugins/all/rm/cluster-
query?api-version=3&pretty=true

Resource Manager Queries

Moab Workload Manager must be configured to use MWS as a resource manager. Do the following:

- First, the following lines must be in the Moab Workload Manager configuration file or one of its included files:

```

RMCFG [mws]          TYPE=MWS
RMCFG [mws]          FLAGS=UserSpaceIsSeparate
RMCFG [mws]          BASEURL=http://localhost:8080/mws

```

*The **BASEURL** must match the configured URL of MWS.*

- The next step is to edit the MWS credential information in the Moab private configuration file (`/opt/moab/etc/moab-private.cfg`, by default). Here are the default values:

```

CLIENTCFG [RM:mws]  USERNAME=moab-admin  PASSWORD=changeme!

```

i **USERNAME** and **PASSWORD** must match the values of `auth.defaultUser.username` and `auth.defaultUser.password`, respectively, found in the MWS configuration file. The MWS RM contacts MWS directly using the base URL, username, and password configured.

Optionally, the **USERNAME** and **PASSWORD** configuration values may be specified directly in the Moab configuration file, though this is not recommended. Likewise, the **BASEURL** configuration value can be specified in the Moab private configuration file.

- Lastly, to enable such actions as submitting jobs as different users, the **ENABLEPROXY=TRUE** option must be present in the **ADMINCFG** configuration line, and the **OSCREDLLOOKUP** option must be set to **NEVER**, as follows:

```
ADMINCFG[1]          USERS=root      ENABLEPROXY=TRUE
OSCREDLLOOKUP       NEVER
```

- You may also want to configure SSL by using the following options (in either the **RMCFG** or **CLIENTCFG** section):

- **SSLCACERT**: Lets you specify the absolute path to your SSL CA certificate. (This also enables the use of self-signed certificates, if desired.) It is recommended that you set this option in the Moab private configuration file. For example:

```
CLIENTCFG[RM:mws]    SSLCACERT=/path/to/cert.pem
```

- **SSLNOHOSTCHECK**: Lets you disable the SSL check to make sure that the actual server name matches the certificate's server name. For example:

```
#In moab-private.cfg
CLIENTCFG[RM:mws]    SSLNOHOSTCHECK=TRUE

#Or in moab.cfg
RMCFG[mws]           SSLNOHOSTCHECK=TRUE
```

WARNING: This setting could compromise the security of the system and should not be used in production environments.

- **SSLNOPEERCHECK**: Lets you disable the SSL check to make sure that the certificate is valid.

```
#In moab-private.cfg
CLIENTCFG[RM:mws]    SSLNOPEERCHECK=TRUE

#Or in moab.cfg
RMCFG[mws]           SSLNOPEERCHECK=TRUE
```

WARNING: This setting could compromise the security of the system and should not be used in production environments.

Plugin Type Management

Plugin types may be managed and accessed with Moab Web Services dynamically, even while running. Operations are provided to upload (add or update) plugin types and to list or show current plugin types. The available fields that are displayed with plugin types are given in [Fields: Plugin Types on page 2414](#). For more information on how these fields are set, see [Plugin Projects and Metadata on page 2056](#).

Plugin Type JAR or groovy files should never be manually copied into the `MWS_HOME/plugins` directory. They must be managed using the methods shown in this section or through the REST API (see [Plugin Types on page 1816](#)).

Bundled plugin types are included automatically in Moab Web Services releases and may be utilized immediately after startup. See [Plugin Management on page 2078](#) for more information on how to utilize these plugin types.

The plugin type documentation is now located in the plugin type management pages. See [Plugin Type Documentation on page 2075](#) for more information.

Add or Update Plugin Types

Plugin types can be uploaded into Moab Web Services using a Groovy file, a Java Archive ([JAR](#)) file, or pasted Groovy code. To access the plugin type upload page, navigate to the **Plugin Type List** page and click **Add or Update Plugin Type**. The default interface of this page enables the uploading of a single Groovy class file or a JAR file.

When a plugin type is updated, by default all corresponding plugins created from the plugin type will be recreated. If this behavior is not desired, clear the **Do you want to reload all plugins to use this new version?** checkbox before uploading the plugin type.

[Single class file](#)

Groovy files containing a single plugin type may be uploaded at the `/mws/admin/plugin-types/create` URL.

The screenshot shows the 'Create Plugin Type' interface. At the top, there is a globe icon and the title 'Create Plugin Type'. Below the title, a checkbox labeled 'Do you want to reload all plugins to use this new version?' is checked. Underneath, there is a horizontal bar containing four buttons: '+ Add files...', 'Start upload', 'Cancel upload', and 'Clear files'. Below this bar is a large empty text area for pasting code. At the bottom left, there is a 'Cancel' button and a link that says 'Type or Paste Code'.

If the upload failed or an error occurred during initialization of the plugin, an error message will be displayed.

Create Plugin Type

Plugin Type with ID 'NotAValidClass' is an invalid plugin: Class name does not end with Plugin

Do you want to reload all plugins to use this new version? ☒

+ Add files...	Start upload	Cancel upload	Clear files
sample.groovy		0.04 KB	

Cancel

Type or Paste Code

JAR file

A JAR file, as described in [Packaging Plugins on page 2055](#), containing one or more plugins may also be uploaded using the same process as the Groovy file.

Click **Add files...**, select the `.jar` file, and click the **Start upload** button. If the upload failed or an error occurred during initialization of the plugin(s), an error message will be displayed.

The JAR upload process differs from the single file in that if successful, the name of the JAR file itself is displayed instead of the plugin name(s).

Create Plugin Type

☒ Reload when poll occurs

Active Plugins

ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:08	00:00:21	  
no-polling	Logging			 

Disabled Plugins

ID	Plugin Type	State	Actions
There are no Disabled Plugins set up at this time			

i If plugins are created from plugin types which do not have a `poll` method, their lifecycle controls will be limited. Any information below which mentions polling does not apply to the 'no-polling' plugin shown in the screenshots.

Active plugins

Active plugins are those which are in the Started or Paused states. These are available to receive events such as polling. If paused, a plugin will not receive events but is not actually stopped, therefore no stop events are triggered.

The following images demonstrate the status of plugins in the active states.

Active Plugins

ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:08	00:00:21	  
no-polling	Logging			 

Started plugins which can include the relative time of the last poll as well as the time of the next poll in a countdown format. Action buttons are available to stop or pause the plugin as well as trigger an immediate poll event.

Active Plugins				
ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:26		  
no-polling	Logging			 

Paused plugins which can include only the last polling time. Action buttons are available to stop or resume the plugin, as well as trigger an immediate poll event.

[Disabled plugins](#)

Disabled plugins are those which are in the Stopped or Errored states. These plugins do not receive events such as polling. If errored, a plugin may either be stopped, which represents a "clearing" of the error, or started normally. However, if no action is taken on an errored plugin, it likely will not start due to the fact that most plugins are put into the errored state during startup of the plugin.

The following images demonstrate the representation of plugins in the disabled states.

Disabled Plugins			
ID	Plugin Type	State	Actions
no-polling	Logging	Stopped	

Stopped plugins. A single action button is available to attempt to start the plugin.

Disabled Plugins			
ID	Plugin Type	State	Actions
with-error	Logging	Errored	 

An errored plugin. As mentioned previously, action buttons are available to stop the plugin or clear the error as well as attempt to start the plugin. If the start fails, an error message will be displayed.

Setting Default Plugin Configuration

Configuration of default values for plugin configuration parameters involves setting fields in the MWS configuration file. These values are used if no values

are provided when creating a new plugin. Additionally, the default values will be displayed to the user on the **Create Plugin** page.

The parameters to configure are documented on [Configuration on page 2114](#) and comprise most values starting with plugins.

Plugin Services

To use the built-in services, declare a variable with the correct name as a property in the plugin class.

The convention for each service name is to remove the leading "I" and lower case the resulting first letter. For example, the property to use the `IMoabRestService` would be called `moabRestService`. The following is an example of using the `IPluginControlService` in this manner.

Using the `IPluginControlService`

```
package example;
import com.adaptec.mws.plugins.*;

class ExamplePlugin {
    IPluginControlService pluginControlService;

    public poll() {
        // Use service...
        pluginControlService.stop("pluginId");
    }
}
```

i Use of the Groovy anonymous type "def" may also be used. For example, the service definition above would use `def pluginControlService` instead of `IPluginControlService pluginControlService`.

⚠ Do *not* attempt to create a new instance of the services before use, such as in a constructor. The services will be automatically injected before any methods are called on the plugin.

[API documentation](#)

The `com.adaptec.mws.plugins` package contains interfaces for all bundled services available to plugin types. These may be used as discussed above. All services begin with "I" and end with "Service", as in [IMoabRestService](#) ([Moab REST Service on page 2085](#)).

Related Topics

- [About Moab Web Services Plugins on page 2003](#)

Job RM Service

The job RM service may be used to report job state data to Moab Workload Manager through the RM interface. See [Reporting State Data on page 2031](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation (see [Data Consolidation on page 2009](#)), old job reports may no longer exist in the database by the time the query is done.

The `jobRMService` property will be injected with a class of type [IJobRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

Related Topics

- [Plugin Services on page 2084](#)

Moab REST Service

The Moab REST service may be used to access the MWS RESTful API (see [Resources Introduction on page 1646](#)) in plugins. All "requests" made through this service are internal only and no data is actually transmitted over the network. See [Accessing MWS REST Resources on page 2036](#) for more information.

The `moabRestService` property will be injected with a class of type [IMoabRestService](#) in all plugin types.

[Accessing resources](#)

In order to access a resource, a relative URL matching that in the documentation must be used along with a HTTP method, such as GET, POST, PUT, or DELETE. The method names on `IMoabRestService` match the HTTP methods directly. For example, to call a GET operation on `/rest/jobs`, use the following code:

```
moabRestService.get("/rest/jobs")
```

[Using parameters correctly](#)

Although the ordering of the parameters for each method on `IMoabRestService` may seem confusing at first glance, this is to allow for easy use with Groovy. Examples are given below for each combination of parameters:

String URL

```
moabRestService.get("/rest/jobs")
```

Map options, String URL

```
moabRestService.get("/rest/jobs", hooks:true, contentType:"application/json")
```

String URL, Closure data

```
moabRestService.get("/rest/jobs/job.1") {
    [flags:"RESTARTABLE"]
}
```

Map options, String URL, Closure data

```
moabRestService.get("/rest/jobs/job.1", hooks:true, contentType:"application/json") {
    [flags:"RESTARTABLE"]
}
```

Options

The following options are valid in each method call supporting the `options` parameter:

Name	Type	Default	Description
data	See Valid data types on page 2086	--	Specifies the body of the "request." This can be overwritten by the data Closure parameter.
hooks	Boolean	false	Specifies whether or not hooks (see Pre- and Post-Processing Hooks on page 1633) are run as part of the "request."
contentType	String	application/json	Indicates the content type used for the request.
params	Map	--	Indicates URL query parameters to use for the "request," such as <code>query</code> , <code>sort</code> , <code>proxy-user</code> , or others.

Valid data types

If the `data` Closure parameter is specified, it overwrites the data option. In each case, there are four valid types for the data option or return value of the data closure:

- A non-null [JSON](#) instance.
- A valid JSON string. This will be converted into a [JSON](#) instance.
- A valid Map instance. This will be converted into a [JSONObject](#) instance.
- A valid List instance. This will be converted into a [JSONArray](#) instance.

i A [JSONException](#) may be thrown if the JSON string is invalid or the Map or List contains values that cannot be serialized to JSON.

Node RM Service

The node RM service may be used to report node state data to Moab Workload Manager through the RM interface. See [Reporting State Data on page 2031](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation (see [Data Consolidation on page 2009](#)), old node reports may no longer exist in the database by the time the query is done.

The `nodeRMService` property will be injected with a class of type [INodeRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

Plugin Control Service

i This service is currently in Beta. Interfaces may change significantly in future releases.

The control service allows lifecycle management operations to be performed on plugins. It also provides methods to create and retrieve plugins. Note that the plugin control service may be used by other plugins, allowing one plugin to dynamically create, retrieve, start, or stop plugins.

The `pluginControlService` property will be injected with a class of type [IPluginControlService](#) in all plugin types.

Examples

Create plugin with default configuration

```

try {
    if (pluginControlService.createPlugin("myPlugin", "Native"))
        log.info "myPlugin was created successfully!"
    else
        log.warn "There was an error creating myPlugin"
} catch(PluginStartException e) {
    log.warn "There was a problem starting the new plugin: ${e.message}"
} catch(InvalidPluginConfigurationException e) {
    log.warn "There were errors with the plugin's configuration: ${e.errors}"
}

```

Create plugin with custom configuration

```

if (pluginControlService.createPlugin("myPlugin", "Native", [autoStart:false,
pollInterval:600]))
    log.info "myPlugin was created successfully!"
else
    log.warn "There was an error creating myPlugin"

```

Start plugin

```

try {
    pluginControlService.start("myPlugin")
} catch(PluginStartException e) {
    log.warn "There was a problem starting the plugin: ${e.message}"
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
} catch(InvalidPluginConfigurationException e) {
    log.warn "The plugin has an invalid configuration: ${e.errors}"
}

```

Stop plugin

```

try {
    pluginControlService.stop("myPlugin")
} catch(PluginStopException e) {
    log.warn "There was a problem stopping the plugin: ${e.message}"
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
}

```

Configure plugin

```

try {
    pluginControlService.configure("myPlugin")
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
} catch(InvalidPluginConfigurationException e) {
    log.warn "The plugin has an invalid configuration: ${e.errors}"
}

```

Plugin Datastore Service

The datastore service is provided to allow a plugin to persist data to the database that is isolated from all other persistent data. In other words, this service provides access to a plugin's individual datastore (see [Individual Datastore on page 2027](#)).

The `pluginDatastoreService` property will be injected with a class of type [IPluginDatastoreService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

Examples

Adding a single custom entry

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = [:]
        ... // Add data here to the Map
        if (pluginDatastoreService.addData(collectionName, data))
            log.info("Data successfully added")
        else
            log.warn("There was an error adding the data")
    }
}
```

Adding multiple entries

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def dataList = []
        dataList.add( /* Custom Map of data here */ )
        dataList << ... // Custom Map of data here
        if (pluginDatastoreService.addData(collectionName, dataList))
            log.info("Data entries successfully added")
        else
            log.warn("There was an error adding the data entries")
    }
}
```

Updating a single entry

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = [:]
        ... // Add data here to the Map
        if (pluginDatastoreService.updateData(collectionName, "key", "value", data))
            log.info("Data successfully updated")
        else
            log.warn("There was an error updating the data")
    }
}

```

Querying if a collection exists

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        if (pluginDatastoreService.exists(collectionName))
            log.info("Collection exists")
        else
            log.warn("The collection does not exist")
    }
}

```

Querying contents of a collection

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def dataList = pluginDatastoreService.getCollection(collectionName)
        if (dataList!=null)
            log.info("Collection successfully queried")
        else
            log.warn("The collection does not exist!")
    }
}

```

Retrieving a single entry

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = pluginDatastoreService.getData(collectionName, "key", "value")
        if (data!=null)
            log.info("Data successfully retrieved")
        else
            log.warn("The entry with key==value does not exist")
    }
}
```

Removing a collection

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = pluginDatastoreService.clearCollection(collectionName)
        // Data now contains the collection that was cleared
        if (data!=null)
            log.info("Collection successfully cleared")
        else
            log.warn("The collection does not exist!")
    }
}
```

Removing a single entry

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        if (pluginDatastoreService.removeData(collectionName, "key", "value"))
            log.info("Data entry successfully removed")
        else
            log.warn("The entry where key==value does not exist!")
    }
}
```

Plugin Event Service

The event service is provided to ease the burden and reduce boilerplate code for creating new events and updating notification conditions. For more information on how to use this service, see [Creating Events and Notifications on page 2038](#).

The `pluginEventService` property will be injected with a class of type [IPluginEventService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

Examples

Creating a custom event

```
package example

import com.adaptec.mws.plugins.IPluginEventService.Severity
import com.adaptec.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptec.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Create a completely custom event
        pluginEventService.createEvent(Severity.INFO, EscalationLevel.USER, 0x4F, "Custom
Type",
                                     "poll", "My event occurred", null, null)
    }
}
```

Creating a custom event with messages

```
package example

import com.adaptec.mws.plugins.IPluginEventService.Severity
import com.adaptec.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptec.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Use i18n messages for another event
        def args = ["arg1", "arg2"]
        pluginEventService.createEvent(Severity.WARN, EscalationLevel.POWER_USER, 0x5F,
"Custom Type",
                                     "poll", message
(code:"examplePlugin.customEvent.message", args:args), args,
                                     // AssociatedObjects or simple maps may be
used
                                     [new AssociatedObject(type:"type1", id:"id1"),
[type:"type2", id:"id2"]])
    }
}
```

Creating an event from EventEnumeration

```
package example

import com.adaptc.mws.plugins.EventEnumeration
import com.adaptc.mws.plugins.IPluginEventService.Severity
import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Messages are pulled for messages.properties file(s) and the arguments are used
        def args = ["arg1", "arg2"]
        pluginEventService.createEvent(MyEvents.EVENT_INFO, args, [[type:"type1", id:"id1"]])
        pluginEventService.createEvent(MyEvents.EVENT_WARN, args, [[type:"type2", id:"id2"]])
    }
}

@EventEnumeration
enum MyEvents {
    EVENT_INFO("Information", INFO, USER),
    EVENT_ERROR("Warning", WARN, USER)

    static final String EVENT_TYPE_PREFIX = "Example Plugin"
    static final String ORIGIN_SUFFIX = "poll"
}
```

Create or update a notification

```
package example

import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        pluginEventService.updateNotification(EscalationLevel.POWER_USER, "There is an error
with node1",
        // If non-null, this must always be an associated object, new
        new AssociatedObject(id:"node1", type:"node"), null)
    }
}
```

Plugin Types

Power Management Plugin

The Power Management plugin is used as a resource manager to Moab to report and manipulate the power state (On or Off) for each node. Moab considers nodes in the power state On or Off; however, through TORQUE and scripts, we are able to separate the Off state into those controlled through the operating system (Standby, Suspend, Hibernate, Shutdown) and those controlled through hardware (Off). This plugin provides an easy way to integrate with Moab to translate Moab's Off action into the desired TORQUE or script action for each node. A cluster will have multiple instances of this plugin when it has varied hardware integration and/or credentials.

Creating a Power Management Plugin

To create a Power Management plugin, see [Creating a Plugin on page 2079](#). During plugin creation, refer to the [Configuration on page 2095](#) section.

Configuration

Configuration Parameters

Name	Key	Required	Type	Description
Node Configuration File	nodeConfigurationFile	Yes	String	File containing list of nodes that use the scripts and credentials in this plugin instance. This is also the file to configure a particular node's off state, or an off state that will override the default off state for this instance.
Username File	usernameFile	Yes	String	File containing username issued to the scripts with the -u option.
Password File	passwordFile	Yes	String	File containing password issued to the scripts with the -p option.
Node Power Script	nodePowerScript	Yes	String	Script that powers on and off nodes and wakes them from a low power state.

Name	Key	Required	Type	Description
Node Query Script	nodeQueryScript	Yes	String	Script that queries power state using an intelligent platform management interface.
Default Power Off State	defaultPowerOffState	Yes	String	Actual state (Standby, Suspend, Hibernate, Shutdown, or Off) nodes will go into when Moab powers them off.
Max Threads	maxThreads	Yes	Integer	Thread count issued to the scripts with the -t option (defaults to 4).

Plugin Management

For information on managing the IPMI plugin, including stopping it, starting it, and checking on its status, see the [Plugin Management on page 2078](#) section of the MWS Guide.

Web Services

Node Power (Secured)

Resource URLs

Resource
/rest/plugins/<pluginId>/services/nodePower
/rest/plugins/<pluginId>/services/node-power

URL Parameters

Parameter	Name	Type	Description
nodes	Moab Nodes	String	A comma-delimited list of Moab node names. It is required.
power	The Power State	String	The power command Moab issues the node (On or Off).

Response Fields

Field	Name	Type	Description
success	Success Indicator	Boolean	True if the power script and/or pbsnodes on page 3457 was successful, otherwise false.
messages	Messages	List of Strings	Only present when the request was not successful or the node was not configured with the plugin instance. Contains error messages describing why the <code>pbsnodes</code> or the power script failed.

Additional Information

This web service was intended for Moab's use only and is exposed for debugging and testing your customized scripts.

Reload Node Configuration (Secured)*Resource URLs*

Resource
<code>/rest/plugins/<pluginId>/services/reloadNodeConfiguration</code>
<code>/rest/plugins/<pluginId>/services/reload-node-configuration</code>

URL Parameters

Parameter	Name	Type	Description
No URL parameters required			

Response Fields

Field	Name	Type	Description
success	Success Indicator	Boolean	True if the reload succeeded, otherwise false.
messages	Messages	List of Strings	Only present when the request failed. Contains error messages describing why the reload failed.

Additional Information

i The reloadNodeConfiguration web service must be run after any change to the node configuration file for it to take effect.

Node Configuration File

The node configuration file is used when the plugin is first instantiated or the reloadNodeConfiguration web service is called. The plugin expects a file that is readable by the tomcat user and has a Moab node name on each line. If the user would like to override the default power-off state of the node, then the node name is followed by a space and the state. For example, a node configuration file might look like this:

```
node01.ac
node02.ac
node03.ac Hibernate
node04.ac Suspend
```

The valid power-off states include Standby, Suspend, Hibernate, Shutdown, and Off. If no power-off state is provided for the node in the configuration file, then the default power-off state will be used.

The Node Power and Query Script

The plugin uses the power script to power on nodes from all power states and to power off nodes only into the Off power state. The plugin uses the power state of the node to decide whether to power on the node with `wake` or `on`. If the node is in Standby or Suspend, the plugin will call the script with the `wake` parameter. If the node is in Hibernate, Shutdown, or Off, the plugin will call the script with the `on` parameter. The plugin calls the power node script with the `off` parameter to put the node in the Off state (it uses TORQUE to put the node in the Standby, Suspend, Hibernate, and Shutdown state).

The plugin uses the query script to know if a node is in the Off power state. If the query script reports the node as Off, the plugin will report the node as Off to Moab. If the query script reports the node as On, the plugin will look to TORQUE to make sure the node is in a Running power state before it reports it as On.

The plugin passes the `usernameFile`, `passwordFile`, and `maxThreads` configuration parameters down to the scripts. The node power script is called with this syntax:

```
<nodePowerScript> -u <usernameFile> -p <passwordFile> -t <maxThreads> node01 node02
node03 ... <on|off|wake>
```

The node query script is called with this syntax:

```
<nodeQueryScript> -u <usernameFile> -p <passwordFile> -t <maxThreads> node01 node02
node03 ...
```

The plugin expects the scripts to print JSON to standard out. An example query script output would look like this:

```
[
  {
    "name": "node01.ac",
    "power": "ON",
    "Processor_2_Temp": 61,
    "Processor_1_Temp": 54
  },
  ...
]
```

Notice it is a list of nodes where each node has the required fields `name` and `power`. All the other key-value pairs will be reported to Moab as a generic resource as long as the value is a number.

The output for the node power plugin is not required; however, the output is read to give the user a detailed error message if needed. For both the node power and query scripts, if the field `error` exists, the plugin will log an error with all the strings in the list. An example error returned to the plugin would look like this:

```
[
  {
    "command": "ipmitool -I lan -H node01i -U admin -f /opt/moab/etc/power-
management/abc-plugin-password-file sdr type temperature",
    "name": "node01.ac",
    "error": [
      "big error"
    ]
  },
  ...
]
```

Troubleshooting

The Power Management plugin logs all errors and warnings to the MWS log file, which is `/opt/mws/log/mws.log` by default. The `stacktrace.log` file, in the same directory as `mws.log`, can also be helpful in diagnosing problems. If your MWS supports notifications, they are also helpful in diagnosing the error states the plugin is in, if any. Just check for notifications from the `PowerManagement` plugin type and the instance that you are interested in. When the issue has been resolved, you can dismiss the notification. For more information, see the Notification and Notification Condition Resource in the MWS documentation.

Set the appropriate MWS RM precedence

The Create/Edit Plugin pages give the option to set the precedence of the Moab RM plugin. The purpose of the Power Management Plugin is to report node power; however, if the precedence is too low another Moab RM plugin with a higher precedence and conflicting node might overwrite the node power. To check what MWS is reporting to Moab, go to the URL:

```
http://<MWS host>:8080/mws/rest/plugins/all/rm/cluster-query[?api-version=3]
```

To check what your plugin instance is reporting to Moab, use the URL:

```
http://<MWS host>:8080/mws/rest/plugins/<instance-name>/rm/cluster-query[?api-version=3]
```

If the power is reported in your instance but not to Moab, please increase the precedence of the Moab RM plugin.

Configure the MWS RM in Moab

First, the following lines must be in the Moab Workload Manager configuration file or one of its included files:

```
RMCFG [mws]          TYPE=MWS
RMCFG [mws]          FLAGS=UserSpaceIsSeparate
RMCFG [mws]          BASEURL=http://<mws host>:8080/mws
```

Next, edit the MWS credential information in the Moab private configuration file (/opt/moab/etc/moab-private.cfg, by default). Here are the default values:

```
CLIENTCFG [RM:mws]  USERNAME=moab-admin  PASSWORD=changeme!
```

For more information see the Resource manager queries section in the MWS documentation.

Configure TORQUE with tomcat administrator

The plugin assumes that TORQUE is installed on the same host as MWS and that tomcat is an administrator. This can be verified with [gmgr on page 3478](#). Run the command:

```
gmgr -c 's s managers += tomcat@<mws_host>'
```

For more information see the Specifying non-root administrators section of the TORQUE documentation.

Make sure the Node and Power scripts work first.

The default scripts are included in /opt/moab/tools/mws/power_management and have their own documentation with the -h option. They need to have a file that maps each node in the Moab cluster to the IPMI address that the script will need to call using ipmitool. It also needs a file that includes the IPMI password. After that is provided and ipmitool is installed and working, the scripts will successfully implement the interface needed for this plugin.

OpenStack Plugin

The OpenStack plugin allows Elastic Computing instances to be provisioned and de-provisioned using an OpenStack service provider. This enables Moab Workload Manager to "burst" to an OpenStack cloud in order to add or remove nodes dynamically based on policies and workload. See [Elastic Computing Overview on page 862](#) for more information.

To use the OpenStack plugin, Moab Workload Manager (MWM) must be properly configured. See [Integration with a Private OpenStack Cloud on page 873](#).

Create an OpenStack Plugin

To create an OpenStack plugin, see [Creating a Plugin on page 2079](#). During plugin creation, refer to the [Configuration on page 2101](#) section.

Configuration

Configuration Parameters

Name	Key	Required	Type	Description
OpenStack Endpoint	osEndpoint	Yes	String	Endpoint URL to connect to OpenStack.
OpenStack Username	osUsername	Yes	String	OpenStack username.
OpenStack Password	osPassword	Yes	String	OpenStack password.
OpenStack Tenant	osTenant	Yes	String	OpenStack tenant that will contain created VMs.
OpenStack Flavor Name	osFlavorName	Yes	String	OpenStack flavor name to use for new VMs.

Name	Key	Required	Type	Description
OpenStack Image Name	osImageName	Yes	String	OpenStack image name to use for new VMs.
OpenStack Keypair Name	osKeyPairName	No	String	OpenStack keypair name to use for new VMs.
OpenStack Customization Script	osInitScript	No	String	OpenStack customization script (also called user data) to use for new VMs. This may be used to install and configure RM agents (such as the TORQUE pbs_mom) on the provisioned servers.
Match Image Prefix	matchImagePrefix	Yes	Boolean	If true, the first OpenStack image starting with the specified name will be used; if false, the full name will be matched.
Use Bootable Image	useBootableImage	Yes	Boolean	If true, non-bootable images will be ignored when searching for a matching image; if false, no bootable checking will be done.
Use Snapshot	useSnapshot	Yes	Boolean	If true, the image used must be a snapshot; if false, the image must not be a snapshot.
OpenStack VLAN Name	osVlanName	No	String	VLAN name configured in OpenStack that contains the IP that Moab should use. If left empty, the first IP address for the first network will be used.
OpenStack Instance Name Pattern	osInstanceNamePattern	Yes	String	Pattern to use for new VM instance names. This must contain the server number token and at least one of the date or request ID tokens.
Active Timeout (s)	activeTimeoutSeconds	Yes	String	Number of seconds to wait for a VM to be active.
Delete Timeout (s)	deleteTimeoutSeconds	Yes	String	Number of seconds to wait for a VM to be deleted successfully.

Name	Key	Required	Type	Description
Maximum Concurrent Requests Limit	maxRequestLimit	Yes	String	Maximum number of OpenStack requests to execute at one time.

Web Services

Elastic Compute Trigger (Secured)

Resource URLs

Resource
/rest/plugins/<pluginId>/services/triggerElastic
/rest/plugins/<pluginId>/services/triggerElastic

URL Parameters

Parameter	Name	Type	Description
requestId	Request ID	String	Request ID for VM naming and logging purposes.
serverCount	Server Count	Integer	Number of VMs to provision for this request.

Response Fields

Field	Name	Type	Description
id	ID	String	OpenStack ID of the provisioned server.
name	Name	String	OpenStack (unqualified) name of the provisioned server.
ipAddress	IP Address	String	IP address of the provisioned server.
powerState	Power State	String	Power state of the provisioned server (Active or Unknown).

Additional Information

This web service provisions OpenStack VMs based on request parameters. VMs are provisioned in parallel and information on the new servers is rendered as a JSON array in the output. If any step of the provisioning fails for any server, all servers are destroyed immediately before returning an error.

 This should only be called as part of processing an elastic compute trigger.

Node End Trigger (Secured)

Resource URLs

Resource
/rest/plugins/<pluginId>/services/triggerNodeEnd
/rest/plugins/<pluginId>/services/trigger-node-end
/rest/plugins/<pluginId>/services/triggerNodeEnd/<id>
/rest/plugins/<pluginId>/services/trigger-node-end/<id>

URL Parameters

Parameter	Name	Type	Description
id	Server Name	String	Name of the VM to delete.

Response Fields

Field	Name	Type	Description
messages	Message(s) describing the result of the delete operation	List of Strings	

Additional Information

This web service deletes OpenStack VMs based on the request parameter.

 This should only be called as part of processing a node end trigger.

Troubleshooting

The OpenStack plugin logs all errors and warnings to the MWS log file, which is `/opt/mws/log/mws.log` by default. The `stacktrace.log` file, which is located in the same directory as `mws.log`, may also be helpful in diagnosing problems.

References

Client Code Samples

The code samples contained in this section of the reference material are provided to help quick start integration with MWS. They are provided as a convenience and not as fully developed APIs.

All examples use the default configuration of MWS, including the default username and password, and assume that MWS is deployed at `http://localhost:8080/mws`.

This section contains these topics:

- [Javascript Code Samples on page 2105](#)
- [PHP Code Samples on page 2107](#)
- [Perl Code Samples on page 2110](#)
- [Python Code Examples on page 2112](#)
- [curl Samples on page 2113](#)

Javascript Code Samples

When utilizing Javascript to interact with MWS, it is recommended to use libraries that provide a simple browser-independent syntax for performing REST calls. It must also be noted that it is not recommended to make calls to MWS directly from client-side Javascript, as this will contain the username and password for MWS and could potentially be retrieved and utilized by a malicious user.

Examples for specific libraries are given below.

jQuery

The jQuery `ajax` function makes it extremely simple to perform all REST calls. There are also some shorthand methods which utilize the `ajax` method in a

simple manner—such as `getJSON` and `post`—but these do not have the ability to specify authentication parameters, which is why they are not used below.

i In all examples given, it is assumed that the `$` variable is mapped to `jQuery`, which is the default configuration of `jQuery`.

GET

```
$.ajax({
  url: "http://localhost:8080/mws/rest/jobs",
  dataType: 'json',
  username: 'admin',
  password: 'secret',
  success: new function(data) {
    $('<div>.result</div>').html(data);
    alert("GET was successful");
  }
});
```

POST

```
$.ajax({
  url: "http://localhost:8080/mws/rest/jobs",
  data: {
    "commandFile": "/tmp/test.sh",
    "initialWorkingDirectory": "/tmp",
    "user": "adaptive",
    "requirements": [{"requiredNodeCountMinimum": 1}]
  },
  dataType: 'json',
  username: 'admin',
  password: 'secret',
  success: new function(data) {
    $('<div>.result</div>').html(data);
    alert("GET was successful");
  }
});
```

PUT

```
$.ajax({
  type: 'PUT',
  url: 'http://localhost:8080/mws/rest/jobs/Moab.1',
  data: {"holds": ["user"]},
  dataType: "json",
  username: 'admin',
  password: 'secret',
  success: function(data) {
    $('<div>.result</div>').html(data);
    alert("PUT was successful");
  }
});
```

DELETE

```
$.ajax({
  type: 'DELETE',
  url: 'http://localhost:8080/mws/rest/jobs/Moab.1',
  username: 'admin',
  password: 'secret',
  success: function(data) {
    $('<div>.result</div>').html(data);
    alert("DELETE was successful");
  }
});
```

PHP Code Samples

All of these examples make use of the [cURL PHP Extension](#). While this library is easy to use for GET and POST requests, it is somewhat more difficult to use for PUT and DELETE requests. Each will be covered in this topic.

i Notice the use of the [JSON PHP Extension](#)'s `json_decode` and `json_encode` functions.

GET

```
<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs";
$username = "admin";
$password = "secret";
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
  print_r($responseInfo);
  echo $responseBody;
} else {
  print_r(json_decode($responseBody));
}
?>
```

POST

```

<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "commandFile"=>"/tmp/test.sh",
    "initialWorkingDirectory"=>"/tmp",
    "user"=>"adaptive",
    "requirements"=>array(
        array("requiredNodeCountMinimum"=>1)
    )
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup POST request
curl_setopt($ch, CURLOPT_POSTFIELDS, json_encode($requestPayload));
curl_setopt($ch, CURLOPT_POST, 1);

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}
?>

```

PUT

```

<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs/Moab.1";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "holds"=>array("user")
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup PUT request
curl_setopt($ch, CURLOPT_POSTFIELDS, json_encode($requestPayload));
curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "PUT");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}

```

DELETE

```

<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs/Moab.1";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "holds"=>array("user")
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup DELETE request
curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "DELETE");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}

```

Perl Code Samples

These examples all utilize the `LWP::UserAgent` module, which must be installed before running them.

GET

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(GET => 'http://localhost:8080/mws/rest/images');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

POST

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(POST => 'http://localhost:8080/mws/rest/images');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");
$req->content('
{"profile":"compute","osVersion":"5","name":"centos5stateless","hypervisor":0,"architecture":"x86_64","osName":"centos","osType":"linux","type":"stateless"}');

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

PUT

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(PUT => 'http://localhost:8080/mws/rest/images/centos5-stateless');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");
$req->content('{"osVersion":"5.5"}');

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

DELETE

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(DELETE => 'http://localhost:8080/mws/rest/images/centos5-
stateless');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

Python Code Examples

Notice the use of the `json` module to build a Python object from the return JSON data. If you want, you can also use `json.dumps` to create a JSON string from a Python object.

Simple request (GET)

```
import urllib
import base64
import string
import json
def get(base, port, url):
    conn = urllib.HTTPConnection(base, port, timeout=60)
    conn.request('GET', url, None, { 'Authorization' : 'Basic '+string.strip(
base64.encodestring('admin:secret'))})
    return conn.getresponse().read()

data = get("localhost", 8080, "/mws/rest/jobs?format=json")
print json.loads(data)
```

Complex request (POST)

```
import urllib
import base64
import string
import json
def post(base, port, url, payload):
    conn = urllib.HTTPConnection(base, port, timeout=60)
    conn.request('POST', url, payload, { 'Authorization' : 'Basic '+string.strip(
(base64.encodestring('admin:secret')), 'Content-Type' : 'application/json' })
    r = conn.getresponse()
    return r.read()

# Note that json.dumps may also be used to create the json string from a python object
data = post("localhost", 8080, "/mws/rest/jobs", '
{"commandFile":"/tmp/test.sh","initialWorkingDirectory":"/tmp","user":"adaptive","requirements":[{"requiredNodeCountMinimum":1}]}'
print json.loads(data)
```

Related Topics

- [Client Code Samples on page 2105](#)

curl Samples

Unlike the other code samples given in this section, these samples are simple commands that can be run from any server command line with the `curl` program installed in order to communicate with MWS.

GET

```
curl -u admin:secret -X GET -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
```

POST

```
curl -u admin:secret -X POST -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
-d '
{"commandFile":"/tmp/test.sh","initialWorkingDirectory":"/tmp","user":"adaptive","requirements":[{"requiredNodeCountMinimum":1}]}'
```

PUT

```
curl -u admin:secret -X PUT -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
-d '{"holds":["user"]}'
```

DELETE

```
curl -u admin:secret -X DELETE -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
```

Configuration

These properties can be modified by setting the appropriate values in the `mws-config.groovy` file. This file is located in `MWS_HOME/etc/` or `/opt/mws/etc/` by default as explained in [Configuring Moab Web Services on page 1570](#).

i The configuration file is read not only on startup, but also each time it is changed. Several properties, including those for Moab Workload Manager (`moab`), Moab Accounting Manager (`mam`), Mongo (`grails.mongo`), and authentication (`auth`) are processed after each change and can affect the runtime behavior of MWS.

Configuration files can also be placed in the `MWS_HOME/etc/mws.d` directory. Any configuration files here get merged with `MWS_HOME/etc/mws-config.groovy`. In case of conflict, the configuration in `MWS_HOME/etc/mws.d` takes precedence.

Configuration reference

For all possible values that can be set, please see the Grails reference guide. For project specific settings (usually the only ones you'll need to change), you may set the following properties:

Property	Type	Default	Description
<code>auth.defaultUser.password</code>	String	changeme!	Unencoded password of the default admin user.
<code>auth.defaultUser.username</code>	String	moab-admin	Username of the default admin user (only created if no other users exist).
<code>grails.mongo.host</code>	String	127.0.0.1	The MongoDB host to use (Note that MongoDB runs on 127.0.0.1 and <i>not</i> localhost by default).
<code>dataSource.insight.password</code>	String	changeme!	The password for the username used to log in to the Insight database.

Property	Type	Default	Description
dataSource.insight.url	String	jdb- c:post- gresql://127.0.0.1:5432/n insight	The JDBC URL for the Insight database. For more information, see Insight Database Configuration Using mws-config.groovy on page 1580 .
dataSource.insight.username	String	mws	The username used to log into the Insight database.
grails.mongo.port	Integer	27017	The MongoDB port to use.
grails.mongo.replicaSet	List of Strings	n/a	The MongoDB replica set servers to use (for example, ["moab1:27017", "moab2:27017"]); note that <code>grails.-mongo.host</code> <i>must</i> be set to null to use this option.
grails.mongo.databaseName	String	mws	The MongoDB database name to use.
grails.mongo.username	String	-	(Optional) The username to use when connecting to MongoDB.
grails.mongo.password	String	-	(Optional) The password to use when connecting to MongoDB.
grails.mongo.options.connectionsPerHost	Integer	50	The number of connections allowed per host.

Property	Type	Default	Description
grails.- mongo.- options.threadsAllowedToBlockForConnectio	Integer	5	The number of threads per connection allowed to wait for an available connection.
grails.mongo.options.autoConnectRetry	Boolean	true	Controls whether the system retries automatically on connection errors.
grails.mime.use.accept.header	Boolean	false	When enabled, uses the HTTP Content-Accept header to determine the content type used for return data (JSON only for now).
grails.plu- gins.springsecurity.basic.realmName	String	Moab Web Services	The HTTP realm used when using basic auth.
grails.plugins.springsecurity.active	Boolean	true	Enables or disables security for MWS as a whole, including all providers.
grails.plugins.springsecurity.useBasicAuth	Boolean	true	Enables or disables basic auth with a simple user-name/password.
grails.plu- gins.springsecurity.oauthProvider.active	Boolean	true	Enables or disables the OAuth2 provider.
ldap.baseDNs	List of Strings	-	A list of distinguished names that are the root entries for LDAP searches.
ldap.bindUser	String	-	The distinguished name of the LDAP bind user.

Property	Type	Default	Description
ldap.directory.type	String	-	The type of LDAP directory (for example, "Microsoft Active Directory"). See Configuring Moab Web Services on page 1570 for valid values..
ldap.password	String	-	The password of the LDAP bind user
ldap.port	Integer	-	LDAP server's port
ldap.security.server.certificate	String	-	The filename of the LDAP server's PEM encoded X.509 certificate. See Setting up MWS Security on page 1585 for more information.
ldap.security.type	String	-	How the connection between MWS and LDAP is secured. See Setting up MWS Security on page 1585 for more information.
ldap.server	String	-	LDAP server hostname or IP address
mam.server	String	localhost	Moab Accounting Manager server hostname or IP address
mam.port	Integer	7112	Moab Accounting Manager server's port
mam.secretKey	String	mamsecret	Secret key used to communicate with Moab Accounting Manager

Property	Type	Default	Description
moab.databaseName	String	moab	The name of the MongoDB database to use to retrieve current Moab data; this should match the database setting in Moab.
moab.messageQueue.port	Integer	5570	The port on which Moab publishes ZeroMQ messages.
moab.messageQueue.secretKey	String	-	Used to encrypt and decrypt messages on the message queue using AES. Must be a Base64 -encoded 128-bit (16-byte) key. For example: "1r6RvfqJa6voezy5wAx0hw=="
moab.port	Integer	42559	Moab server's port
moab.secretKey	String	moabsecret	Secret key used to communicate with Moab. See Moab Configuration.
moab.server	String	localhost	Moab server hostname or IP address
mws.cache.duration.default	Integer	60	The default number of seconds to use for caching objects from Moab. This is only supported in certain objects such as policies.

Property	Type	Default	Description
mws.cache.duration.policy	Integer	180	The number of seconds that the cache for policies is valid. If set to null, the default is used.
mws.certificates.location	String	etc/ssl.crt	The directory (relative or absolute) where plugin certificates are stored. See the Managing SSL Connections on page 2048 .
mws.events.expireAfterSeconds	Integer	2592000	Events older than this many seconds (30 days by default) will be deleted from the database. Effective only with MongoDB 2.2 or later.
mws.health.check.period	Integer	30	The number of seconds in between health checks. Used in creating notification conditions if problems exist in configuration or connections. For more information, see Notification Conditions on page 1789 .
mws.hooks.location	String	hooks	The directory (relative or absolute) where Hooks are stored. See Pre- and Post-Processing Hooks on page 1633 for more information.

Property	Type	Default	Description
mws.plugins.location	String	plugins	The directory (relative or absolute) where Plugins are stored. See About Moab Web Services Plugins on page 2003 for more information.
mws.messageQueue.port	Integer	5564	The port on which MWS publishes ZeroMQ messages.
mws.messageQueue.address	String	-	The IP address on which MWS publishes ZeroMQ messages.
mws.services.hooks.syncInterval	Integer	30	The number of seconds between each time MWS checks for service phase transition hooks that completed or timed out.
mws.services.phases.syncInterval	Integer	14400	The number of seconds between each time MWS checks with Moab Workload Manager to verify that the service phases are correctly synchronized.
mws.suite	String	CLOUD	The suite or context that MWS is running in (see Suite for valid values)

Property	Type	Default	Description
pam.configuration.service	String	-	The name of the PAM configuration file located in <code>/etc/pam.d</code> . This parameter and specification tells MWS which PAM configuration file you want to use. For more information, see PAM (Pluggable Authentication Module) Configuration Using mws-config.groovy on page 1581.
plugins.pluginType	String	-	Default configuration value for the plugin <code>pluginType</code> field (see Setting Default Plugin Configuration on page 2083).
plugins.autoStart	Boolean	true	Default configuration value for the plugin <code>autoStart</code> field (see Setting Default Plugin Configuration on page 2083).
plugins.pollInterval	Integer	30	Default configuration value for the plugin <code>pollInterval</code> field (see Setting Default Plugin Configuration on page 2083).
plugins.config	Map	-	Default configuration value for the plugin <code>config</code> field (see Setting Default Plugin Configuration on page 2083).

Property	Type	Default	Description
plugins.loadInitialPlugins	Boolean	true	If true, loads the initial plugins defined for uploaded or built-in plugin types (see Plugin Projects and Metadata on page 2056).
plugins.stateConsolidationPolicy	NodeStatePolicy	null	If "optimistic", treats state data optimistically. If "pessimistic", treats state data pessimistically. May be null. See Data Consolidation on page 2009 for more information.
plugins.defaultHypervisorType	String	ESX	This is reported to Moab when a node report references a hypervisor image that does not have the hypervisorType or extensions.xcat.hvType fields set. See Fields: Images on page 2211 .

[Logging reference](#)

The following loggers are available to use for debugging purposes:

Logger	Default	Description
grails.app	debug	Most classes in the main MWS application.
grails.app.bootstrap.BootStrap	debug	Handles startup and initialization of MWS.

Logger	Default	Description
com.ace.mws	debug	The base logger for MWS specific functionality not included in other loggers (this comprises very few classes).
grails.app.services.com.ace.mws.plugins.PluginUtilityService	debug	Class for initializing and helper methods of plugins.
com.ace.mws.hooks.HookUtils	debug	Helper class for loading hooks during startup process.
plugins	debug	All MWS plugins (see About Moab Web Services Plugins on page 2003).
com.ace.mws.plugins	debug	MWS plugin helper class, used to create and initialize plugins.
com.ace.mws.gapi	warn	Base logger for all Moab connections, requests, and responses.
com.ace.mws.gapi.Connection	info	Logger which controls all requests and responses from Moab.
com.ace.mws.gapi.parsers	info	Loggers for parsers of Moab's data.
com.ace.mws.gapi.serializers	info	Loggers for all serialization from MWS to Moab Wire Protocol.
grails.app.service.grails.plugins.reloadconfig	info	Handles dynamic reloading of configuration files.
net.sf.json	error	JSON and XML processing library.
org.springframework.security	info	Authentication/authorization logger.

Logger	Default	Description
<code>org.codehaus.groovy.grails.web.servlet</code>	error	Loggers for request handlers.
<code>org.codehaus.groovy.grails.web.mapping</code>	error	URL mapping.
<code>org.codehaus.groovy.grails.web.mapping.filter</code>	error	URL mapping.
<code>org.codehaus.groovy.grails.plugins</code>	error	All grails plugins (MWS internal).
<code>org.codehaus.groovy.grails.commons</code>	error	Core application and class-loading.

Resource Reference

Resources reference

This section contains the type and description of all possible fields in each MWS resource object. Because of significant changes in the API introduced between releases, MWS possesses a versioned API. Each resource contains drop-down sections for each API version.

This section contains these topics:

- [Fields: Access Control Lists \(ACLs\) on page 2126](#)
- [Fields: Accounts on page 2134](#)
- [Fields: Allocations on page 2138](#)
- [Fields: All Service Definitions on page 2659](#)

Tenant-supported	No	Tenants on page 1970
Distinct query-supported	No	Distinct on page 1726

API version 3

AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	PUT	Description
affinity	AclAffinity	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity. Defaults to AclAffinity.POSITIVE .
comparator	ComparisonOperator	Yes	The type of comparison to make against the ACL object. Defaults to ComparisonOperator.EQUAL .
type	AclType	Yes	The type of the object that is being granted (or denied) access.
value	String	Yes	The name of the object that is being granted (or denied) access.

AclAffinity

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AclType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported

Accounting

Fields: Accounts

i See the associated [Accounting Accounts on page 1652](#) resource section for more information on how to use this resource and supported operations.

[Additional references](#)

Type	Value	Additional information
Permissions resource	accounting/accounts	Permissions on page 1802
Hooks filename	accounting.accounts.groovy	Pre- and Post-Processing Hooks on page 1633
Tenant-supported	No	Tenants on page 1970
Distinct query-supported	No	Distinct on page 1726

API version 3

Account

Users may be designated as members of an account and may be allowed to share its allocations. The user members may be designated as active or inactive, and as an account admin or not an account admin. Default account properties include the description, the organization it is part of, and whether or not it is active. An account's user membership can also be adjusted. By default, a standard user may only query accounts they belong to.

Field Name	Type	Description
id	String	The unique account identifier
active	Boolean	A boolean indicating whether this account is active or not
creationTime	Date	The time this account was created
deleted	Boolean	A boolean indicating whether this account is deleted or not
description	String	The account description
modificationTime	Date	The time this account was last modified
organization	String	The organization to which the account belongs
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction
users	Set<AccountUser>	The users associated with this account

AccountUser

An account user is a person authorized to use an account.

Field Name	Type	Description
id	String	The unique user identifier
active	Boolean	A boolean indicating whether this user is active or not

Field Name	Type	Description
admin	Boolean	A boolean indicating wheter this user is an admin or not

API version 2

Account

Tenant-supported	No	Tenants on page 1970
Distinct query-supported	No	Distinct on page 1726

API version 3

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive

Field Name	Type	Description
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

API version 2

API version 3

FundBalance

Represents a report of fund balance.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	The total adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	Set<Allocation>	Allocations associated with this fund
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
available	BigDecimal	The total amount available for charging. amount - reserved + creditLimit
balance	BigDecimal	The allocation total not blocked by liens. amount - reserved
capacity	BigDecimal	The total amount allocated via deposits and credit limits. allocated + creditLimit
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
description	String	The fund description
fundConstraints	Set<FundConstraint>	Constraints on fund usage.
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
percentRemaining	Double	The percentage of allocation remaining. amount * 100 / allocated

Field Name	Type	Description
percentUsed	Double	The percentage of allocated used. used * 100 / allocated
reserved	BigDecimal	The sum of active lien amounts against this fund
used	BigDecimal	The total amount used this allocation cycle. allocated - amount

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

API version 2

FundBalance

Represents a report of fund balance.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	The total adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	<u>Set<Allocation></u>	Allocations associated with this fund
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
available	BigDecimal	The total amount available for charging. <u>amount</u> - <u>reserved</u> + <u>creditLimit</u>
balance	BigDecimal	The allocation total not blocked by liens. <u>amount</u> - <u>reserved</u>
capacity	BigDecimal	The total amount allocated via deposits and credit limits. <u>allocated</u> + <u>creditLimit</u>
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
description	String	The fund description
fundConstraints	<u>Set<FundConstraint></u>	Constraints on fund usage.
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
percentRemaining	Double	The percentage of allocation remaining. <u>amount</u> * 100 / <u>allocated</u>

Field Name	Type	Description
percentUsed	Double	The percentage of allocated used. $\text{used} * 100 / \text{allocated}$
reserved	BigDecimal	The sum of active lien amounts against this fund
used	BigDecimal	The total amount used this allocation cycle. $\text{allocated} - \text{amount}$

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created

Field Name	Type	Description
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

API version 3

FundStatementSummary

An fund statement summary is related to and quite similar to the [FundStatement](#) report, but differs in the [transactions](#) field by using the [FundTransactionSummary](#).

Field Name	Type	Description
id	Long	
endBalance	BigDecimal	The balance of the funds at the endTime of the statement
endTime	Date	The ending time that the statement covers
funds	Set<Fund>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
generationTime	Date	The date that the statement report was generated
startBalance	BigDecimal	The balance of the funds at the startTime of the statement
startTime	Date	The starting time that the statement covers
totalCredits	BigDecimal	The total number of credits that occurred during the time period that the statement covers
totalDebits	BigDecimal	The total number of debits that occurred during the time period that the statement covers
transactions	Set<FundTransactionSummary>	Summaries of the specific transactions which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these

resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	Set<Allocation>	The allocations associated with this fund.
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
defaultDeposit	String	The default deposit amount

Field Name	Type	Description
deleted	Boolean	A boolean indicating whether this fund is deleted or not
description	String	The fund description
fundConstraints	<u>Set<FundConstraint></u>	Constraints on fund usage.
initialDeposit	BigDecimal	The initial deposit amount
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
priority	Integer	The fund priority
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction

[Allocation](#)

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

FundTransactionSummary

Represents a Moab Accounting Manager transaction summary, which is a consolidated view of multiple transactions. The transactions are grouped by [object](#) and [action](#), and a total [count](#) is given for the summary.

Field Name	Type	Description
id	Long	
count	Long	The number of transactions in this grouping of object and action
action	String	Action name for the transaction
amount	BigDecimal	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
object	String	Object's name associated with the transaction

API version 2

FundStatementSummary

An fund statement summary is related to and quite similar to the [FundStatement](#) report, but differs in the [transactions](#) field by using the [FundTransactionSummary](#).

Field Name	Type	Description
id	Long	
endBalance	BigDecimal	The balance of the funds at the endTime of the statement
endTime	Date	The ending time that the statement covers
funds	Set<Fund>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
generationTime	Date	The date that the statement report was generated
startBalance	BigDecimal	The balance of the funds at the startTime of the statement
startTime	Date	The starting time that the statement covers
totalCredits	BigDecimal	The total number of credits that occurred during the time period that the statement covers
totalDebits	BigDecimal	The total number of debits that occurred during the time period that the statement covers
transactions	Set<FundTransactionSummary>	Summaries of the specific transactions which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these

resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	<u>Set<Allocation></u>	The allocations associated with this fund.
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
defaultDeposit	String	The default deposit amount

Field Name	Type	Description
deleted	Boolean	A boolean indicating whether this fund is deleted or not
description	String	The fund description
fundConstraints	<u>Set<FundConstraint></u>	Constraints on fund usage.
initialDeposit	BigDecimal	The initial deposit amount
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
priority	Integer	The fund priority
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction

[Allocation](#)

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

FundTransactionSummary

Represents a Moab Accounting Manager transaction summary, which is a consolidated view of multiple transactions. The transactions are grouped by [object](#) and [action](#), and a total [count](#) is given for the summary.

Field Name	Type	Description
id	Long	
count	Long	The number of transactions in this grouping of object and action
action	String	Action name for the transaction
amount	BigDecimal	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
object	String	Object's name associated with the transaction

API version 3

FundStatement

An fund statement is a report generated from Moab Accounting Manager fund, allocation, and transaction data. It contains fields detailing the specific time period covered, the starting and ending balances, the total of the transactions, and fund and transaction details.

Field Name	Type	Description
id	Long	
endBalance	BigDecimal	The balance of the funds at the endTime of the statement
endTime	Date	The ending time that the statement covers
funds	Set<Fund>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
generationTime	Date	The date that the statement report was generated
startBalance	BigDecimal	The balance of the funds at the startTime of the statement
startTime	Date	The starting time that the statement covers
totalCredits	BigDecimal	The total number of credits that occurred during the time period that the statement covers
totalDebits	BigDecimal	The total number of debits that occurred during the time period that the statement covers
transactions	Set<FundTransaction>	Details of each specific transaction which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints

designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	<u>Set<Allocation></u>	The allocations associated with this fund.
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
defaultDeposit	String	The default deposit amount
deleted	Boolean	A boolean indicating whether this fund is deleted or not

Field Name	Type	Description
description	String	The fund description
fundConstraints	<u>Set<FundConstraint></u>	Constraints on fund usage.
initialDeposit	BigDecimal	The initial deposit amount
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
priority	Integer	The fund priority

These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation

Field Name	Type	Description
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

FundTransaction

Represents a Moab Accounting Manager transaction.

Field Name	Type	Description
id	Long	
account	String	The account associated with the transaction. For a credit this will likely be zero
action	String	Action name for the transaction
amount	BigDecimal	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
instance	String	Instance name
machine	String	The machine associated with the transaction. For a credit this will likely be zero. This field is not available in the Cloud context.
object	String	Object's name associated with the transaction
time	Date	The date at which the transaction occurred
user	String	The user associated with the transaction. For a credit this will likely be zero

API version 2

FundStatement

An fund statement is a report generated from Moab Accounting Manager fund, allocation, and transaction data. It contains fields detailing the specific time period covered, the starting and ending balances, the total of the transactions, and fund and transaction details.

Field Name	Type	Description
id	Long	
endBalance	BigDecimal	The balance of the funds at the endTime of the statement
endTime	Date	The ending time that the statement covers
funds	Set<Fund>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
generationTime	Date	The date that the statement report was generated
startBalance	BigDecimal	The balance of the funds at the startTime of the statement
startTime	Date	The starting time that the statement covers
totalCredits	BigDecimal	The total number of credits that occurred during the time period that the statement covers
totalDebits	BigDecimal	The total number of debits that occurred during the time period that the statement covers
transactions	Set<FundTransaction>	Details of each specific transaction which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints

designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
id	Long	The unique fund identifier
allocated	BigDecimal	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
allocations	<u>Set<Allocation></u>	The allocations associated with this fund.
amount	BigDecimal	The sum of active allocation amounts within this fund. It does not take into fund current liens.
creationTime	Date	Date this fund was created
creditLimit	BigDecimal	The sum of active credit limits within this fund
defaultDeposit	String	The default deposit amount
deleted	Boolean	A boolean indicating whether this fund is deleted or not

Field Name	Type	Description
description	String	The fund description
fundConstraints	<u>Set<FundConstraint></u>	Constraints on fund usage.
initialDeposit	BigDecimal	The initial deposit amount
modificationTime	Date	The date this fund was last modified
name	String	The name of this fund
priority	Integer	The fund priority
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction

[Allocation](#)

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation

Field Name	Type	Description
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

FundTransaction

Represents a Moab Accounting Manager transaction.

Field Name	Type	Description
id	Long	
account	String	The account associated with the transaction. For a credit this will likely be zero
action	String	Action name for the transaction
amount	BigDecimal	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
instance	String	Instance name
machine	String	The machine associated with the transaction. For a credit this will likely be zero. This field is not available in the Cloud context.
object	String	Object's name associated with the transaction
time	Date	The date at which the transaction occurred
user	String	The user associated with the transaction. For a credit this will likely be zero

By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft

protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
id	String	The unique identifier for this allocation
active	Boolean	Indicates whether this allocation is active or not
allocated	BigDecimal	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
amount	BigDecimal	The amount of this allocation
creationTime	Date	The date this allocation was created
creditLimit	BigDecimal	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
deleted	Boolean	A boolean indicating whether this allocation is deleted or not
description	String	The description of this allocation
endTime	Date	The date this allocation becomes inactive
fund	String	The fund Id associated with this allocation
modificationTime	Date	The date this allocation was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The date this allocation becomes active
transactionId	Long	The id of the last modifying transaction

FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
id	String	The unique identifier of this constraint.
fund	String	The fund ID that this constraint is associated with.
name	String	The name of the constraint.
value	String	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

API version 3

Lien

A lien is a reservation or hold placed against an allocation. Before usage of a resource or service begins, a lien is placed against one or more allocations within the requesting user's applicable funds. Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Field Name	Type	Description
id	Long	The unique lien identifier
allocations	<u>Set<LienAllocation></u>	The allocation amounts reserved with this lien.
creationTime	Date	The date this lien was created
deleted	Boolean	A boolean indicating whether this lien is deleted or not
description	String	The lien description
duration	Long	The expected duration of the reserved usage in seconds
endTime	Date	The time the lien becomes inactive
instance	String	The lien is against the specified instance (i.e. job id)
modificationTime	Date	The date this lien was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The time the lien becomes active
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The id of the usage record associated with the lien and containing the usage properties

LienAllocation

Amounts of the allocations that the lien has holds against

Field Name	Type	Description
id	String	The child allocation id
amount	Long	The amount reserved against the allocation by this lien
fund	Long	The fund that the allocation is in
lien	String	The parent lien id

API version 2

Lien

A lien is a reservation or hold placed against an allocation. Before usage of a resource or service begins, a lien is placed against one or more allocations within the requesting user's applicable funds. Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Field Name	Type	Description
id	Long	The unique lien identifier
allocations	<u>Set<LienAllocation></u>	The allocation amounts reserved with this lien.
creationTime	Date	The date this lien was created
deleted	Boolean	A boolean indicating whether this lien is deleted or not
description	String	The lien description
duration	Long	The expected duration of the reserved usage in seconds
endTime	Date	The time the lien becomes inactive
instance	String	The lien is against the specified instance (i.e. job id)
modificationTime	Date	The date this lien was last modified
requestId	Long	The id of the last modifying request
startTime	Date	The time the lien becomes active
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The id of the usage record associated with the lien and containing the usage properties

LienAllocation

Amounts of the allocations that the lien has holds against

Field Name	Type	Description
id	String	The child allocation id
amount	Long	The amount reserved against the allocation by this lien
fund	Long	The fund that the allocation is in
lien	String	The parent lien id

API version 3

Organization

An organization is a virtual organization in which accounts are grouped. An account may only belong to a single organization while an organization may have multiple accounts. For example, an account may represent a project or cost-center while an organization may represent an institutional department or business division. The purpose of defining organizations is to support the ability to produce reporting for higher-order organizational entities beyond the individual account. Default organization properties include an id (name in MAM) and a description. An organization can be created, queried, modified, and deleted.

Field Name	Type	Description
id	String	The unique organization identifier
creationTime	Date	The date this organization was created
deleted	Boolean	A boolean indicating whether this organization is deleted or not
description	String	The organization description
modificationTime	Date	The date this organization was last modified
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction

API version 2

Organization

Fields: Quotes

 See the associated [Accounting Quotes on page 1680](#) resource section for more information on how to use this resource and supported operations.

Additional references

Type	Value	Additional information
Permissions resource	accounting/quotes	Permissions on page 1802
Hooks filename	accounting.quotes.groovy	Pre- and Post-Processing Hooks on page 1633
Tenant-supported	No	Tenants on page 1970
Distinct query-supported	No	Distinct on page 1726

API version 3

Quote

Quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

Field Name	Type	Description
id	Long	The unique quote identifier
amount	BigDecimal	The total amount of the quote
chargeRates	<u>Set<QuoteChargeRate></u>	The applied charges that make up this quote.
creationTime	Date	The date this quote was created
deleted	Boolean	A boolean indicating whether this quote is deleted or not
description	String	The quote description
duration	Long	The expected duration of the quoted usage in seconds
endTime	Date	The time the quote becomes inactive
instance	String	The quote instance name. (i.e. job id)
modificationTime	Date	The date this quote was last modified
pinned	Boolean	Boolean indicating whether the quote is pinned or not
requestId	Long	The id of the last modifying request

Field Name	Type	Description
startTime	Date	The time the quote becomes active
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The usage record id associated with this quote

QuoteChargeRate

Saved charge rates to be used when the quote is referenced

Field Name	Type	Description
id	Long	
amount	String	The charge rate amount
name	String	The child charge rate name
quote	String	The parent quote id
value	String	The child charge rate value

API version 2

Quote

Quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

Field Name	Type	Description
id	Long	The unique quote identifier
amount	BigDecimal	The total amount of the quote
chargeRates	<u>Set<QuoteChargeRate></u>	The applied charges that make up this quote.
creationTime	Date	The date this quote was created
deleted	Boolean	A boolean indicating whether this quote is deleted or not
description	String	The quote description
duration	Long	The expected duration of the quoted usage in seconds
endTime	Date	The time the quote becomes inactive
instance	String	The quote instance name. (i.e. job id)
modificationTime	Date	The date this quote was last modified
pinned	Boolean	Boolean indicating whether the quote is pinned or not
requestId	Long	The id of the last modifying request

Field Name	Type	Description
startTime	Date	The time the quote becomes active
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The usage record id associated with this quote

QuoteChargeRate

Saved charge rates to be used when the quote is referenced

Field Name	Type	Description
id	Long	
amount	String	The charge rate amount
name	String	The child charge rate name
quote	String	The parent quote id
value	String	The child charge rate value

API version 3

Transaction

Moab Accounting Manager logs all modifying transactions in a detailed transaction journal (queries are not recorded). Previous transactions can be queried but not modified or deleted. By default, a standard user may only query transactions performed by them.

Field Name	Type	Description
id	Long	The unique transaction identifier
account	String	The account name associated with the transaction
action	String	The transaction action name
actor	String	The authenticated user that performed the action
allocation	Long	The allocation id associated with the transaction
amount	BigDecimal	The amount
child	String	If the transaction object is an association, this is the value of the child
creationTime	Date	The date this transaction was created
deleted	Boolean	A boolean indicating whether this transaction is deleted or not
delta	BigDecimal	The effective change (positive or negative) to the balance of an allocation
description	String	The description for the transaction
duration	Long	The duration associated with the transaction in seconds
fund	Long	The fund id associated with the transaction
instance	String	The instance name (e.g. the job id)
key	String	The object primary key value

Field Name	Type	Description
machine	String	The machine name associated with the transaction (e.g. the cluster name)
modificationTime	Date	The date this transaction was last modified
object	String	The transaction object name
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The usage record id associated with the transaction
user	String	The user name associated with the transaction

API version 2

Transaction

Moab Accounting Manager logs all modifying transactions in a detailed transaction journal (queries are not recorded). Previous transactions can be queried but not modified or deleted. By default, a standard user may only query transactions performed by them.

Field Name	Type	Description
id	Long	The unique transaction identifier
account	String	The account name associated with the transaction
action	String	The transaction action name
actor	String	The authenticated user that performed the action
allocation	Long	The allocation id associated with the transaction
amount	BigDecimal	The amount
child	String	If the transaction object is an association, this is the value of the child
creationTime	Date	The date this transaction was created
deleted	Boolean	A boolean indicating whether this transaction is deleted or not
delta	BigDecimal	The effective change (positive or negative) to the balance of an allocation
description	String	The description for the transaction
duration	Long	The duration associated with the transaction in seconds
fund	Long	The fund id associated with the transaction
instance	String	The instance name (e.g. the job id)
key	String	The object primary key value

Field Name	Type	Description
machine	String	The machine name associated with the transaction (e.g. the cluster name)
modificationTime	Date	The date this transaction was last modified
object	String	The transaction object name
requestId	Long	The id of the last modifying request
transactionId	Long	The id of the last modifying transaction
usageRecord	Long	The usage record id associated with the transaction
user	String	The user name associated with the transaction

Distinct query-supported	No	Distinct on page 1726

API version 3

UsageRecord

A usage record tracks the usage of resources and services on your system, recording the charge and the details of the usage in a usage record.

Usage Record quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The replace option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The modify option may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one.

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors. By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed. If a usage record already exists for the instance being charged it will be updated with the data properties passed in with the charge request, otherwise a new usage record will be created.

Field Name	Type	POST	Description
id	Long	No	The unique usage record identifier
charge	String	No	The cumulative amount charged
creationTime	Date	No	The date this usage record was created

Field Name	Type	POST	Description
deleted	Boolean	No	A boolean indicating whether this usage record is deleted or not
instance	String	No	The usage record instance name (i.e. job id)
modificationTime	Date	No	The date this usage record was last modified
qualityOfService	String	No	The quality of service associated with the usage
quote	Long	No	The associated quote id
requestId	Long	No	The id of the last modifying request
stage	String	No	The last affecting action (i.e. Create, Quote, Reserve, Query)
transactionId	Long	No	The id of the last modifying transaction
type	String	No	The usage record type
user	String	No	The user name associated with the usage

API version 2

UsageRecord

A usage record tracks the usage of resources and services on your system, recording the charge and the details of the usage in a usage record.

Usage Record quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The replace option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The modify option may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one.

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors. By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed.  See the associated [Events on page 1728](#) resource section for more information on how to use this resource and supported operations.

Additional references

Type	Value	Additional information
Permissions resource	events	Permissions on page 1802
Hooks filename	events.groovy	Pre- and Post-Processing Hooks on page 1633
Tenant-supported	Yes	Tenants on page 1970
Distinct query-supported	Yes	Distinct on page 1726

API version 3

Event

Represents an event originating from any component in the system (MWM, MWS, MAM, etc). Events are related to, but not the same as, [Notifications](#). See [NotificationCondition](#) for an explanation of when to use an event vs a notification.

Field Name	Type	POST	Description
id	String	No	The unique ID for this event
arguments	List<String>	Yes	The event's arguments
associatedObjects	Set<AssociatedObject>	Yes	Objects relating to the event
code	int	Yes	This is a positive, 32-bit numeric value. Source code that needs to take action on events based on which event (error) occurred can switch based on this value. The top 16 bits are determined by the severity of the event and the component that emits it. The bottom 16 bits are assigned by any arbitrary mechanism convenient to a component. Each component thus has 64k unique event codes that it can assign. Once assigned, event codes are immutable; it can never be the case that error 12345 means one thing in release A, and a different thing in release B.
eventDate	Date	Yes	The date and time the event occurred, not the date and time MWS received the event. It is up to the reporting component to report this time accurately. Required during POST.
eventType	String	Yes	Signifies what type of event. Cannot contain single quotes(') or double quotes(").
message	String	Yes	A summary of what happened that caused this event
origin	String	Yes	The origin of this event. Cannot contain single quotes(') or double quotes(").

Field Name	Type	POST	Description
severity	EventSeverity	Yes	Signifies the severity of an event.
tenant	Map<String, String>	No	The event's tenant (contains tenant id and name)

AssociatedObject

Represents and uniquely identifies an object associated with an event. (e.g node, job, reservation, trigger)

Field Name	Type	POST	Description
id	String	Yes	The object id (e.g. reservation.1, job.21, vm3). Cannot contain single quotes(') or double quotes(").
type	String	Yes	The type of object (e.g. node, job, reservation). Cannot contain single quotes(') or double quotes(").

EventSeverity

Value	Description
INFO	
WARN	
ERROR	
FATAL	

API version 2

EventVersion2

Field Name	Type	POST	Description
id	String	No	The unique ID for this event
details	Map<String, Map>	Yes	A map where detail name maps to detail value. (e.g. "sourceHypervisor" => "blade256", "destinationHypervisor" => "blade257", "os" => "centos-5.5-stateless")
errorMessage	<u>ErrorMessageVersion2</u>	Yes	Details about any errors associated with the event. If this event was not associated with any errors this field will be null
eventCategory	String	Yes	Signifies what category of event.
eventTime	Date	Yes	The time the event occurred, not the time MWS received the event. It is up to the reporting component to report this time accurately. Corresponds to eventDate in API Version 3. Required during POST.
eventType	String	Yes	Signifies what type of event.
facility	String	Yes	A categorization of how this event fits in with other events.
initiatedBy	<u>UserDetailsVersion2</u>	Yes	Details about the user that initiated this event
primaryObject	<u>MoabObjectVersion2</u>	Yes	Most events will have a "primary object" associated with it. An event can have at most ONE primary object. For example, a JobStart event will have a primary job object, so the type would be "job" and the object ID would be the ID of the job. Primary objects are, however, optional, depending on the type of event. For example, a "SchedulerCommand" event does not have a primary object.

Field Name	Type	POST	Description
relatedObjects	Set<MoabObjectVersion2>	Yes	Objects relating to the event that are not the primary object. Corresponds to associatedObjects in API Version 3.
severity	String	Yes	Signifies the severity of an event. Severity can be "FATAL", "ERROR", "WARN", "INFO"
sourceComponent	String	Yes	What Adaptive Computing component reported this event. Examples: "MWM", "MWS", "MAM", etc. Corresponds to origin in API Version 3.
status	String	Yes	The status of the reported event.

ErrorMessageVersion2

Field Name	Type	POST	Description
errorCode	String	Yes	The original error code generated or detected by the originator.
message	String	Yes	If an event has a status of "failure" or other non-successful operation, this field should provide a human-friendly error message Corresponds to Event.message in API Version 3 and above.
originator	String	Yes	The software component or entity that generated or detected the error (e.g. Moab, Torque, MWS, Viewpoint, RM, Database, etc).

UserDetailsVersion2

Field Name	Type	POST	Description
proxyUser	String	Yes	The proxy user that initiated the event.
user	String	Yes	The user that initiated the event.

MoabObjectVersion2

Field Name	Type	POST	Description
id	String	Yes	The moab object id (e.g. reservation.1, job.21, vm3)
serialization	String	Yes	A serialized representation of the object
type	String	Yes	The moab object type (e.g. node, job, reservation)

Image

An image is used to track the different types of operating systems and hypervisors available in a data center. If the image is a hypervisor, it can contain other images which are the available virtual machines of the hypervisor.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this image.
active	Boolean	Yes	Yes	If false, the image is flagged as inactive and should not be used. Defaults to true.

Field Name	Type	POST	PUT	Description
extensions	Map<String, Map>	Yes	Yes	<p>A map containing maps which represent settings for provisioning managers. Only one extension may be present on an image at a time currently. Valid default provisioning manager specific extensions include 'xcat'.</p> <p>Required properties for 'xcat' when hypervisor is false:</p> <ul style="list-style-type: none"> • os - The name of the operating system according to xCAT • architecture - The architecture, such as x86_64 • profile - The xCAT profile to use for the image <p>Required properties for 'xcat' when hypervisor is true:</p> <ul style="list-style-type: none"> • os - The name of the operating system according to xCAT • architecture - The architecture, such as x86_64 • profile - The xCAT profile to use for the image • hvGroupName - The name of the xCAT hypervisor group • vmGroupName - The name of the xCAT VM group
features	Set<String>	Yes	Yes	The set of features used by the provisioning manager.

Field Name	Type	POST	PUT	Description
hypervisor	Boolean	Yes	Yes	Whether or not the image is a hypervisor. Required during POST. Note that this is related to, but not the same as, supportsPhysicalMachine . Also, when this is false, no virtualizedImages may be specified for an image.
hypervisorType	String	Yes	Yes	The type of the hypervisor, which is indicative of the hypervisor technology used in this image. Required if this image is a hypervisor image.
name	String	Yes	Yes	The unique human-readable name of this image. Required during POST.
osType	String	Yes	Yes	The type of the operating system such as 'Linux' or 'Windows'. Required during POST.
supportsPhysicalMachine	Boolean	Yes	Yes	Specifies whether the image can be used to provision a physical machine, defaults to false. Either this or supportsVirtualMachine must be set to true. Note that this is related to, but not the same as, hypervisor . Some images may not be hypervisors but can be provisioned on a physical machine.
supportsVirtualMachine	Boolean	Yes	Yes	Specifies whether the image can be used to provision a virtual machine, defaults to false. Either this or supportsPhysicalMachine must be set to true.
templateName	String	Yes	Yes	The VM template to use for this image. Only valid if the type is set to a valid template type such as 'ImageType.LINKED_CLONE'.

Field Name	Type	POST	PUT	Description
type	ImageType	Yes	Yes	The type of the image. This property may affect the valid values to use for other fields. See ImageType for more information. (See also: templateName .)
virtualizedImages	Set<Image>	Yes	Yes	The set of images available on this hypervisor.

[ImageType](#)

Represents an image type, such as stateful or stateless. This is used by provisioning managers and applications to correctly provision and represent the image.

Certain types are only valid for images configured as templates using the [Image.templateName](#) field. This currently includes [ImageType.LINKED_CLONE](#) and [ImageType.FULL_CLONE](#).

Value	Description
STATEFUL	
STATELESS	
STATELITE	
LINKED_CLONE	Template type. When this image type is used, the Image.hypervisor field must be set to false, Image.supportsVirtualMachine must be true, and Image.supportsPhysicalMachine must be false.
FULL_CLONE	Template type. When this image type is used, the Image.hypervisor field must be set to false, Image.supportsVirtualMachine must be true, and Image.supportsPhysicalMachine must be false.

API version 2

Image

An image is used to track the different types of operating systems and hypervisors available in a data center. If the image is a hypervisor, it can contain other images which are the available virtual machines of the hypervisor.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this image.
active	Boolean	Yes	Yes	If false, the image is flagged as inactive and should not be used. Defaults to true.

Field Name	Type	POST	PUT	Description
extensions	Map<String, Map>	Yes	Yes	<p>A map containing maps which represent settings for provisioning managers. Only one extension may be present on an image at a time currently. Valid default provisioning manager specific extensions include 'xcat'.</p> <p>Required properties for 'xcat' when hypervisor is false:</p> <ul style="list-style-type: none"> • os - The name of the operating system according to xCAT • architecture - The architecture, such as x86_64 • profile - The xCAT profile to use for the image <p>Required properties for 'xcat' when hypervisor is true:</p> <ul style="list-style-type: none"> • os - The name of the operating system according to xCAT • architecture - The architecture, such as x86_64 • profile - The xCAT profile to use for the image • hvGroupName - The name of the xCAT hypervisor group • vmGroupName - The name of the xCAT VM group
features	Set<String>	Yes	Yes	The set of features used by the provisioning manager.

Field Name	Type	POST	PUT	Description
hypervisor	Boolean	Yes	Yes	Whether or not the image is a hypervisor. Required during POST. Note that this is related to, but not the same as, supportsPhysicalMachine . Also, when this is false, no virtualizedImages may be specified for an image.
hypervisorType	String	Yes	Yes	The type of the hypervisor, which is indicative of the hypervisor technology used in this image. Required if this image is a hypervisor image.
name	String	Yes	Yes	The unique human-readable name of this image. Required during POST.
osType	String	Yes	Yes	The type of the operating system such as 'Linux' or 'Windows'. Required during POST.
supportsPhysicalMachine	Boolean	Yes	Yes	Specifies whether the image can be used to provision a physical machine, defaults to false. Either this or supportsVirtualMachine must be set to true. Note that this is related to, but not the same as, hypervisor . Some images may not be hypervisors but can be provisioned on a physical machine.
supportsVirtualMachine	Boolean	Yes	Yes	Specifies whether the image can be used to provision a virtual machine, defaults to false. Either this or supportsPhysicalMachine must be set to true.
templateName	String	Yes	Yes	The VM template to use for this image. Only valid if the type is set to a valid template type such as 'ImageType.LINKED_CLONE'.

Field Name	Type	POST	PUT	Description
type	ImageType	Yes	Yes	The type of the image. This property may affect the valid values to use for other fields. See ImageType for more information. (See also: templateName .)
virtualizedImages	Set<Image>	Yes	Yes	The set of images available on this hypervisor.

[ImageType](#)

Represents an image type, such as stateful or stateless. This is used by provisioning managers and applications to correctly provision and represent the image.

Certain types are only valid for images configured as templates using the [Image.templateName](#) field. This currently includes [ImageType.LINKED_CLONE](#) and [ImageType.FULL_CLONE](#).

Value	Description
STATEFUL	
STATELESS	
STATELITE	
LINKED_CLONE	Template type. When this image type is used, the Image.hypervisor field must be set to false, Image.supportsVirtualMachine must be true, and Image.supportsPhysicalMachine must be false.
FULL_CLONE	Template type. When this image type is used, the Image.hypervisor field must be set to false, Image.supportsVirtualMachine must be true, and Image.supportsPhysicalMachine must be false.

API version 3

JobArray

Job arrays are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if 235[1] is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Field Name	Type	POST	Description
cancellationPolicy	CancellationPolicyInformation	Yes	Represents the cancellation policy to use for the job array.
indexRanges	List<JobArrayIndexRange>	Yes	The index ranges used to generate the sub-job indices. To use hard-coded values, see indexValues .
indexValues	List<Long>	Yes	The index values to use for the sub-jobs. To use ranges, see indexRanges .
jobPrototype	Job	Yes	The definition of the job to use for each sub-job.
name	String	Yes	The name of the job array. In MWS API version 1, this is stored in the <code>name</code> field of the created jobs. In MWS API version 2, this is stored in the <code>customName</code> field of the created jobs.
slotLimit	Long	Yes	(Optional) The number of sub-jobs in the array that can run at a time.

CancellationPolicyInformation

Job arrays can be canceled based on the success or failure of the first or any sub-job. This class represents the failure policies.

Field Name	Type	POST	Description
anyJob	CancellationPolicy	Yes	The cancellation policy based on the result of any sub-job. May be used in combination with firstJob .

Field Name	Type	POST	Description
firstJob	CancellationPolicy	Yes	The cancellation policy based on the result of the first sub-job (array index 1). May be used in combination with anyJob .

[CancellationPolicy](#)

This enumeration represents job array cancellation policies, and is to be used in combination with [CancellationPolicyInformation](#).

Value	Description
SUCCESS	Cancels the job array if the specified sub-job succeeds.
FAILURE	Cancels the job array if the specified sub-job fails.

[JobArrayIndexRange](#)

Represents information about a job index expression. This is used when creating job arrays only.

Field Name	Type	POST	Description
endIndex	Long	Yes	The end of the index range. i.e. 10 for 1-10.
increment	Long	Yes	The increment of the index range, defaults to 1 and must be greater than 0. For a range of 1-10 with an increment of 2, the list of indices will be [1, 3, 5, 7, 9].
startIndex	Long	Yes	The start of the index range. i.e. 1 for 1-10.

[Job](#)

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be

starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	Description
id	String	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	Reasons the job is blocked from running.
bypassCount	Integer	No	The number of times the job has been backfilled.
cancelCount	Integer	No	The number of times a job has received a cancel request.

Field Name	Type	POST	Description
commandFile	String	Yes	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	The exit code from this job.
cpuTime	Long	No	CPU usage time in seconds as reported by the resource manager.
credentials	JobCredentials	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	The user-specified name of this job.
dates	JobDates	Yes	Various dates associated with this job.
deferCount	Integer	No	The number of times a job has been deferred.

Field Name	Type	POST	Description
dependencies	<u>Set<JobDependency></u>	Yes	Dependencies that must be fulfilled before the job can start.
description	String	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	The list of addresses to whom email is sent by the execution server.
emailNotifyTypes	<u>Set<JobEmailNotifyType></u>	Yes	The list of email notify types attached to the job.
environmentRequested	Boolean	Yes	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.

Field Name	Type	POST	Description
environmentVariables	Map<String, Map>	Yes	The list of environment variables for this job.
epilogScript	String	Yes	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	The flags that are set on this job.
holdDate	Date	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	The path to the directory in which the job will be started.
isActive	Boolean	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	The job group to which this job belongs (different from credentials.group).
masterNode	<u>DomainProxy</u>	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
memorySecondsDedicated	Double	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	Description
memorySecondsUtilized	Double	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	Set<Message>	No	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
nodesExcluded	Set<DomainProxy>	Yes	The list of nodes that should not be considered for this job.
nodesRequested	Set<DomainProxy>	Yes	The exact set, superset, or subset of nodes on which this job must run. (See also: nodesRequestedPolicy .)
nodesRequestedPolicy	JobHostListMode	Yes	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: nodesRequested .)

Field Name	Type	POST	Description
partitionAccessList	Set<String>	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	The number of times the job has been preempted.
priorities	<u>JobPriority</u>	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	The limit for processorSecondsUtilized.
processorSecondsUtilized	Double	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
prologScript	String	Yes	The path to the TORQUE prolog script.
queueStatus	<u>JobQueueStatus</u>	No	The status of the job in its queue.
rejectPolicies	<u>Set<JobRejectPolicy></u>	No	The list of policies enabled when a job is rejected.
requirements	<u>Set<JobRequirement></u>	Yes	The list of items required for this job to run. Only <u>JobRequirement.features</u> is valid during PUT.

Field Name	Type	POST	Description
reservationRequested	DomainProxy	Yes	The reservation that the job requested.
resourceFailPolicy	JobResourceFailPolicyType	Yes	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
resourceManagers	Set<ResourceManager>	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	The path to the remote file containing the standard error of the job.
rmStandardOutputFilePath	String	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	The path to the file containing the standard output of the job.
startCount	Integer	No	The number of times the job has been started.

Field Name	Type	POST	Description
states	JobStateInformation	No	Information about the state of the job.
submitHost	String	Yes	The host from which the job was submitted.
systemJobAction	String	No	The action the system job will take.
systemJobType	JobSystemJobType	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	JobActionType	No	The action that this job is performing on another job.
targetedJobName	String	No	The name of the job on which this job is performing the targetedJobAction.
templates	Set<DomainProxy>	Yes	The list of all job templates to be set on this job.
triggers	Set<String>	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	Set<DomainProxy>	Yes	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	Set<DomainProxy>	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	VMUsagePolicy	Yes	The requested Virtual Machine Usage Policy for this job.

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	Description
account	String	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.

Field Name	Type	POST	Description
group	String	Yes	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
qos	String	No	The quality of service assigned to this job. The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
qosRequested	String	Yes	The quality of service requested for this job.
user	String	Yes	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	Description
completedDate	Date	No	
createdDate	Date	No	
deadlineDate	Date	Yes	The deadline for completion of the job.
dispatchedDate	Date	No	
earliestRequestedStartDate	Date	Yes	The job will start no sooner than this date.
earliestStartDate	Date	No	
eligibleDate	Date	No	
lastCanceledDate	Date	No	
lastChargedDate	Date	No	
lastPreemptedDate	Date	No	
lastUpdatedDate	Date	No	
startDate	Date	No	
submitDate	Date	No	
terminationDate	Date	No	

JobDependency

Field Name	Type	POST	Description
name	String	Yes	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	The type of job dependency. Only set is valid for POST.

Field Name	Type	POST	Description
value	String	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.

Value	Description
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.

Value	Description
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.

Value	Description
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	Description
name	String	Yes	The name of the object.

Message

Field Name	Type	POST	Description
count	Integer	No	The number of times this message has occurred.
createdDate	Date	No	The date this message was created.
expireDate	Date	No	The date this message expires.
message	String	No	The message itself.

JobHostListMode

Value	Description
superset	
subset	
exactset	

JobPriority

Field Name	Type	POST	Description
run	Long	No	
start	Long	No	
system	Long	No	

Field Name	Type	POST	Description
user	Long	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

JobRequirement

Field Name	Type	P O S T	Description
architecture	String	Yes	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Yes	Required node attributes with version number support.
features	Set<String>	No	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Yes	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Yes	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Yes	Requested node features. (See also: featuresRequestedMode .)
featuresRequestedMode	JobRequirementFeaturesMode	Yes	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	The image required by the job.
index	Integer	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.

Field Name	Type	POST	Description
nodeAllocationPolicy	NodeAllocationPolicy	Yes	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	The number of nodes required by the job.
nodeSet	String	Yes	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigmem • FIRSTOF:VARATTR:atacenter=Provo:atacenter=SaltLake
nodes	Set<AllocatedNode>	No	Nodes that have been allocated to meet this requirement.
reservation	DomainProxy	No	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	Map<String, JobResource>	Yes	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Yes	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Yes	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	Description
comparator	String	Yes	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	Yes	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .
value	String	Yes	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	

Value	Description
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	Description
name	String	No	
taskCount	Integer	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	Description
dedicated	Integer	No	The amount of this resource that has been allocated for running workload.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

API version 2

JobArray

Job arrays are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if 235[1] is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Field Name	Type	POST	Description
cancellationPolicy	CancellationPolicyInformation	Yes	Represents the cancellation policy to use for the job array.
indexRanges	List<JobArrayIndexRange>	Yes	The index ranges used to generate the sub-job indices. To use hard-coded values, see indexValues .
indexValues	List<Long>	Yes	The index values to use for the sub-jobs. To use ranges, see indexRanges .
jobPrototype	Job	Yes	The definition of the job to use for each sub-job.
name	String	Yes	The name of the job array. In MWS API version 1, this is stored in the <code>name</code> field of the created jobs. In MWS API version 2, this is stored in the <code>customName</code> field of the created jobs.
slotLimit	Long	Yes	(Optional) The number of sub-jobs in the array that can run at a time.

CancellationPolicyInformation

Job arrays can be canceled based on the success or failure of the first or any sub-job. This class represents the failure policies.

Field Name	Type	POST	Description
anyJob	CancellationPolicy	Yes	The cancellation policy based on the result of any sub-job. May be used in combination with firstJob .

Field Name	Type	POST	Description
firstJob	CancellationPolicy	Yes	The cancellation policy based on the result of the first sub-job (array index 1). May be used in combination with anyJob .

[CancellationPolicy](#)

This enumeration represents job array cancellation policies, and is to be used in combination with [CancellationPolicyInformation](#).

Value	Description
SUCCESS	Cancels the job array if the specified sub-job succeeds.
FAILURE	Cancels the job array if the specified sub-job fails.

[JobArrayIndexRange](#)

Represents information about a job index expression. This is used when creating job arrays only.

Field Name	Type	POST	Description
endIndex	Long	Yes	The end of the index range. i.e. 10 for 1-10.
increment	Long	Yes	The increment of the index range, defaults to 1 and must be greater than 0. For a range of 1-10 with an increment of 2, the list of indices will be [1, 3, 5, 7, 9].
startIndex	Long	Yes	The start of the index range. i.e. 1 for 1-10.

[Job](#)

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be

starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	Description
id	String	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	Reasons the job is blocked from running.
bypassCount	Integer	No	The number of times the job has been backfilled.
cancelCount	Integer	No	The number of times a job has received a cancel request.

Field Name	Type	POST	Description
commandFile	String	Yes	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	The exit code from this job.
cpuTime	Long	No	CPU usage time in seconds as reported by the resource manager.
credentials	<u>JobCredentials</u>	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	The user-specified name of this job.
dates	<u>JobDates</u>	Yes	Various dates associated with this job.
deferCount	Integer	No	The number of times a job has been deferred.

Field Name	Type	POST	Description
dependencies	<u>Set<JobDependency></u>	Yes	Dependencies that must be fulfilled before the job can start.
description	String	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	The list of addresses to whom email is sent by the execution server.
emailNotifyTypes	<u>Set<JobEmailNotifyType></u>	Yes	The list of email notify types attached to the job.
environmentRequested	Boolean	Yes	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.

Field Name	Type	POST	Description
environmentVariables	Map<String, Map>	Yes	The list of environment variables for this job.
epilogScript	String	Yes	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	The flags that are set on this job.
holdDate	Date	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	The path to the directory in which the job will be started.
isActive	Boolean	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	The job group to which this job belongs (different from credentials.group).
masterNode	<u>DomainProxy</u>	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
memorySecondsDedicated	Double	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	Description
memorySecondsUtilized	Double	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	<u>Set<Message></u>	No	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
nodesExcluded	<u>Set<DomainProxy></u>	Yes	The list of nodes that should not be considered for this job.
nodesRequested	<u>Set<DomainProxy></u>	Yes	The exact set, superset, or subset of nodes on which this job must run. (See also: <u>nodesRequestedPolicy</u> .)
nodesRequestedPolicy	<u>JobHostListMode</u>	Yes	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <u>nodesRequested</u> .)

Field Name	Type	POST	Description
partitionAccessList	Set<String>	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	The number of times the job has been preempted.
priorities	JobPriority	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	The limit for processorSecondsUtilized.
processorSecondsUtilized	Double	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
prologScript	String	Yes	The path to the TORQUE prolog script.
queueStatus	JobQueueStatus	No	The status of the job in its queue.
rejectPolicies	Set<JobRejectPolicy>	No	The list of policies enabled when a job is rejected.
requirements	Set<JobRequirement>	Yes	The list of items required for this job to run. Only JobRequirement.features is valid during PUT.

Field Name	Type	POST	Description
reservationRequested	DomainProxy	Yes	The reservation that the job requested.
resourceFailPolicy	JobResourceFailPolicyType	Yes	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
resourceManagers	Set<ResourceManager>	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	The path to the remote file containing the standard error of the job.
rmStandardOutputFilePath	String	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	The path to the file containing the standard output of the job.
startCount	Integer	No	The number of times the job has been started.

Field Name	Type	POST	Description
states	JobStateInformation	No	Information about the state of the job.
submitHost	String	Yes	The host from which the job was submitted.
systemJobAction	String	No	The action the system job will take.
systemJobType	JobSystemJobType	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	JobActionType	No	The action that this job is performing on another job.
targetedJobName	String	No	The name of the job on which this job is performing the targetedJobAction.
templates	Set<DomainProxy>	Yes	The list of all job templates to be set on this job.
triggers	Set<String>	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	Set<DomainProxy>	Yes	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	Set<DomainProxy>	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	VMUsagePolicy	Yes	The requested Virtual Machine Usage Policy for this job.

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	Description
account	String	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.

Field Name	Type	POST	Description
group	String	Yes	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
qos	String	No	<p>The quality of service assigned to this job.</p> <p>The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.</p>
qosRequested	String	Yes	The quality of service requested for this job.
user	String	Yes	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	Description
completedDate	Date	No	
createdDate	Date	No	
deadlineDate	Date	Yes	The deadline for completion of the job.
dispatchedDate	Date	No	
earliestRequestedStartDate	Date	Yes	The job will start no sooner than this date.
earliestStartDate	Date	No	
eligibleDate	Date	No	
lastCanceledDate	Date	No	
lastChargedDate	Date	No	
lastPreemptedDate	Date	No	
lastUpdatedDate	Date	No	
startDate	Date	No	
submitDate	Date	No	
terminationDate	Date	No	

JobDependency

Field Name	Type	POST	Description
name	String	Yes	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	The type of job dependency. Only set is valid for POST.

Field Name	Type	POST	Description
value	String	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.

Value	Description
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.

Value	Description
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.

Value	Description
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	Description
name	String	Yes	The name of the object.

Message

Field Name	Type	POST	Description
count	Integer	No	The number of times this message has occurred.
createdDate	Date	No	The date this message was created.
expireDate	Date	No	The date this message expires.
message	String	No	The message itself.

JobHostListMode

Value	Description
superset	
subset	
exactset	

JobPriority

Field Name	Type	POST	Description
run	Long	No	
start	Long	No	
system	Long	No	

Field Name	Type	POST	Description
user	Long	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobRequirement

Field Name	Type	P O S T	Description
architecture	String	Yes	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Yes	Required node attributes with version number support.
features	Set<String>	No	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Yes	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Yes	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Yes	Requested node features. (See also: featuresRequestedMode .)
featuresRequestedMode	JobRequirementFeaturesMode	Yes	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	The image required by the job.
index	Integer	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.

Field Name	Type	POST	Description
nodeAllocationPolicy	NodeAllocationPolicy	Yes	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	The number of nodes required by the job.
nodeSet	String	Yes	<p>The requested node set of the job. This must follow the format <code>SETSELECTION:SETTYPE[:SETLIST]</code></p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigmem • FIRSTOF:VARATTR:datacenter=Provo:atacenter=SaltLake
nodes	Set<AllocatedNode>	No	Nodes that have been allocated to meet this requirement.
reservation	DomainProxy	No	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	Map<String, JobResource>	Yes	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Yes	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Yes	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	Description
comparator	String	Yes	The comparison operator. Valid values: <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	The display value for the required attribute.
restriction	<u>JobRequirementAttributeRestriction</u>	Yes	The restriction of this attribute. May be null, but defaults to <u>JobRequirementAttributeRestriction.must</u> .
value	String	Yes	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	

Value	Description
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	Description
name	String	No	
taskCount	Integer	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	Description
dedicated	Integer	No	The amount of this resource that has been allocated for running workload.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

API version 3

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	No	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	No	Reasons the job is blocked from running.

Field Name	Type	POST	PUT	Description
bypassCount	Integer	No	No	The number of times the job has been backfilled.
cancelCount	Integer	No	No	The number of times a job has received a cancel request.
commandFile	String	Yes	No	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	No	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	No	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	No	The exit code from this job.
cpuTime	Long	No	No	CPU usage time in seconds as reported by the resource manager.
credentials	<u>JobCredentials</u>	Yes	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	Yes	The user-specified name of this job.

Field Name	Type	POST	PUT	Description
dates	JobDates	Yes	Yes	Various dates associated with this job.
deferCount	Integer	No	No	The number of times a job has been deferred.
dependencies	Set<JobDependency>	Yes	No	Dependencies that must be fulfilled before the job can start.
description	String	No	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	No	The list of addresses to whom email is sent by the execution server.

Field Name	Type	POST	PUT	Description
emailNotifyTypes	<u>Set<JobEmailNotifyType></u>	Yes	No	The list of email notify types attached to the job.
environmentRequested	Boolean	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
environmentVariables	Map<String, Map>	Yes	No	The list of environment variables for this job.
epilogScript	String	Yes	No	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	Yes	The flags that are set on this job.
holdDate	Date	No	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	No	The path to the directory in which the job will be started.
isActive	Boolean	No	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	No	The job group to which this job belongs (different from credentials.group).

Field Name	Type	POST	PUT	Description
masterNode	DomainProxy	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
memorySecondsDedicated	Double	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
memorySecondsUtilized	Double	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	Set<Message>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).

Field Name	Type	POST	PUT	Description
nodesExcluded	<u>Set<DomainProxy></u>	Yes	No	The list of nodes that should not be considered for this job.
nodesRequested	<u>Set<DomainProxy></u>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: <u>nodesRequestedPolicy</u> .)
nodesRequestedPolicy	<u>JobHostListMode</u>	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <u>nodesRequested</u> .)
partitionAccessList	Set<String>	No	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	No	The number of times the job has been preempted.
priorities	<u>JobPriority</u>	Yes	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	No	The limit for processorSecondsUtilized.

Field Name	Type	POST	PUT	Description
processorSecondsUtilized	Double	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
prologScript	String	Yes	No	The path to the TORQUE prolog script.
queueStatus	<u>JobQueueStatus</u>	No	No	The status of the job in its queue.
rejectPolicies	<u>Set<JobRejectPolicy></u>	No	No	The list of policies enabled when a job is rejected.
requirements	<u>Set<JobRequirement></u>	Yes	Yes	The list of items required for this job to run. Only <u>JobRequirement.features</u> is valid during PUT.
reservationRequested	<u>DomainProxy</u>	Yes	Yes	The reservation that the job requested.
resourceFailPolicy	<u>JobResourceFailPolicyType</u>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.

Field Name	Type	POST	PUT	Description
resourceManagers	<u>Set<ResourceManager></u>	No	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	No	The path to the remote file containing the standard error of the job.
rmStandardOutputFilePath	String	No	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	No	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	No	The path to the file containing the standard output of the job.
startCount	Integer	No	No	The number of times the job has been started.
states	<u>JobStateInformation</u>	No	No	Information about the state of the job.
submitHost	String	Yes	No	The host from which the job was submitted.
systemJobAction	String	No	No	The action the system job will take.
systemJobType	<u>JobSystemJobType</u>	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	<u>JobActionType</u>	No	No	The action that this job is performing on another job.

Field Name	Type	POST	PUT	Description
targetedJobName	String	No	No	The name of the job on which this job is performing the targetedJobAction.
templates	<u>Set<DomainProxy></u>	Yes	No	The list of all job templates to be set on this job.
triggers	Set<String>	No	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	<u>Set<DomainProxy></u>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	<u>Set<DomainProxy></u>	No	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	<u>VMUsagePolicy</u>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
account	String	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
group	String	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.

Field Name	Type	POST	PUT	Description
qos	String	No	No	<p>The quality of service assigned to this job.</p> <p>The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.</p>
qosRequested	String	Yes	Yes	The quality of service requested for this job.
user	String	Yes	No	<p>The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.</p>

JobDates

Field Name	Type	POST	PUT	Description
completedDate	Date	No	No	
createdDate	Date	No	No	
deadlineDate	Date	Yes	No	The deadline for completion of the job.
dispatchedDate	Date	No	No	
earliestRequestedStartDate	Date	Yes	Yes	The job will start no sooner than this date.

Field Name	Type	POST	PUT	Description
earliestStartDate	Date	No	No	
eligibleDate	Date	No	No	
lastCanceledDate	Date	No	No	
lastChargedDate	Date	No	No	
lastPreemptedDate	Date	No	No	
lastUpdatedDate	Date	No	No	
startDate	Date	No	No	
submitDate	Date	No	No	
terminationDate	Date	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	No	The type of job dependency. Only set is valid for POST.
value	String	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.

Value	Description
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.

Value	Description
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.

Value	Description
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object.

Message

Field Name	Type	POST	PUT	Description
count	Integer	No	No	The number of times this message has occurred.
createdDate	Date	No	No	The date this message was created.
expireDate	Date	No	No	The date this message expires.
message	String	No	Yes	The message itself.

JobHostListMode

Value	Description
superset	
subset	
exactset	

JobPriority

Field Name	Type	POST	PUT	Description
run	Long	No	No	
start	Long	No	No	
system	Long	No	No	
user	Long	Yes	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobRequirement

Field Name	Type	P O S T	P U T	Description
architecture	String	Yes	No	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Yes	No	Required node attributes with version number support.
features	Set<String>	No	Yes	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Yes	No	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Yes	No	Requested node features. (See also: featuresRequestedMode .)

Field Name	Type	P O S T	P U T	Description
featuresRequestedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	No	The image required by the job.
index	Integer	No	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
nodeAllocationPolicy	NodeAllocationPolicy	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	No	The number of nodes required by the job.

Field Name	Type	P O S T	P U T	Description
nodeSet	String	Ye s	N o	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigm em • FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake
nodes	<u>Set<AllocatedNode></u>	No	N o	Nodes that have been allocated to meet this requirement.
reservation	<u>DomainProxy</u>	No	N o	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	<u>Map<String, JobResource></u>	Ye s	N o	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Ye s	N o	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Ye s	N o	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	PUT	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	<u>JobRequirementAttributeRestriction</u>	Yes	No	The restriction of this attribute. May be null, but defaults to <u>JobRequirementAttributeRestriction.must</u> .
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.

Value	Description
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

API version 2

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	No	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	No	Reasons the job is blocked from running.

Field Name	Type	POST	PUT	Description
bypassCount	Integer	No	No	The number of times the job has been backfilled.
cancelCount	Integer	No	No	The number of times a job has received a cancel request.
commandFile	String	Yes	No	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	No	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	No	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	No	The exit code from this job.
cpuTime	Long	No	No	CPU usage time in seconds as reported by the resource manager.
credentials	<u>JobCredentials</u>	Yes	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	Yes	The user-specified name of this job.

Field Name	Type	POST	PUT	Description
dates	JobDates	Yes	Yes	Various dates associated with this job.
deferCount	Integer	No	No	The number of times a job has been deferred.
dependencies	Set<JobDependency>	Yes	No	Dependencies that must be fulfilled before the job can start.
description	String	No	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	No	The list of addresses to whom email is sent by the execution server.

Field Name	Type	POST	PUT	Description
emailNotifyTypes	<u>Set<JobEmailNotifyType></u>	Yes	No	The list of email notify types attached to the job.
environmentRequested	Boolean	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
environmentVariables	Map<String, Map>	Yes	No	The list of environment variables for this job.
epilogScript	String	Yes	No	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	Yes	The flags that are set on this job.
holdDate	Date	No	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	No	The path to the directory in which the job will be started.
isActive	Boolean	No	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	No	The job group to which this job belongs (different from credentials.group).

Field Name	Type	POST	PUT	Description
masterNode	DomainProxy	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
memorySecondsDedicated	Double	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
memorySecondsUtilized	Double	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	Set<Message>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).

Field Name	Type	POST	PUT	Description
nodesExcluded	<u>Set<DomainProxy></u>	Yes	No	The list of nodes that should not be considered for this job.
nodesRequested	<u>Set<DomainProxy></u>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: <u>nodesRequestedPolicy</u> .)
nodesRequestedPolicy	<u>JobHostListMode</u>	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <u>nodesRequested</u> .)
partitionAccessList	Set<String>	No	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	No	The number of times the job has been preempted.
priorities	<u>JobPriority</u>	Yes	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	No	The limit for processorSecondsUtilized.

Field Name	Type	POST	PUT	Description
processorSecondsUtilized	Double	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
prologScript	String	Yes	No	The path to the TORQUE prolog script.
queueStatus	<u>JobQueueStatus</u>	No	No	The status of the job in its queue.
rejectPolicies	<u>Set<JobRejectPolicy></u>	No	No	The list of policies enabled when a job is rejected.
requirements	<u>Set<JobRequirement></u>	Yes	Yes	The list of items required for this job to run. Only <u>JobRequirement.features</u> is valid during PUT.
reservationRequested	<u>DomainProxy</u>	Yes	Yes	The reservation that the job requested.
resourceFailPolicy	<u>JobResourceFailPolicyType</u>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.

Field Name	Type	POST	PUT	Description
resourceManagers	<u>Set<ResourceManager></u>	No	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	No	The path to the remote file containing the standard error of the job.
rmStandardOutputFilePath	String	No	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	No	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	No	The path to the file containing the standard output of the job.
startCount	Integer	No	No	The number of times the job has been started.
states	<u>JobStateInformation</u>	No	No	Information about the state of the job.
submitHost	String	Yes	No	The host from which the job was submitted.
systemJobAction	String	No	No	The action the system job will take.
systemJobType	<u>JobSystemJobType</u>	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	<u>JobActionType</u>	No	No	The action that this job is performing on another job.

Field Name	Type	POST	PUT	Description
targetedJobName	String	No	No	The name of the job on which this job is performing the targetedJobAction.
templates	<u>Set<DomainProxy></u>	Yes	No	The list of all job templates to be set on this job.
triggers	Set<String>	No	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	<u>Set<DomainProxy></u>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	<u>Set<DomainProxy></u>	No	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	<u>VMUsagePolicy</u>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
account	String	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
group	String	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.

Field Name	Type	POST	PUT	Description
qos	String	No	No	<p>The quality of service assigned to this job.</p> <p>The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.</p>
qosRequested	String	Yes	Yes	The quality of service requested for this job.
user	String	Yes	No	<p>The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.</p>

JobDates

Field Name	Type	POST	PUT	Description
completedDate	Date	No	No	
createdDate	Date	No	No	
deadlineDate	Date	Yes	No	The deadline for completion of the job.
dispatchedDate	Date	No	No	
earliestRequestedStartDate	Date	Yes	Yes	The job will start no sooner than this date.

Field Name	Type	POST	PUT	Description
earliestStartDate	Date	No	No	
eligibleDate	Date	No	No	
lastCanceledDate	Date	No	No	
lastChargedDate	Date	No	No	
lastPreemptedDate	Date	No	No	
lastUpdatedDate	Date	No	No	
startDate	Date	No	No	
submitDate	Date	No	No	
terminationDate	Date	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	No	The type of job dependency. Only set is valid for POST.
value	String	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.

Value	Description
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.

Value	Description
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.

Value	Description
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

JobHoldReason

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object.

Message

Field Name	Type	POST	PUT	Description
count	Integer	No	No	The number of times this message has occurred.
createdDate	Date	No	No	The date this message was created.
expireDate	Date	No	No	The date this message expires.
message	String	No	Yes	The message itself.

JobHostListMode

Value	Description
superset	
subset	
exactset	

JobPriority

Field Name	Type	POST	PUT	Description
run	Long	No	No	
start	Long	No	No	
system	Long	No	No	
user	Long	Yes	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

RETRY	

JobRequirement

Field Name	Type	P O S T	P U T	Description
architecture	String	Yes	No	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Yes	No	Required node attributes with version number support.
features	Set<String>	No	Yes	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Yes	No	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Yes	No	Requested node features. (See also: featuresRequestedMode .)

Field Name	Type	P O S T	P U T	Description
featuresRequestedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	No	The image required by the job.
index	Integer	No	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
nodeAllocationPolicy	NodeAllocationPolicy	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	No	The number of nodes required by the job.

Field Name	Type	P O S T	P U T	Description
nodeSet	String	Ye s	N o	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigm em • FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake
nodes	<u>Set<AllocatedNode></u>	No	N o	Nodes that have been allocated to meet this requirement.
reservation	<u>DomainProxy</u>	No	N o	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	<u>Map<String, JobResource></u>	Ye s	N o	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Ye s	N o	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Ye s	N o	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	PUT	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	<u>JobRequirementAttributeRestriction</u>	Yes	No	The restriction of this attribute. May be null, but defaults to <u>JobRequirementAttributeRestriction.must</u> .
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.

Value	Description
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	PUT	Description
name	String	No	No	
taskCount	Integer	No	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	PUT	Description
dedicated	Integer	No	No	The amount of this resource that has been allocated for running workload.
utilized	Integer	No	No	The amount of this resource that is currently reported as utilized by resource managers.

API version 3

JobTemplate

This class represents a job template in the Moab Workload Manager. Job templates are used for two primary purposes: (1) to provide a means of generically matching and categorizing jobs, and (2) to provide a means of setting arbitrary default or forced attributes for certain jobs.

Field Name	Type	Description
id	String	The unique identifier for this job template.
account	String	The account under which this job will run for billing purposes.
args	String	Command-line arguments that get passed to commandFile.
commandFile	String	The path to the file that is executed when the job runs. This is the script that will actually call all the work of the job. Can be null.
description	String	The description of the job.
durationRequested	Long	The amount of time (in seconds) requested for the job.
genericSystemJob	Boolean	True if this template will instantiate a generic system job.
inheritResources	Boolean	True if jobs instantiated from this template inherit resources.
jobDependencies	<u>Set<JobTemplateDependency></u>	The list of dependencies for this job template.
jobFlags	<u>Set<JobFlag></u>	Job flags for this template.
jobTemplateFlags	<u>Set<JobTemplateFlag></u>	Job template flags for this template.
jobTemplateRequirements	<u>Set<JobTemplateRequirement></u>	The requirements for this job template.

Field Name	Type	Description
priority	Long	Relative job priority.
qos	String	The Quality of Service for the job.
queue	String	The class or queue in which the job will run.
select	Boolean	True if job template can be directly requested by job at submission.
trigger	<u>Trigger</u>	The trigger that is typically assigned to generic system jobs.
vmUsagePolicy	<u>VMUsagePolicy</u>	The virtual machine usage policy.

[JobTemplateDependency](#)

Field Name	Type	Description
name	String	The name of the template on which this template depends.
type	<u>JobDependencyTypeVersion1</u>	The type of the dependency.

[JobDependencyTypeVersion1](#)

Value	Description
JOBSTART	Job may start at any time after specified jobs have started execution.
JOBSUCCESSFULCOMPLETE	Job may be start at any time after all specified jobs have successfully completed.
JOBFAILEDCOMPLETE	Job may start at any time after any specified jobs have completed unsuccessfully.

Value	Description
JOBCOMPLETE	Job may start at any time after all specified jobs have completed regardless of completion status.
BEFORE	Job may start at any time before specified jobs have started execution. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
BEFOREANY	Job may start at any time before all specified jobs have completed regardless of completion status. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
BEFOREOK	Job may start at any time before all specified jobs have successfully completed. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
BEFORENOTOK	Job may start at any time before any specified jobs have completed unsuccessfully. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
HIBERNATE	Job was set to Hibernate mode.
SYNCWITH	Job will wait until it can start simultaneously with a master job
SYNCCOUNT	This job will wait until it can start simultaneously with synccount jobs of type syncwith that have all specified this synccount job is their master job.
SET	Job will wait until a variable on a Moab object is set before starting.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.

Value	Description
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.

Value	Description
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).

Value	Description
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

JobTemplateFlag

This enumeration specifies the flag types of a job template.

Value	Description
GLOBALRSVACCESS	
HIDDEN	
HWJOB	
PRIVATE	
SYNCJOBID	
TEMPLATEISDYNAMIC	True if the template is dynamic (not specified via moab.cfg).
SELECT	True if a job can select this template.

JobTemplateRequirement

Field Name	Type	Description
architecture	String	The architecture requirement.
diskRequirement	Integer	The amount of disk space required (in MB).
genericResources	Map<String, Integer>	Consumable generic attributes associated with individual nodes or the special pseudo-node global, which provides shared cluster (floating) consumable resources.
nodeAccessPolicy	<u>NodeAccessPolicy</u>	The node access policy. Specifies how node resources will be shared by a job.
operatingSystem	String	The operating system requirement.
requiredDiskPerTask	Integer	Disk space (in MB).
requiredFeatures	Set<String>	The features required by this template.
requiredMemoryPerTask	Integer	Memory (in MB).
requiredProcessorsPerTask	Integer	Number of processors.
requiredSwapPerTask	Integer	Swap space (in MB).
taskCount	Integer	The number of tasks required.

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.

Value	Description
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

Trigger

Field Name	Type	Description
id	String	Trigger id - internal ID used by moab to track triggers
action	String	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	
blockTime	Date	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	
eventType	TriggerEventType	

Field Name	Type	Description
expireTime	Date	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	<u>Set<TriggerFlag></u>	
interval	Boolean	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <u>TriggerEventType.EPOCH</u> to create a Standing Trigger. Defaults to false
maxRetry	Integer	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	The ID of the object which this is attached to.
objectType	String	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	Relative time offset from event when trigger can fire.
period	<u>TriggerPeriod</u>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.

Field Name	Type	Description
requires	String	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
sets	String	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	The type of the trigger.
unsets	String	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.

Value	Description
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	
MODIFY	

Value	Description
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

[TriggerFlag](#)

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.

Value	Description
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	

Value	Description
HOURL	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic	
elastic	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

API version 2

JobTemplate

This class represents a job template in the Moab Workload Manager. Job templates are used for two primary purposes: (1) to provide a means of generically matching and categorizing jobs, and (2) to provide a means of setting arbitrary default or forced attributes for certain jobs.

Field Name	Type	Description
id	String	The unique identifier for this job template.
account	String	The account under which this job will run for billing purposes.
args	String	Command-line arguments that get passed to commandFile.
commandFile	String	The path to the file that is executed when the job runs. This is the script that will actually call all the work of the job. Can be null.
description	String	The description of the job.
durationRequested	Long	The amount of time (in seconds) requested for the job.
genericSystemJob	Boolean	True if this template will instantiate a generic system job.
inheritResources	Boolean	True if jobs instantiated from this template inherit resources.
jobDependencies	<u>Set<JobTemplateDependency></u>	The list of dependencies for this job template.
jobFlags	<u>Set<JobFlag></u>	Job flags for this template.
jobTemplateFlags	<u>Set<JobTemplateFlag></u>	Job template flags for this template.
jobTemplateRequirements	<u>Set<JobTemplateRequirement></u>	The requirements for this job template.

Field Name	Type	Description
priority	Long	Relative job priority.
qos	String	The Quality of Service for the job.
queue	String	The class or queue in which the job will run.
select	Boolean	True if job template can be directly requested by job at submission.
trigger	<u>Trigger</u>	The trigger that is typically assigned to generic system jobs.
vmUsagePolicy	<u>VMUsagePolicy</u>	The virtual machine usage policy.

[JobTemplateDependency](#)

Field Name	Type	Description
name	String	The name of the template on which this template depends.
type	<u>JobDependencyTypeVersion1</u>	The type of the dependency.

[JobDependencyTypeVersion1](#)

Value	Description
JOBSTART	Job may start at any time after specified jobs have started execution.

Node

This class represents a node in the Moab Workload Manager. Moab recognizes a node as a collection of resources with a particular set of associated attributes. This definition is similar to the traditional notion of a node found in a Linux cluster or supercomputer wherein a node is defined as one or more CPUs, associated memory, and possibly other compute resources such as local disk, swap, network adapters, and software licenses. Additionally, this node is described by various attributes such as an architecture type or operating system. Nodes range in size from small uniprocessor PCs to large symmetric multiprocessing (SMP) systems where a single node may consist of hundreds of CPUs and massive amounts of memory.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of this node. Note: this field is not user-assigned and is generated by the database.
aclRules	Set<NodeAclRule>	No	The set of access control rules associated with this node.
architecture	String	No	This node's processor architecture.
attributes	Map<String, Map>	No	Attributes is a map of attribute names to tuples (maps) that describe the scheduling attributes of a node. Each tuple should contain the following entries: <ul style="list-style-type: none"> • value - the attribute value • displayValue - the attribute display value
classes	Set<String>	No	The classes that this node can be scheduled for.

Field Name	Type	P UT	Description
featuresCustom	Set<String>	Yes	The features this node advertises which are customizable at run-time. This can be used to define node sets. (See also: featuresReported .)
featuresReported	Set<String>	No	The features this node advertises which are reported by resource managers or are present in the Moab Workload Manager configuration. This can be used to define node sets. (See also: featuresCustom .)
index	Integer	No	The index for this node as reported by the resource manager.
ipAddress	String	No	This node's IPv4 address.
isHypervisor	Boolean	No	True if the node is a hypervisor, false otherwise. This is based on the NodeOperatingSystemInformation.hypervisorType field. If hypervisorType is present, the node is a hypervisor. If it is null, then it is not a hypervisor.
jobs	Set<DomainProxy>	No	Jobs associated with this node.
lastUpdatedDate	Date	No	The timestamp of the last moment when this node was updated. There is no guarantee that all user modifications to a node would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this node.
messages	Set<Message>	Yes	The list of messages attached to this node. They can be attached by admins, the resource manager layer, or triggers.

Field Name	Type	PUT	Description
metrics	Map<String, Double>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this node. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this node. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. For example, Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationDisabled	Boolean	No	True if VM migration is disabled on this node.
name	String	No	The name of this node. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	<u>NodeOperatingSystemInformation</u>	Yes	Describes the current or expected operating system image information for this node. The operatingSystem.image field can be changed using PUT.
partition	String	Yes	The partition this node belongs to.
processorSpeed	Integer	No	The speed, in MHz, or the processors on this node.

Field Name	Type	P U T	Description
profilingEnabled	Boolean	No	Indicates whether historical data gathering and reporting is enabled for this node. This is also controlled by the same setting on the default node (i.e. all nodes). If set to false (default), node statistics are not gathered.
rack	Integer	No	The rack where this node is located in the datacenter/cluster.
requestId	String	No	An ID that can be used to track the request that created the node.
reservations	<u>Set<DomainProxy></u>	No	Reservations associated with this node.
resourceManagerMessages	Map<String, Map>	No	The resource manager messages for this node. Each key is the name of a resource manager, and the value is the message that the resource manager has posted onto the node.
resourceManagers	<u>Set<NodeResourceManager></u>	No	The resource managers that are reporting or have previously reported this node. Each object also contains information on the resource manager reports.
resources	<u>Map<String, Resource></u>	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.
slot	Integer	No	The slot in the rack where this node is located.

Field Name	Type	PUT	Description
states	NodeStateInformation	Yes	This node's state. The states.powerState and states.state fields can be changed using PUT.
timeToLive	Date	No	Specifies the time that the node is supposed to be retired by Moab. Moab will not schedule any jobs on a node after its time to live has passed.
triggers	Set<DomainProxy>	No	Triggers associated with this node.
type	NodeType	No	The type of this node is governed by the types of resources it offers.
variables	Map<String, Map>	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this node.
virtualContainers	Set<DomainProxy>	No	The set of virtual containers that directly (not recursively) contain this node.
virtualMachines	Set<DomainProxy>	No	Virtual machines associated with this node.

[NodeAclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) for a node.

The basic NodeAclRule information is the object's name and type. The type directly maps to an [NodeAclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	PUT	Description
affinity	AclAffinity	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>
comparator	ComparisonOperator	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to ComparisonOperator.EQUAL.</p>
credentialLock	Boolean	No	Matching jobs will be required to run on the resources reserved by this reservation. You can use this modifier on accounts, classes, groups, qualities of service, and users.
excludeFromAcl	Boolean	No	If attribute is met, the requestor is denied access regardless of any other satisfied ACLs.
hardPolicyOnly	Boolean	No	ACLs marked with this modifier are ignored during soft policy scheduling and are only considered for hard policy scheduling once all eligible soft policy jobs start.
requireAll	Boolean	No	All required ACLs must be satisfied for requestor access to be granted.
type	NodeAclType	Yes	The type of the object that is being granted (or denied) access.

Field Name	Type	PUT	Description
value	String	Yes	The name of the object that is being granted (or denied) access.
xorWithAcl	Boolean	No	All attributes of the type specified other than the ones listed in the ACL satisfy the ACL.

AclAffinity

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"

Value	Description
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

[NodeAcIType](#)

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template

Value	Description
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
TASKSPERNODE	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
name	String	No	The name of the object.

Message

Field Name	Type	PUT	Description
count	Integer	No	The number of times this message has occurred.
createdDate	Date	No	The date this message was created.
expireDate	Date	No	The date this message expires.
message	String	Yes	The message itself.

NodeOperatingSystemInformation

Describes the current or expected operating system image information for a node.

Field Name	Type	PUT	Description
hypervisorType	String	No	The hypervisor technology that this node uses. May be null if the node is not a hypervisor.
image	String	Yes	The name of the operating system currently running on this node. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageExpected	String	No	The name of the image that was requested to run on this node (i.e. with <code>mnodectl -m os=myOs</code>). In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	The last time the image of this node was modified.

Field Name	Type	PUT	Description
imagesAvailable	Set<String>	No	The list of image names that can be applied to this node. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)
virtualMachineImages	Set<String>	No	The list of virtual machine image names the node is capable of supporting. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	PUT	Description
isMaster	Boolean	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
name	String	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	The state reported by this resource manager. See the State section for more details.

NodeState

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.

Value	Description
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
available	Integer	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, $\text{configured} = \text{overcommitFactor} * \text{real}$.
dedicated	Integer	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
real	Integer	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
powerState	NodePower	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	Yes	The scheduling state of the Node, as reported by the resource management layer.
stateExpected	NodeState	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	A timestamp recording when the sub-state was last modified.

NodePower

Represents the various options for a Node's power state.

Value	Description
NONE	
ON	
OFF	

NodeType

Represents the type of node as reported by a resource manager.

Value	Description
Compute	
License	
Network	
Storage	

API version 2

Node

This class represents a node in the Moab Workload Manager. Moab recognizes a node as a collection of resources with a particular set of associated attributes. This definition is similar to the traditional notion of a node found in a Linux cluster or supercomputer wherein a node is defined as one or more CPUs, associated memory, and possibly other compute resources such as local disk, swap, network adapters, and software licenses. Additionally, this node is described by various attributes such as an architecture type or operating system. Nodes range in size from small uniprocessor PCs to large symmetric multiprocessing (SMP) systems where a single node may consist of hundreds of CPUs and massive amounts of memory.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of this node. Note: this field is not user-assigned and is generated by the database.
aclRules	<u>Set<NodeAclRule></u>	No	The set of access control rules associated with this node.
architecture	String	No	This node's processor architecture.
attributes	Map<String, Map>	No	<p>Attributes is a map of attribute names to tuples (maps) that describe the scheduling attributes of a node. Each tuple should contain the following entries:</p> <ul style="list-style-type: none"> • value - the attribute value • displayValue - the attribute display value
classes	Set<String>	No	The classes that this node can be scheduled for.

Field Name	Type	P UT	Description
featuresCustom	Set<String>	Yes	The features this node advertises which are customizable at run-time. This can be used to define node sets. (See also: featuresReported .)
featuresReported	Set<String>	No	The features this node advertises which are reported by resource managers or are present in the Moab Workload Manager configuration. This can be used to define node sets. (See also: featuresCustom .)
index	Integer	No	The index for this node as reported by the resource manager.
ipAddress	String	No	This node's IPv4 address.
isHypervisor	Boolean	No	True if the node is a hypervisor, false otherwise. This is based on the NodeOperatingSystemInformation.hypervisorType field. If hypervisorType is present, the node is a hypervisor. If it is null, then it is not a hypervisor.
jobs	Set<DomainProxy>	No	Jobs associated with this node.
lastUpdatedDate	Date	No	The timestamp of the last moment when this node was updated. There is no guarantee that all user modifications to a node would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this node.
messages	Set<Message>	Yes	The list of messages attached to this node. They can be attached by admins, the resource manager layer, or triggers.

Field Name	Type	PUT	Description
metrics	Map<String, Double>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this node. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this node. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. For example, Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationDisabled	Boolean	No	True if VM migration is disabled on this node.
name	String	No	The name of this node. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	<u>NodeOperatingSystemInformation</u>	Yes	Describes the current or expected operating system image information for this node. The operatingSystem.image field can be changed using PUT.

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
name	String	No	The name of the object.

Message

Field Name	Type	PUT	Description
count	Integer	No	The number of times this message has occurred.
createdDate	Date	No	The date this message was created.
expireDate	Date	No	The date this message expires.
message	String	Yes	The message itself.

NodeOperatingSystemInformation

Describes the current or expected operating system image information for a node.

Field Name	Type	PUT	Description
hypervisorType	String	No	The hypervisor technology that this node uses. May be null if the node is not a hypervisor.
image	String	Yes	The name of the operating system currently running on this node. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageExpected	String	No	The name of the image that was requested to run on this node (i.e. with <code>mnodectl -m os=myOs</code>). In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	The last time the image of this node was modified.

Field Name	Type	PUT	Description
imagesAvailable	Set<String>	No	The list of image names that can be applied to this node. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)
virtualMachineImages	Set<String>	No	The list of virtual machine image names the node is capable of supporting. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	PUT	Description
isMaster	Boolean	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
name	String	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	The state reported by this resource manager. See the State section for more details.

NodeState

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.

Value	Description
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
available	Integer	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, $\text{configured} = \text{overcommitFactor} * \text{real}$.
dedicated	Integer	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
real	Integer	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
powerState	NodePower	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	Yes	The scheduling state of the Node, as reported by the resource management layer.
stateExpected	NodeState	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	A timestamp recording when the sub-state was last modified.

NodePower

Represents the various options for a Node's power state.

Value	Description
NONE	
ON	
OFF	

NodeType

Represents the type of node as reported by a resource manager.

Value	Description
Compute	
License	
Network	
Storage

API version 3

NotificationCondition

A notification condition is related to an [Event](#), but differs in three distinct areas:

- Notification conditions are a persistent condition of the system or a component rather than a single occurrence.
 - They are ongoing rather than reoccurring, which is why they are generated from [NotificationConditions](#).
 - They may be observed many times, but the condition is always the same.
 - A good test for this is if something "is" wrong rather than something "went" wrong.
- Notification conditions can be acted on to result in a resolved state, mean the administrator or user can and must take actions to "fix" the condition or problem.
- Notification conditions contain state information based on administrator or user input, meaning that they contain information about the condition (similar to events), but also contain the "status" of the administrator's view of the notification, whether it is currently open, dismissed, or ignored.

In general, questions may be asked to ascertain whether an Event or a Notification Condition is the right fit for an occurrence. These questions, along with some sample situations, are provided below.

- Is the occurrence the root cause of a potentially ongoing condition?
 - A VM migration failed because the VM's state was unknown. The root cause was that the state was unknown, not that the VM migration failed. Therefore, VM migration failed would be an event, while the unknown state would be a notification condition.

- A VM service provision fails because there are no hypervisors that satisfy the requirements. This would be an event. Note that there may be a notification related to this failure, such as a service template requires a feature that does not exist on *any* hypervisors in the system, but this would be distinctly detected and managed from the provision failure event.
 - A request to MWS failed because the connection between MWM and MongoDB was misconfigured. The failed request may be represented as an event, but a notification condition should exist that the connection between MWM and MongoDB was down.
- Can an administrator or user affect the outcome of the occurrence?
 - The outcome of a VM migration failing is in the past and cannot be changed by the administrator. However, the outcome of a *future* VM migration may be changed when the administrator resolves the root problem (i.e. VM state is unknown).

A notification condition is an observed condition for which [Notifications](#) are created. These conditions are created or updated on every PUT request based on the [NotificationCondition.escalationLevel](#), [NotificationCondition.origin](#), [NotificationCondition.message](#), [NotificationCondition.objectType](#), and [NotificationCondition.objectId](#) fields. When notifications are requested, these observed conditions are used to create the notifications for the requesting user.

While notification conditions may not be deleted, they "expire" after a specified amount of time and are no longer considered as active conditions for which notifications are created.

Field Name	Type	PUT	Description
id	String	No	The identifier of the condition.
createdDate	Date	No	The date that the condition first started appearing.
details	Map<String, Map>	No	Arbitrary storage of details for this notification. This could include "pluginType", "pluginId", etc.

Field Name	Type	PUT	Description
escalationLevel	EscalationLevel	No	The escalation level of the condition. This indicates who should care about the condition or who can respond to it. This may NOT be EscalationLevel.INTERNAL .
expirationDate	Date	No	The date at which the condition is considered "expired" and notifications are no longer created for it. This is typically set using the expirationDuration field.
expirationDuration	Long	No	The duration in seconds that may pass before a notification will not be created for a user. Effectively this can disable notifications from being created if they are too old. When this field is set, it will set the expirationDate field automatically each time the condition is updated or on creation. This field must be set to 1 or greater or else set to null.
message	String	No	A message detailing the notification and why it exists, with possible action items.
objectId	String	No	The identifier of the object which this notification affects, such as "node1" or "vm1".
objectType	String	No	The object type that this notification affects, such as "Node", "VM", "System", etc.
observedDate	Date	No	The latest date that the condition was observed. If this field is not set in an update request, it will automatically be set to the current date.
origin	String	No	The origin of the notification.
tenant	Map<String, Map>	No	The tenant that this notification came from. (contains tenant id and name)

EscalationLevel

Value	Description
USER	

Value	Description
POWER_USER	
ADMIN	
INTERNAL

API version 3

Notification

Notifications, while related to [Events](#), are used for different purposes. See [NotificationCondition](#) for more information on when notifications should be used as opposed to events.

Notifications are a per-user representation of all notification conditions present in the system at any one time. When an administrator or user requests this resource, notifications are automatically created from the notification conditions that they have access to (determined by the [Notification.tenant](#) or the [NotificationCondition.escalationLevel](#) fields).

Notifications are expected to contain messages and details that may be understood by a user or admin depending on the escalation level, and contain fields that control whether the user or admin will be notified of future updates to their corresponding condition.

Notifications cannot be deleted, but they can be marked as ignored (see [Notification.ignoredDate](#) or dismissed (see [Notification.dismissedDate](#)).

Field Name	Type	PUT	Description
id	String	No	The identifier of the notification.
conditionId	String	No	The identifier of the NotificationCondition from which this notification was created.
createdDate	Date	No	The date that the notification condition first appeared.
details	Map<String, Map>	No	Arbitrary storage of details for this notification. This could include "pluginType", "pluginId", etc.
dismissedDate	Date	No	The date that the notification was dismissed by a user or admin, meaning that they acknowledged the notification and wanted to know of future updates to this notification. This field is cleared every time the attached notification condition is updated/observed again. (See also: conditionId .)
ignoredDate	Date	No	The date that the notification was ignored by a user or admin, meaning that they acknowledged the notification now and in the future and did not wish to know of any updates. This field is never cleared, even if the attached notification condition is updated/observed again.

Field Name	Type	PUT	Description
message	String	No	A message detailing the notification and why it exists, with possible action items.
objectId	String	No	The identifier of the object which this notification affects, such as "node1" or "vm1".
objectType	String	No	The object type that this notification affects, such as "Node", "VM", "System", etc.
observedDate	Date	No	The latest date that the notification condition was observed. If this field, ignoredDate , and dismissedDate are not set during an update (i.e. a user/admin is not ignoring or dismissing the notification), this field will automatically be set to the current date.
origin	String	No	The origin of the notification.
user	String	No	The user that this notification was created for.

API version 3

PluginInstance

This class represents a configured plugin created from a plugin type.

Field Name	Type	POST	PUT	Description
id	String	Yes	No	Unique identifier for the plugin. Must contain at least one letter and must also start with a letter. Reserved IDs are "all" and "moab". If these are used an error will be returned.
autoStart	Boolean	Yes	Yes	Whether the plugin should start automatically when created.
config	Map<String, Map>	Yes	Yes	The configuration of the plugin. Plugin types may define constraints on the configuration, therefore it is recommended to view the plugin type's documentation for more information on required and optional fields. Regardless, the plugin configuration supports arbitrary keys and values.
dateCreated	Date	No	No	The date that this plugin was created.
lastPollDate	Date	No	No	The date of the last polling event that occurred. This may be null if the plugin is in the STOPPED state or has not yet been polled.
lastUpdated	Date	No	No	The date that this plugin was last updated.
nextPollDate	Date	No	No	The date of the next polling event that is scheduled to occur. This may be null if the plugin is in the STOPPED state.
pluginType	String	Yes	No	The plugin name as in Native or Example for the plugin called ExamplePlugin.
pollInterval	Integer	Yes	Yes	The polling interval to use for the plugin in seconds. This is ignored if the plugin type does not support polling.

Field Name	Type	POST	PUT	Description
precedence	Long	Yes	Yes	<p>The precedence of this plugin, with the lowest value being the highest precedence. Minimum of 1. This is used when doing data consolidation when reporting current state data. Lower numbers results in a higher precedence (i.e. 1 is higher precedence than 10).</p> <p>If not specified during creation, this will be automatically set to 1 for the first plugin created, then 1 greater for each subsequently created plugin (i.e. 1 for plugin1, 2 for plugin2, etc). It is always set to 1 greater than the plugin with the greatest precedence number (i.e. 11 if two plugins exist with precedence 1 and 10).</p>
state	<u>PluginState</u>	No	No	The current state of the plugin. Defaults to <u>PluginState.STOPPED</u> .

[PluginState](#)

Represents the current state of a plugin.

Value	Description
STOPPED	The plugin is created and ready for use, but is not currently receiving any events
STARTED	The plugin is currently receiving events and is working correctly.
PAUSED	<p>The plugin is currently not receiving any events but is also not stopped.</p> <p>This should be used when polling or other events should stop only temporarily without firing the stop events.</p>
ERRORED	<p>MWS has detected an error with the plugin and has automatically stopped it. Errors could be due to the following reasons:</p> <ol style="list-style-type: none"> 1. An invalid configuration was detected when running the <u>AbstractPlugin.configure</u> method. 2. An unexpected exception was thrown during an event, such as during polling.

API version 2

PluginInstance

This class represents a configured plugin created from a plugin type.

Field Name	Type	POST	PUT	Description
id	String	Yes	No	Unique identifier for the plugin. Must contain at least one letter and must also start with a letter. Reserved IDs are "all" and "moab". If these are used an error will be returned.
autoStart	Boolean	Yes	Yes	Whether the plugin should start automatically when created.
config	Map<String, Map>	Yes	Yes	The configuration of the plugin. Plugin types may define constraints on the configuration, therefore it is recommended to view the plugin type's documentation for more information on required and optional fields. Regardless, the plugin configuration supports arbitrary keys and values.
dateCreated	Date	No	No	The date that this plugin was created.
lastPollDate	Date	No	No	The date of the last polling event that occurred. This may be null if the plugin is in the STOPPED state or has not yet been polled.
lastUpdated	Date	No	No	The date that this plugin was last updated.
nextPollDate	Date	No	No	The date of the next polling event that is scheduled to occur. This may be null if the plugin is in the STOPPED state.
pluginType	String	Yes	No	The plugin name as in Native or Example for the plugin called ExamplePlugin.
pollInterval	Integer	Yes	Yes	The polling interval to use for the plugin in seconds. This is ignored if the plugin type does not support polling.

Field Name	Type	POST	PUT	Description
precedence	Long	Yes	Yes	<p>The precedence of this plugin, with the lowest value being the highest precedence. Minimum of 1. This is used when doing data consolidation when reporting current state data. Lower numbers results in a higher precedence (i.e. 1 is higher precedence than 10).</p> <p>If not specified during creation, this will be automatically set to 1 for the first plugin created, then 1 greater for each subsequently created plugin (i.e. 1 for plugin1, 2 for plugin2, etc). It is always set to 1 greater than the plugin with the greatest precedence number (i.e. 11 if two plugins exist with precedence 1 and 10).</p>
state	<u>PluginState</u>	No	No	The current state of the plugin. Defaults to <u>PluginState.STOPPED</u> .

[PluginState](#)

Represents the current state of a plugin.

Value	Description
STOPPED	The plugin is created and ready for use, but is not currently receiving any events
STARTED	The plugin is currently receiving events and is working correctly.
PAUSED	<p>The plugin is currently not receiving any events but is also not stopped.</p> <p>This should be used when polling or other events should stop only temporarily without firing the stop events.</p>
ERRORED	<p>MWS has detected an error with the plugin and has automatically stopped it. Errors could be due to the following reasons:</p> <ol style="list-style-type: none"> 1. An invalid configuration was detected when running the <u>AbstractPlugin.configure</u> method. 2. An unexpected exception was thrown during an event, such as during polling.

API version 3

PluginType

Represents a MWS plugin type. All fields in this class are generated from plugin project and type metadata and cannot be modified directly. Consequentially, all fields are only valid for list/show/GET operations.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of the plugin type. This is based on the class name of the plugin. Ex: Plugin Class Name -> ID NativePlugin -> Native MSMPlugin -> MSM MyExamplePlugin -> MyExample
author	String	No	The main author (company or person) of the plugin type.
commonsVersion	String	No	A string representing the restriction on which version of the plugin framework (plugins-commons dependency) is required for the plugin type. In the format 'COMMONS_VERSION > *', meaning that any version greater or equal to COMMONS_VERSION is valid.
description	String	No	The full description of the plugin type.
documentationLink	String	No	A full URL to the complete documentation for the plugin type.
email	String	No	The email of the author.
eventComponent	Integer	No	The event component ID of the plugin type. This should be unique for each plugin type and should be 1 or greater.
initialPlugins	Map<String, Map>	No	Represents the plugins that are initially configured when the plugin type is loaded. Each key represents the plugin ID.
issueManagementLink	String	No	A full URL to the issue management system or project for the plugin type.

Field Name	Type	PUT	Description
license	String	No	The license of this plugin type, typically APACHE.
mwsVersion	String	No	A string representing the restriction on which version of MWS is required for the plugin type. In the format 'MWS_VERSION > *', meaning that any version greater or equal to MWS_VERSION is valid.
pollMethod	boolean	No	Indicates whether the plugin type has a defined 'poll' method (event handler) or not.
realizedEventComponent	Integer	No	The fully realized event component ID of the plugin type, including the MWS bits. This should take the form of 0x201. If the eventComponent is not set, this will be 0x2FF, meaning the component ID is an unknown plugin type.
scmLink	String	No	A full URL to the Source Control Management (SCM) system or project for the plugin type.
title	String	No	A short name describing the plugin type.
website	String	No	The website of the author.

API version 2

PluginType

Represents a MWS plugin type. All fields in this class are generated from plugin project and type metadata and cannot be modified directly. Consequentially, all fields are only valid for list/show/GET operations.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of the plugin type. This is based on the class name of the plugin. Ex: Plugin Class Name -> ID NativePlugin -> Native MSMPlugin -> MSM MyExamplePlugin -> MyExample
author	String	No	The main author (company or person) of the plugin type.
commonsVersion	String	No	A string representing the restriction on which version of the plugin framework (plugins-commons dependency) is required for the plugin type. In the format 'COMMONS_VERSION > *', meaning that any version greater or equal to COMMONS_VERSION is valid.
description	String	No	The full description of the plugin type.
documentationLink	String	No	A full URL to the complete documentation for the plugin type.
email	String	No	The email of the author.
eventComponent	Integer	No	The event component ID of the plugin type. This should be unique for each plugin type and should be 1 or greater.
initialPlugins	Map<String, Map>	No	Represents the plugins that are initially configured when the plugin type is loaded. Each key represents the plugin ID.
issueManagementLink	String	No	A full URL to the issue management system or project for the plugin type.

Field Name	Type	PUT	Description
license	String	No	The license of this plugin type, typically APACHE.
mwsVersion	String	No	A string representing the restriction on which version of MWS is required for the plugin type. In the format 'MWS_VERSION > *', meaning that any version greater or equal to MWS_VERSION is valid.
pollMethod	boolean	No	Indicates whether the plugin type has a defined 'poll' method (event handler) or not.
realizedEventComponent	Integer	No	The fully realized event component ID of the plugin type, including the MWS bits. This should take the form of 0x201. If the eventComponent is not set, this will be 0x2FF, meaning the component ID is an unknown plugin type.
scmLink	String	No	A full URL to the Source Control Management (SCM) system or project for the plugin type.
title	String	No	A short name describing the plugin type.
website	String	No	The website of the author.

API version 3

Policy

A Moab Workload Manager policy which can affect scheduling decisions such as resource allocation. A policy contains state, identifying information, a priority, and metadata about the policy.

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	<u>PolicyState</u>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <u>PolicyState.DISABLED</u> .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

AutoVMMigrationPolicy

The Moab policy used to enabled and configure policy-based VM migration. Using information about data center applications and server load, Moab can aim to keep VMs in the data center optimally distributed across all hypervisors.

This class inherits fields from [Policy](#).

Field Name	Type	P U T	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
genericMetricThresholds	Map<String, Double>	Yes	A map of generic metric pairings where each value must be greater than or equal to 0 such as: METRIC1 => 5.6 METRIC2 => 0.0 METRIC3 => 102.4
memoryUtilizationThreshold	Double	Yes	Defines the utilization threshold for memory. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.

Field Name	Type	P U T	Description
migrationAlgorithmType	AutoVMMigrationPolicyType	Yes	Configures the VM migration algorithm utilized when the policy is active. Defaults to NONE . When ENABLED , this must not be set to NONE.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
processorUtilizationThreshold	Double	Yes	Defines the load utilization threshold for processors. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[AutoVMMigrationPolicyType](#)

Represents the algorithm used to migrate VMs when the [AutoVMMigrationPolicy](#) is used.

Value	Description
NONE	<p>Used when the Auto VM Migration policy is currently disabled in Moab and before any settings are saved the first time.</p> <p>For example, if the policy is disabled on the first read of Moab policies, the AutoVMMigrationPolicy.migrationAlgorithmType will be set to NONE. If the policy is enabled and the type is set to OVERCOMMIT, followed by a disabling of the policy, it will then be represented as having a state of DISABLED with a migrationAlgorithmType of OVERCOMMIT.</p>
OVERCOMMIT	Use the "overcommit" algorithm for migration. The goal of this algorithm is to equalize loads across hypervisors as migrations are queued due to overcommit conditions. This places VMs to be migrated on the least-loaded hypervisor available.
CONSOLIDATION	Use the "consolidation" algorithm for migration. The goal of this algorithm is to load hypervisors as close to thresholds as possible, without exceeding them. This policy places VMs to be migrated on the most loaded hypervisor possible, within these constraints. A second loop of this policy will select lightly-loaded hypervisors to be evacuated completely.

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

[HVAllocationOvercommitPolicy](#)

The Hypervisor Allocation Overcommit policy controls how many virtual machines can be placed on a hypervisor. By enabling this policy, you are allowing Moab to allocate more resources to a set of virtual machines than a hypervisor may actually have. This is possible due to virtualization. In other words, this policy allows you to set the high-water mark for virtual machine allocation for hypervisors. At least one of these limits must be greater than 1.0, or the policy will not be able to set to a state of [PolicyState.ENABLED](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
memoryAllocationLimit	Double	Yes	Setting this to 1 effectively disables the allocation overcommit based on memory. If this and processorAllocationLimit are both set to 1.0 (the default), the policy state cannot be set to PolicyState.ENABLED .
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
processorAllocationLimit	Double	Yes	<p>The Allocation Limit defines the upper bound or maximum amount of VCPUs that can be created on any given hypervisor (HV). For example, if you have a hypervisor with 12 processors or cores (Moab sees them as 12 processors), and have an Allocation Limit of 2.0 for procs, then Moab will not allow, under any condition, more than 24 VCPU's to be allocated on this hypervisor. Remember: a VM can have one or more VCPU's. So, in this example, the HV could only support 8 VM's if they all had 3 VPCU's each. It could support 4 VM's if they had 6 VPCU's each, and so forth</p> <p>From http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html</p> <p>Setting this to 1 effectively disables the allocation overcommit based on processors. If this and memoryAllocationLimit are both set to 1.0 (the default), the policy state cannot be set to PolicyState.ENABLED.</p>
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

[NodeAllocationPolicy](#)

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Moab contains a number of allocation algorithms that address this in the [NodeAllocationPolicy](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
customPriorityFunction	String	Yes	Defines the priority function when the CustomPriority algorithm is used.
description	String	No	The user friendly description of the policy.
name	String	No	The user friendly name of the policy.
nodeAllocationAlgorithm	NodeAllocationAlgorithm	Yes	Configures the node allocation algorithm utilized when the policy is active. Defaults to NONE . When ENABLED , this must not be set to NONE .
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[NodeAllocationAlgorithm](#)

Represents the algorithm used to allocate Nodes when the [NodeAllocationPolicy](#) is used.

Value	Description
NONE	
InReportedOrder	
InReverseReportedOrder	
CustomPriority	
ProcessorLoad	
MinimumConfiguredResources	
Contiguous	
ProcessorSpeedBalance	
NodeSpeed	

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

MigrationExclusionListPolicy

Specify which virtual machines and hypervisors to exclude from automatic migration operations.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
hvExclusionList	List<String>	Yes	The list of hypervisor IDs on the exclusion list.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.

Field Name	Type	PUT	Description
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.
vmExclusionList	List<String>	Yes	The list of VM IDs on the exclusion list.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

FairsharePolicy

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect. <http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php>

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.

Field Name	Type	PUT	Description
decayFactor	Double	Yes	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing aged usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage.
depth	Integer	Yes	Number of fairshare windows factored into current fairshare utilization. Note: The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab).
description	String	No	The user friendly description of the policy.
intervalSeconds	Long	Yes	Specifies the length of each fairshare window in seconds.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

Field Name	Type	PUT	Description
usageMetric	FairshareUsageMetric	Yes	As Moab runs, it records how available resources are used. Each iteration it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the usage metric allowing various aspects of resource consumption information to be measured. The usage metric allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

[FairshareUsageMetric](#)

Specifies the unit of tracking [FairsharePolicy](#) usage.

<http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php#fspolicy>

Value	Description
NONE	
DEDICATED_PROCESSOR_SECONDS_DELIVERED	Usage tracked by processor seconds dedicated to each job relative to other processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)
DEDICATED_PROCESSOR_SECONDS_AVAILABLE	Usage tracked by processor seconds dedicated to each job relative to all available processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)

Value	Description
DEDICATED_ PROCESSOR_ EQUIVALENT_ SECONDS_DELIVERED	Usage tracked by processor-equivalent seconds dedicated to each job relative to other processor-equivalent seconds dedicated to other jobs on the system. (Useful in dedicated and shared nodes environments).
UTILIZED_ PROCESSOR_ SECONDS_DELIVERED	Usage tracked by processor seconds used by each job relative to other processor seconds used by other jobs on the system. (Useful in shared node/SMP environments.)

API version 2

Policy

A Moab Workload Manager policy which can affect scheduling decisions such as resource allocation. A policy contains state, identifying information, a priority, and metadata about the policy.

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

AutoVMMigrationPolicy

The Moab policy used to enable and configure policy-based VM migration. Using information about data center applications and server load, Moab can aim to keep VMs in the data center optimally distributed across all hypervisors.

This class inherits fields from [Policy](#).

Field Name	Type	P U T	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
genericMetricThresholds	Map<String, Double>	Yes	A map of generic metric pairings where each value must be greater than or equal to 0 such as: METRIC1 => 5.6 METRIC2 => 0.0 METRIC3 => 102.4
memoryUtilizationThreshold	Double	Yes	Defines the utilization threshold for memory. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.

Field Name	Type	P U T	Description
migrationAlgorithmType	AutoVMMigrationPolicyType	Yes	Configures the VM migration algorithm utilized when the policy is active. Defaults to NONE . When ENABLED , this must not be set to NONE.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
processorUtilizationThreshold	Double	Yes	Defines the load utilization threshold for processors. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[AutoVMMigrationPolicyType](#)

Represents the algorithm used to migrate VMs when the [AutoVMMigrationPolicy](#) is used.

Value	Description
NONE	<p>Used when the Auto VM Migration policy is currently disabled in Moab and before any settings are saved the first time.</p> <p>For example, if the policy is disabled on the first read of Moab policies, the AutoVMMigrationPolicy.migrationAlgorithmType will be set to NONE. If the policy is enabled and the type is set to OVERCOMMIT, followed by a disabling of the policy, it will then be represented as having a state of DISABLED with a migrationAlgorithmType of OVERCOMMIT.</p>
OVERCOMMIT	Use the "overcommit" algorithm for migration. The goal of this algorithm is to equalize loads across hypervisors as migrations are queued due to overcommit conditions. This places VMs to be migrated on the least-loaded hypervisor available.
CONSOLIDATION	Use the "consolidation" algorithm for migration. The goal of this algorithm is to load hypervisors as close to thresholds as possible, without exceeding them. This policy places VMs to be migrated on the most loaded hypervisor possible, within these constraints. A second loop of this policy will select lightly-loaded hypervisors to be evacuated completely.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

HVAllocationOvercommitPolicy

The Hypervisor Allocation Overcommit policy controls how many virtual machines can be placed on a hypervisor. By enabling this policy, you are allowing Moab to allocate more resources to a set of virtual machines than a hypervisor may actually have. This is possible due to virtualization. In other words, this policy allows you to set the high-water mark for virtual machine allocation for hypervisors. At least one of these limits must be greater than 1.0, or the policy will not be able to set to a state of [PolicyState.ENABLED](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
memoryAllocationLimit	Double	Yes	Setting this to 1 effectively disables the allocation overcommit based on memory. If this and processorAllocationLimit are both set to 1.0 (the default), the policy state cannot be set to PolicyState.ENABLED .
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
processorAllocationLimit	Double	Yes	<p>The Allocation Limit defines the upper bound or maximum amount of VCPUs that can be created on any given hypervisor (HV). For example, if you have a hypervisor with 12 processors or cores (Moab sees them as 12 processors), and have an Allocation Limit of 2.0 for procs, then Moab will not allow, under any condition, more than 24 VCPU's to be allocated on this hypervisor. Remember: a VM can have one or more VCPU's. So, in this example, the HV could only support 8 VM's if they all had 3 VPCU's each. It could support 4 VM's if they had 6 VPCU's each, and so forth</p> <p>From http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html</p> <p>Setting this to 1 effectively disables the allocation overcommit based on processors. If this and memoryAllocationLimit are both set to 1.0 (the default), the policy state cannot be set to PolicyState.ENABLED.</p>
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

[NodeAllocationPolicy](#)

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Moab contains a number of allocation algorithms that address this in the NodeAllocationPolicy.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
customPriorityFunction	String	Yes	Defines the priority function when the CustomPriority algorithm is used.
description	String	No	The user friendly description of the policy.
name	String	No	The user friendly name of the policy.
nodeAllocationAlgorithm	NodeAllocationAlgorithm	Yes	Configures the node allocation algorithm utilized when the policy is active. Defaults to NONE . When ENABLED , this must not be set to NONE.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[NodeAllocationAlgorithm](#)

Represents the algorithm used to allocate Nodes when the [NodeAllocationPolicy](#) is used.

Value	Description
NONE	
InReportedOrder	
InReverseReportedOrder	
CustomPriority	
ProcessorLoad	
MinimumConfiguredResources	
Contiguous	
ProcessorSpeedBalance	
NodeSpeed	

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

MigrationExclusionListPolicy

Specify which virtual machines and hypervisors to exclude from automatic migration operations.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.
description	String	No	The user friendly description of the policy.
hvExclusionList	List<String>	Yes	The list of hypervisor IDs on the exclusion list.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.

Field Name	Type	PUT	Description
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.
vmExclusionList	List<String>	Yes	The list of VM IDs on the exclusion list.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

FairsharePolicy

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect. <http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php>

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
id	String	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
conflicted	Boolean	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a potential conflict.

Field Name	Type	PUT	Description
decayFactor	Double	Yes	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing aged usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage.
depth	Integer	Yes	Number of fairshare windows factored into current fairshare utilization. Note: The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab).
description	String	No	The user friendly description of the policy.
intervalSeconds	Long	Yes	Specifies the length of each fairshare window in seconds.
name	String	No	The user friendly name of the policy.
potentialConflicts	Set<String>	No	A set of policy IDs that may potentially conflict with this policy.
priority	Integer	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
state	PolicyState	Yes	Defines the current state of the policy: enabled or disabled. Defaults to PolicyState.DISABLED .
tags	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
types	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

Field Name	Type	PUT	Description
usageMetric	FairshareUsageMetric	Yes	As Moab runs, it records how available resources are used. Each iteration it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the usage metric allowing various aspects of resource consumption information to be measured. The usage metric allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
ENABLED	The policy is enabled or active.
DISABLED	The policy is disabled or inactive.

[FairshareUsageMetric](#)

Specifies the unit of tracking [FairsharePolicy](#) usage.
<http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php#fspolicy>

Value	Description
NONE	
DEDICATED_PROCESSOR_SECONDS_DELIVERED	Usage tracked by processor seconds dedicated to each job relative to other processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)
DEDICATED_PROCESSOR_SECONDS_AVAILABLE	Usage tracked by processor seconds dedicated to each job relative to all available processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)

Value	Description
DEDICATED_PROCESSOR_EQUIVALENT_SECONDS_DELIVERED	Usage tracked by processor-equivalent seconds dedicated to each job relative to other processor-equivalent seconds dedicated to other jobs on the system. (Useful in dedicated and shared nodes environments).
UTILIZED_PROCESSOR_SECONDS_DELIVERED	Usage tracked by processor seconds used by each job relative to other processor seconds used by other jobs on the system. (Useful in shared node/SMP environments.)

Distinct query-supported	Yes	Distinct on page 1726

API version 3

Principal

A principal maps to a set of ldap users, ldap groups, pam users, and/or pam groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this principal.
attachedRoles	Set<Role>	Yes	Yes	The MWS roles this principal is authorized to use.
description	String	Yes	Yes	The principal description.
groups	List<Map>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, PAMGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"} or {"name": "engineering", "type": "PAMGROUP"}
name	String	Yes	Yes	The unique human-readable name of this principal. Required during POST.
users	List<Map>	Yes	Yes	The users associated with this principal. Each user has a name and type. The valid types of users are LDAP and PAM. Example user: {"name": "jhammon", "type": "LDAP"} or {"name": "jhammon", "type": "PAM"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
description	String	Yes	Yes	The role description.
name	String	Yes	Yes	The unique human-readable name of this role. Required during POST.
permissions	List<Permission>	Yes	Yes	The set of permissions enforced based on the proxy-user.
scope	PrivilegeScope	No	No	

[Permission](#)

Represents a permission

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
action	String	No	No	The action that can be performed on the resource.
description	String	No	No	A description of this permission.
fieldPath	String	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
label	String	No	No	A human readable label for this permission.
resource	String	No	No	The resource the permission applies to.

Field Name	Type	POST	PUT	Description
resourceFilter	Map<String, Map>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
scope	PrivilegeScope	No	No	Whether this permission applies to the principal's tenant-associated resources or globally
type	String	No	No	The type of the permission. Only 'api' type permissions are enforced.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.

Value	Description
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 2

Principal

A principal maps to a set of ldap users, ldap groups, pam users, and/or pam groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this principal.
attachedRoles	Set<Role>	Yes	Yes	The MWS roles this principal is authorized to use.
description	String	Yes	Yes	The principal description.
groups	List<Map>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, PAMGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"} or {"name": "engineering", "type": "PAMGROUP"}
name	String	Yes	Yes	The unique human-readable name of this principal. Required during POST.
users	List<Map>	Yes	Yes	The users associated with this principal. Each user has a name and type. The valid types of users are LDAP and PAM. Example user: {"name": "jhammon", "type": "LDAP"} or {"name": "jhammon", "type": "PAM"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
description	String	Yes	Yes	The role description.
name	String	Yes	Yes	The unique human-readable name of this role. Required during POST.
permissions	List<Permission>	Yes	Yes	The set of permissions enforced based on the proxy-user.
scope	PrivilegeScope	No	No	

[Permission](#)

Represents a permission

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
action	String	No	No	The action that can be performed on the resource.
description	String	No	No	A description of this permission.
fieldPath	String	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
label	String	No	No	A human readable label for this permission.
resource	String	No	No	The resource the permission applies to.

Field Name	Type	POST	PUT	Description
resourceFilter	Map<String, Map>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
scope	PrivilegeScope	No	No	Whether this permission applies to the principal's tenant-associated resources or globally
type	String	No	No	The type of the permission. Only 'api' type permissions are enforced.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.

Value	Description
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 3

Datapoint

A metric that measures system state over a specified period of time. For example, a datapoint may contain data on CPU utilization by specific users. A datapoint is generated by the consolidation of zero or more [Samples](#). It could be said that a datapoint represents a smoothing of samples.

Field Name	Type	Description
id	Long	
data	Map<String, Map>	The actual consolidated sample data. This property may be 'null' if the Report.minimumSampleSize was not met when consolidating the datapoint.
endDate	Date	The ending date that the datapoint covers.
firstSampleDate	Date	The date of the first sample consolidated in this datapoint. (See also: Sample.timestamp .)
lastSampleDate	Date	The date of the last sample consolidated in this datapoint. (See also: Sample.timestamp .)
startDate	Date	The beginning date that the datapoint covers.

API version 2

Datapoint

A metric that measures system state over a specified period of time. For example, a datapoint may contain data on CPU utilization by specific users. A datapoint is generated by the consolidation of zero or more [Samples](#). It could be said that a datapoint represents a smoothing of samples.

Field Name	Type	Description
id	Long	
data	Map<String, Map>	The actual consolidated sample data. This property may be 'null' if the Report.minimumSampleSize was not met when consolidating the datapoint.
endDate	Date	The ending date that the datapoint covers.
firstSampleDate	Date	The date of the first sample consolidated in this datapoint. (See also: Sample.timestamp .)
lastSampleDate	Date	The date of the last sample consolidated in this datapoint. (See also: Sample.timestamp .)
startDate	Date	The beginning date that the datapoint covers.

API version 3

Report

A set of time-based values that share similar context. For example, a report may contain data on CPU or power utilization for all nodes in a cluster.

A report is composed of metadata and a collection of [Datapoints](#). [Samples](#) are also associated with reports, but these are consolidated using the [Report.consolidationFunction](#) to create [Datapoints](#).

If the datapoint documents are being truncated in any way or there are warnings about documents being too large, it may be necessary to increase the [Report.reportDocumentSize](#).

Field Name	Type	POST	Description
id	String	No	The unique identifier for the report. This is automatically assigned and will be ignored if specified during creation.
consolidationFunction	String	Yes	The consolidation function is the process used to convert a set of samples into a datapoint. Currently the only supported function is "average", which is used if none is specified.
datapointDuration	Long	Yes	Required. How long the datapoints are, in seconds.
datapoints	List<Datapoint>	Yes	This is the set of datapoints that have been consolidated for the report or are desired to be included in the report during creation time. In the latter case, these represent historical data created outside of the reporting framework. Only present when getting a single report.
description	String	Yes	A description of the report.
keepSamples	Boolean	Yes	Controls if samples are retained after consolidation. Defaults to false, which means that after consolidation, samples are discarded.
minimumSampleSize	Integer	Yes	If number of samples is below this number, the datapoint data field is "null". Defaults to 1.

Field Name	Type	POST	Description
name	String	Yes	Required. A unique name identifying the report. Valid characters are all alphanumeric characters, dashes (-), periods (.), and underscores (_).
reportDocumentSize	Long	Yes	<p>The maximum size in bytes of each datapoint document stored for this report. This option is provided to maximize the amount of disk space used for a single report. The default value for this option is 100*1024, or 100 KB. The maximum value of this option is 16*1024*1024 (16777216) or 16 MB, which represents the maximum document size in MongoDB. See also http://www.mongodb.org/display/DOCS/Documents.</p> <p>Keep in mind that when creating a new report, MongoDB will initialize all needed space for all possible datapoint documents up front. This can easily fill a disk unless this parameter is modified.</p>
reportSize	Long	Yes	<p>Required. The size of the report in datapoints. After this number of datapoints is reached, the old datapoints will be discarded.</p> <p>WARNING: On report creation, a Mongo collection will be initialized that is the maximum size of a single entry (currently 16 MB) multiplied by the report size. Be careful in setting a large report size as this will quickly allocate the entire disk if many reports with large report sizes are created.</p>

Hooks filename	reservations.groovy	Pre- and Post-Processing Hooks on page 1633
Tenant-supported	No	Tenants on page 1970
Distinct query-supported	No	Distinct on page 1726

API version 3

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.

Field Name	Type	POST	PUT	Description
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.

Field Name	Type	POST	PUT	Description
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	Set<MessageVersion1>	No	No	Messages for the reservation.

Field Name	Type	POST	PUT	Description
owner	EmbeddedCredential	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	ReservationRequirement	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	ReservationStatistics	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>
comparator	ComparisonOperator	No	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to ComparisonOperator.EQUAL.</p>
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.

Value	Description
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "=", "eq", "= "
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported

Value	Description
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

ReservationFlag

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.

Value	Description
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRE	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.

Value	Description
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

Value	Description
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.

Field Name	Type	POST	PUT	Description
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers

Field Name	Type	POST	PUT	Description
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.

Field Name	Type	POST	PUT	Description
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	POST	PUT	Description
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).

Value	Description
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	

Value	Description
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.

Value	Description
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	

Value	Description
HOURL	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.

Field Name	Type	POST	PUT	Description
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.

Field Name	Type	POST	PUT	Description
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	No	No	Messages for the reservation.

Field Name	Type	POST	PUT	Description
owner	EmbeddedCredential	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	ReservationRequirement	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	ReservationStatistics	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>
comparator	ComparisonOperator	No	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to ComparisonOperator.EQUAL.</p>
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.

Value	Description
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

[ComparisonOperator](#)

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

[AclType](#)

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported

Value	Description
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

ReservationFlag

The flag types of a reservation.

Value	Description
ALLOWJOB OVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.

Value	Description
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRE	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.

Value	Description
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

Value	Description
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.

Field Name	Type	POST	PUT	Description
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers

Field Name	Type	POST	PUT	Description
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.

Field Name	Type	POST	PUT	Description
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	POST	PUT	Description
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).

Value	Description
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	

Value	Description
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.

Value	Description
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	

Value	Description
HOURL	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic	
elastic

Distinct query-supported	Yes	Distinct on page 1726

API version 3

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
description	String	Yes	Yes	The role description.
name	String	Yes	Yes	The unique human-readable name of this role. Required during POST.
permissions	List<Permission>	Yes	Yes	The set of permissions enforced based on the proxy-user.
scope	PrivilegeScope	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
action	String	No	No	The action that can be performed on the resource.
description	String	No	No	A description of this permission.
fieldPath	String	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update

Field Name	Type	POST	PUT	Description
label	String	No	No	A human readable label for this permission.
resource	String	No	No	The resource the permission applies to.
resourceFilter	Map<String, Map>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
scope	PrivilegeScope	No	No	Whether this permission applies to the principal's tenant-associated resources or globally
type	String	No	No	The type of the permission. Only 'api' type permissions are enforced.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 2

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.

Service

Represents a Moab Service

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this service. Generated during POST.
account	String	Yes	No	The account associated with this service.
attributes	ServiceAttributes	Yes	Yes	The attributes of this service. Moab dependency attributes can only be defined on container services.
dateCreated	Date	No	No	The date this service was created. Generated during POST.
dateDeleted	Date	No	No	The Date the service was deleted in Moab.
durationRequested	Long	No	No	The duration in seconds for this service.
hookDefinitions	List<ServiceLocalHook>	Yes	Yes	Hook definitions local to the service.
includedServices	Set<String>	Yes	No	The names of the services that this service contains. This can only be defined on container services.

Field Name	Type	POST	PUT	Description
jobDetails	Job	No	No	This field will only exist when a single VM service is requested with API version 2 or greater and contains the full job output for the job matching <code>attributes.moab.job.id</code> for the given API version. If the field does not exist on the service or it does not reference a valid job, this field will not be present.
label	String	Yes	Yes	(Required) A human readable description of this service. Valid for service template extension.
lastUpdated	Date	No	No	The date this service was last updated. Generated during POST.
name	String	Yes	No	The name of this service. A UUID is automatically generated when the name is not specified.
parent	String	No	No	The name of the service that contains this service. Generated during POST.
serviceTemplate	ServiceTemplate	Yes	No	The service template name and ID (if any) used to create the service.
startDateRequested	Date	Yes	No	The date this service was requested.
startDateScheduled	Date	No	No	The date this service is scheduled to run. Generated during POST.

Field Name	Type	POST	PUT	Description
status	String	No	Yes	The description of the current provisioning status. Generated during POST.
statusCode	Long	No	Yes	A numeric code representing the current provisioning status. What this code means is dependent on the provisioning scripts that create this service. Generated during POST.
stepsCompleted	List<String>	Yes	Yes	List of steps completed during service creation.
tenant	Map<String, Map>	Yes	No	Owning tenant for this service. This is optional during POST.
type	ServiceType	Yes	No	The type of the service.
user	String	Yes	No	The user associated with this service.
virtualMachineDetails	VirtualMachine	No	No	This field will only exist when a single VM service is requested with API version 2 or greater and contains the full virtual machine output for the VM matching <code>attributes.vmId</code> for the given API version. If the field does not exist on the service or it does not reference a valid virtual machine, this field will not be present.

ServiceAttributes

Field Name	Type	POST	PUT	Description
id	Long	No	No	

Field Name	Type	POST	PUT	Description
moab	ServiceMoabAttributes	Yes	No	Reserved space for Moab job configuration and attributes.
sharedData	Map<String, Map>	Yes	Yes	Arbitrary data. Valid for service template extension.

ServiceMoabAttributes

Field Name	Type	POST	PUT	Description
id	Long	No	No	
dependencies	Set<ServiceMoabDependency>	Yes	No	Temporal dependencies between included services. This only applies to type container services.
job	ServiceJob	Yes	No	The resources requested for a service of type vm, pm, or storage. This field is only valid during service submission. Once the service has been created the requested resources will appear in the jobRequested field.
jobRequested	ServiceJob	No	No	The resources requested for a service of type vm, pm, or storage. Cannot be modified.
vc	VirtualContainer	No	No	The virtual container that holds this service. Generated during POST. Only the virtual container ID is shown by default but can be expanded with the show-vc or show-recursive-vc URL parameter.

ServiceMoabDependency

Field Name	Type	POST	PUT	Description
id	Long	No	No	
dependency	Set<String>	Yes	No	The names of services that must be run before the service can start.
service	String	Yes	No	The name of the service that needs to wait until the dependencies are met before it can start.

ServiceJob

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of the job. Generated during POST.
features	Set<String>	Yes	No	The node features Moab uses to schedule the service. Valid for service template extension.
image	String	Yes	No	The image name used by the service. This only applies to type vm and pm services. Valid for service template extension.
nodeSet	NodeSet	Yes	No	The node set of this service.
resources	Map<String, Map>	Yes	No	The set of resources of the service. This includes both generic resources and the resources procs, mem, and disk. Typically we use generic resources 'gold' and 'OSStorage' for storage. The resources procs, mem, and disk only apply to type pm and vm services. Valid for service template extension.
rules	Map<String, JobRequirementAttribute>	Yes	No	Node attribute restrictions. Valid for service template extension.
template	String	Yes	No	The job template of this service.

Field Name	Type	POST	PUT	Description
variables	Map<String, Map>	Yes	No	The variables of the service. Variables name "serviceId", "topLevelServiceId", and "imageName" are reserved keys in the map and are created during the POST. Valid for service template extension.

NodeSet

Field Name	Type	POST	PUT	Description
displayValues	List<String>	No	No	The human readable name of each value.
name	String	Yes	No	The name of the VARATTR used when type is VARATTR.
selection	NodeSetSelection	Yes	No	The node set selection policy.
type	NodeSetType	Yes	No	The node set selection type.
values	List<String>	Yes	No	The values of the node set which MWM schedules against.

NodeSetSelection

This enumeration specifies the node set selection policy.

Value	Description
ANYOF	Select resources from all sets contained in node set list.
FIRSTOF	Select resources from first set to match specified constraints.
ONEOF	Select all sets that contain adequate resources to support job.

NodeSetType

This enumeration specifies the node set boundaries.

Value	Description
FEATURE	Specifies that the node sets are to be constructed along node feature boundaries.
VARATTR	Specifies that the node sets are to be constructed according to VARATTR values of the job.

JobRequirementAttribute

Field Name	Type	POST	PUR	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	Yes	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .

Field Name	Type	POST	PUT	Description
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

VirtualContainer

A virtual container is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, physical machines, jobs, reservations, and/or nodes and req node sets. Containers can also be nested inside other containers.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this virtual container.
aclRules	<u>Set<AclRule></u>	No	No	The set of access control rules associated with this virtual container.
createDate	Date	No	No	The date/time that the virtual container was created.
creator	String	No	No	The creator of the virtual container.
description	String	Yes	Yes	A user-defined string that acts as a label.

Field Name	Type	POST	PUT	Description
flags	<u>Set<VirtualContainerFlag></u>	No	Yes	The flags on this virtual container.
jobs	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of jobs in this virtual container.
nodes	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of nodes in this virtual container.
owner	<u>EmbeddedCredential</u>	Yes	Yes	The owner of the virtual container.
reservations	<u>Set<Reservation></u>	No	Yes	The set of reservations in this virtual container.
variables	Map<String, Map>	No	Yes	Variables associated with the virtual container.
virtualContainers	<u>Set<VirtualContainer></u>	No	Yes	The set of virtual containers in this virtual container.
virtualMachines	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of virtual machines in this virtual container.

[AcIRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AcIRule information is the object's name and type. The type directly maps to an [AcIType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>
comparator	ComparisonOperator	No	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to ComparisonOperator.EQUAL.</p>
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.

Value	Description
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

[ComparisonOperator](#)

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

[AclType](#)

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported

Value	Description
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

VirtualContainerFlag

This enumeration specifies the flag types of a virtual container.

Value	Description
DESTROYOBJECTS	Destroy reservations, jobs, and virtual machines in virtual container when the virtual container is destroyed.
DESTROYWHENEMPTY	Destroy virtual container when it contains no objects.
DELETING	Virtual container has started removal process -- might be waiting on workflows, etc. to finish.
HASSTARTED	Virtual container has jobs that have started -- workflows only.
HOLDJOBS	Virtual container will place a hold on jobs that are submitted to it while this flag is set .
WORKFLOW	Virtual container for a workflow -- maximum of one workflow virtual container per workflow.

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.

Field Name	Type	POST	PUT	Description
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).

Field Name	Type	POST	PUT	Description
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.

Field Name	Type	POST	PUT	Description
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	No	No	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.

Field Name	Type	POST	PUT	Description
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	<u>ReservationStatistics</u>	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[ReservationFlag](#)

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.

Value	Description
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRED	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.

Value	Description
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.

Value	Description
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false

Field Name	Type	POST	PUT	Description
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	POST	PUT	Description
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).

Value	Description
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	

Value	Description
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.

Value	Description
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	

Value	Description
HOUR	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic	
elastic	

ServiceLocalHook

Field Name	Type	POST	PUT	Description
id	String	No	No	
currentPhase	ServicePhase	No	No	The service phase that will trigger a running instance of this hook definition when the service leaves the phase.
includeServiceAsBody	Boolean	No	No	If set to true, the service json body we be piped to the STDIN of the script. Defaults to false
name	String	No	No	The service hook definition name.

Field Name	Type	POST	PUT	Description
nextPhase	ServicePhase	No	No	The service phase that will trigger a running instance of this hook definition when the service enters the phase.
timeoutInSeconds	Long	No	No	The duration in seconds before the hook will timeout and terminate automatically, resulting in a failure. Defaults to 900 seconds (15 minutes) when not specified.
transition	Transition	No	No	The service phase transition that will trigger a running instance of this hook definition.
type	ServiceHookType	No	No	The type of service hook that will be run. Before hook failures will stop the service phase transition from taking place.
url	String	No	No	The executable script to be run. e.g. <code>exec:///opt/mws/hooks/service-hooks/hook1.sh?arg1&arg2</code>

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be

starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	No	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	No	Reasons the job is blocked from running.
bypassCount	Integer	No	No	The number of times the job has been backfilled.
cancelCount	Integer	No	No	The number of times a job has received a cancel request.

Field Name	Type	POST	PUT	Description
commandFile	String	Yes	No	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	No	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	No	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	No	The exit code from this job.
cpuTime	Long	No	No	CPU usage time in seconds as reported by the resource manager.
credentials	<u>JobCredentials</u>	Yes	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	Yes	The user-specified name of this job.
dates	<u>JobDates</u>	Yes	Yes	Various dates associated with this job.
deferCount	Integer	No	No	The number of times a job has been deferred.

Field Name	Type	POST	PUT	Description
dependencies	Set<JobDependency>	Yes	No	Dependencies that must be fulfilled before the job can start.
description	String	No	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	No	The list of addresses to whom email is sent by the execution server.
emailNotifyTypes	Set<JobEmailNotifyType>	Yes	No	The list of email notify types attached to the job.

Field Name	Type	POST	PUT	Description
environmentRequested	Boolean	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
environmentVariables	Map<String, Map>	Yes	No	The list of environment variables for this job.
epilogScript	String	Yes	No	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	Yes	The flags that are set on this job.
holdDate	Date	No	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	No	The path to the directory in which the job will be started.
isActive	Boolean	No	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	No	The job group to which this job belongs (different from credentials.group).
masterNode	<u>DomainProxy</u>	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."

Field Name	Type	POST	PUT	Description
memorySecondsDedicated	Double	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
memorySecondsUtilized	Double	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	<u>Set<Message></u>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
nodesExcluded	<u>Set<DomainProxy></u>	Yes	No	The list of nodes that should not be considered for this job.

Field Name	Type	POST	PUT	Description
nodesRequested	Set<DomainProxy>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: nodesRequestedPolicy .)
nodesRequestedPolicy	JobHostListMode	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: nodesRequested .)
partitionAccessList	Set<String>	No	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	No	The number of times the job has been preempted.
priorities	JobPriority	Yes	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	No	The limit for processorSecondsUtilized.
processorSecondsUtilized	Double	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	PUT	Description
prologScript	String	Yes	No	The path to the TORQUE prolog script.
queueStatus	<u>JobQueueStatus</u>	No	No	The status of the job in its queue.
rejectPolicies	<u>Set<JobRejectPolicy></u>	No	No	The list of policies enabled when a job is rejected.
requirements	<u>Set<JobRequirement></u>	Yes	Yes	The list of items required for this job to run. Only <u>JobRequirement.features</u> is valid during PUT.
reservationRequested	<u>DomainProxy</u>	Yes	Yes	The reservation that the job requested.
resourceFailPolicy	<u>JobResourceFailPolicy Type</u>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
resourceManagers	<u>Set<ResourceManager></u>	No	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	No	The path to the remote file containing the standard error of the job.

Field Name	Type	POST	PUR	Description
rmStandardOutputFilePath	String	No	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	No	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	No	The path to the file containing the standard output of the job.
startCount	Integer	No	No	The number of times the job has been started.
states	JobStateInformation	No	No	Information about the state of the job.
submitHost	String	Yes	No	The host from which the job was submitted.
systemJobAction	String	No	No	The action the system job will take.
systemJobType	JobSystemJobType	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	JobActionType	No	No	The action that this job is performing on another job.
targetedJobName	String	No	No	The name of the job on which this job is performing the targetedJobAction.
templates	Set<DomainProxy>	Yes	No	The list of all job templates to be set on this job.

Field Name	Type	POST	PUT	Description
triggers	Set<String>	No	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	<u>Set<DomainProxy></u>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	<u>Set<DomainProxy></u>	No	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	<u>VMUsagePolicy</u>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
account	String	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
group	String	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.

Field Name	Type	POST	PUT	Description
qos	String	No	No	<p>The quality of service assigned to this job.</p> <p>The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.</p>
qosRequested	String	Yes	Yes	The quality of service requested for this job.
user	String	Yes	No	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	PUT	Description
completedDate	Date	No	No	
createdDate	Date	No	No	
deadlineDate	Date	Yes	No	The deadline for completion of the job.
dispatchedDate	Date	No	No	
earliestRequestedStartDate	Date	Yes	Yes	The job will start no sooner than this date.

Field Name	Type	POST	PUT	Description
earliestStartDate	Date	No	No	
eligibleDate	Date	No	No	
lastCanceledDate	Date	No	No	
lastChargedDate	Date	No	No	
lastPreemptedDate	Date	No	No	
lastUpdatedDate	Date	No	No	
startDate	Date	No	No	
submitDate	Date	No	No	
terminationDate	Date	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	No	The type of job dependency. Only set is valid for POST.
value	String	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.

Value	Description
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBSRV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.

Value	Description
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.

Value	Description
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

JobRequirement

Field Name	Type	P O S T	P U T	Description
architecture	String	Ye s	N o	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Ye s	N o	Required node attributes with version number support.
features	Set<String>	No	Y e s	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Ye s	N o	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Ye s	N o	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Ye s	N o	Requested node features. (See also: featuresRequestedMode .)

Field Name	Type	P O S T	P U T	Description
featuresRequestedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	No	The image required by the job.
index	Integer	No	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
nodeAllocationPolicy	NodeAllocationPolicy	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	No	The number of nodes required by the job.

Field Name	Type	P O S T	P U T	Description
nodeSet	String	Ye s	N o	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigm em • FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake
nodes	Set<AllocatedNode>	No	N o	Nodes that have been allocated to meet this requirement.
reservation	DomainProxy	No	N o	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	Map<String, JobResource>	Ye s	N o	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Ye s	N o	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Ye s	N o	The number of tasks to map to each node.

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	

Value	Description
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	PUT	Description
name	String	No	No	
taskCount	Integer	No	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	PUT	Description
dedicated	Integer	No	No	The amount of this resource that has been allocated for running workload.
utilized	Integer	No	No	The amount of this resource that is currently reported as utilized by resource managers.

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

[ServiceTemplate](#)

A Service Template is a service pattern that may be modified to create custom services. Each template may be a service or a service container. Containers contain other templates. An example is a virtual machine template that may contain an operating system template.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this Service Template.

Field Name	Type	POST	PUT	Description
attributes	Map<String, Map>	No	No	

Field Name	Type	POST	PUT	Description
createdBy	String	No	No	The name of the user that created this Service Template.
hookDefinitions	List<Map>	Yes	Yes	A list of local hook definitions for this service template. (See also: ServiceLocalHook .)
includedServices	List<Map>	No	No	<p>A list of objects describing the services templates included in this service template. When a service is created from this service template, the created service will contain services created from all included service templates. Only service templates of type container can include other service templates. Each entry in the includedServices list is an object containing two properties:</p> <ol style="list-style-type: none"> 1. localName - The name of the template which is unique to the holding template container 2. serviceTemplate - The name of the service template
label	String	No	No	(Required) A short description of this Service Template.
modified	Date	No	No	The most recent date this Service Template was changed.
name	String	No	No	The name of this Service Template. A UUID is automatically generated when the name is not specified.
tags	List<String>	No	No	Arbitrary strings used to group service templates.
tenant	Map<String, Map>	Yes	No	Owning tenant for this service template. This is mandatory during POST.
type	String	No	No	The type of service template. Valid values are "vm", "pm", "storage", and "container". (See also: ServiceType .)

VirtualMachine

This class represents a virtual machine: a software implementation of a computer that executes programs like a physical machine (i.e. like a node). A virtual machine, therefore, requires a host machine, usually called a hypervisor, which partitions its resources to be used by the one or many virtual machines it hosts.

A virtual machine needs to have a name, will typically report an OS, and have a list of operating systems that it can run.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of the virtual machine. Note: this field is not user-assigned and is generated by the database.
attributes	<u>Map<String, JobRequirementAttribute></u>	No	No	A copy of the attributes from the tracking job associated with this VM.
description	String	No	No	A description of this VM.
host	<u>DomainProxy</u>	No	Yes	The physical machine (hypervisor) on which this VM is running.

Field Name	Type	POST	PUT	Description
hostnames	Set<String>	No	No	The set of host names (aliases) that refer to this VM.
ipAddress	String	No	No	This VM's IPv4 address.
lastMigrationDate	Date	No	No	The date when this VM was last migrated.
lastUpdatedDate	Date	No	No	The timestamp of the last moment when this VM was updated. There is no guarantee that all user modifications to a VM would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this VM.

Field Name	Type	POST	PUT	Description
metrics	Map<String, Double>	No	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this VM. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this VM. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. i.e. Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationCount	Integer	No	No	The number of times this VM has been migrated.

Field Name	Type	POST	PUT	Description
migrationDisabled	Boolean	No	Yes	True if migration is disabled for this VM, false otherwise.
name	String	No	No	The name of the virtual machine. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	VMOperatingSystemInformation	No	Yes	Describes the current or expected operating system image information for this VM.
requiredFeatures	Set<String>	No	No	The set of features required by this VM.
resourceManagers	Set<NodeResourceManager>	No	No	The resource managers that are reporting or have previously reported this VM. Each object also contains information on the resource manager reports.
resources	Map<String, Resource>	No	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.

Field Name	Type	POST	PUT	Description
startDate	Date	No	No	Date that this VM was started (ready and usable).
states	NodeStateInformation	No	Yes	State information for this VM.
trackingJob	DomainProxy	No	No	The tracking job for this VM.
triggers	Set<DomainProxy>	No	Yes	The set of triggers associated with this VM.
variables	Map<String, Map>	No	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this VM.
virtualContainers	Set<DomainProxy>	No	No	The set of virtual containers that directly (not recursively) contain this VM.

[VMOperatingSystemInformation](#)

Describes the current or expected operating system image information for a virtual machine.

Field Name	Type	POST	PUT	Description
image	String	No	No	The name of the image currently running on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)

Field Name	Type	POST	PUT	Description
imageExpected	String	No	No	The name of the image that was requested to run on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	No	The last time the image of this VM was modified.
imagesAvailable	Set<String>	No	No	The list of image names which can be applied to this VM. In cloud mode, these correspond to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	POST	PUT	Description
isMaster	Boolean	No	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
name	String	No	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	No	The state reported by this resource manager. See the State section for more details.

NodeState

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.

Value	Description
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	POST	PUT	Description
available	Integer	No	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, <code>configured = overcommitFactor * real</code> .
dedicated	Integer	Yes	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.

Field Name	Type	POST	PUT	Description
real	Integer	No	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	POST	PUT	Description
powerState	NodePower	No	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	No	Yes	The scheduling state of the Node, as reported by the resource management layer.

Field Name	Type	POST	PUT	Description
stateExpected	NodeState	No	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	No	A timestamp recording when the sub-state was last modified.

[NodePower](#)

Represents the various options for a Node's power state.

Value	Description
NONE	
ON	
OFF	

API version 2

Service

Represents a Moab Service

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this service. Generated during POST.
account	String	Yes	No	The account associated with this service.
attributes	ServiceAttributes	Yes	Yes	The attributes of this service. Moab dependency attributes can only be defined on container services.
dateCreated	Date	No	No	The date this service was created. Generated during POST.
dateDeleted	Date	No	No	The Date the service was deleted in Moab.
durationRequested	Long	No	No	The duration in seconds for this service.
hookDefinitions	List<ServiceLocalHook>	Yes	Yes	Hook definitions local to the service.
includedServices	Set<String>	Yes	No	The names of the services that this service contains. This can only be defined on container services.

Field Name	Type	POST	PUT	Description
jobDetails	Job	No	No	This field will only exist when a single VM service is requested with API version 2 or greater and contains the full job output for the job matching <code>attributes.moab.job.id</code> for the given API version. If the field does not exist on the service or it does not reference a valid job, this field will not be present.
label	String	Yes	Yes	(Required) A human readable description of this service. Valid for service template extension.
lastUpdated	Date	No	No	The date this service was last updated. Generated during POST.
name	String	Yes	No	The name of this service. A UUID is automatically generated when the name is not specified.
parent	String	No	No	The name of the service that contains this service. Generated during POST.
serviceTemplate	ServiceTemplate	Yes	No	The service template name and ID (if any) used to create the service.
startDateRequested	Date	Yes	No	The date this service was requested.
startDateScheduled	Date	No	No	The date this service is scheduled to run. Generated during POST.

Field Name	Type	POST	PUT	Description
status	String	No	Yes	The description of the current provisioning status. Generated during POST.
statusCode	Long	No	Yes	A numeric code representing the current provisioning status. What this code means is dependent on the provisioning scripts that create this service. Generated during POST.
stepsCompleted	List<String>	Yes	Yes	List of steps completed during service creation.
tenant	Map<String, Map>	Yes	No	Owning tenant for this service. This is optional during POST.
type	ServiceType	Yes	No	The type of the service.
user	String	Yes	No	The user associated with this service.
virtualMachineDetails	VirtualMachine	No	No	This field will only exist when a single VM service is requested with API version 2 or greater and contains the full virtual machine output for the VM matching <code>attributes.vmId</code> for the given API version. If the field does not exist on the service or it does not reference a valid virtual machine, this field will not be present.

[ServiceAttributes](#)

Field Name	Type	POST	PUT	Description
id	Long	No	No	

Field Name	Type	POST	PUT	Description
moab	ServiceMoabAttributes	Yes	No	Reserved space for Moab job configuration and attributes.
sharedData	Map<String, Map>	Yes	Yes	Arbitrary data. Valid for service template extension.

ServiceMoabAttributes

Field Name	Type	POST	PUT	Description
id	Long	No	No	
dependencies	Set<ServiceMoabDependency>	Yes	No	Temporal dependencies between included services. This only applies to type container services.
job	ServiceJob	Yes	No	The resources requested for a service of type vm, pm, or storage. This field is only valid during service submission. Once the service has been created the requested resources will appear in the jobRequested field.
jobRequested	ServiceJob	No	No	The resources requested for a service of type vm, pm, or storage. Cannot be modified.
vc	VirtualContainer	No	No	The virtual container that holds this service. Generated during POST. Only the virtual container ID is shown by default but can be expanded with the show-vc or show-recursive-vc URL parameter.

ServiceMoabDependency

Field Name	Type	POST	PUT	Description
id	Long	No	No	
dependency	Set<String>	Yes	No	The names of services that must be run before the service can start.
service	String	Yes	No	The name of the service that needs to wait until the dependencies are met before it can start.

ServiceJob

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of the job. Generated during POST.
features	Set<String>	Yes	No	The node features Moab uses to schedule the service. Valid for service template extension.
image	String	Yes	No	The image name used by the service. This only applies to type vm and pm services. Valid for service template extension.
nodeSet	<u>NodeSet</u>	Yes	No	The node set of this service.
resources	Map<String, Map>	Yes	No	The set of resources of the service. This includes both generic resources and the resources procs, mem, and disk. Typically we use generic resources 'gold' and 'OSStorage' for storage. The resources procs, mem, and disk only apply to type pm and vm services. Valid for service template extension.
rules	<u>Map<String, JobRequirementAttribute></u>	Yes	No	Node attribute restrictions. Valid for service template extension.
template	String	Yes	No	The job template of this service.

Field Name	Type	POST	PUT	Description
variables	Map<String, Map>	Yes	No	The variables of the service. Variables name "serviceId", "topLevelServiceId", and "imageName" are reserved keys in the map and are created during the POST. Valid for service template extension.

NodeSet

Field Name	Type	POST	PUT	Description
displayValues	List<String>	No	No	The human readable name of each value.
name	String	Yes	No	The name of the VARATTR used when type is VARATTR.
selection	NodeSetSelection	Yes	No	The node set selection policy.
type	NodeSetType	Yes	No	The node set selection type.
values	List<String>	Yes	No	The values of the node set which MWM schedules against.

NodeSetSelection

This enumeration specifies the node set selection policy.

Value	Description
ANYOF	Select resources from all sets contained in node set list.
FIRSTOF	Select resources from first set to match specified constraints.
ONEOF	Select all sets that contain adequate resources to support job.

NodeSetType

This enumeration specifies the node set boundaries.

Value	Description
FEATURE	Specifies that the node sets are to be constructed along node feature boundaries.
VARATTR	Specifies that the node sets are to be constructed according to VARATTR values of the job.

JobRequirementAttribute

Field Name	Type	POS T	PU T	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	Yes	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .

Field Name	Type	POST	PUT	Description
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
must	

VirtualContainer

A virtual container is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, physical machines, jobs, reservations, and/or nodes and req node sets. Containers can also be nested inside other containers.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this virtual container.
aclRules	<u>Set<AclRule></u>	No	No	The set of access control rules associated with this virtual container.
createDate	Date	No	No	The date/time that the virtual container was created.
creator	String	No	No	The creator of the virtual container.
description	String	Yes	Yes	A user-defined string that acts as a label.

Field Name	Type	POST	PUT	Description
flags	<u>Set<VirtualContainerFlag></u>	No	Yes	The flags on this virtual container.
jobs	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of jobs in this virtual container.
nodes	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of nodes in this virtual container.
owner	<u>EmbeddedCredential</u>	Yes	Yes	The owner of the virtual container.
reservations	<u>Set<Reservation></u>	No	Yes	The set of reservations in this virtual container.
variables	Map<String, Map>	No	Yes	Variables associated with the virtual container.
virtualContainers	<u>Set<VirtualContainer></u>	No	Yes	The set of virtual containers in this virtual container.
virtualMachines	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of virtual machines in this virtual container.

[AcIRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AcIRule information is the object's name and type. The type directly maps to an [AcIType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>
comparator	ComparisonOperator	No	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to ComparisonOperator.EQUAL.</p>
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.

Value	Description
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "=", "eq", "= "
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported

Value	Description
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

VirtualContainerFlag

This enumeration specifies the flag types of a virtual container.

Value	Description
DESTROYOBJECTS	Destroy reservations, jobs, and virtual machines in virtual container when the virtual container is destroyed.
DESTROYWHENEMPTY	Destroy virtual container when it contains no objects.
DELETING	Virtual container has started removal process -- might be waiting on workflows, etc. to finish.
HASSTARTED	Virtual container has jobs that have started -- workflows only.
HOLDJOBS	Virtual container will place a hold on jobs that are submitted to it while this flag is set .
WORKFLOW	Virtual container for a workflow -- maximum of one workflow virtual container per workflow.

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.

Field Name	Type	POST	PUT	Description
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).

Field Name	Type	POST	PUT	Description
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.

Field Name	Type	POST	PUT	Description
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	No	No	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.

Field Name	Type	POST	PUT	Description
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	<u>ReservationStatistics</u>	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[ReservationFlag](#)

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.

Value	Description
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRED	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.

Value	Description
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.

Value	Description
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

[ReservationRequirement](#)

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

[ReservationStatistics](#)

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false

Field Name	Type	POST	PUT	Description
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	POST	PUT	Description
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).

Value	Description
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	

Value	Description
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

[TriggerFlag](#)

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.

Value	Description
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	

Value	Description
HOURL	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description

elastic	

ServiceLocalHook

Field Name	Type	POST	PUT	Description
id	String	No	No	
currentPhase	ServicePhase	No	No	The service phase that will trigger a running instance of this hook definition when the service leaves the phase.
includeServiceAsBody	Boolean	No	No	If set to true, the service json body we be piped to the STDIN of the script. Defaults to false
name	String	No	No	The service hook definition name.

Field Name	Type	POST	PUT	Description
nextPhase	ServicePhase	No	No	The service phase that will trigger a running instance of this hook definition when the service enters the phase.
timeoutInSeconds	Long	No	No	The duration in seconds before the hook will timeout and terminate automatically, resulting in a failure. Defaults to 900 seconds (15 minutes) when not specified.
transition	Transition	No	No	The service phase transition that will trigger a running instance of this hook definition.
type	ServiceHookType	No	No	The type of service hook that will be run. Before hook failures will stop the service phase transition from taking place.
url	String	No	No	The executable script to be run. e.g. <code>exec:///opt/mws/hooks/service-hooks/hook1.sh?arg1&arg2</code>

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be

starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POS T	PU T	Description
id	String	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
arrayIndex	Long	No	No	If this job is a sub-job of a JobArray , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
arrayMasterName	String	No	No	If this job is a sub-job of a JobArray , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
attributes	Set<String>	Yes	No	The list of generic attributes associated with this job.
blocks	Set<JobBlock>	No	No	Reasons the job is blocked from running.
bypassCount	Integer	No	No	The number of times the job has been backfilled.
cancelCount	Integer	No	No	The number of times a job has received a cancel request.

Field Name	Type	POST	PUT	Description
commandFile	String	Yes	No	The name of the job script file (absolute path). If commandFile is set and commandScript is not set, then MWS must have read access to the file. If commandFile and commandScript are both set, then MWS does not read the contents of the file, but it does provide the name of the file to Moab.
commandLineArguments	String	Yes	No	The command line arguments passed to the job script specified by commandFile or commandScript.
commandScript	String	Yes	No	The contents of the job script. This field must be Base64-encoded.
completionCode	Integer	No	No	The exit code from this job.
cpuTime	Long	No	No	CPU usage time in seconds as reported by the resource manager.
credentials	<u>JobCredentials</u>	Yes	Yes	The credentials (user and group, for example) associated with this job.
customName	String	Yes	Yes	The user-specified name of this job.
dates	<u>JobDates</u>	Yes	Yes	Various dates associated with this job.
deferCount	Integer	No	No	The number of times a job has been deferred.

Field Name	Type	POS T	PU T	Description
dependencies	Set<JobDependency>	Yes	No	Dependencies that must be fulfilled before the job can start.
description	String	No	No	The description of the job. Can be set only in a job template.
duration	Long	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
durationActive	Long	No	No	The length of time in seconds the job has been active or running.
durationQueued	Long	No	No	The length of time in seconds the job has been eligible to run in the queue.
durationRemaining	Long	No	No	An estimate of the time remaining, in seconds, before the job will complete.
durationSuspended	Long	No	No	The length of time in seconds the job has been suspended.
emailNotifyAddresses	Set<String>	Yes	No	The list of addresses to whom email is sent by the execution server.
emailNotifyTypes	Set<JobEmailNotifyType>	Yes	No	The list of email notify types attached to the job.

Field Name	Type	POST	PUT	Description
environmentRequested	Boolean	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
environmentVariables	Map<String, Map>	Yes	No	The list of environment variables for this job.
epilogScript	String	Yes	No	The path to the TORQUE epilog script.
flags	<u>Set<JobFlag></u>	Yes	Yes	The flags that are set on this job.
holdDate	Date	No	No	The date the most recent hold was placed on the job.
holdReason	<u>JobHoldReason</u>	No	No	The reason the job is on hold.
holds	<u>Set<JobHoldType></u>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
initialWorkingDirectory	String	Yes	No	The path to the directory in which the job will be started.
isActive	Boolean	No	No	True if the job is active, false if the job is complete.
jobGroup	String	Yes	No	The job group to which this job belongs (different from credentials.group).
masterNode	<u>DomainProxy</u>	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."

Field Name	Type	POST	PUT	Description
memorySecondsDedicated	Double	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
memorySecondsUtilized	Double	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
messages	<u>Set<Message></u>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
migrateCount	Integer	No	No	The number of times the job has been migrated.
minimumPreemptTime	Long	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
mwmName	String	No	No	The name of the Moab Workload Manager instance that owns this job.
name	String	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
nodesExcluded	<u>Set<DomainProxy></u>	Yes	No	The list of nodes that should not be considered for this job.

Field Name	Type	POST	PUT	Description
nodesRequested	Set<DomainProxy>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: nodesRequestedPolicy .)
nodesRequestedPolicy	JobHostListMode	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: nodesRequested .)
partitionAccessList	Set<String>	No	No	The list of partitions that this job can access.
partitionAccessListRequested	Set<String>	Yes	Yes	The list of partitions that this job has requested.
preemptCount	Integer	No	No	The number of times the job has been preempted.
priorities	JobPriority	Yes	Yes	The list of priorities for the job.
processorSecondsDedicated	Double	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
processorSecondsLimit	Double	No	No	The limit for processorSecondsUtilized.
processorSecondsUtilized	Double	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	PUT	Description
prologScript	String	Yes	No	The path to the TORQUE prolog script.
queueStatus	<u>JobQueueStatus</u>	No	No	The status of the job in its queue.
rejectPolicies	<u>Set<JobRejectPolicy></u>	No	No	The list of policies enabled when a job is rejected.
requirements	<u>Set<JobRequirement></u>	Yes	Yes	The list of items required for this job to run. Only <u>JobRequirement.features</u> is valid during PUT.
reservationRequested	<u>DomainProxy</u>	Yes	Yes	The reservation that the job requested.
resourceFailPolicy	<u>JobResourceFailPolicy Type</u>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
resourceManagerExtension	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
resourceManagers	<u>Set<ResourceManager></u>	No	No	The list of resource managers associated with this job.
rmStandardErrorFilePath	String	No	No	The path to the remote file containing the standard error of the job.

Field Name	Type	POST	PUT	Description
rmStandardOutputFilePath	String	No	No	The path to the remote file containing the standard output of the job.
standardErrorFilePath	String	Yes	No	The path to the file containing the standard error of the job.
standardOutputFilePath	String	Yes	No	The path to the file containing the standard output of the job.
startCount	Integer	No	No	The number of times the job has been started.
states	JobStateInformation	No	No	Information about the state of the job.
submitHost	String	Yes	No	The host from which the job was submitted.
systemJobAction	String	No	No	The action the system job will take.
systemJobType	JobSystemJobType	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
targetedJobAction	JobActionType	No	No	The action that this job is performing on another job.
targetedJobName	String	No	No	The name of the job on which this job is performing the targetedJobAction.
templates	Set<DomainProxy>	Yes	No	The list of all job templates to be set on this job.

Field Name	Type	POST	PUT	Description
triggers	Set<String>	No	No	The list of triggers associated with this job.
variables	Map<String, Map>	Yes	Yes	The list of variables that this job owns or sets on completion.
virtualContainers	<u>Set<DomainProxy></u>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
virtualMachines	<u>Set<DomainProxy></u>	No	No	The list of virtual machines that are allocated to this job.
vmUsagePolicy	<u>VMUsagePolicy</u>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobBlock

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
account	String	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
group	String	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
jobClass	String	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.

Field Name	Type	POST	PUT	Description
qos	String	No	No	<p>The quality of service assigned to this job.</p> <p>The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.</p>
qosRequested	String	Yes	Yes	The quality of service requested for this job.
user	String	Yes	No	<p>The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.</p>

JobDates

Field Name	Type	POST	PUT	Description
completedDate	Date	No	No	
createdDate	Date	No	No	
deadlineDate	Date	Yes	No	The deadline for completion of the job.
dispatchedDate	Date	No	No	
earliestRequestedStartDate	Date	Yes	Yes	The job will start no sooner than this date.

Field Name	Type	POST	PUT	Description
earliestStartDate	Date	No	No	
eligibleDate	Date	No	No	
lastCanceledDate	Date	No	No	
lastChargedDate	Date	No	No	
lastPreemptedDate	Date	No	No	
lastUpdatedDate	Date	No	No	
startDate	Date	No	No	
submitDate	Date	No	No	
terminationDate	Date	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object on on which the job is dependent.
type	<u>JobDependencyType</u>	Yes	No	The type of job dependency. Only set is valid for POST.
value	String	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
set	

JobEmailNotifyType

Value	Description
JobStart	
JobEnd	
JobFail	
All	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.

Value	Description
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.

Value	Description
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.

Value	Description
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

JobHoldReason

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	PUT	Description
name	String	Yes	No	The name of the object.

Message

Field Name	Type	POST	PUT	Description
count	Integer	No	No	The number of times this message has occurred.
createdDate	Date	No	No	The date this message was created.
expireDate	Date	No	No	The date this message expires.
message	String	No	Yes	The message itself.

JobHostListMode

Value	Description
superset	
subset	
exactset	

JobPriority

Field Name	Type	POST	PUT	Description
run	Long	No	No	
start	Long	No	No	
system	Long	No	No	
user	Long	Yes	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
active	
blocked	
completed	
eligible	

JobRejectPolicy

Value	Description
CANCEL	
HOLD	
IGNORE	
MAIL	
RETRY	

JobRequirement

Field Name	Type	P O S T	P U T	Description
architecture	String	Yes	No	The architecture required by the job.
attributes	Map<String, JobRequirementAttribute>	Yes	No	Required node attributes with version number support.
features	Set<String>	No	Yes	The list of node features the job is scheduled against.
featuresExcluded	Set<String>	Yes	No	Excluded node features. That is, do not select nodes with these features. (See also: featuresExcludedMode .)
featuresExcludedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: featuresExcluded .)
featuresRequested	Set<String>	Yes	No	Requested node features. (See also: featuresRequestedMode .)

Field Name	Type	P O S T	P U T	Description
featuresRequestedMode	JobRequirementFeaturesMode	Yes	No	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: featuresRequested .)
image	String	Yes	No	The image required by the job.
index	Integer	No	No	The index of the requirement, starting with 0.
metrics	Map<String, Double>	No	No	Generic metrics associated with the job as reported by the resource manager.
nodeAccessPolicy	NodeAccessPolicy	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
nodeAllocationPolicy	NodeAllocationPolicy	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
nodeCount	Integer	Yes	No	The number of nodes required by the job.

Field Name	Type	P O S T	P U T	Description
nodeSet	String	Ye s	N o	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> • SETSELECTION - ANYOF, ONEOF, or FIRSTOF • SETTYPE - FEATURE or VARATTR • SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair. <p>Examples:</p> <ul style="list-style-type: none"> • ONEOF:FEATURE:fastos,hiprio,bigm em • FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake
nodes	<u>Set<AllocatedNode></u>	No	N o	Nodes that have been allocated to meet this requirement.
reservation	<u>DomainProxy</u>	No	N o	The allocated reservation (assigned after the job has a reservation).
resourcesPerTask	<u>Map<String, JobResource></u>	Ye s	N o	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
taskCount	Integer	Ye s	N o	The number of tasks (processors) required by this job.
tasksPerNode	Integer	Ye s	N o	The number of tasks to map to each node.

JobRequirementFeaturesMode

Value	Description
OR	
AND	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
NONE	
SHARED	Tasks from any combination of jobs may utilize available resources.
SHAREDONLY	Only jobs requesting shared node access may utilize available resources.
SINGLEJOB	Tasks from a single job may utilize available resources.
SINGLETASK	A single task from a single job may run on the node.
SINGLEUSER	Tasks from any jobs owned by the same user may utilize available resources.
UNIQUEUSER	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
SINGLEGROUP	Any number of tasks from the same group may utilize node.
SINGLEACCOUNT	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
FIRSTSET	

Value	Description
MINGLOBAL	
MINLOCAL	
PLUGIN	
NONE	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
FIRSTAVAILABLE	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
LASTAVAILABLE	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
MINRESOURCE	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
CPULOAD	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
LOCAL	This will call the locally created contrib node allocation algorithm.
CONTIGUOUS	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
MAXBALANCE	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
PRIORITY	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
FASTEST	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
PROCESSORLOAD	Alias for CPULOAD.
NODESPEED	Alias for FASTEST.
INREPORTEDORDER	Alias for FIRSTAVAILABLE.
INREVERSEREPORTEDORDER	Alias for LASTAVAILABLE.
CUSTOMPRIORITY	Alias for PRIORITY.
PROCESSORSPEEDBALANCE	Alias for MAXBALANCE.
MINIMUMCONFIGUREDRESOURCES	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	PUT	Description
name	String	No	No	
taskCount	Integer	No	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	PUT	Description
dedicated	Integer	No	No	The amount of this resource that has been allocated for running workload.
utilized	Integer	No	No	The amount of this resource that is currently reported as utilized by resource managers.

JobResourceFailPolicyType

Value	Description
CANCEL	
FAIL	
HOLD	
IGNORE	
NOTIFY	
REQUEUE	

ResourceManager

Field Name	Type	POST	PUT	Description
isDestination	Boolean	No	No	
isSource	Boolean	No	No	
jobName	String	No	No	
name	String	No	No	

JobStateInformation

Field Name	Type	POST	PUT	Description
state	JobState	No	No	
stateExpected	JobState	No	No	
stateLastUpdatedDate	Date	No	No	
subState	JobSubState	No	No	

JobState

Value	Description

vmmap	
vmmigrate	
vmtracking	

JobActionType

Value	Description
DESTROY	
MIGRATE	
MODIFY	

[VMUsagePolicy](#)

This enumeration describes the virtual machine requirements of a job

Value	Description
REQUIREPM	Requires a physical machine.
PREFPM	Prefers a physical machine.
CREATEVM	Creates a virtual machine.
CREATEPERSISTENTVM	Creates a virtual machine that doesn't go away after the job is done.
REQUIREVM	Requires a virtual machine.
PREFVM	Prefers a virtual machine.

[ServiceTemplate](#)

A Service Template is a service pattern that may be modified to create custom services. Each template may be a service or a service container. Containers contain other templates. An example is a virtual machine template that may contain an operating system template.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this Service Template.

Field Name	Type	POST	PUT	Description
attributes	Map<String, Map>	No	No	

Field Name	Type	POST	PUT	Description
createdBy	String	No	No	The name of the user that created this Service Template.
hookDefinitions	List<Map>	Yes	Yes	A list of local hook definitions for this service template. (See also: ServiceLocalHook .)
includedServices	List<Map>	No	No	<p>A list of objects describing the services templates included in this service template. When a service is created from this service template, the created service will contain services created from all included service templates. Only service templates of type container can include other service templates. Each entry in the includedServices list is an object containing two properties:</p> <ol style="list-style-type: none"> 1. localName - The name of the template which is unique to the holding template container 2. serviceTemplate - The name of the service template
label	String	No	No	(Required) A short description of this Service Template.
modified	Date	No	No	The most recent date this Service Template was changed.
name	String	No	No	The name of this Service Template. A UUID is automatically generated when the name is not specified.
tags	List<String>	No	No	Arbitrary strings used to group service templates.
tenant	Map<String, Map>	Yes	No	Owning tenant for this service template. This is mandatory during POST.
type	String	No	No	The type of service template. Valid values are "vm", "pm", "storage", and "container". (See also: ServiceType .)

ServiceType

Value	Description
VM	
PM	
STORAGE	
CONTAINER	

VirtualMachine

This class represents a virtual machine: a software implementation of a computer that executes programs like a physical machine (i.e. like a node). A virtual machine, therefore, requires a host machine, usually called a hypervisor, which partitions its resources to be used by the one or many virtual machines it hosts.

A virtual machine needs to have a name, will typically report an OS, and have a list of operating systems that it can run.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of the virtual machine. Note: this field is not user-assigned and is generated by the database.
attributes	<u>Map<String, JobRequirementAttribute></u>	No	No	A copy of the attributes from the tracking job associated with this VM.
description	String	No	No	A description of this VM.
host	<u>DomainProxy</u>	No	Yes	The physical machine (hypervisor) on which this VM is running.

Field Name	Type	POST	PUT	Description
hostnames	Set<String>	No	No	The set of host names (aliases) that refer to this VM.
ipAddress	String	No	No	This VM's IPv4 address.
lastMigrationDate	Date	No	No	The date when this VM was last migrated.
lastUpdatedDate	Date	No	No	The timestamp of the last moment when this VM was updated. There is no guarantee that all user modifications to a VM would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this VM.

Field Name	Type	POST	PUT	Description
metrics	Map<String, Double>	No	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this VM. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this VM. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. i.e. Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationCount	Integer	No	No	The number of times this VM has been migrated.

Field Name	Type	POST	PUT	Description
migrationDisabled	Boolean	No	Yes	True if migration is disabled for this VM, false otherwise.
name	String	No	No	The name of the virtual machine. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	<u>VMOperatingSystemInformation</u>	No	Yes	Describes the current or expected operating system image information for this VM.
requiredFeatures	Set<String>	No	No	The set of features required by this VM.
resourceManagers	<u>Set<NodeResourceManager></u>	No	No	The resource managers that are reporting or have previously reported this VM. Each object also contains information on the resource manager reports.
resources	<u>Map<String, Resource></u>	No	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.

Field Name	Type	POST	PUT	Description
startDate	Date	No	No	Date that this VM was started (ready and usable).
states	NodeStateInformation	No	Yes	State information for this VM.
trackingJob	DomainProxy	No	No	The tracking job for this VM.
triggers	Set<DomainProxy>	No	Yes	The set of triggers associated with this VM.
variables	Map<String, Map>	No	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this VM.
virtualContainers	Set<DomainProxy>	No	No	The set of virtual containers that directly (not recursively) contain this VM.

[VMOperatingSystemInformation](#)

Describes the current or expected operating system image information for a virtual machine.

Field Name	Type	POST	PUT	Description
image	String	No	No	The name of the image currently running on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)

Field Name	Type	POST	PUT	Description
imageExpected	String	No	No	The name of the image that was requested to run on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	No	The last time the image of this VM was modified.
imagesAvailable	Set<String>	No	No	The list of image names which can be applied to this VM. In cloud mode, these correspond to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	POST	PUT	Description
isMaster	Boolean	No	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
name	String	No	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	No	The state reported by this resource manager. See the State section for more details.

NodeState

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.

Value	Description
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	POST	PUT	Description
available	Integer	No	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, $\text{configured} = \text{overcommitFactor} * \text{real}$.
dedicated	Integer	Yes	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.

Field Name	Type	POST	PUT	Description
real	Integer	No	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	POST	PUT	Description
powerState	NodePower	No	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	No	Yes	The scheduling state of the Node, as reported by the resource management layer.

Field Name	Type	POST	PUT	Description
stateExpected	NodeState	No	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	No	A timestamp recording when the sub-state was last modified.

[NodePower](#)

Represents the various options for a Node's power state.

Value	Description
NONE	
ON	
OFF

ServiceCombinedHook

Field Name	Type	Description
id	String	
currentPhase	ServicePhase	The service phase that will trigger a running instance of this hook definition when the service leaves the phase.
global	boolean	
includeServiceAsBody	Boolean	If set to true, the service json body will be piped to the STDIN of the script. Defaults to false
name	String	The service hook definition name.
nextPhase	ServicePhase	The service phase that will trigger a running instance of this hook definition when the service enters the phase.
timeoutInSeconds	Long	The duration in seconds before the hook will timeout and terminate automatically, resulting in a failure. Defaults to 900 seconds (15 minutes) when not specified.
transition	Transition	The service phase transition that will trigger a running instance of this hook definition.
type	ServiceHookType	The type of service hook that will be run. Before hook failures will stop the service phase transition from taking place.
url	String	The executable script to be run. e.g. exec:///opt/mws/hooks/service-hooks/hook1.sh?arg1&arg2

ServiceTemplate

A Service Template is a service pattern that may be modified to create custom services. Each template may be a service or a service container. Containers contain other templates. An example is a virtual machine template that may contain an operating system template.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this Service Template.

Field Name	Type	POST	PUT	Description
attributes	Map<String, Map>	No	No	

Field Name	Type	POST	PUT	Description
createdBy	String	No	No	The name of the user that created this Service Template.
hookDefinitions	List<Map>	Yes	Yes	A list of local hook definitions for this service template. (See also: ServiceLocalHook .)
includedServices	List<Map>	No	No	<p>A list of objects describing the services templates included in this service template. When a service is created from this service template, the created service will contain services created from all included service templates. Only service templates of type container can include other service templates. Each entry in the includedServices list is an object containing two properties:</p> <ol style="list-style-type: none"> 1. localName - The name of the template which is unique to the holding template container 2. serviceTemplate - The name of the service template
label	String	No	No	(Required) A short description of this Service Template.
modified	Date	No	No	The most recent date this Service Template was changed.
name	String	No	No	The name of this Service Template. A UUID is automatically generated when the name is not specified.
tags	List<String>	No	No	Arbitrary strings used to group service templates.
tenant	Map<String, Map>	Yes	No	Owning tenant for this service template. This is mandatory during POST.
type	String	No	No	The type of service template. Valid values are "vm", "pm", "storage", and "container". (See also: ServiceType .)

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.

Value	Description
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.

Value	Description
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

[JobRequirementAttribute](#)

Field Name	Type	POST	PUT	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	Yes	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

[JobRequirementAttributeRestriction](#)

Represents a restriction for a job requirement attribute.

Value	Description
must	

API version 2

ServiceTemplate

A Service Template is a service pattern that may be modified to create custom services. Each template may be a service or a service container. Containers contain other templates. An example is a virtual machine template that may contain an operating system template.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique identifier of this Service Template.

SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.

Value	Description
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.

Value	Description
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

[JobRequirementAttribute](#)

Field Name	Type	POST	PUT	Description
comparator	String	Yes	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	Yes	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	Yes	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .
value	String	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

[JobRequirementAttributeRestriction](#)

Represents a restriction for a job requirement attribute.

Value	Description
must

API version 3

StandingReservation

This class represents a standing reservation.

A standing reservation is any reservation that is not a one-time reservation. This includes reservations that recur every day or every week, or infinite reservations.

Field Name	Type	Description
id	String	The unique ID of the standing reservation.
access	ReservationAccess	If set to ReservationAccess.SHARED , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
accounts	Set<String>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
aclRules	Set<AclRule>	The set of access control rules associated with this standing reservation.
chargeAccount	String	Specifies the account to which Moab will charge all idle cycles within the reservation (via the accounting manager).
chargeUser	String	Specifies the user to which Moab will charge all idle cycles within the reservation (via the accounting manager). Must be used in conjunction with chargeAccount
classes	Set<String>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
clusters	Set<String>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
comment	String	Specifies a descriptive message associated with the standing reservation and all child reservations

Field Name	Type	Description
days	Set<String>	Specifies which days of the week the standing reservation is active. Valid values are Mon, Tue, Wed, Thu, Fri, Sat, Sun, or [ALL].
depth	Integer	Specifies the depth of standing reservations to be created, starting at depth 0 (one per period).
disabled	Boolean	Specifies if the standing reservation should no longer spawn child reservations.
endOffset	Long	The ending offset, in seconds, from the beginning of the current period (DAY or WEEK), for this standing reservation. See examples at startOffset .
flags	Set<ReservationFlag>	Specifies special reservation attributes.
groups	Set<String>	Specifies the groups allowed access to this standing reservation.
hosts	Set<String>	Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the class:X format, Moab only selects hosts that support the specified class. If TASKCOUNT is also specified, only TASKCOUNT tasks are reserved. Otherwise, all matching hosts are reserved.
jobAttributes	Set<JobFlag>	Specifies job attributes that grant a job access to the reservation. Values can be specified with a != assignment to only allow jobs NOT requesting a certain feature inside the reservation.
maxJob	Integer	Specifies the maximum number of jobs that can run in the reservation.
maxTime	Integer	Specifies the maximum time for jobs allowable. Can be used with affinity to attract jobs with same maxTime.
messages	Set<String>	Messages associated with the reservation.

Field Name	Type	Description
nodeFeatures	Set<String>	Specifies the required node features for nodes that are part of the standing reservation.
os	String	Specifies the operating system that should be in place during the reservation. Moab provisions this OS at reservation start and restores the original OS at reservation completion.
owner	<u>EmbeddedCredential</u>	<p>Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it.</p> <p>Setting a user as the owner of a reservation gives that user privileges to query and release the reservation.</p> <p>For sandbox reservations, sandboxes are applied to a specific peer only if owner is set to CLUSTER:<PEERNAME></p>
partition	String	Specifies the partition in which to create the standing reservation. Defaults to ALL.
period	<u>TimeWindow</u>	Period of the Standing reservation. Defaults to <u>TimeWindow.DAY</u> .
procLimit	<u>IntLimit</u>	Specifies the processor limit for jobs requesting access to this standing reservation.
psLimit	<u>IntLimit</u>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
qoses	Set<String>	Specifies that jobs with the listed QoS names can access the reserved resources.
reservationAccessList	<u>Set<Reservation></u>	A list of reservations to which the specified reservation has access.
reservationGroup	String	The group of the reservation.

Field Name	Type	Description
resources	Map<String, Integer>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.) Supported resources currently include the following:</p> <ul style="list-style-type: none"> • PROCS (number of processors) • MEM (real memory in MB) • DISK (local disk in MB) • SWAP (virtual memory in MB)
rollbackOffset	Integer	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See QoS Credential in the Moab Workload Manager documentation for more information on quality of service and service level agreements.</p>
startOffset	Long	<p>The starting offset, in seconds, from the beginning of the current period (DAY or WEEK), for this standing reservation. If period is DAY, the offset is from midnight (00:00) of the current day. If period is WEEK, the offset is from midnight Sunday of the current week.</p> <p>Example 1: For a standing reservation that begins at 9:00 and ends at 17:00 every day, period is DAY, startOffset is 32400 (9*60*60), and endOffset is 61200 (17*60*60).</p> <p>Example 2: For a standing reservation that begins at 9:00 Monday and ends at 17:00 Friday every week, period is WEEK, startOffset is 118800 ((24+9)*60*60), and endOffset is 493200 (((5*24)+17)*60*60).</p>

Field Name	Type	Description
taskCount	Integer	Specifies how many tasks should be reserved for the reservation Default is 0 (unlimited tasks).
tasksPerNode	Integer	Specifies the minimum number of tasks per node that must be available on eligible nodes. Default is 0 (no TPN constraint)
timeLimit	Integer	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access. Default is null (-1 in moab)
triggers	Set<Trigger>	Triggers associated with the reservation.
type	String	The type of the reservation.
users	Set<String>	Specifies which users have access to the resources reserved by this reservation.

[ReservationAccess](#)

The access type of a standing reservation. If set to SHARED, allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.

Value	Description
DEDICATED	
SHARED	

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	Description
affinity	<u>AclAffinity</u>	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to <u>AclAffinity.POSITIVE</u>.</p>
comparator	<u>ComparisonOperator</u>	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to <u>ComparisonOperator.EQUAL</u>.</p>
type	<u>AclType</u>	The type of the object that is being granted (or denied) access.
value	String	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.

Value	Description
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User

Value	Description
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported
RACK	Not supported

Value	Description
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

ReservationFlag

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).

Value	Description
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRED	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.

Value	Description
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.

Value	Description
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.

Value	Description
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.

Value	Description
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

value	Integer	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	Description
id	String	The unique ID of the reservation.
accountingAccount	String	Accountable Account.

Field Name	Type	Description
accountingGroup	String	Accountable Group.
accountingQOS	String	Accountable QOS.
accountingUser	String	Accountable User.
aclRules	<u>Set<AclRule></u>	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	The number of allocated nodes for this reservation.
allocatedNodes	<u>Set<DomainProxyVersion1></u>	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	The number of allocated processors.
allocatedTaskCount	Integer	The number of allocated tasks.
comments	String	Reservation's comments or description.
creationDate	Date	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	The duration of the reservation (in seconds).
endDate	Date	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	The flags associated with the reservation.

Field Name	Type	Description
globalId	String	Global reservation ID.
hostListExpression	String	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	State whether or not this reservation is currently active.
isTracked	Boolean	States whether reservation resource usage is tracked.
label	String	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	The owner of the reservation
partitionId	String	The ID of the partition this reservation is for.
profile	String	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	The reservation's requirements.

Field Name	Type	Description
reservationGroup	String	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	<u>ReservationStatistics</u>	The reservation's statistical information.
subType	String	The reservation sub-type.
taskCount	Integer	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	<u>Trigger</u>	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	The IDs of the triggers attached to this reservation.
uniqueIndex	String	The globally-unique reservation index.
variables	Map<String, Map>	The set of variables for this reservation.

[DomainProxyVersion1](#)

Field Name	Type	Description
id	String	The id of the object.

[MessageVersion1](#)

Field Name	Type	Description
author	String	The author of the message.
creationTime	Date	The time the message was created in epoch time.
expireTime	Date	The time the message will be deleted in epoch time.
index	Integer	The index of the message relative to other messages in Moab's memory.
message	String	The comment information itself.
messageCount	Integer	The number of times this message has been displayed.
priority	Double	An optional priority that can be attached to the comment.

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	Description
architecture	String	Required architecture.
featureList	Set<String>	The list of features required for this reservation.
featureMode	String	Required feature mode.
memory	Integer	Required node memory, in MB.
nodeCount	Integer	Required number of nodes.
nodeIds	Set<String>	The list of node IDs required for this reservation.
os	String	Required Operating System.
taskCount	Integer	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	Description
caps	Long	The current active processor-seconds in the last reported iteration.
cips	Long	The current idle processor-seconds in the last reported iteration.
taps	Long	The total active processor-seconds over the life of the reservation.
tips	Long	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	Description
id	String	Trigger id - internal ID used by moab to track triggers
action	String	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	
blockTime	Date	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	
eventType	TriggerEventType	
expireTime	Date	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
failOffset	Date	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	<u>Set<TriggerFlag></u>	
interval	Boolean	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <u>TriggerEventType.EPOCH</u> to create a Standing Trigger. Defaults to false
maxRetry	Integer	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	The ID of the object which this is attached to.
objectType	String	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	Relative time offset from event when trigger can fire.
period	<u>TriggerPeriod</u>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
sets	String	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	The type of the trigger.
unsets	String	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.

Value	Description
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

[TriggerEventType](#)

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	
MODIFY	
PREEMPT	
STANDING	

Value	Description
START	
THRESHOLD	
DISCOVER	
LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:

Value	Description
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	
HOURL	
DAY	

Value	Description
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic	
elastic	

Trigger

Field Name	Type	Description
id	String	Trigger id - internal ID used by moab to track triggers
action	String	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	
blockTime	Date	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	
eventType	TriggerEventType	

Field Name	Type	Description
expireTime	Date	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	<u>Set<TriggerFlag></u>	
interval	Boolean	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <u>TriggerEventType.EPOCH</u> to create a Standing Trigger. Defaults to false
maxRetry	Integer	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	The ID of the object which this is attached to.
objectType	String	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	Relative time offset from event when trigger can fire.
period	<u>TriggerPeriod</u>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.

Field Name	Type	Description
requires	String	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
sets	String	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	<u>TriggerType</u>	The type of the trigger.
unsets	String	Variable this trigger destroys upon success or failure.

API version 2

StandingReservation

This class represents a standing reservation.

A standing reservation is any reservation that is not a one-time reservation. This includes reservations that recur every day or every week, or infinite reservations.

Field Name	Type	Description
id	String	The unique ID of the standing reservation.
access	ReservationAccess	If set to ReservationAccess.SHARED , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
accounts	Set<String>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
aclRules	Set<AclRule>	The set of access control rules associated with this standing reservation.
chargeAccount	String	Specifies the account to which Moab will charge all idle cycles within the reservation (via the accounting manager).
chargeUser	String	Specifies the user to which Moab will charge all idle cycles within the reservation (via the accounting manager). Must be used in conjunction with chargeAccount
classes	Set<String>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
clusters	Set<String>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
comment	String	Specifies a descriptive message associated with the standing reservation and all child reservations

Field Name	Type	Description
days	Set<String>	Specifies which days of the week the standing reservation is active. Valid values are Mon, Tue, Wed, Thu, Fri, Sat, Sun, or [ALL].
depth	Integer	Specifies the depth of standing reservations to be created, starting at depth 0 (one per period).
disabled	Boolean	Specifies if the standing reservation should no longer spawn child reservations.
endOffset	Long	The ending offset, in seconds, from the beginning of the current period (DAY or WEEK), for this standing reservation. See examples at startOffset .
flags	Set<ReservationFlag>	Specifies special reservation attributes.
groups	Set<String>	Specifies the groups allowed access to this standing reservation.
hosts	Set<String>	Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the class:X format, Moab only selects hosts that support the specified class. If TASKCOUNT is also specified, only TASKCOUNT tasks are reserved. Otherwise, all matching hosts are reserved.
jobAttributes	Set<JobFlag>	Specifies job attributes that grant a job access to the reservation. Values can be specified with a != assignment to only allow jobs NOT requesting a certain feature inside the reservation.
maxJob	Integer	Specifies the maximum number of jobs that can run in the reservation.
maxTime	Integer	Specifies the maximum time for jobs allowable. Can be used with affinity to attract jobs with same maxTime.
messages	Set<String>	Messages associated with the reservation.

Field Name	Type	Description
nodeFeatures	Set<String>	Specifies the required node features for nodes that are part of the standing reservation.
os	String	Specifies the operating system that should be in place during the reservation. Moab provisions this OS at reservation start and restores the original OS at reservation completion.
owner	<u>EmbeddedCredential</u>	<p>Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it.</p> <p>Setting a user as the owner of a reservation gives that user privileges to query and release the reservation.</p> <p>For sandbox reservations, sandboxes are applied to a specific peer only if owner is set to CLUSTER:<PEERNAME></p>
partition	String	Specifies the partition in which to create the standing reservation. Defaults to ALL.
period	<u>TimeWindow</u>	Period of the Standing reservation. Defaults to <u>TimeWindow.DAY</u> .
procLimit	<u>IntLimit</u>	Specifies the processor limit for jobs requesting access to this standing reservation.
psLimit	<u>IntLimit</u>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
qoses	Set<String>	Specifies that jobs with the listed QoS names can access the reserved resources.
reservationAccessList	<u>Set<Reservation></u>	A list of reservations to which the specified reservation has access.
reservationGroup	String	The group of the reservation.

Field Name	Type	Description
resources	Map<String, Integer>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.)</p> <p>Supported resources currently include the following:</p> <ul style="list-style-type: none"> • PROCS (number of processors) • MEM (real memory in MB) • DISK (local disk in MB) • SWAP (virtual memory in MB)
rollbackOffset	Integer	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See QoS Credential in the Moab Workload Manager documentation for more information on quality of service and service level agreements.</p>
startOffset	Long	<p>The starting offset, in seconds, from the beginning of the current period (DAY or WEEK), for this standing reservation. If period is DAY, the offset is from midnight (00:00) of the current day. If period is WEEK, the offset is from midnight Sunday of the current week.</p> <p>Example 1: For a standing reservation that begins at 9:00 and ends at 17:00 every day, period is DAY, startOffset is 32400 (9*60*60), and endOffset is 61200 (17*60*60).</p> <p>Example 2: For a standing reservation that begins at 9:00 Monday and ends at 17:00 Friday every week, period is WEEK, startOffset is 118800 ((24+9)*60*60), and endOffset is 493200 (((5*24)+17)*60*60).</p>

Field Name	Type	Description
taskCount	Integer	Specifies how many tasks should be reserved for the reservation Default is 0 (unlimited tasks).
tasksPerNode	Integer	Specifies the minimum number of tasks per node that must be available on eligible nodes. Default is 0 (no TPN constraint)
timeLimit	Integer	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access. Default is null (-1 in moab)
triggers	Set<Trigger>	Triggers associated with the reservation.
type	String	The type of the reservation.
users	Set<String>	Specifies which users have access to the resources reserved by this reservation.

[ReservationAccess](#)

The access type of a standing reservation. If set to SHARED, allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.

Value	Description
DEDICATED	
SHARED	

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	Description
affinity	<u>AclAffinity</u>	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to <u>AclAffinity.POSITIVE</u>.</p>
comparator	<u>ComparisonOperator</u>	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to <u>ComparisonOperator.EQUAL</u>.</p>
type	<u>AclType</u>	The type of the object that is being granted (or denied) access.
value	String	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.

Value	Description
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "==", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User

Value	Description
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported
RACK	Not supported

Value	Description
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

ReservationFlag

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).

Value	Description
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRE	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.

Value	Description
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTTE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.

Value	Description
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
NONE	
BACKFILL	The job is using backfill to run.
COALLOC	The job can use resources from multiple resource managers and partitions.
ADVRES	The job requires the use of a reservation.
NOQUEUE	The job will attempt to execute immediately or fail.
ARRAYJOB	The job is part of a job array.
ARRAYJOBPARLOCK	This array job will only run in one partition.
ARRAYJOBPARSPAN	This array job will span partitions (default).
ARRAYMASTER	This job is the master of a job array.
BESTEFFORT	The job will succeed if even partial resources are available.
RESTARTABLE	The job is restartable.
SUSPENDABLE	The job is suspendable.
HASPREEMPTED	This job preempted other jobs to start.

Value	Description
PREEMPTTEE	The job is a preemptee and therefore can be preempted by other jobs.
PREEMPTOR	The job is a preemptor and therefore can preempt other jobs.
RSVMAP	The job is based on a reservation.
SPVIOLATION	The job was started with a soft policy violation.
IGNNODEPOLICIES	The job will ignore node policies.
IGNPOLICIES	The job will ignore idle, active, class, partition, and system policies.
IGNNODESTATE	The job will ignore node state in order to run.
IGNIDLEJOBRSV	The job can ignore idle job reservations. The job granted access to all idle job reservations.
INTERACTIVE	The job needs to interactive input from the user to run.
FSVIOLATION	The job was started with a fairshare violation.
GLOBALQUEUE	The job is directly submitted without doing any authentication.
NORESOURCES	The job is a system job that does not need any resources.
NORMSTART	The job will not query a resource manager to run.
CLUSTERLOCKED	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
FRAGMENT	The job can be run across multiple nodes in individual chunks.
SYSTEMJOB	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
ADMINSETIGNPOLICIES	The IGNPOLICIES flag was set by an administrator.

Value	Description
EXTENDSTARTWALLTIME	The job duration (walltime) was extended at job start.
SHAREDMEM	The job will share its memory across nodes.
BLOCKEDBYGRES	The job's generic resource requirement caused the job to start later.
GRESONLY	The job is requesting only generic resources, no compute resources.
TEMPLATESAPPLIED	The job has had all applicable templates applied to it.
META	META job, just a container around resources.
WIDERSVSEARCHALGO	This job prefers the wide search algorithm.
VMTRACKING	The job is a VMTracking job for an externally-created VM (via job template).
DESTROYTEMPLATESUBMITTED	A destroy job has already been created from the template for this job.
PROCSPECIFIED	The job requested processors on the command line.
CANCELONFIRSTFAILURE	Cancel job array on first array job failure.
CANCELONFIRSTSUCCESS	Cancel job array on first array job success.
CANCELONANYFAILURE	Cancel job array on any array job failure.
CANCELONANYSUCCESS	Cancel job array on any array job success.
CANCELONEXITCODE	Cancel job array on a specific exit code.
NOVMMIGRATE	Do not migrate the virtual machine that this job sets up.
PURGEONSUCCESSONLY	Only purge the job if it completed successfully
ALLPROCS	Each job compute task requests all the procs on its node

[EmbeddedCredential](#)

qualifier	String	One of: <ul style="list-style-type: none"> • < • <= • == • >= • >
value	Integer	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	Description
id	String	The unique ID of the reservation.
accountingAccount	String	Accountable Account.

Field Name	Type	Description
accountingGroup	String	Accountable Group.
accountingQOS	String	Accountable QOS.
accountingUser	String	Accountable User.
aclRules	<u>Set<AclRule></u>	The set of access control rules associated with this reservation.
allocatedNodeCount	Integer	The number of allocated nodes for this reservation.
allocatedNodes	<u>Set<DomainProxyVersion1></u>	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	The number of allocated processors.
allocatedTaskCount	Integer	The number of allocated tasks.
comments	String	Reservation's comments or description.
creationDate	Date	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	The duration of the reservation (in seconds).
endDate	Date	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
expireDate	Date	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	The flags associated with the reservation.

Field Name	Type	Description
globalId	String	Global reservation ID.
hostListExpression	String	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	State whether or not this reservation is currently active.
isTracked	Boolean	States whether reservation resource usage is tracked.
label	String	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	The owner of the reservation
partitionId	String	The ID of the partition this reservation is for.
profile	String	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	The reservation's requirements.

Field Name	Type	Description
reservationGroup	String	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
startDate	Date	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	<u>ReservationStatistics</u>	The reservation's statistical information.
subType	String	The reservation sub-type.
taskCount	Integer	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	<u>Trigger</u>	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	The IDs of the triggers attached to this reservation.
uniqueIndex	String	The globally-unique reservation index.
variables	Map<String, Map>	The set of variables for this reservation.

[DomainProxyVersion1](#)

Field Name	Type	Description
id	String	The id of the object.

[MessageVersion1](#)

Field Name	Type	Description
author	String	The author of the message.
creationTime	Date	The time the message was created in epoch time.
expireTime	Date	The time the message will be deleted in epoch time.
index	Integer	The index of the message relative to other messages in Moab's memory.
message	String	The comment information itself.
messageCount	Integer	The number of times this message has been displayed.
priority	Double	An optional priority that can be attached to the comment.

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	Description
architecture	String	Required architecture.
featureList	Set<String>	The list of features required for this reservation.
featureMode	String	Required feature mode.
memory	Integer	Required node memory, in MB.
nodeCount	Integer	Required number of nodes.
nodeIds	Set<String>	The list of node IDs required for this reservation.
os	String	Required Operating System.
taskCount	Integer	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	Description
caps	Long	The current active processor-seconds in the last reported iteration.
cips	Long	The current idle processor-seconds in the last reported iteration.
taps	Long	The total active processor-seconds over the life of the reservation.
tips	Long	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	Description
id	String	Trigger id - internal ID used by moab to track triggers
action	String	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	<u>TriggerActionType</u>	
blockTime	Date	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	
eventType	<u>TriggerEventType</u>	
expireTime	Date	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
failOffset	Date	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	<u>Set<TriggerFlag></u>	
interval	Boolean	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <u>TriggerEventType.EPOCH</u> to create a Standing Trigger. Defaults to false
maxRetry	Integer	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	The ID of the object which this is attached to.
objectType	String	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	Relative time offset from event when trigger can fire.
period	<u>TriggerPeriod</u>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
sets	String	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	The type of the trigger.
unsets	String	Variable this trigger destroys upon success or failure.

[TriggerActionType](#)

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.

Value	Description
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	
MODIFY	
PREEMPT	
STANDING	

Value	Description
START

LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:

Value	Description
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	
HOURL	
DAY	

Value	Description
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic

Trigger

Field Name	Type	Description
id	String	Trigger id - internal ID used by moab to track triggers
action	String	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	<u>TriggerActionType</u>	
blockTime	Date	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	
eventType	<u>TriggerEventType</u>	

Field Name	Type	Description
expireTime	Date	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	
interval	Boolean	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false
maxRetry	Integer	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	The ID of the object which this is attached to.
objectType	String	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> • vm - Virtual Machine
offset	Date	Relative time offset from event when trigger can fire.
period	TriggerPeriod	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.

Field Name	Type	Description
requires	String	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
sets	String	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	The type of the trigger.
unsets	String	Variable this trigger destroys upon success or failure.

API version 3

Tenant

Principal group associates zero or more principals with a defined set of resources. The exact link between the principal group and the resource depends on the resource type. Principal group defines a system-wide unique group code used for linking the principal group to nodes, jobs, and vm's

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this principal group.
attachedNodes	Set<String>	Yes	Yes	Names of nodes assigned to this tenant. Services and service templates created for this tenant will only be placed on/migrated to the assigned nodes.
attachedPrincipals	<u>Set<Principal></u>	Yes	Yes	The MWS principals this group contains.
description	String	Yes	Yes	The principal group description.
name	String	Yes	Yes	The unique human-readable name of this principal group. Required during POST.

Principal

A principal maps to a set of ldap users, ldap groups, pam users, and/or pam groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this principal.
attachedRoles	<u>Set<Role></u>	Yes	Yes	The MWS roles this principal is authorized to use.
description	String	Yes	Yes	The principal description.

Field Name	Type	POST	PUT	Description
groups	List<Map>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, PAMGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"} or {"name": "engineering", "type": "PAMGROUP"}
name	String	Yes	Yes	The unique human-readable name of this principal. Required during POST.
users	List<Map>	Yes	Yes	The users associated with this principal. Each user has a name and type. The valid types of users are LDAP and PAM. Example user: {"name": "jhammon", "type": "LDAP"} or {"name": "jhammon", "type": "PAM"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
description	String	Yes	Yes	The role description.
name	String	Yes	Yes	The unique human-readable name of this role. Required during POST.
permissions	List<Permission>	Yes	Yes	The set of permissions enforced based on the proxy-user.
scope	PrivilegeScope	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this role.
action	String	No	No	The action that can be performed on the resource.
description	String	No	No	A description of this permission.
fieldPath	String	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
label	String	No	No	A human readable label for this permission.
resource	String	No	No	The resource the permission applies to.
resourceFilter	Map<String, Map>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
scope	PrivilegeScope	No	No	Whether this permission applies to the principal's tenant-associated resources or globally
type	String	No	No	The type of the permission. Only 'api' type permissions are enforced.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.

Value	Description
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
GLOBAL	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
TENANT	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
NONE	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 3

VirtualContainer

A virtual container is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, physical machines, jobs, reservations, and/or nodes and req node sets. Containers can also be nested inside other containers.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this virtual container.
aclRules	<u>Set<AclRule></u>	No	No	The set of access control rules associated with this virtual container.
createDate	Date	No	No	The date/time that the virtual container was created.
creator	String	No	No	The creator of the virtual container.
description	String	Yes	Yes	A user-defined string that acts as a label.
flags	<u>Set<VirtualContainerFlag></u>	No	Yes	The flags on this virtual container.
jobs	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of jobs in this virtual container.
nodes	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of nodes in this virtual container.
owner	<u>EmbeddedCredential</u>	Yes	Yes	The owner of the virtual container.
reservations	<u>Set<Reservation></u>	No	Yes	The set of reservations in this virtual container.
variables	Map<String, Map>	No	Yes	Variables associated with the virtual container.

Field Name	Type	POST	PUT	Description
virtualContainers	Set<VirtualContainer>	No	Yes	The set of virtual containers in this virtual container.
virtualMachines	Set<DomainProxyVersion1>	No	Yes	The set of virtual machines in this virtual container.

AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>

Field Name	Type	POST	PUT	Description
comparator	ComparisonOperator	No	Yes	The type of comparison to make against the ACL object. Defaults to ComparisonOperator.EQUAL .
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

[ComparisonOperator](#)

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "=", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AclType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID

Value	Description
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

VirtualContainerFlag

This enumeration specifies the flag types of a virtual container.

Value	Description
DESTROYOBJECTS	Destroy reservations, jobs, and virtual machines in virtual container when the virtual container is destroyed.
DESTROYWHENEMPTY	Destroy virtual container when it contains no objects.
DELETING	Virtual container has started removal process -- might be waiting on workflows, etc. to finish.
HASSTARTED	Virtual container has jobs that have started -- workflows only.
HOLDJOBS	Virtual container will place a hold on jobs that are submitted to it while this flag is set .
WORKFLOW	Virtual container for a workflow -- maximum of one workflow virtual container per workflow.

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	

Value	Description
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.

Field Name	Type	POST	PUT	Description
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.

Field Name	Type	POST	PUT	Description
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	Set<ReservationFlag>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.

Field Name	Type	POST	PUT	Description
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	No	No	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.

Field Name	Type	POST	PUT	Description
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	ReservationStatistics	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[ReservationFlag](#)

The flag types of a reservation.

Value	Description
ALLOWJOBOVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.

Value	Description
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRED	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.

Value	Description
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.

Field Name	Type	POST	PUT	Description
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	

Field Name	Type	POST	PUT	Description
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.

Field Name	Type	POST	PUT	Description
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	

Value	Description
EPOCH	
FAIL	
HOLD	
MIGRATE	
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	
DISCOVER	
LOGROLL	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.

Value	Description
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.

Value	Description
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	
HOURL	
DAY	
WEEK	
MONTH	

TriggerType

This enumeration specifies the type of the trigger.

Value	Description
generic	
elastic	

API version 2

VirtualContainer

A virtual container is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, physical machines, jobs, reservations, and/or nodes and req node sets. Containers can also be nested inside other containers.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of this virtual container.
aclRules	<u>Set<AclRule></u>	No	No	The set of access control rules associated with this virtual container.
createDate	Date	No	No	The date/time that the virtual container was created.
creator	String	No	No	The creator of the virtual container.
description	String	Yes	Yes	A user-defined string that acts as a label.
flags	<u>Set<VirtualContainerFlag></u>	No	Yes	The flags on this virtual container.
jobs	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of jobs in this virtual container.
nodes	<u>Set<DomainProxyVersion1></u>	No	Yes	The set of nodes in this virtual container.
owner	<u>EmbeddedCredential</u>	Yes	Yes	The owner of the virtual container.
reservations	<u>Set<Reservation></u>	No	Yes	The set of reservations in this virtual container.
variables	Map<String, Map>	No	Yes	Variables associated with the virtual container.

Field Name	Type	POST	PUT	Description
virtualContainers	Set<VirtualContainer>	No	Yes	The set of virtual containers in this virtual container.
virtualMachines	Set<DomainProxyVersion1>	No	Yes	The set of virtual machines in this virtual container.

AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
affinity	AclAffinity	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to AclAffinity.POSITIVE.</p>

Field Name	Type	POST	PUT	Description
comparator	ComparisonOperator	No	Yes	The type of comparison to make against the ACL object. Defaults to ComparisonOperator.EQUAL .
type	AclType	No	Yes	The type of the object that is being granted (or denied) access.
value	String	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
NEGATIVE	Access to the object is repelled using this rule until access is the last choice.
NEUTRAL	Access to the object is not affected by affinity.
POSITIVE	Access to the object is looked at as the first choice.
PREEMPTIBLE	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
REQUIRED	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
UNAVAILABLE	The rule does not have its affinity available. Supported only during GET.

[ComparisonOperator](#)

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
GREATER_THAN	Valid values: ">", "gt"
GREATER_THAN_OR_EQUAL	Valid values: ">=", "ge"
LESS_THAN	Valid values: "<", "lt"
LESS_THAN_OR_EQUAL	Valid values: "<=", "le"
EQUAL	Valid values: "=", "eq", "="
NOT_EQUAL	Valid values: "!=", "ne", "<>"
LEXIGRAPHIC_SUBSTRING	Valid value: "%<"
LEXIGRAPHIC_NOT_EQUAL	Valid value: "%!"
LEXIGRAPHIC_EQUAL	Valid value: "%="

AclType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
USER	User
GROUP	Group
ACCOUNT	Account or Project
CLASS	Class or Queue
QOS	Quality of Service
CLUSTER	Cluster
JOB_ID	Job ID

Value	Description
RESERVATION_ID	Reservation ID
JOB_TEMPLATE	Job Template
JOB_ATTRIBUTE	Job Attribute
DURATION	Duration in Seconds
PROCESSOR_SECONDS	Processor Seconds
JPRIORITY	Not supported
MEMORY	Not supported
NODE	Not supported
PAR	Not supported
PROC	Not supported
QTIME	Not supported
QUEUE	Not supported
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

VirtualContainerFlag

This enumeration specifies the flag types of a virtual container.

Value	Description
DESTROYOBJECTS	Destroy reservations, jobs, and virtual machines in virtual container when the virtual container is destroyed.
DESTROYWHENEMPTY	Destroy virtual container when it contains no objects.
DELETING	Virtual container has started removal process -- might be waiting on workflows, etc. to finish.
HASSTARTED	Virtual container has jobs that have started -- workflows only.
HOLDJOBS	Virtual container will place a hold on jobs that are submitted to it while this flag is set .
WORKFLOW	Virtual container for a workflow -- maximum of one workflow virtual container per workflow.

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
id	String	No	No	The id of the object.

EmbeddedCredential

Field Name	Type	POST	PUT	Description
name	String	No	No	
type	CredentialType	No	No	

CredentialType

Value	Description
USER	

Value	Description
GROUP	
ACCOUNT	
CLASS	
QOS	
NOT_SPECIFIED	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
id	String	No	No	The unique ID of the reservation.
accountingAccount	String	Yes	No	Accountable Account.
accountingGroup	String	Yes	No	Accountable Group.
accountingQOS	String	Yes	No	Accountable QOS.
accountingUser	String	Yes	No	Accountable User.
aclRules	Set<AclRule>	Yes	No	The set of access control rules associated with this reservation.

Field Name	Type	POST	PUT	Description
allocatedNodeCount	Integer	No	No	The number of allocated nodes for this reservation.
allocatedNodes	Set<DomainProxyVersion1>	No	No	The nodes allocated to the reservation.
allocatedProcessorCount	Integer	No	No	The number of allocated processors.
allocatedTaskCount	Integer	No	No	The number of allocated tasks.
comments	String	Yes	No	Reservation's comments or description.
creationDate	Date	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
duration	Long	Yes	No	The duration of the reservation (in seconds).
endDate	Date	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
excludeJobs	Set<String>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.

Field Name	Type	POST	PUT	Description
expireDate	Date	No	No	The date/time when the reservation expires and vacates.
flags	<u>Set<ReservationFlag></u>	Yes	No	The flags associated with the reservation.
globalId	String	No	No	Global reservation ID.
hostListExpression	String	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
idPrefix	String	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
isActive	Boolean	No	No	State whether or not this reservation is currently active.
isTracked	Boolean	No	No	States whether reservation resource usage is tracked.

Field Name	Type	POST	PUT	Description
label	String	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
maxTasks	Integer	No	No	The maximum number of tasks for this reservation.
messages	<u>Set<MessageVersion1></u>	No	No	Messages for the reservation.
owner	<u>EmbeddedCredential</u>	Yes	No	The owner of the reservation
partitionId	String	Yes	No	The ID of the partition this reservation is for.
profile	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
requirements	<u>ReservationRequirement</u>	Yes	No	The reservation's requirements.
reservationGroup	String	Yes	No	The reservation group to which the reservation belongs.
resources	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.

Field Name	Type	POST	PUT	Description
startDate	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
statistics	ReservationStatistics	No	No	The reservation's statistical information.
subType	String	Yes	No	The reservation sub-type.
taskCount	Integer	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
trigger	Trigger	Yes	No	Trigger for reservation. Used only during reservation creation.
triggerIds	Set<String>	No	No	The IDs of the triggers attached to this reservation.
uniqueIndex	String	No	No	The globally-unique reservation index.
variables	Map<String, Map>	Yes	Yes	The set of variables for this reservation.

[ReservationFlag](#)

The flag types of a reservation.

Value	Description
ALLOWJOB OVERLAP	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
APPLYPROFRESOURCES	Only apply resource allocation info from profile.
DEADLINE	Reservation should be scheduled against a deadline.
IGNIDLEJOBS	Ignore idle job reservations.
IGNJOBRSV	Ignore job reservations, but not user or other reservations.
CHARGE	Charge the idle cycles in the accounting manager.
NOVMMIGRATIONS	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
OWNERPREEMPTIGNOREMINTIME	Owner ignores preemptmintime for this reservation.
PROVISION	Reservation should be capable of provisioning.
NOACLOVERLAP	Reservation will not look at ACLs to overlap job (when using exclusive).
ADVRES	If set, the reservation is created in advance of needing it.
ADVRESJOBDESTROY	Cancel any jobs associated with the reservation when it is released.
ALLOWGRID	The reservation is set up for use in a grid environment.
ALLOWPRSV	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
BYNAME	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.

Value	Description
DEDICATEDNODE	If set, only one active reservation is allowed on a node.
DEDICATEDRESOURCE	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
EXCLUDEJOBS	Makes a reservation job exclusive, where only one job can run in the reservation.
ENDTRIGHASFIRED	A trigger has finished firing.
ENFORCENODESET	Enforce node sets when creating reservation.
EXCLUDEALLBUTSB	Reservation only shares resources with sandboxes.
EXCLUDEMYGROUP	Exclude reservations within the same group.
IGNRSV	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
IGNSTATE	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
ISACTIVE	If set, the reservation is currently active.
ISCLOSED	If set, the reservation is closed.
ISGLOBAL	If set the reservation applies to all resources.
OWNERPREEMPT	The owner of the reservation is given preemptor status for resources contained in the reservation.
PARENTLOCK	The reservation can only be destroyed by destroying its parent.
PREEMPTEE	The reservation is preemptible.
PLACEHOLDER	The reservation is a placeholder for resources.

Value	Description
PRSV	The reservation is a non-administrator, non-standing reservation, user-created reservation.
REQFULL	The reservation will fail if all resources requested cannot be allocated.
SCHEDULEVCRSV	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
SINGLEUSE	The reservation is automatically removed after completion of the first job to use the reserved resources.
SPACEFLEX	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
STANDINGRSV	If set, the reservation was created by a standing reservation instance.
STATIC	Makes a reservation ineligible to modified or canceled by an administrator.
SYSTEMJOB	The reservation was created by a system job.
TIMEFLEX	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
TRIGHASFIRED	The reservation has one or more triggers that have fired on it.
WASACTIVE	The reservation was previously active.
EVACVMS	Evacuate virtual machines on the node when the reservation starts.

MessageVersion1

Field Name	Type	POST	PUT	Description
author	String	No	No	The author of the message.
creationTime	Date	No	No	The time the message was created in epoch time.

Field Name	Type	POST	PUT	Description
expireTime	Date	No	No	The time the message will be deleted in epoch time.
index	Integer	No	No	The index of the message relative to other messages in Moab's memory.
message	String	No	Yes	The comment information itself.
messageCount	Integer	No	No	The number of times this message has been displayed.
priority	Double	No	No	An optional priority that can be attached to the comment.

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
architecture	String	Yes	No	Required architecture.
featureList	Set<String>	Yes	No	The list of features required for this reservation.
featureMode	String	No	No	Required feature mode.
memory	Integer	Yes	No	Required node memory, in MB.
nodeCount	Integer	No	No	Required number of nodes.
nodeIds	Set<String>	No	No	The list of node IDs required for this reservation.
os	String	Yes	No	Required Operating System.
taskCount	Integer	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
caps	Long	No	No	The current active processor-seconds in the last reported iteration.
cips	Long	No	No	The current idle processor-seconds in the last reported iteration.
taps	Long	No	No	The total active processor-seconds over the life of the reservation.
tips	Long	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
id	String	No	No	Trigger id - internal ID used by moab to track triggers
action	String	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
actionType	TriggerActionType	No	No	
blockTime	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
description	String	No	No	
eventType	TriggerEventType	No	No	

Field Name	Type	POST	PUT	Description
expireTime	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
failOffset	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
flags	Set<TriggerFlag>	No	No	
interval	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with TriggerEventType.EPOCH to create a Standing Trigger. Defaults to false
maxRetry	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
multiFire	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
name	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
objectId	String	No	No	The ID of the object which this is attached to.
objectType	String	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> vm - Virtual Machine
offset	Date	No	No	Relative time offset from event when trigger can fire.

Field Name	Type	POST	PUT	Description
period	TriggerPeriod	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
rearmTime	Date	No	No	Time between MultiFire triggers. Rearm time is enforced from the trigger event time.
requires	String	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
sets	String	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
threshold	String	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
timeout	Date	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
type	TriggerType	No	No	The type of the trigger.
unsets	String	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
CANCEL	Only apply to reservation triggers.
CHANGE_PARAM	Run changeparam (NOT PERSISTENT).
JOB_PREEMPT	Indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
MAIL	Sends an e-mail.
INTERNAL	Modifies an object internally in Moab. This can be used to set a job hold for example.
EXEC	Execute the trigger action. Typically used to run a script.
MODIFY	Can modify object that trigger is attached to.
QUERY	
RESERVE	
SUBMIT	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	

Value	Description
EPOCH	
FAIL

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
ATTACH_ERROR	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
CLEANUP	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
CHECKPOINT	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.

Value	Description
GLOBAL_VARS	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
INTERVAL	Trigger is periodic.
MULTIFIRE	Trigger can fire multiple times.
OBJECT_XML_STDIN	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
USER	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
GLOBAL_TRIGGER	The trigger will be (or was) inserted into the global trigger list.
ASYNCHRONOUS	An asynchronous trigger.
LEAVE_FILES	Do not remove stderr and stdout files.
PROBE	The trigger's stdout will be monitored.
PROBE_ALL	The trigger's stdout will be monitored.
GENERIC_SYSTEM_JOB	The trigger belongs to a generic system job (for checkpointing).
REMOVE_STD_FILES	The trigger will delete stdout/stderr files after it has been reset.
RESET_ON_MODIFY	The trigger resets if the object it is attached to is modified, even if multifire is not set.

Value	Description
SOFT_KILL	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

API version 3

VirtualMachine

This class represents a virtual machine: a software implementation of a computer that executes programs like a physical machine (i.e. like a node). A virtual machine, therefore, requires a host machine, usually called a hypervisor, which partitions its resources to be used by the one or many virtual machines it hosts.

A virtual machine needs to have a name, will typically report an OS, and have a list of operating systems that it can run.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of the virtual machine. Note: this field is not user-assigned and is generated by the database.
attributes	Map<String, JobRequirementAttribute>	No	A copy of the attributes from the tracking job associated with this VM.
description	String	No	A description of this VM.
host	DomainProxy	Yes	The physical machine (hypervisor) on which this VM is running.
hostnames	Set<String>	No	The set of host names (aliases) that refer to this VM.
ipAddress	String	No	This VM's IPv4 address.
lastMigrationDate	Date	No	The date when this VM was last migrated.
lastUpdatedDate	Date	No	The timestamp of the last moment when this VM was updated. There is no guarantee that all user modifications to a VM would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this VM.

Field Name	Type	PUT	Description
metrics	Map<String, Double>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this VM. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this VM. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. i.e. Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationCount	Integer	No	The number of times this VM has been migrated.
migrationDisabled	Boolean	Yes	True if migration is disabled for this VM, false otherwise.
name	String	No	The name of the virtual machine. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	<u>VMOperatingSystemInformation</u>	Yes	Describes the current or expected operating system image information for this VM.
requiredFeatures	Set<String>	No	The set of features required by this VM.

Field Name	Type	PUT	Description
resourceManagers	Set<NodeResourceManager>	No	The resource managers that are reporting or have previously reported this VM. Each object also contains information on the resource manager reports.
resources	Map<String, Resource>	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.
startDate	Date	No	Date that this VM was started (ready and usable).
states	NodeStateInformation	Yes	State information for this VM.
trackingJob	DomainProxy	No	The tracking job for this VM.
triggers	Set<DomainProxy>	Yes	The set of triggers associated with this VM.
variables	Map<String, Map>	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metdata which is useful to external systems in memory on this VM.
virtualContainers	Set<DomainProxy>	No	The set of virtual containers that directly (not recursively) contain this VM.

[JobRequirementAttribute](#)

Field Name	Type	PUT	Description
comparator	String	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .
value	String	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

[JobRequirementAttributeRestriction](#)

Represents a restriction for a job requirement attribute.

Value	Description
must	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
name	String	No	The name of the object.

VMOperatingSystemInformation

Describes the current or expected operating system image information for a virtual machine.

Field Name	Type	PUT	Description
image	String	No	The name of the image currently running on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageExpected	String	No	The name of the image that was requested to run on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	The last time the image of this VM was modified.
imagesAvailable	Set<String>	No	The list of image names which can be applied to this VM. In cloud mode, these correspond to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	PUT	Description
isMaster	Boolean	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.

Field Name	Type	PUT	Description
name	String	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	The state reported by this resource manager. See the State section for more details.

[NodeState](#)

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
available	Integer	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, <code>configured = overcommitFactor * real</code> .
dedicated	Integer	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
real	Integer	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
powerState	NodePower	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	Yes	The scheduling state of the Node, as reported by the resource management layer.

Field Name	Type	PUT	Description
stateExpected	NodeState	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	A timestamp recording when the sub-state was last modified.

[NodePower](#)

Represents the various options for a Node's power state.

Value	Description
NONE	
ON	
OFF	

API version 2

VirtualMachine

This class represents a virtual machine: a software implementation of a computer that executes programs like a physical machine (i.e. like a node). A virtual machine, therefore, requires a host machine, usually called a hypervisor, which partitions its resources to be used by the one or many virtual machines it hosts.

A virtual machine needs to have a name, will typically report an OS, and have a list of operating systems that it can run.

Field Name	Type	PUT	Description
id	String	No	The unique identifier of the virtual machine. Note: this field is not user-assigned and is generated by the database.
attributes	Map<String, JobRequirementAttribute>	No	A copy of the attributes from the tracking job associated with this VM.
description	String	No	A description of this VM.
host	DomainProxy	Yes	The physical machine (hypervisor) on which this VM is running.
hostnames	Set<String>	No	The set of host names (aliases) that refer to this VM.
ipAddress	String	No	This VM's IPv4 address.
lastMigrationDate	Date	No	The date when this VM was last migrated.
lastUpdatedDate	Date	No	The timestamp of the last moment when this VM was updated. There is no guarantee that all user modifications to a VM would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this VM.

Field Name	Type	PUT	Description
metrics	Map<String, Double>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this VM. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> • speed - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis. • cpuLoad - This is the CPU load on this VM. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. i.e. Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.
migrationCount	Integer	No	The number of times this VM has been migrated.
migrationDisabled	Boolean	Yes	True if migration is disabled for this VM, false otherwise.
name	String	No	The name of the virtual machine. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
operatingSystem	<u>VMOperatingSystemInformation</u>	Yes	Describes the current or expected operating system image information for this VM.
requiredFeatures	Set<String>	No	The set of features required by this VM.

Field Name	Type	PUT	Description
resourceManagers	<u>Set<NodeResourceManager></u>	No	The resource managers that are reporting or have previously reported this VM. Each object also contains information on the resource manager reports.
resources	<u>Map<String, Resource></u>	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.
startDate	Date	No	Date that this VM was started (ready and usable).
states	<u>NodeStateInformation</u>	Yes	State information for this VM.
trackingJob	<u>DomainProxy</u>	No	The tracking job for this VM.
triggers	<u>Set<DomainProxy></u>	Yes	The set of triggers associated with this VM.
variables	Map<String, Map>	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this VM.
virtualContainers	<u>Set<DomainProxy></u>	No	The set of virtual containers that directly (not recursively) contain this VM.

[JobRequirementAttribute](#)

Field Name	Type	PUT	Description
comparator	String	No	<p>The comparison operator. Valid values:</p> <ul style="list-style-type: none"> • >= - Greater than or equal to • > - Greater than • <= - Less than • < - Less than • %= - Equals • %! - Not equals • Null - Defaults to %= • = - (Deprecated) Equivalent to %=
displayValue	String	No	The display value for the required attribute.
restriction	JobRequirementAttributeRestriction	No	The restriction of this attribute. May be null, but defaults to JobRequirementAttributeRestriction.must .
value	String	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

[JobRequirementAttributeRestriction](#)

Represents a restriction for a job requirement attribute.

Value	Description
must	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
name	String	No	The name of the object.

VMOperatingSystemInformation

Describes the current or expected operating system image information for a virtual machine.

Field Name	Type	PUT	Description
image	String	No	The name of the image currently running on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageExpected	String	No	The name of the image that was requested to run on this VM. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: Image.id , Image.name .)
imageLastUpdatedDate	Date	No	The last time the image of this VM was modified.
imagesAvailable	Set<String>	No	The list of image names which can be applied to this VM. In cloud mode, these correspond to IDs or names of images in the image management API in MWS. (See also: Image.id , Image.name .)

NodeResourceManager

Field Name	Type	PUT	Description
isMaster	Boolean	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.

Field Name	Type	PUT	Description
name	String	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code>).
stateReported	NodeState	No	The state reported by this resource manager. See the State section for more details.

[NodeState](#)

This enumeration tracks the state of a node.

Value	Description
NONE	The node is set to none by the resource manager.
DOWN	The node is not available for workload.
IDLE	The node is available for workload but is not running anything.
BUSY	The node is running workload and cannot accept more.
RUNNING	The node is running workload and can accept more.
DRAINED	The node has been sent the drain request and has no workload on it.
DRAINING	The node has been sent the drain request, but still has workload on it.
FLUSH	The node is being reprovisioned.
RESERVED	The node is being reserved. This is an internal Moab state.
UNKNOWN	The state of the node is unknown.

[Resource](#)

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
available	Integer	No	The amount of this resource that is currently available for allocation to workload.
configured	Integer	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, <code>configured = overcommitFactor * real</code> .
dedicated	Integer	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
real	Integer	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
utilized	Integer	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
powerState	NodePower	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
powerStateExpected	NodePower	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the powerState attribute to NodePower.OFF), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.
state	NodeState	Yes	The scheduling state of the Node, as reported by the resource management layer.

Field Name	Type	PUT	Description
stateExpected	NodeState	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
stateLastUpdatedDate	Date	No	A timestamp recording when the state of the Node was last modified.
subState	String	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
subStateLast	String	No	The previous sub-state of the Node as reported by the resource management layer.
subStateLastUpdatedDate	Date	No	A timestamp recording when the sub-state was last modified.

Moab Accounting Manager

Overview

Moab Accounting Manager is an accounting management system that allows for usage tracking, charge accounting, and allocation enforcements for resource usage in technical computing environments. It acts somewhat like a bank in which credits are deposited into funds with constraints designating which entities may access the funds. As resources or services are utilized, funds are charged and usage recorded. It supports familiar operations such as deposits, withdrawals, transfers, and refunds. It provides balance and usage feedback to users, managers, and system administrators.

Since the accounting and billing models vary widely from organization to organization, Moab Accounting Manager has been designed to be extremely flexible, featuring customizable usage and fund configurations, and supporting a variety of tracking, charging and allocation models. Attention has been given to scalability, security, and fault tolerance.

Background

Moab Accounting Manager was originally developed as open source software called the Gold Allocation Manager at Pacific Northwest National Laboratory (PNNL) under the Department of Energy (DOE) Scalable Systems Software (SSS) SciDAC project. It has been extended and enhanced by Adaptive Computing Enterprises, Inc. (formerly Cluster Resources, Inc.) and is in production use at many commercial, government and educational sites.

Conceptual Overview

Moab Accounting Manager was designed to be used in technical computing environments for usage tracking, charge accounting and allocation enforcement. Usage tracking involves [resource usage in customizable usage records](#). Charge accounting involves calculating and recording charges for usage for invoicing or cost tracking. Allocation enforcement involves establishing limits on the use of system resources by defining separate funds having limited debit or credit balances.

In this overview, we will assume that you want to track or charge for workload resource usage. The use of resources by a job or reservation may result in a

usage record. The usage record tracks the resources that were used, whom they were used by, and (optionally) how much the usage cost.

With Moab Accounting Manager, it is possible to allocate resource credits to various parties. This is done by associating a cost for the usage by deciding on a currency unit (generically referred to as credits), whether based on a real currency such as dollars, or a reference currency such as billing units or processor seconds. Next you will define charge rates in this currency for the components of your usage (consumable resource costs, multipliers, fees, etc.). You may create pools of funds called allocations via deposits that can be debit- or credit-based, finite or infinite, and limited to a time frame in which they can be used. These allocations are deposited into logical containers called funds which have constraints that distinguish the conditions under which the funds can be used.

Moab Workload Manager interacts with Moab Accounting Manager to ensure sufficient funds and to track and charge for usage. A typical usage pattern might be as follows. When a job is submitted, a quote is obtained to see how much it will cost and to verify that you have sufficient funds. When it is time for the job to start, a lien (or hold) is placed against your funds for the amount of the requested resources. When the job ends, the appropriate fund is debited and the lien is removed. A usage record is updated with the charge amount and job usage details. The actual composition of the interactions is very flexible and will be defined by the accounting mode and interaction methods.

Features

Feature	Description
Dynamic Charging	Rather than post-processing resource usage records on a periodic basis to rectify fund balances, charging can occur incrementally throughout usage or at usage completion.
Liens	A hold (called a lien) is placed against the funds for the estimated amount of credits before the usage begins, followed by appropriate charges during and/or at the end of the usage, thereby preventing accounts from using more resources or services than were allocated to them.
Customizable Usage Records	Usage record fields can be configured by the site to track custom usage properties.
Flexible Fund Allocation	A uniquely flexible design allows resource or service credits to be allocated to arbitrary entities and purposes.

Feature	Description
Expiring Allocations	Credits may be restricted for use within a designated time period allowing sites to implement a use-it-or-lose-it policy to prevent year-end resource exhaustion and establishing an allocation cycle.
Flexible Charging	The billing system can track and charge for composite time-based or non-time-based resource or service usage, and apply flexible charge multipliers and fees.
Guaranteed Quotes	Users and resource brokers can determine ahead of time the cost of using resources or services.
Credit and Debit Allocations	Allocations feature an optional credit limit allowing support for both debit and credit models. This feature can also be used to enable overdraft protection for specific funds.
Infinite Allocations	Deposits can be made with infinite amounts or infinite credit limits when used with a supporting database.
Powerful Querying	A powerful querying and update mechanism (based on SQL queries) that facilitates flexible reporting and streamlines administrative tasks.
Nonintrusiveness	Object-level, attribute-level and correlated defaults may be established for arbitrary objects such as users, accounts and organizations. Additionally, these objects may be configured to be automatically created the first time they are seen by the resource management system. These features allow the accounting system to be used with less impact and involvement from users and administrators.
Consistency	Moab Accounting Manager has been engineered for robustness, consistency and resiliency. Complex operations are atomic and are automatically rolled back on failure.
Security	Multiple security mechanisms for strong authentication and encryption.
Role-Based Authorization	Fine-grained (instance-level) Role Based Access Controls are provided for all operations which allows users to view and manipulate only those objects permitted to them.
Dynamic Customization	Sites can create or modify record types on the fly enabling them to meet their custom accounting needs. Dynamic object creation allows sites to customize the types of accounting data they collect without modifying the code. This capability turns this system into a generalized information service. This capability is extremely powerful and can be used to manage all varieties of custom configuration data, or to function as a persistence interface for other components.

Feature	Description
Web Interface	A powerful dynamic web-based GUI is provided for easy remote access for users, managers and administrators which displays only the actions allowed by their role.
Journaling	A journaling mechanism preserves the indefinite historical state of all objects and records. This powerful mechanism allows historical bank statements to be generated, provides an undo/redo capability and allows commands to be run as if it were any arbitrary time in the past.
Event Scheduler	An event engine can be used to schedule arbitrary Moab Accounting Manager commands to run periodically or at a designated time in the future.

Interfaces

Moab Accounting Manager provides a variety of means of interaction, including command-line interfaces, graphical user interfaces, application programming interfaces, and communication protocols.

Command-Line Clients

The command-line clients provided feature rich argument sets and built-in documentation. These commands allow scripting and are the preferred way to interact with Moab Accounting Manager for basic usage and administration. Use the `--help` option for usage information or the `--man` option for a manual page on any command.

Example 5-1: Listing Users Using a Command-Line Client

```
glsuser
```

Interactive Control Program

The `goldsh` command uses a control language to issue object-oriented requests to the server and display the results. The commands may be included directly as command-line arguments or read from stdin. Use the `ShowUsage:=True` option after a valid Object Action combination for usage information on the command.

Example 5-2: Listing Users Using the goldsh Control Program

```
goldsh User Query
```

The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. Do not use this command unless you understand the syntax and the potential for unintended results.

Web-based Graphical User Interface

A powerful and easy-to-use web-based GUI permits browser access by users, managers and administrators according to their role definitions.

Example 5-3: Listing Users via the Web GUI

Click on **Manage Users** -> **List Users**

Perl API

You can access the full functionality via the Perl API. Use perldoc to obtain usage information for the Moab Accounting Manager Perl Gold modules.

Example 5-4: Listing Users Using the Perl API

```
use Gold;
my $request = new Gold::Request(object => "User", action => "Query");
my $response = $request->getResponse();
foreach my $datum ($response->getData())
{
    print $datum->toString(), "\n";
}
```

Java API

Although deprecated, the Java API may still be usable to interact with Moab Accounting Manager. The `javadoc` command can be run on the `contrib/java/gold` directory to generate documentation for the Gold java classes.

Example 5-5: Listing Users Using the Java API

```
import java.util.*;
import gold.*;
public class Test
{
    public static void main (String [] args) throws Exception
    {
        Gold.initialize();
        Request request = new Request("User", "Query");
        Response response = request.getResponse();
        Iterator dataItr = response.getData().iterator();
        while (dataItr.hasNext())
        {
            System.out.println((Datum)dataItr.next().toString());
        }
    }
}
```

SSSRMAP Wire Protocol

It is also possible to interact with Moab Accounting Manager by directly using the SSSRMAP Wire Protocol and Message Format over the network.

Documentation for these protocols can be found at [SSS Resource Management and Accounting Documentation](#).

Example 5-6: Listing Users via the SSSRMAP Wire Protocol

```
POST /SSSRMAP HTTP/1.1
Content-Type: text/xml; charset="utf-8"
Transfer-Encoding: chunked
190
<?xml version="1.0" encoding="UTF-8"?>
<Envelope>
  <Body actor="scottmo" chunking="True">
    <Request action="Query" object="User"></Request>
  </Body>
  <Signature>
    <DigestValue>azu4obZswzBt89OgATukBeLyt6Y=</DigestValue>
    <SignatureValue>YXE/C08XX3RX4PMU1bWju+5/E5M=</SignatureValue>
    <SecurityToken type="Symmetric" name="scottmo"></SecurityToken>
  </Signature>
</Envelope>
0
```

Documentation

The documentation for Moab Accounting Manager includes this Administrator Guide, release notes, built-in man pages, module documentation and online documentation.

- **Moab Accounting Manager Administrator Guide** — The Moab Accounting Manager Administrator Guide is a comprehensive manual for users and administrators of Moab Accounting Manager and includes information about features, interfaces, installation, getting started, usage, configuration and customization. The Administrator Guide can be found under the `$PREFIX/doc` directory in `.pdf` and `.html` formats. These documents are also available online.
- *Release Notes* — The Release Notes describe the primary features and fixes included in the release, along with notes to aid in migration from previous versions and can be found under the `doc` directory in the distribution tarball.
- *Command Line built-in Man Pages and Usage Synopsis* — All command-line clients support a `--man` option that provides full documentation of the command options and a `--help` option that provides a brief usage synopsis.
- *Module Perl Pod Documentation* — Documentation for Moab Accounting Manager Perl modules can be viewed by changing directory to the `$PREFIX/lib` directory and running `perldoc <modulename>`, e.g. `perldoc Gold::Request`.

- *Online Documentation* — The Moab Accounting Manager Administrator Guide can be found online at <http://www.adaptivecomputing.com/documentation>. The Gold project web page at <http://www.adaptivecomputing.com/resources/docs/gold/files/index.php> and includes the original Gold project documentation.

Initial Setup

After installation, you will need to perform certain steps to prepare Moab Accounting Manager to fulfill its desired role in your environment.

Moab Accounting Manager can be configured in a myriad of use cases. It can be used in different accounting modes such as for usage tracking, notional charging, or allocation enforcement. This chapter will walk you through some of the steps you need to take to integrate and initialize the accounting manager.

[Select an Appropriate Accounting Mode on page 2823](#)

[Follow the Setup Guide for Your Selected Accounting Mode on page 2824](#)

Integration with Moab Workload Manager and Moab Web Services

If you have not already done so, you will need to integrate with the resource management system (Moab Workload Manager) and Moab Web Services. See [Integration on page 2949](#).

Select an Appropriate Accounting Mode

Moab Accounting Manager can be configured to be used in a variety of different accounting modes. Some sites may wish to create and enforce resource usage limits through allocations. Others may want to impute a charge amount to their workload, but never deny workload based on availability of funds. Still others may not wish to calculate a charge at all, but simply record the usage details of the workload. Select the accounting mode from the following options that best matches your requirements.

- **strict-allocation** - Use this mode if you wish to strictly enforce allocation limits. Under this mode, you can prevent workload from running if the end-users do not have sufficient funds. Funds, allocations, quotes, liens, charge rates, and usage records support this mode. Before a job runs, MAM places a lien (or hold) against the user's funds to prevent overcommitment of their allocation. When a job completes, MAM removes the lien, debits the user's allocation, and records the workload usage details and charge in a usage record. This is the normal default.

- **fast-allocation** - Use this mode if you wish to debit allocations but need higher throughput by eliminating the lien and quote of strict-allocation mode. If you implement it properly through scripts, you can replace the lien and quote of strict-allocation mode with an asynchronous balance check, causing MAM to disable the accounts from further use after the first job that causes the fund to become negative. Funds, allocations, balance checks, charge rates and usage records support this mode.
- **notional-charging** - Use this mode if you wish to calculate and record charges for workload usage but not keep track of fund balances or allocation limits. Charge rates and usage records support this mode. The workload usage details and charge are recorded in a usage record.
- **usage-tracking** - Use this mode if you wish to simply record workload usage details but not to calculate a charge nor keep track of fund balances or allocation limits. Usage records support this mode.

Once you have determined the accounting mode that best matches your requirements, refer to the corresponding setup guide to prepare Moab Accounting Manager and Moab Workload Manager for your selected accounting mode. See [Follow the Setup Guide for Your Selected Accounting Mode on page 2824](#).

Follow the Setup Guide for Your Selected Accounting Mode

Once you have determined the accounting mode that best matches your requirements (see [Select an Appropriate Accounting Mode on page 2823](#)), refer to the corresponding setup guide to prepare Moab Accounting Manager and Moab Workload Manager for your selected accounting mode.

- strict-allocation - See [Strict Allocation Setup Guide on page 2824](#)
- fast-allocation - See [Fast Allocation Setup Guide on page 2834](#)
- notional-charging - See [Notional Charging Setup Guide on page 2844](#)
- usage-tracking - See [Usage Tracking Setup Guide on page 2848](#)

Strict Allocation Setup Guide

This chapter will walk you through the typical steps needed to set up Moab Workload Manager and Moab Accounting Manager to use the strict allocation accounting mode.

With the strict allocation accounting mode, you can establish rigorous limits on the use of compute resources by your various parties. This is done by associating a cost for the usage by deciding on a currency unit, generically

referred to as credits, whether based on a real currency such as dollars, or a reference currency such as billing units or processor-seconds, and then creating charge rates based on this currency. Funds are established to contain credit allocations attributed to specific accounts. Users are designated as members of the accounts. Deposits are made into funds associated with the accounts creating allocations. An allocation cycle may be established whereby allocations are considered for renewal on a regular periodic basis (such as yearly, quarterly or monthly).

Before a job is started, Moab Workload Manager will verify that the user has sufficient credits to run the job by attempting to place a hold against their funds (referred to as a lien). When a job completes, the user's funds will be debited via a charge, usage information will be recorded for the job and the lien will be removed. Users or managers can query the status of their allocations or details of their job charges and resource utilization.

You will need to be a Moab Accounting Manager System Administrator to perform many of the tasks in this chapter. It is assumed that you have already installed Moab Workload Manager and installed, bootstrapped, and started Moab Accounting Manager before performing the steps discussed in this chapter.

For testing or demo purposes, an initialization script is available that provides a similar affect to running the example commands in this chapter to minimally set up MAM for the strict-allocation accounting mode with a small amount of dummy sample data. It will not perform the Moab configuration steps described in this chapter. It can be cleaned up by running the `hpc-cleanup.sh` script.

```
$ ./hpc-strict-allocation.sh
```

Set the Strict Allocation Accounting Mode

Set the `AMCFG[mam] MODE` parameter to `strict-allocation` in `moab.cfg` and set the `accounting.mode` parameter to `strict-allocation` in both the `goldd.conf` and `gold.conf` files. Since strict allocation is the default accounting mode in both Moab Workload Manager and Moab Accounting Manager, it may not be necessary to do anything here unless you were previously using a different accounting mode.

Example 6-1: Setting the Accounting Mode to strict-allocation

`AMCFG[] MODE` parameter must be set in the Moab server configuration file (`moab.cfg`). After editing the `moab.cfg` file, you will need to restart `moab`.

```
# vi /opt/moab/etc/moab.cfg
AMCFG[mam] MODE=strict-allocation

# mschedctl -R
```

The `accounting.mode` parameter must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). After editing the `goldd.conf` file, you will need to restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
accounting.mode = strict-allocation

$ vi /opt/mam/etc/gold.conf
accounting.mode = strict-allocation

$ goldd -r
```

Decide on a Currency and Set the Currency Precision

Since we will be calculating charges, we will need to decide which currency unit a MAM credit represents and sets the currency precision accordingly. For this example we will define a currency in which one credit represents the value of using one processor core for one hour. We will assume for simplicity that a processor-hour on one machine will have the same value as a processor-hour on another machine. Charge rates will be specified relative to this currency unit. Monetary transactions such as deposits and charges will be specified in terms of this currency. Since we want to be able to track and account for short jobs, we will specify a currency precision of two so that our currency credits will be represented as a floating point number with two decimal places. If instead we were to have chosen to use processor-seconds as the currency base, we would want to set the `currency.precision` value to zero since processor seconds can easily be represented as an integer with no decimal places. If we were to have chosen to use dollars as the currency base, we would have set the `currency.precision` value to two.

Example 6-2: Setting the Currency Precision to Two

The currency precision value must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). It must also be set in the GUI configuration file (`goldg.conf`) if you will be using the web GUI. If you make changes in `goldd.conf`, you must restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
currency.precision = 2

$ vi /opt/mam/etc/gold.conf
currency.precision = 2

$ goldd -r
```

Define Charge Rates

Since we are charging, we must establish the charge rates for the usage. In our example, we will define a charge rate that charges 1 credit for each processor-

hour utilized by the job. See [Managing Charge Rates on page 2905](#) for more detailed information on setting up charge rates.

Example 6-3: Define a Charge Rate for Processors

```
$ gmkrate -n Processors -z 1/h -d "1 credit per processor-hour"
Successfully created 1 charge rate

$ glsrate
```

Name	Value	Amount	Description
Processors	1/h	1	credit per processor-hour

Define Accounts

Next we will define some accounts and assign users to the accounts. We will also associated each account with an organization so that usage reports can be generated for the organization level as well as the account and user level. We will create accounts for biology, chemistry, and film and assign them some users. The biology and chemistry account will be associated with the sciences organization while the film account will be associated with the arts organization. See [Managing Accounts on page 2855](#) for more information on setting up accounts.

Example 6-4: Define the Biology, Chemistry, and Film Accounts

```
$ gmkaccount -a biology -o sciences -u amy,bob -d "Biology Department"
Successfully created 1 account

$ gmkaccount -a chemistry -o sciences -u amy,dave -d "Chemistry Department"
Successfully created 1 account

$ gmkaccount -a film -o arts -u bob,dave -d "Film Department"
Successfully created 1 account

$ glsaccount
```

Name	Active	Users	Organization	Description
biology	True	amy, bob	sciences	Biology Department
chemistry	True	amy, dave	sciences	Chemistry Department
film	True	bob, dave	arts	Film Department

Create Funds

The next task will be to create the funds which will hold the allocated credits. A fund is much like a numbered bank account, where credits can be deposited and are defined by constraints that distinguish who or what can use the contained credits and for what purposes. In this example, we will create a fund for each of the three accounts. The reason that funds are defined separately from accounts is that it is possible to create multiple funds for the same account. For example, you might have a fund that can be used for the chemistry account only when running the red cluster, and another fund that is

used for the chemistry account when using a certain quality of service. See [Managing funds on page 2865](#) for more detailed information on setting up funds.

In this example, we will assume that we want to establish a periodic allocation cycle with predesignated allocation amounts being deposited on a quarterly schedule. In order to facilitate this, we will associate a default deposit amount with the science funds. For the biology fund, we will configure it to make a resetting deposit for 5000 credits for each period. The chemistry fund is going to be disabled at the end of the allocation period. The film account will remain unaffected by allocation renewals. See [Managing Allocations on page 2877](#) for more information on periodic allocations.

Example 6-5: Create a Fund for Each of the Three Accounts

```
$ gmkfund -a biology -n "biology" --default-deposit 5000
Successfully created 1 fund with id 1 and 1 constraint

$ gmkfund -a chemistry -n "chemistry" --default-deposit 0
Successfully created 1 fund with id 2 and 1 constraint

$ gmkfund -a film -n "film"
Successfully created 1 fund with id 3 and 1 constraint

$ glsfund
```

ID	Name	Constraints	Allocated	Balance	DefaultDeposit	Description
1	biology	Account=biology	0.00	0.00	5000.00	
2	chemistry	Account=chemistry	0.00	0.00	0.00	
3	film	Account=film	0.00	0.00		

Make Deposits

Now we need to allocate credits to these funds by making deposits to them. An allocation has a start and end time associated with it declaring the time frame in which it can be used (defaulting to a start time of the present and an end time of infinity). It can also have a credit limit which defines the extent to which the allocation is allowed to go negative. Allocations can be reset on a periodic basis or future allocations with different time frames can be pre-created within a fund to establish an allocation cycle and set expectations for credit expenditure. See [Managing Allocations on page 2877](#) and [Making Deposits on page 2868](#) for additional information.

In this example, we will allocate 5000 and 3000 credits to the biology and chemistry accounts respectively. The film account will be given a credit limit of 2000 credits which allows them to charge up to 2000 credits before rectifying their fund. When making a deposit we must specify the fund we are depositing into unless the fund can be unambiguously determined by its constraint references (i.e. there is only a single fund associated with the account biology). In the next example, we will utilize the fund's deposit amount in the first deposit, specify the amount explicitly in the second deposit, and establish a credit allocation in the third deposit.

Example 6-6: Making Deposits

```
$ gdeposit -a biology
Successfully deposited 5000.00 credits into fund 1
Successfully created 1 allocation

$ gdeposit -z 3000 -a chemistry
Successfully deposited 3000.00 credits into fund 2
Successfully created 1 allocation

$ gdeposit -L 2000 -a film
No credits were deposited into fund 3
Successfully created 1 allocation
```

Let's examine the allocations we just created and its effect on the funds.

```
$ glsalloc

Id Fund StartTime      EndTime  InitialDeposit Allocated CreditLimit Remaining
PercentUsed
-----
1  1    2015-08-09 18:18:56 Infinity    5000.00   5000.00      0.00   5000.00
0.00
2  2    2015-08-09 18:18:56 Infinity    3000.00   3000.00      0.00   3000.00
0.00
3  3    2015-08-09 18:18:57 Infinity     0.00     0.00    2000.00     0.00
0.00

$ glsfund

Id Name      Constraints      Allocated Balance DefaultDeposit Description
-----
1  biology   Account=biology    5000.00 5000.00      5000.00
2  chemistry Account=chemistry   3000.00 3000.00       0.00
3  film      Account=film        0.00 0.00
```

Check the Balance

We can verify the resulting balance (see [Querying the Balance on page 2870](#)).

Example 6-7: Let's Look at Amy's Balance

```
$ gbalance -u amy

Id Name      Balance CreditLimit Available
-----
1  biology   5000.00      0.00   5000.00
1  chemistry 3000.00      0.00   3000.00
```

Automate Allocation Renewal

To facilitate the automatic renewal of our allocations, we will create a repeating event that resets all funds (see [Creating Events on page 2913](#)) at the

beginning of each new quarter.

Example 6-8: Create an Automatic Allocation Renewal Event

```
$ gmkevent --fire-command "Fund Reset" -s "2016-01-01" --rearm-period "3 months^"
Successfully created 1 event

$ glsevent
```

Id	FireCommand	FireTime	ArmTime	RearmPeriod	EndTime	Notify
RearmOnFailure	FailureCommand	CatchUp	CreationTime	Description		
1	Fund Reset	2016-01-01	2015-08-09 18:21:28	3 months^		False
		True	2015-08-09 18:21:28			

Run a Job

Let's submit a job and examine the effects on the accounting system.

Example 6-9: Submit a Job

```
$ echo sleep 300 | msub -A chemistry -l procs=12,walltime=600
```

The Usage Lien

When a job starts, Moab Workload Manager typically creates a lien (or hold) against the appropriate allocations based on the estimated duration of the job. We will examine the effect of a running job on the accounting system (see [Managing Liens on page 2883](#)).

Example 6-10: Examine the Effect of a Running Job on the Accounting System

```
$ glslien
```

Id	Instance	Amount	StartTime	EndTime	Duration	UsageRecord	Funds
Description							
1	74	2.00	2015-08-09 18:22:42	2015-08-09 18:22:42	600	1	2

This lien will decrease our available balance by the amount reserved.

```
$ gbalance -u amy -a chemistry
```

Id	Name	Balance	Reserved	Effective	CreditLimit	Available
2	chemistry	3000.00	2.00	2998.00	0.00	2998.00

The actual allocation has not changed.

```
$ glsalloc -a chemistry
```

Id	Fund	Active	StartTime	EndTime	Amount	CreditLimit	Deposited
2	2	True	2015-08-09 18:18:56	Infinity	3000.00	0.00	3000.00

Note that the lien resulted in the initial creation of a usage record for the job with Stage Reserve.

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	EndTime
Description									
1	Job	74	0.00	Reserve	amy	faculty	chemistry	sciences	batch normal
colony	1	12				0			

The Usage Charge

After a job completes, any associated liens are removed and a charge is issued against the appropriate allocations based on the resources and actual wallclock time used by the job. An allocation is debited and the usage record is modified with the charge and usage information.

Example 6-11: Examine the Effect of a Completed Job on the Accounting System

Your allocation will now have gone down by the amount of the charge.

```
$ glsalloc -u amy -a chemistry
```

Id	Fund	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
2	2	2015-08-09 18:18:56	Infinity	3000.00	3000.00	0.00	2999.00
		0.03					

However, your balance actually goes up (because the lien that was removed was larger than the actual charge).

```
$ gbalance -u amy -a chemistry
```

Id	Name	Balance	Reserved	Effective	CreditLimit	Available
2	chemistry	2999.00	0.00	2999.00	0.00	2999.00

A usage record for the job was updated as a side-effect of the charge (see [Querying Usage Records on page 2892](#)).

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	EndTime
Description									
1	Job	74	1.00	Charge	amy	faculty	chemistry	sciences	batch normal
colony	1	12				300	2015-08-09 18:22:42	2015-08-09 18:27:42	

Usage Refund

Now, we will illustrate the effect of issuing a refund for the user's job. For more information, see [Issuing Usage Refunds on page 2896](#).

Example 6-12: Refund the Job

```
$ grefund -J 74
```

```
Successfully refunded 1.00 credits to usage record 1 for instance 74
```

Our balance is back as it was before the job ran.

```
$ gbalance -u amy -a chemistry
```

Id	Name	Balance	Reserved	Effective	CreditLimit	Available
2	chemistry	3000.00	0.00	3000.00	0.00	3000.00

The allocation, of course, is likewise restored.

```
$ glsalloc -u amy -a chemistry
```

Id	Fund	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
PercentUsed							
2	2	2015-08-09 18:18:56	Infinity	3000.00	3000.00	0.00	3000.00
0.00							

Notice that the usage charge is now zero because the job has been fully refunded.

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	EndTime
Description									
1	Job	74	0.00	Charge	amy	faculty	chemistry	sciences	batch normal
colony	1	12				300	2015-08-09 18:22:42	2015-08-09 18:27:42	

List Transactions

Let's list the transactions relating to this job (see [Querying Transactions on page 2911](#)).

Example 6-13: Listing Transaction Details for This Job

```
$ glstrans -J 74 --full
```

ID	Object	Action	Actor	Key Child Instance Count	Amount	Delta	Balance
Remaining User Account	Machine Fund Allocation	UsageRecord Duration	Description

Fast Allocation Setup Guide

This chapter will walk you through the typical steps needed to set up Moab Workload Manager and Moab Accounting Manager to use the fast allocation accounting mode.

If you want to enforce allocations by debiting funds in Moab Accounting Manager, but need higher throughput by eliminating the lien and quote operations of the strict allocation accounting mode, you can use the fast allocation accounting mode. With the fast allocation accounting mode, Moab Workload Manager checks a cached account balance, and jobs or reservations may be prevented from starting or continuing after the balance has become zero or negative. As with the strict allocation accounting mode, you establish limits on the use of compute resources by your various parties. This is done by associating a cost for the usage by deciding on a currency unit, generically referred to as credits, whether based on a real currency such as dollars, or a reference currency such as billing units or processor-seconds, and then creating charge rates based on this currency. Funds are established to contain credit allocations attributed to specific accounts. Users are designated as members of the accounts. Deposits are made into funds associated with the accounts creating allocations. An allocation cycle may be established whereby allocations are considered for renewal on a regular periodic basis (such as yearly, quarterly or monthly).

Before a job is started, Moab Workload Manager will check its internal cache to verify that the user has a positive account balance. When a job completes, the user's funds will be debited via a charge, usage information will be recorded for the job and Moab's account balance cache is updated. Since Moab Accounting Manager is not contacted at job submission or start time in order to verify account membership, additional configuration is needed in Moab to synchronize account information with Moab Accounting Manager. Additionally, since the cache in Moab Workload Manager supports only account based funds, when using the fast allocation accounting mode, funds having no constraints or having non-account constraints should not be used.

You will need to be a Moab Accounting Manager System Administrator to perform many of the tasks in this chapter. It is assumed that you have already installed Moab Workload Manager and installed, bootstrapped, and started Moab Accounting Manager before performing the steps discussed in this chapter.

For testing or demo purposes, an initialization script is available that provides a similar affect to running the example commands in this chapter to minimally set up MAM for the fast-allocation accounting mode with a small amount of dummy sample data. It will not perform the Moab configuration steps described in this chapter. It can be cleaned up by running the `hpc-cleanup.sh` script.

```
$ ./hpc-fast-allocation.sh
```

Set the Fast Allocation Accounting Mode

Set the `AMCFG[mam] MODE` parameter to `fast-allocation` in `moab.cfg` and set the `accounting.mode` parameter to `fast-allocation` in both the `goldd.conf` and `gold.conf` files.

Example 6-15: Setting the Accounting Mode to fast-allocation

`AMCFG[] MODE` parameter must be set in the Moab server configuration file (`moab.cfg`). After editing the `moab.cfg` file, you will need to restart `moab`.

```
# vi /opt/moab/etc/moab.cfg
AMCFG[mam] MODE=fast-allocation

# mschedctl -R
```

The `accounting.mode` parameter must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). After editing the `goldd.conf` file, you will need to restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
accounting.mode = fast-allocation

$ vi /opt/mam/etc/gold.conf
accounting.mode = fast-allocation

$ goldd -r
```

Additional Moab Configuration

Since Moab will be checking an internal account balance cache when starting jobs and reservations instead of contacting Moab Accounting Manager, we need to periodically update Moab Workload Manager with account information from Moab Accounting Manager so that Moab can correctly apply default accounts and enforce account memberships. Additionally, it is beneficial to poll the account balances periodically so that external actions such as new deposits, transfers, etc. will be reflected properly in Moab's account balance cache.

Example 6-16: Configuring Moab to Synchronize Account Information

We will set `AMCFG[] CREATECRED=TRUE` in order to enable Moab to query accounts, users, user membership in accounts, and users' default accounts from Moab Accounting Manager and define them in Moab. We will set the `AMCFG[] REFRESHPERIOD` parameter to the interval that we want Moab to update these credential updates as well as its account balance cache. We will also set the `ENFORCEACCOUNTACCESS` parameter to `TRUE` in order to tell Moab to restrict users to use only accounts to which they belong.

```
# vi /opt/moab/etc/moab.cfg

AMCFG[mam] CREATECRED=TRUE
AMCFG[mam] REFRESHPERIOD=2:00:00
ENFORCEACCOUNTACCESS TRUE

# mschedctl -R
```

Decide on a Currency and Set the Currency Precision

Since we will be calculating charges, we will need to decide what currency unit a MAM credit represents and set the currency precision accordingly. For this example we will define a currency in which one credit represents the value of using one processor core for one hour. We will assume for simplicity that a processor-hour on one machine will have the same value as a processor-hour on another machine. Charge rates will be specified relative to this currency unit. Monetary transactions such as deposits and charges will be specified in terms of this currency. Since we want to be able to track and account for short jobs, we will specify a currency precision of two so that our currency credits will be represented as a floating point number with two decimal places. If instead we were to have chosen to use processor-seconds as the currency base, we would want to set the `currency.precision` value to zero since processor seconds

can easily be represented as an integer with no decimal places. If we were to have chosen to use dollars as the currency base, we would have set the `currency.precision` value to two.

Example 6-17: Setting the Currency Precision to Two

The currency precision value must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). It must also be set in the GUI configuration file (`goldg.conf`) if you will be using the web GUI. If you make changes in `goldd.conf`, you must restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
currency.precision = 2
$ vi /opt/mam/etc/gold.conf
currency.precision = 2
$ goldd -r
```

Define Charge Rates

Since we are charging, we must establish the charge rates for the usage. In our example, we will define a charge rate that charges 1 credit for each processor-hour utilized by the job. See [Managing Charge Rates on page 2905](#) for more detailed information on setting up charge rates.

Example 6-18: Define a Charge Rate for Processors

```
$ gmkrate -n Processors -z 1/h -d "1 credit per processor-hour"
Successfully created 1 charge rate
$ glsrate
```

Name	Value	Amount	Description
Processors	1/h	1	credit per processor-hour

Define Accounts

Next we will define some accounts and assign users to the accounts. We will also associate each account with an organization so that usage reports can be generated for the organization level as well as the account and user level. We will create accounts for biology, chemistry and film and assign them some users. The biology and chemistry account will be associated with the sciences organization while the film account will be associated with the arts organization. See [Managing Accounts on page 2855](#) for more information on setting up accounts.

Example 6-19: Define the Biology, Chemistry, and Film Accounts

```
$ gmkaccount -a biology -o sciences -u amy,bob -d "Biology Department"
Successfully created 1 account

$ gmkaccount -a chemistry -o sciences -u amy,dave -d "Chemistry Department"
Successfully created 1 account

$ gmkaccount -a film -o arts -u bob,dave -d "Film Department"
Successfully created 1 account

$ glsaccount
```

Name	Active	Users	Organization	Description
biology	True	amy,bob	sciences	Biology Department
chemistry	True	amy,dave	sciences	Chemistry Department
film	True	bob,dave	arts	Film Department

Create Funds

The next task will be to create the funds which will hold the allocated credits. A fund is much like a numbered bank account, where credits can be deposited and are defined by constraints that distinguish who or what can use the contained credits and for what purposes. In this example, we will create a fund for each of the three accounts. The reason that funds are defined separately from accounts is that it is possible to create multiple funds for the same account. For example, you might have a fund that can be used for the chemistry account only when running the red cluster, and another fund that is used for the chemistry account when using a certain quality of service. See [Managing funds on page 2865](#) for more detailed information on setting up funds.

In this example, we will assume that we want to establish a periodic allocation cycle with predesignated allocation amounts being deposited on a quarterly schedule. In order to facilitate this, we will associate a default deposit amount with the science funds. For the biology fund, we will configure it to make a resetting deposit of 5000 credits for each period. The chemistry fund is going to be disabled at the end of the allocation period. The film account will remain unaffected by allocation renewals. See [Managing Allocations on page 2877](#) for more information on periodic allocations.

Example 6-20: Create a Fund for Each of the Three Accounts

```
$ gmkgfund -a biology -n "biology" --default-deposit 5000
Successfully created 1 fund with id 1 and 1 constraint

$ gmkgfund -a chemistry -n "chemistry" --default-deposit 0
Successfully created 1 fund with id 2 and 1 constraint

$ gmkgfund -a film -n "film"
Successfully created 1 fund with id 3 and 1 constraint

$ glsfund
```

Id	Name	Constraints	Allocated	Balance	DefaultDeposit	Description
1	biology	Account=biology	0.00	0.00	5000.00	
2	chemistry	Account=chemistry	0.00	0.00	0.00	
3	film	Account=film	0.00	0.00		

Make Deposits

Now we need to allocate credits to these funds by making deposits to them. An allocation has a start and end time associated with it declaring the time frame in which it can be used (defaulting to a start time of the present and an end time of infinity). It can also have a credit limit which defines the extent to which the allocation is allowed to go negative. Allocations can be reset on a periodic basis or future allocations with different time frames can be precreated within a fund to establish an allocation cycle and set expectations for credit expenditure. See [Managing Allocations on page 2877](#) and [Making Deposits on page 2868](#) for additional information.

In this example, we will allocate 5000 and 3000 credits to the biology and chemistry accounts respectively. The film account will be given a credit limit of 2000 credits which allows them to charge up to 2000 credits before settling their fund. When making a deposit we must specify the fund we are depositing into unless the fund can be unambiguously determined by its constraint references (i.e. there is only a single fund associated with the account biology). In the next example, we will utilize the fund's default deposit amount in the first deposit, specify the amount explicitly in the second deposit and establish a credit allocation in the third deposit.

Example 6-21: Making Deposits

```
$ gdeposit -a biology
Successfully deposited 5000.00 credits into fund 1
Successfully created 1 allocation

$ gdeposit -z 3000 -a chemistry
Successfully deposited 3000.00 credits into fund 2
Successfully created 1 allocation

$ gdeposit -L 2000 -a film
No credits were deposited into fund 3
Successfully created 1 allocation
```

Let's examine the allocations we just created and its effect on the funds.

```
$ glsalloc
```

	Id	Fund	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
			PercentUsed					
1	1		2015-08-09 18:18:56	Infinity	5000.00	5000.00	0.00	5000.00
			0.00					
2	2		2015-08-09 18:18:56	Infinity	3000.00	3000.00	0.00	3000.00
			0.00					
3	3		2015-08-09 18:18:57	Infinity	0.00	0.00	2000.00	0.00
			0.00					

```
$ glsfund
```

	Id	Name	Constraints	Allocated	Balance	DefaultDeposit	Description
1	biology	Account=biology	5000.00	5000.00	5000.00		
2	chemistry	Account=chemistry	3000.00	3000.00	0.00		
3	film	Account=film	0.00	0.00			

Check the Balance

We can verify the resulting balance (see [Querying the Balance on page 2870](#)).

Example 6-22: Let's Look at Amy's Balance

```
$ gbalance -u amy
```

	Id	Name	Balance	CreditLimit	Available
1	biology	5000.00	0.00	5000.00	
1	chemistry	3000.00	0.00	3000.00	

Automate Allocation Renewal

To facilitate the automatic renewal of our allocations, we will create a repeating event that resets all funds (see [Creating Events on page 2913](#)) at the beginning of each new quarter.

Example 6-23: Create an Automatic Allocation Renewal Event

```
$ gmkevent --fire-command "Fund Reset" -s "2016-01-01" --rearm-period "3 months^"
Successfully created 1 event
```

```
$ glsevent
```

	Id	FireCommand	FireTime	ArmTime	RearmPeriod	EndTime	Notify
		RearmOnFailure	FailureCommand	CatchUp	CreationTime	Description	
1	Fund Reset	2016-01-01	2015-08-09 18:21:28	3 months^		False	
		True	2015-08-09 18:21:28				

Run a Job

Now, let's submit a job and examine the effects on the accounting system.

Example 6-24: Submit a Job

```
$ echo sleep 300 | msub -A chemistry -l procs=12,walltime=600
```

The Usage Charge

After a job completes, a charge is issued against the appropriate allocations based on the resources and actual wallclock time used by the job. An allocation is debited and the usage record is modified with the charge and usage information.

Example 6-25: Examine the Effect of a Completed Job on the Accounting System

Your allocation and balance will have gone down by the amount of the charge.

```
$ glsalloc -u amy -a chemistry
```

Id	Fund	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
2	2	2015-08-09 18:18:56	Infinity	3000.00	3000.00	0.00	2999.00

```
$ gbalance -u amy -a chemistry
```

Id	Name	Balance	CreditLimit	Available
2	chemistry	2999.00	0.00	2999.00

The usage record for the job was updated as a side-effect of the charge (see [Querying Usage Records on page 2892](#)).

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
1	Job	74	1.00	Charge	amy	faculty	chemistry	sciences	batch normal
	colony	1	12				300	2015-08-09 18:22:42	2015-08-09 18:27:42

Usage Refund

Now, we will illustrate the effect of issuing a refund for the user's job (see [Issuing Usage Refunds on page 2896](#)).

Example 6-26: Refund the Job

```
$ grefund -J 74
```

```
Successfully refunded 1.00 credits to usage record 1 for instance 74
```

Our balance is back as it was before the job ran.

```
$ gbalance -u amy -a chemistry
```

Id	Name	Balance	CreditLimit	Available
2	chemistry	3000.00	0.00	3000.00

The allocation, of course, is likewise restored.

```
$ glsalloc -u amy -a chemistry
```

Id	Fund	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
		PercentUsed					
2	2	2015-08-09 18:18:56	Infinity	3000.00	3000.00	0.00	3000.00
		0.00					

Notice that the usage charge is now zero because the job has been fully refunded.

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
		QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration
		EndTime	Description						
1	Job	74	0.00	Charge	amy	faculty	chemistry	sciences	batch normal
	colony	1	12				300	2015-08-09 18:22:42	2015-08-
		09 18:27:42							

List Transactions

Let's list the transactions relating to this job (see [Querying Transactions on page 2911](#)).

Example 6-27: Listing Transaction Details for This Job

```
$ glstrans -J 74 --full

Id   Object      Action  Actor   Key Child Instance Count Amount Delta Balance
Remaining User Account  Machine Fund Allocation UsageRecord Duration Description

Notional Charging Setup Guide

This chapter will walk you through the typical steps needed to set up Moab Workload Manager and Moab Accounting Manager to use the notional charging accounting mode.

Some sites may want to use Moab Accounting Manager to calculate and record charges, but not to impose allocation limits or prevent any workload from running. With notional charging, charge rates will be used to calculate a cost for using resources, but there is no need to make deposits, debit funds or keep track of allocation limits. Although it would be possible to set up accounts and assign users to specific accounts, this chapter will assume that account membership is not going to be enforced. If you would prefer to enforce account membership, you can continue to use the notional charging accounting setup as described in this chapter, but you will need to additionally define accounts and account memberships as well as configure Moab to synchronize account information from Moab Accounting Manager as described in the [Fast Allocation Setup Guide](#). Liens, balance queries and quotes are not needed. Our main task is to define charge rates.

At the end of a job, Moab Workload Manager will send usage information to the accounting manager. Moab Accounting Manager will calculate a charge and store this with the job usage record.

 You will need to be a Moab Accounting Manager System Administrator to perform many of the tasks in this chapter. It is assumed that you have already installed Moab Workload Manager and installed, bootstrapped, and started Moab Accounting Manager before performing the steps discussed in this chapter.

 For testing or demo purposes, an initialization script is available that provides a similar affect to running the example commands in this chapter to minimally set up MAM for the notional-charging accounting mode with a small amount of dummy sample data. It will not perform the Moab configuration steps described in this chapter. It can be cleaned up by running the `hpc-cleanup.sh` script.

```
$ ./hpc-notional-charging.sh
```

Set the Notional Charging Accounting Mode

Set the `AMCFG[mam] MODE` parameter to `notional-charging` in `moab.cfg` and set the `accounting.mode` parameter to `notional-charging` in both the `goldd.conf` and `gold.conf` files.

Example 6-29: Setting the Accounting Mode to notional-charging

`AMCFG[] MODE` parameter must be set in the Moab server configuration file (`moab.cfg`). After editing the `moab.cfg` file, you will need to restart `moab`.

```
# vi /opt/moab/etc/moab.cfg
AMCFG[mam] MODE=notional-charging

# mschedctl -R
```

The `accounting.mode` parameter must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). After editing the `goldd.conf` file, you will need to restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
accounting.mode = notional-charging

$ vi /opt/mam/etc/gold.conf
accounting.mode = notional-charging

$ goldd -r
```

Decide on a Currency and Set the Currency Precision

Since we will be calculating charges, we will need to decide what currency unit a MAM credit represents and set the currency precision accordingly. For this example we will define a currency in which one credit represents the value of using one processor core for one hour. We will assume for simplicity that a processor-hour on one machine will have the same value as a processor-hour on another machine. Charge rates will be specified relative to this currency unit. Monetary transactions such as deposits and charges will be specified in terms of this currency. Since we want to be able to track and account for short jobs, we will specify a currency precision of two so that our currency credits will be represented as a floating point number with two decimal places. If instead we were to have chosen to use processor-seconds as the currency base, we would want to set the currency.precision value to zero since processor seconds can easily be represented as an integer with no decimal places. If we were to have chosen to use dollars as the currency base, we would have set the currency.precision value to two.

Example 6-30: Setting the Currency Precision to Two

The currency precision value must be set in the server and client configuration files (`goldd.conf` and `gold.conf`). It must also be set in the GUI configuration file (`goldg.conf`) if you will be using the web GUI. If you make changes in `goldd.conf`, you must restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
currency.precision = 2
$ vi /opt/mam/etc/gold.conf
currency.precision = 2
$ goldd -r
```

Define Charge Rates

Since we are charging, we must establish the charge rates for the usage. In our example, we will define a charge rate that charges 1 credit for each processor-hour utilized by the job. See [Managing Charge Rates on page 2905](#) for more detailed information on setting up charge rates.

Example 6-31: Define a Charge Rate for Processors

```
$ gmkrate -n Processors -z 1/h -d "1 credit per processor-hour"
Successfully created 1 charge rate
$ glsrate
```

Name	Value	Amount	Description
Processors	1/h		1 credit per processor-hour

Run a Job

Now, let's submit a job and examine the effects on the accounting system.

Example 6-32: Submit a Job

```
$ echo sleep 300 | msub -A chemistry -l procs=12,walltime=600
```

The Usage Charge

After a job completes, a usage record is generated with the charge and resource usage information.

Example 6-33: List the Usage and Charge for Our Job

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	
EndTime	Description								
1	Job	74	1.00	Charge	amy	faculty	chemistry	sciences	batch normal
colony 1		12					300	2015-08-09 18:22:42	2015-08-
09 18:27:42									

Usage Refund

Now, we will illustrate the effect of issuing a refund for the user's job (see [Issuing Usage Refunds on page 2896](#)).

Example 6-34: Refund the Job

```
$ grefund -J 74
```

Successfully refunded 1.00 credits to usage record 1 for instance 74

Notice that the usage charge is now zero because the job has been fully refunded.

```
$ glsusage
```

Id	Type	Instance	Charge	Stage	User	Group	Account	Organization	Class
QualityOfService	Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	
EndTime	Description

```

Usage Tracking Setup Guide

This chapter will walk you through the typical steps needed to set up Moab Workload Manager and Moab Accounting Manager to use the usage tracking accounting mode.

When used solely for usage tracking, Moab Accounting Manager logs resource usage in usage records. This usage can be queried to report what resources were used when and by whom. In this case, there is no need for charge rates, funds, allocations, liens or quotes. There is no need to define account membership.

At the end of a job, Moab Workload Manager will send usage information to the accounting manager. Moab Accounting Manager will store this information in a job usage record.

You will need to be a Moab Accounting Manager System Administrator to perform many of the tasks in this chapter. It is assumed that you have already installed Moab Workload Manager and installed, bootstrapped, and started Moab Accounting Manager before performing the steps discussed in this chapter.

For testing or demo purposes, an initialization script is available that provides a similar affect to running the example commands in this chapter to minimally set up MAM for the usage-tracking accounting mode with a small amount of dummy sample data. It will not perform the Moab configuration steps described in this chapter. It can be cleaned up by running the `hpc-cleanup.sh` script.

```
$ ./hpc-usage-tracking.sh
```

Set the Usage Tracking Accounting Mode

Set the `AMCFG[mam] MODE` parameter to `usage-tracking` in `moab.cfg` and set the `accounting.mode` parameter to `usage-tracking` in both the `goldd.conf` and `gold.conf` files.

Example 6-36: Setting the Accounting Mode to usage-tracking.

`AMCFG[] MODE` parameter must be set in the Moab server configuration file (`moab.cfg`). After editing the `moab.cfg` file, you will need to restart `moab`.

```
# vi /opt/moab/etc/moab.cfg
AMCFG[mam] MODE=usage-tracking

# mschedctl -R
```

The `accounting.mode` parameter must be set in the server configuration files (`goldd.conf`). After editing the `goldd.conf` file, you will need to restart `goldd`.

```
$ vi /opt/mam/etc/goldd.conf
accounting.mode = usage-tracking

$ goldd -r
```

Run a Job

Now, let's submit a job and examine the effects on the accounting system.

Example 6-37: Submit a Job

```
$ echo sleep 300 | msub -A chemistry -l procs=12,walltime=600
```

Query Job Usage Information

After a job completes, usage information is recorded. Let's examine the usage record that was created (see [Querying Usage Records on page 2892](#)).

Example 6-38: List Usage Records

```
$ glsusage
```

Id	Type	Instance	Stage	User	Group	Account	Organization	Class	QualityOfService
Machine	Nodes	Processors	CPUTime	Memory	Disk	Duration	StartTime	EndTime	
Description									
1	Job	74		Charge	amy	faculty	chemistry sciences	batch	normal
colony	1	12				300	2015-09-17 15:42:43	2015-09-17	
15:47:22									

Managing Users

A user is a person authorized to use a resource or service. Default user properties include the common name, phone number, email address, default account, and description for that person. A user can be created, queried, modified, and deleted. By default, a standard user may only query his or her own user record.

User queries allow the specification of filter options which narrow down the users that will be returned to those belonging to the specified account.

Creating Users

To create a new user, use the command `gmksuser`:

```
gmksuser [-A | -I] [-n common_name] [-F phone_number] [-E email_address] [-a default_account] [-d description] [-X, --extension property=value]... [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] {[-u] user_name}
```

Example 7-1: Creating a user

```
$ gmksuser -n "Smith, Robert F." -E "bob@bank.com" -F "(509) 555-1234" bob
Successfully created 1 user
```

Related Topics

[gmksuser on page 3147](#)

Querying Users

To display user information, use the command `glsuser`:

```
glsuser [-A | -I] [-X, --extension property=value]... [-a account_name] [--full] [--show attribute_name,...] [--long] [--wide] [--format csv|standard] [--debug] [--site site_name] [--help] [--man] [--quiet] [--version] {[-u] user_pattern}
```

Example 7-2: Listing standard info about active users

```
$ glsuser -A
```

Name	Active	CommonName	PhoneNumber	EmailAddress
	DefaultAccount	Description		
amy	True	Wilkes, Amy	(509) 555-8765	amy@bank.com
bob	True	Smith, Robert F.	(509) 555-1234	bob@bank.com

Example 7-3: Displaying bob's phone number

```
$ glsuser -show PhoneNumber bob -quiet
```

(509) 555-1234

Example 7-4: Listing amy's accounts

```
$ glsuser -show Accounts amy -l -q
```

chemistry
biology

Example 7-5: Listing all users belonging to the chemistry account

```
$ glsuser -show Name -a chemistry -q
```

amy
dave

Related Topics

[glsuser on page 3107](#)

Modifying Users

To modify a user, use the command `gchuser`:

```
gchuser [-A | -I] [-n common_name] [-F phone_number] [-E email_address] [-a default_account] [-d description] [-X, --extension property=value]... [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] {[-u] user_name}
```

Example 7-6: Deactivating a user

```
$ gchuser -I bob
```

Successfully modified 1 user

i In order for user validity enforcement to occur, the Values property for the UsageRecord User attribute must be set to '@User'.

```
$ goldsh Attribute Modify Object==UsageRecord Name==User Values=@User
```

Example 7-7: Setting a user's default account

```
$ gchuser -a chemistry amy
Successfully modified 1 user
```

Example 7-8: Changing a user's email address

```
$ gchuser -E "rsmith@cs.univ.edu" bob
Successfully modified 1 user
```

Deleting Users

To delete a user, use the command `grmuser`:

```
grmuser [--debug] [--site site_name] [--help] [--man] [--quiet]
[--verbose] [--version] {[-u] user_name}
```

Example 7-9: Deleting a user

```
$ grmuser bob
Successfully deleted 1 user
```

Related Topics

[grmuser on page 3196](#)

User Auto-Generation

If user auto-generation is enabled (this is the default), users are automatically created when first added as a member to an account or role. It is also possible to automatically create users when first encountered in a usage function (charge, reserve or quote). In order for user auto-generation to occur, the **AutoGen** property for the User object must be set to *True* (this is the default). Additionally, for user auto-generation to occur when a user is added as a member of another object (such as Account) via an association table (e.g. AccountUser), the **Values** property for the user attribute of the Association (e.g. Name) must be set to *@User*, indicating that that value should be constrained to be a valid instance of the User object. For user auto-generation to occur

when initially encountered in a usage function, the **Values** property of the user attribute of the UsageRecord object must be similarly set to `@User`. The auto-creation of users can be completely disabled by setting the **AutoGen** property for the User object to *False*.

Example 7-10: Enable auto-generation of users when initially seen in a charge

```
$ goldsh Attribute Modify Object==UsageRecord Name==User Values=@User
Successfully modified 1 attribute
```

Example 7-11: Disable all auto-generation of users

```
$ goldsh Object Modify Name==User AutoGen=False
Successfully modified 1 object
```

See [Object Auto-Generation on page 2939](#) for more information about the auto-generation of objects.

Default User

It is possible to set a global default user to which usage would be ascribed in quotes, liens, or charges where no user is specified. This can be accomplished by setting the **DefaultValue** property for the User object to the desired user.

It is also possible to set a custom user default or a specific object, which will result in usage being ascribed to the specified user when the object is attributed to the usage. This is done by creating a default usage override modifier. For example, to specify that `acmeuser` be the default user for usage associated with the acme organization, you might first create an attribute called **DefaultUser** for the **Organization** Object with the **Values** property of `@?=User`. Then you would populate the new **DefaultUser** property for the acme organization with the value of `acmeuser`. See [Customizing Objects on page 2937](#) for more information on default and other usage override modifiers.

Example 7-12: Assign a global default user

```
$ goldsh Object Modify Name==User DefaultValue=anonymous
Successfully modified 1 object
```

Managing Accounts

An account represents a work entity requiring the use of resources or services for a common purpose. Users may be designated as members of an account and may be allowed to share its allocations. If the special 'ANY' user is added to an account, then any user may use funds allocated to the account. The user members may be designated as active or inactive, and as an administrator for the account. Default account properties include the description, the organization it is part of, and whether or not it is active. An account can be created, queried, modified and deleted. An account's user membership can also be adjusted. By default, a standard user may only query accounts they belong to.

Account queries allow the specification of filter options which narrow down the accounts that will be returned to those having the specified users in them.

Creating Accounts

To create a new account, use the command `gmkaaccount`:

```
gmkaaccount [-A | -I] [-o organization name] [-d description] [-X, --extension property=value]... [-u [^|!][+|-]user name,...]... [--createFund=True|False] [--debug] [--site site name] [--help] [--man] [--quiet] [--verbose] [--version] {[-a] account_name}
```

When defining users, the optional caret or exclamation symbol indicates whether the user should be created as an admin (^) or not (!) for the account. The optional plus or minus sign can precede each member to indicate whether the member should be created in the active (+) or inactive (-) state. By default, a user will be created in the active state but not an admin. Multiple users may be passed to the `-u` option in a comma-delimited list. Alternatively, multiple `-u` options may be specified.

i If the Fund object's AutoGen property is set to true (see **Fund Auto-generation** on page 2874), a fund will be automatically created for the account (unless overridden with the `--createFund` option). The auto-generated fund will be associated with the new account.

Example 8-1: Creating an account

```
$ gmkaaccount -d "Chemistry Department" chemistry
Successfully created 1 account
```

Example 8-2: Creating an account that can be used by any user

```
$ gmkaccount -d "Common Account" -u ANY common
Successfully created 1 account.
```

Example 8-3: Creating an account and specifying user members at the same time

In this example, we make amy the account admin and associate the account with the sciences organization.

```
$ gmkaccount -d "Chemistry Department" -u ^amy,bob,dave chemistry -o sciences
Successfully created 1 account
```

Querying Accounts

To display account information, use the command `glsaccount`:

```
glsaccount [-A | -I] [-o organization name] [-X, --extension
property=value]... [-u user name] [--full] [--show attribute
name,...] [--long] [--wide] [--format csv|standard] [--debug]
[--site site name] [--help] [--man] [--quiet] [--version] [[-
a] account pattern]
```

Example 8-4: Listing all info about all accounts

```
$ glsaccount
```

Name	Active	Users	Organization	Description
biology	True	amy,^bob	sciences	Biology Department
chemistry	True	^amy,^dave	sciences	Chemistry Department
film	True	amy,^dave	arts	Film Department

Example 8-5: Displaying the name and user members of an account in long format

```
$ glsaccount --show Name,Users -long chemistry
```

Name	Users
chemistry	^amy
dave	

Example 8-6: Listing all account names

```
$ glsaccount --show Name --quiet
```

biology
chemistry
film

Example 8-7: Listing all accounts that have dave as a member

```
$ glsaccount --show Name -u dave --quiet
chemistry
film
```

[glsaccount on page 3036](#)

Modifying Accounts

To modify an account, use the command `gchaccount`:

```
gchaccount [-A | -I] [-o organization] [-d description] [-X, --extension property=value]... [--add-user(s) [^|!][+|-]user_name,...]... [--del-user(s) user_name,...] [--mod-user(s) [^|!][+|-]user_name,...]... [--debug] [--site site_man] [--help] [--man] [--quiet] [--verbose] [--version] {[-a] account_name}
```

User members may be added, removed or modified in an account. When adding user members to an account, the optional caret or exclamation symbol indicates whether the user should be created as an admin (^) or not (!) for the account. The optional plus or minus signs can precede each member to indicate whether the member should be created in the active (+) or inactive (-) state. When modifying user members of an account, the caret symbol or exclamation symbol indicates the user should be changed to become an admin (^) or not (!) for the account. The plus or minus signs indicate whether the user should be changed to become active (+) or inactive (-). If an active or admin modifier is not specified, that aspect of the user member will remain unchanged. If the **user.firstaccountdefault** server parameter is set to true, the first account that a user is added to will additionally become the default account for that user.

Example 8-8: Deactivating an account

```
$ gchaccount -I chemistry
Successfully modified 1 account
```

i In order for account validity enforcement to occur, the Values property for the UsageRecord Account attribute must be set to '@Account'.

```
$ goldsh Attribute Modify Object==UsageRecord Name==Account Values=@Account
```

Example 8-9: Adding users as members of an account

```
$ gchaccount --add-users jsmith,barney chemistry
Successfully added 2 users
```

Example 8-10: Deactivating a user in an account

```
$ gchaccount --mod-user -dave chemistry
Successfully modified 1 user
```

Deleting Accounts

To delete an account, use the command `grmaccount`:

```
grmaccount [--debug] [--site site_name] [--help] [--man] [--quiet]
[--verbose] [--version] {[-a] account_name}
```

Example 8-11: Deleting an account

```
$ grmaccount chemistry
Successfully deleted 1 account
```

Account Auto-Generation

It is possible to have accounts be created automatically when first encountered in a usage function (charge, reserve or quote). It is also possible for accounts to be automatically created when initially added as a member of another object. In order for account auto-generation to occur, the **AutoGen** property for the Account object must be set to `True`. This is the default. For account auto-generation to occur when initially encountered in a usage function, the **Values** property of the account attribute of the UsageRecord object must be set to `@Account`. Additionally, for account auto-generation to occur when an account is added as a member of another object (such as the Organization object) via an association table (e.g. OrganizationAccount), the **Values** property for the account attribute of the Association (e.g. Name) must be set to `@Account`, indicating that that value should be constrained to be a valid instance of the Account object. The auto-creation of accounts can be completely disabled by setting the **AutoGen** property for the Account object to `False`.

Example 8-12: Enable auto-generation of accounts when initially seen in a charge

```
$ goldsh Attribute Modify Object==UsageRecord Name==Account Values=@Account
Successfully modified 1 attribute
```

Example 8-13: Disable all auto-generation of accounts

```
$ goldsh Object Modify Name==Account AutoGen=False
Successfully modified 1 object
```

See [Object Auto-Generation on page 2939](#) for more information about the auto-generation of objects.

Default Account

It is possible to set a global default account to which usage would be ascribed in quotes, liens, or charges where no account is specified. This can be accomplished by setting the **DefaultValue** property for the **Account** object to the desired account name.

A per-user default account can be established by setting the **DefaultAccount** property for the user. If the **user.firstaccountdefault** server parameter is set to true (the default), the first account that a user is added to will automatically become the default account for that user. Otherwise, you can use the `gchuser` command along with the `-a` option to set or change the default account for the user.

It is also possible to set a custom account default for a specific object, which will result in usage being ascribed to the specified account when the object is attributed to the usage. This is done by creating a default usage override modifier. For example, to specify a default account of testing for the beta organization, you might first create an attribute called **DefaultAccount** for the **Organization** Object with the **Values** property of `@?=Account`. Then you would populate the new **DefaultAccount** property for the beta organization with the value of testing. See [Customizing Objects on page 2937](#) for more information on default and other usage override modifiers.

Example 8-14: Assign a global default account

```
$ goldsh Object Modify Name==Account DefaultValue=common
Successfully modified 1 object
```

Managing Organization

An organization is a virtual organization in which accounts are grouped. An account may only belong to a single organization while an organization may have multiple accounts. For example, an account may represent a project or cost-center while an organization may represent an institutional department or business division. The purpose of defining organizations is to support the ability to produce reporting for higher-order organizational entities beyond the individual account. Default organization properties include a name and a description. An organization can be created, queried, modified, and deleted.

Creating Organizations

To create a new organization, use the command `gmkgorg`:

```
gmkgorg [-d description] [-X, --extension property=value]... [--debug] [--site site_man] [--help] [--man] [--quiet] [--verbose] [--version] {[-o] organization_name}
```

Example 9-1: Creating an organization

```
$ gmkgorg -d "Sciences Department" sciences
Successfully created 1 organization
```

Organization Auto-Generation

It is possible to have organizations be created automatically when initially added as a member of another object. In order for organization auto-generation to occur, the **AutoGen** property for the Organization object must be set to `True`. This is the default. For organization auto-generation to occur when initially encountered in a usage function, the `Values` property of the organization attribute of the UsageRecord object must be set to `@Organization`. Additionally, for organization auto-generation to occur when an organization is added as a member of another object (such as a hypothetical Site object) via an association table (e.g. SiteOrganization), the **Values** property for the organization attribute of the Association (e.g. Name) must be set to `@Organization`, indicating that that value should be constrained to be a valid instance of the Organization object. The auto-creation

of organizations can be completely disabled by setting the **AutoGen** property for the Organization object to `False`.

Example 9-5: Enable auto-generation of organizations when initially seen in a charge

```
$ goldsh Attribute Modify Object==UsageRecord Name==Organization Values=@Organization
Successfully modified 1 attribute
```

Example 9-6: Disable all auto-generation of organizations

```
$ goldsh Object Modify Name==Organization AutoGen=False
Successfully modified 1 object
```

See [Object Auto-Generation on page 2939](#) for more information about the auto-generation of objects.

Default Organization

It is possible to set a global default organization to which usage would be ascribed in quotes, liens, or charges where no organization is specified. This can be accomplished by setting the **DefaultValue** property for the **Organization** object to the desired organization name.

It is also possible to set an organization default for a specific object, which will result in usage being ascribed to the specified organization when the object is attributed to the usage. This is done by creating a default usage override modifier. For example, to specify that retail be the default organization for usage associated with the user amy, you might first create an attribute called **DefaultOrganization** for the User Object with the **Values** property of `@?=Organization`. Then you would populate the new **DefaultOrganization** property for the amy user with the value of retail. See the chapter on [Customizing Objects on page 2937](#) for more information on default and other usage override modifiers.

Example 9-7: Assign a global default organization

```
$ goldsh Object Modify Name==Organization DefaultValue=whitecloud
Successfully modified 1 object
```

Managing funds

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, a fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

Funds may have a name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging. A default deposit amount can be set for a fund which is used when the amount is not specified for a deposit. Derived properties such as Allocated, Balance, Effective, Available, Capacity, PercentRemaining, PercentUsed and Used can be displayed via the `glsfund` or `gbalance` commands (see the commands reference for [glsfund on page 3058](#) or [gbalance on page 2968](#) for more details). Operations include creating, querying, modifying, deleting and resetting funds as well as making deposits, withdrawals, transfers and balance queries. By default, a standard user may only query and view the balance for funds which pertain to them.

Credits are added to a fund via a deposit. If no amount is specified for the deposit, the fund's default deposit value is used for the deposit amount. When credits are deposited into a fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. The initial deposit into a fund will create a new allocation having the specified or default time boundaries. A fund may be reset, causing the currently active allocation to end and creating a new allocation. Alternatively, allocations with predesignated start and end times may be created ahead of time. By using one of these methods to implement periodic allocations, it is possible to establish an allocation cycle. See the [Managing Allocations on page 2877](#) chapter for more information on periodic allocations as well as credit limits and infinite allocations.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for credits deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Some fund operations (Query, Deposit, Withdraw, and Refund) allow the specification of filter options which narrow down the funds that will be acted on for that operation. There are two fund filter types that can be employed: Exclusive and NonExclusive. If an exclusive filter type is used, the query will

return only the funds for which the specified filters meet all constraints for usage. Another way to think of an exclusive filter is to ask if usage were to be posted given only the specified filter options as ACLs, which funds would be eligible for charging? For example, `Fund Query FilterType:=Exclusive Filter:=User=scottmo` would not return a fund with the sole constraint `Machine=blue` because `Machine=blue` was not included in the filters. Not only must the filters be a non-conflicting superset of the fund constraints, but all constraint dependencies must also be satisfied (for example, an appropriate user may need to be specified with the account). If a non-exclusive filter type is used, the query will return all funds for which the filters do not specifically exclude the constraints. The query assumes that if constraints are not specified within the filters, they can be assumed as a wildcard and will return all funds that are not specifically excluded by the filter. For example, `Fund Query FilterType:=NonExclusive Filter:=User=scottmo` would return a fund whose only constraint was `Machine=blue` (because it does not conflict) but would not return a fund with the constraint `User=bob` (because it does conflict).

Creating Funds

`gmkgfund` is used to create a new fund. You can specify a fund name, a description, and any number of fund constraints. If a name is not specified and constraints are specified, a name will be automatically generated based on the constraints. A new unique id is automatically generated for the fund.

```
gmkgfund [-n fund_name] [--priority fund_priority] [--default-deposit deposit_amount] [-d description] [-X, --extension property=value]... [-u user_name,...]... [-g group_name,...]... [-a account_name,...]... [-o organization_name,...]... [-c class_name,...]... [-m machine_name,...]... [--constraint constraint_name=[!]constraint_value,...]... [--parent parent_fund_id] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version]
```

i It is possible to have funds be created automatically when accounts are created by setting the Fund object's `AutoGen` property to `true` (see [Fund Auto-generation](#) on page 2874). The auto-generated fund will be associated with the new account.

Example 10-1: Creating a fund valid for the chemistry account

```
$ gmkgfund -a chemistry -n "Chemistry"
Successfully created 1 fund with id 7 and 1 constraint
```

Example 10-2: Creating a wide-open fund that can be used by anyone for anything

```
$ gmkgfund -n "Windfall"
Successfully created 1 fund with id 8
```

Example 10-3: Creating a fund valid toward all *biology* account members except for *dave* and just the machine colony

```
$ gmkfund --constraint Account=biology,User!=dave,Machine=colony -n "Biology on Colony not for Dave"

Successfully created 1 fund with id 9 and 3 constraints
```

Querying Funds

To display fund information, use the command `glsfund`:

```
glsfund [-A | -I] [-n fund_name] [-X, --extension property=value]... [-u user_name] [-g group_name] [-a account_name] [-o organization_name] [-c class_name] [-m machine_name] [--filter filter_name=filter_value]... [--filter-type Exclusive|NonExclusive] [--full] [--show attribute_name,...] [--long] [--wide] [--format csv|standard] [-h, --hours] [--debug] [--site site_man] [--help] [--man] [--quiet] [--version] [[-f] fund_id]
```

Example 10-4: Listing all info about all funds with multi-valued fields displayed in a multi-line format

```
$ glsfund --long
```

Id	Name	Constraints	Allocated	Balance	DefaultDeposit	Description
1	biology	Account=biology	25000000	25000000	25000000	
2	chemistry for amy	User=amy	35000000	34802392	35000000	
		Account=chemistry				
3	chemistry not amy	User!=amy	50000000	50000000	50000000	
		Account=chemistry				
4	film on colony	Account=film	0	0		
		Machine=colony				

Example 10-5: Wide listing all info about all funds useable by *amy*

```
$ glsfund -u amy
```

Id	Name	Constraints	Allocated	Balance	DefaultDeposit
Description					
1	biology	Account=biology	25000000	25000000	25000000
2	chemistry for amy	Account=chemistry,User=amy	35000000	34802392	35000000
4	film on colony	Machine=colony,Account=film	0	0

Modifying Funds

To modify a fund, use the command `gchfund`:

```
gchfund { [-n fund_name] [--priority fund_priority] [--default-deposit deposit_amount] [-d description] [-X, --extension property=value]... [--add-constraint constraint_name=[!] constraint_value,...] [--del-constraint(s) constraint_name [=constraint_value],...]... [--parent parent_fund_id] } | { --reset [--all]} [-u user_name] [-g group_name] [-a account_name] [-o organization_name] [-c class_name] [-m machine_name] [--filter filter_name=filter_value]... [--filter-type Exclusive|NonExclusive] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] ([-f] fund_id)
```

Example 10-6: Adding a constraint to a fund so that it can only be used by the `acme` organization

```
$ gchfund --add-constraint Organization=acme 7
Successfully created 1 constraint
```

Example 10-7: Setting the default deposit amount for a fund

```
$ gchfund --default-deposit 5000000 -f 1
Successfully modified 1 fund
```

Example 10-8: Resetting a fund

```
$ gchfund --reset 1
Successfully deposited 5000000 credits into fund 1
Successfully stopped 1 allocation
Successfully created 1 allocation
```

Related Topics

[gchfund on page 2995](#)

Making Deposits

`gdeposit` is used to deposit time-bounded resource credits into a fund resulting in the creation or increase of an allocation. (See [Managing Allocations on page 2877](#) for information about managing allocations). The start time will default to `-infinity` and the end time will default to `infinity` if not specified. Filter options can be specified to help select a unique fund for the deposit. If multiple funds are matched by the filters, the matching funds will be listed and you will be prompted to respecify the deposit with one of the fund ids. If an allocation for the deposit fund is found having the start and end times for the deposit, the amount of the allocation will be increased by the deposit amount. Otherwise, a new allocation will be created for the fund with the amount of the deposit. If no funds match your criteria, if fund auto-generation is enabled, a

fund will be created and the deposit made into it. Otherwise, the deposit will fail (the fund will need to be first created using `gmkgfund`).

Deposits may be used to extend the debit ceiling by specifying an amount for the deposit (with the `-z` option) or extend the credit floor by specifying a credit limit for the deposit (with the `-L` option) or a combination of both options may be used. Additionally, `Infinity` may be used for either of these option values when Moab Accounting Manager is coupled with a database that supports IEEE Standard 754 for Floating-Point Arithmetic (e.g. PostgreSQL).

```
gdeposit [-L credit_limit] [-s start_time] [-e end_time] [-d
description] [-f fund_id] [-i allocation_id] [-u user_name] [-g
group_name] [-a account_name] [-o organization_name] [-c
class_name] [-m machine_name] [--filter filter_name=filter
value]... [--filterType Exclusive|NonExclusive] [--create-fund
True|False] [--reset] [-h, --hours] [--debug] [--site site
name] [--help] [--man] [--quiet] [--verbose] [--version] [--z
amount]
```

Example 10-9: Making a deposit into fund 1

```
$ gdeposit -z 360000000 -f 1
Successfully created 1 allocation
```

Example 10-10: Making a deposit "into" an account

If an account has a single fund then a deposit can be made against the account.

```
$ gdeposit -z 360000000 -a chemistry
Successfully deposited 360000000 credits into fund 2
```

Example 10-11: Creating a credit allocation

```
$ gdeposit -L 10000000000 -f 3
Successfully created 1 allocation
```

Example 10-12: Making a reset deposit

Stop the active allocation within a fund and create a new allocation.

```
$ gdeposit -f 4 -z 36000000 --reset
Successfully deposited 36000000 credits into fund 4
Successfully stopped 1 allocation
Successfully created 1 allocation
```

Example 10-13: Creating an infinite allocation

```
$ gdeposit -z Infinity -f 5
Successfully deposited inf credits into fund 5
Successfully created 1 allocation
```

i The use of infinite allocations requires the use of a database that supports the IEEE Standard 754 for Floating-Point Arithmetic (e.g. PostgreSQL).

Example 10-14: Creating a future quarterly allocation

```
$ gdeposit -s 2015-10-01 -e 2016-01-01 -z 25000000 -a biology
Successfully created 1 allocation
```

Querying the Balance

To display balance information, use the command `gbalance`:

```
gbalance [-u user_name] [-g group_name] [-a account_name] [-o
organization_name] [-c class_name] [-m machine_name] [--filter
filter_name=filter_value]... [--filterType
Exclusive|NonExclusive] [--ignore-ancestors] [--full] [--show
attribute_name,...] [--long] [--wide] [--format csv|standard]
[-h, --hours] [--debug] [--site site_name] [--help] [--man] [-
quiet] [--version]
```

Example 10-15: Querying amy's balance

```
$ gbalance -u amy
```

ID	Name	Balance	Reserved	Effective	CreditLimit	Available
1	biology	2785.87	103.22	2682.65	0.00	2682.65
2	chemistry	1785.87	0.00	1785.87	0.00	1785.87

Example 10-16: List the available balances that amy can charge against along with the constraints on those balances

```
$ gbalance -u amy --show Available,Constraints
```

Available	Constraints
25000000	Account=biology
34802392	Account=chemistry, User=amy
0	Machine=colony, Account=film

Personal Balance

The `mybalance` has been provided as a wrapper script to show users their personal balance. It provides a list of balances for the funds that they can

charge to:

mybalance [-h, --hours] [--help] [--man]

Example 10-17: List my fund balances

```
$ mybalance

Name                Available
-----
biology              25000000
chemistry for amy    34802392
```

Example 10-18: List my balance in (Processor) hours

```
$ mybalance -h

Name                Available
-----
biology              6944.44
chemistry for amy    9667.33
```

Making Withdrawals

A withdrawal can be used to debit a fund without being associated with the usage charge from some item. To issue a withdrawal, use the command `gwithdraw`:

```
gwithdraw [-f fund_id] [-i allocation_id] [-u user-name] [-g
group_name] [-a account_name] [-o organization_name] [-c
class_name] [-m machine_name] [--filter filter_name=filter
value]... [--filter-type Exclusive|NonExclusive] [-d
description] [-h, --hours] [--debug] [--site site_name] [--
help] [--man] [--quiet] [--verbose] [--version] {[-z] amount}
```

Example 10-19: Making a withdrawal

```
$ gwithdraw -z 12800 -f 1 -d "Grid Tax"

Successfully withdrew 12800 credits from fund 1
```

Example 10-20: Making a withdrawal "from" an account

If an account has a single fund then a withdrawal can be made against the account.

```
$ gwithdraw -z 12800 -a biology

Successfully withdrew 12800 credits from fund 1
```

If more than one fund exists for the account or filter, you will be asked to be more specific:

```
$ gwithdraw -z 12800 -a chemistry
```

```
Multiple funds were matched for the withdrawal.  
Please respecify using one of the following fund ids:  
2 [chemistry for amy]  
3 [chemistry not amy]
```

[gwithdraw on page 3208](#)

Making Transfers

To issue a transfer between funds, use the command `gtransfer`. If the allocation id is specified, then only credits associated with the specified allocation will be transferred, otherwise, only active credits will be transferred. Fund transfers preserve the allocation time periods associated with the resource or service credits from the source to the destination funds. Source and destination filters may be used if they result in a single source fund and single destination fund.

```
gtransfer {--from-fund source fund id &| --from-allocation  
source allocation id &| --from-filter filter name=filter  
value...} {--to-fund destination fund &| --to-allocation  
destination allocation id &| --to-filter filter name=filter  
value...} [--filter-type Exclusive|NonExclusive] [-d  
description] [-h, --hours] [--debug] [--site site_name] [--  
help] [--man] [--quiet] [--verbose] [--version] {[-z] amount}
```

Example 10-21: Transferring credits between two funds

```
$ gtransfer --from-fund 1 --to-fund 2 10000  
Successfully transferred 10000 credits from fund 1 to fund 2
```

Example 10-22: Transferring credits between two single-fund accounts

```
$ gtransfer --from-filter Account=biology --to-filter Account=chemistry 10000  
Successfully transferred 10000 credits from fund 1 to fund 2
```

[gtransfer on page 3204](#)

Obtaining a Fund Statement

To generate a fund statement, use the command `gstatement`. For a specified time frame it displays the beginning and ending balances as well as the total credits and debits to the fund over that period. This is followed by an itemized report of the debits and credits. Summaries of the debits and credits will be displayed instead of the itemized report if the `--summarize` option is specified.

If filter options are specified instead of a fund, then the statement will consist of information merged from all funds valid toward the specified entities.

```
gstatement [-f] fund_id [-n fund_name] [-u user_name] [-g
group_name] [-a account_name] [-o organization_name] [-c
class_name] [-m machine_name] [--filter filter_name=filter
value]... [--filter-type Exclusive|NonExclusive] [-s start
time] [-e end_time] [--summarize] [-h, --hours] [--debug] [--
site site_man] [--help] [--man] [--version]
```

Example 10-23: Generating a fund statement for all chemistry funds for the fourth quarter of 2014

```
$ gstatement -a chemistry -s 2014-10-01 -e 2015-01-01 --summarize

#####
#
# Includes fund 3 (chemistry not amy)
# Includes fund 2 (chemistry for amy)
# Generated on Mon Feb 7 18:44:23 2015.
# Reporting fund activity from 2014-10-01 to 2015-01-01.
#
#####
Beginning Balance:          0
-----

[grmfund on page 3179](#)

Fund Auto-generation

It is possible to enable the auto-generation of funds by setting the **AutoGen** property of the Fund object to `True`. When creating a new account, if fund auto-generation is enabled, a fund will automatically be created for the account (unless overridden with the `--create-fund` option). The fund will be usable only by usage attributed to the new account. Additionally, if fund auto-generation is set, a deposit that does not match an existing fund will automatically generate a fund using the filters as constraint options. Objects associated with the constraint that have **AutoGen** set to `True` will be auto-generated as well (unless overridden with the `--create-fund` option).

Example 10-25: Enable auto-generation of funds

```
$ goldsh Object Modify Name==Fund AutoGen=True
Successfully modified 1 object
```

Hierarchical Funds

A hierarchy can be established between funds. When creating a fund or by modifying it later, one can specify a parent fund id via the `--parent` option to establish the object fund as a child of the specified parent fund. A fund may have multiple children funds but only a single parent fund.

Example 10-26: Establishing a child relationship with another fund

```
$ gchfund --parent 3 -f 6
Successfully added 1 parent
```

Deposit shares may be established between the parent fund and its children that assist to automate a trickle-down effect for funds deposited at higher level funds (**DepositShare** is an attribute of the FundFund association object). Deposit shares are integers and are treated as a percentage of each deposit and the sum of the deposit shares for a fund's children may not exceed 100. If the deposit shares for the children of a fund totals less than 100, the difference is taken to be the share of the deposit that will be allocated to the parent. When a deposit is made into a parent fund, for each child fund that has a non-zero deposit share a recursive deposit amounting to the designated percentage of the parent deposit is issued to that child. After the share amounts have been

deposited to each of the child funds, the remaining percentage of the deposit is allocated to the parent fund. This effect is recursive with each child. If a start time and/or end time are specified in the original deposit, these time frames will be recursively applied to all descendant deposits. You have to use the goldsh interactive control program to manage deposit shares. For the FundFund association object, the Fund is the parent and the Id is the child.

Example 10-27: Establishing a 10% deposit share between a parent and a child fund

```
$ goldsh FundFund Modify Fund==3 Id==6 DepositShare=10
```

Fund	Id	DepositShare	Overflow
3	6	10	False

Successfully modified 1 fundFund

An overflow policy may be established between the parent fund and its children to enable a trickle-up effect for charges, liens, and quotes from the lower level funds (Overflow is an attribute of the FundFund association object). The Overflow attribute is a boolean value (True or False). If the overflow value between a child and its parent is set to True, any charges, liens, or quotes issued against the child fund that cannot be satisfied by the balance in the child fund, will recursively issue the unsatisfied portion of the charge, lien, or quote against the parent fund. If the charge, lien, or quote cannot be satisfied by the ancestors, no charges, liens, or quotes will result against any of funds. The balance in the descendant funds will be depleted before ancestor funds. This effect is recursive with each parent. If a parent fund is linked with overflow to a child fund and a charge, lien, or quote overflows to the parent fund, the constraints of the parent fund will not be checked against the properties of the item. One must use the goldsh control program to manage the overflow policy. For the FundFund association object, the Fund is the parent and the Id is the child.

Example 10-28: Enabling overflow between a parent and a child fund

```
$ goldsh FundFund Modify Fund==3 Id==6 Overflow=True
```

Fund	Id	DepositShare	Overflow
3	6	10	True

Successfully modified 1 fundFund

Fund Priority

By default, when an item can charge to multiple funds, funds with more constraints are chosen over funds with fewer constraints. For example, if the user amy is charging against the chemistry account for usage of an item and there are two viable funds, one with a single constraint (e.g. Account=chemistry) and another with two constraints (e.g. Account=chemistry and User=amy), credits will be taken from the more specific fund (with 2 constraints) before they are taken from the more general

fund (with 1 constraint). To override this behavior, it is possible to give a priority to a fund. The priority factor of a fund has higher precedence than the specificity (constraint count) of the fund. Thus, all else being equal, if a fund with a lower number of constraints is given a higher priority than a fund with a higher number of constraints, the higher priority fund will be depleted first. Other factors, such as the end time of the allocation or whether there is an existing lien for the item against a fund, have a higher precedence than the specificity of the fund. If you want the allocations in a particular fund to be chosen before allocations that expire sooner or that have a lien, you may need to specify fund priorities that are in the millions (see [Allocation Precedence on page 2881](#) for a discussion of the manner of sorting allocations for charging).

Example 10-29: Setting a fund priority

```
$ gchfund -f 3 --priority 1
Successfully modified 1 fund
```

Managing Allocations

An allocation is a time-bound pool of credits associated with a fund. A fund may have multiple allocations, each for use during a different time period. Normally, only a single allocation will be active within a fund at any given time.

Allocations are normally created via a fund deposit. An allocation has an amount, an initial deposit, and an allocated value. The **Amount** attribute tracks the current amount of credits in the allocation. The **InitialDeposit** attribute stores the amount originally deposited into an allocation when it is initially created. The **Allocated** attribute stores the current adjusted allocated amount. It begins set to the initial deposit amount and is incremented with each crediting deposit or incoming transfer and decremented with each withdrawal or outgoing transfer. When a deposit is made to a fund, if a matching allocation already exists with the appropriate time period, the existing allocation is modified. Otherwise, a new allocation is created. A resetting deposit will end the currently active allocation and create a new allocation.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. If a start time or end time is specified when making a deposit, an existing allocation having the specified boundary times will be credited. If no start time or end time is specified, the active allocation will be credited. If no matching or active allocations can be found, a new allocation will be created with the specified or default start and end time (the start time defaults to the present and the end time defaults to infinity). An active flag is automatically updated to `True` if the allocation is within its valid time frame or `False` if it is not. An allocation that becomes active because the current time is greater than its start time undergoes an activation which normally registers as a credit to the fund. An allocation that becomes inactive because the current time is greater than its end time undergoes a deactivation which normally registers as a debit to the fund.

By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle. There are two primary methods to implement periodic allocations. In the first method, called Resetting Allocations, funds are reset (ending the current allocation and creating a new one) at the beginning of each allocation period. By setting and maintaining an appropriate default deposit amount for each fund, the process of resetting funds can be simplified. The periodic reset can be performed either by making a resetting deposit for each fund (e.g. `gdeposit -f 1 --reset`) which allows you to override default deposit amounts, by calling the reset action for each fund (e.g. `gchfund -f 1 --reset`) which allows you to select which funds to reset, or by invoking a reset across all funds (e.g. `gchfund --reset --all`). The effect of any of these commands is to end the currently active allocation in the fund and then make a fresh deposit. The fund's default deposit amount is used any time the amount is not specified in a deposit (as in

the case of a fund reset command). If the default deposit amount is positive, the currently active allocation is ended and a new allocation is created with the default amount. If the default deposit amount is set to a value of zero, the active allocation is ended and no new allocation is created. If the default deposit amount is not set, the fund's allocations are not affected. The reset can be performed via a scheduled event or via a cron script. If default deposit amounts are kept up-to-date (including being zeroed out for funds that are slated to end and being unset for funds that you do not want affected by the reset), automation of this method can be as simple as creating a single periodic event with a FireCommand of "Fund Reset (see [Creating Events on page 2913](#)). In the second method, called Expiring Allocations, funds with predesignated start and end times are created head of time. When the beginning of an allocation period is reached, the currently active allocation automatically expires and the next one automatically becomes active. A future allocation is created by making a deposit while specifying a start time and an end time in the future (e.g. `gdeposit -f 1 -s 2015-10-01 -e 2016-01-01`). This method can also take advantage of default deposit amounts. The overall effect of either of these methods is very similar.

By default, Moab Accounting Manager attempts to enforce Discrete allocations, or ensure that allocations within a fund are non-overlapping (in time) and non-reusable (each allocation period should use a distinct allocation). This behavior is designated by the **allocation.enforcediscrete** server configuration parameter. If set to `true`, this policy prevents new allocations within a fund from overlapping existing ones. Enabling this policy helps to improve clarity when reporting on allocation usage during a particular period. If set to `false`, overlapping allocations within a fund can be created. This might be useful if you want to allow the remaining balance from a prior allocation period to carry over into the new allocation period. With overlapping allocations, it is harder to describe what percentage of a group's allocation has been used. This policy is applied when making deposits that create new allocations, when making transfers that create new allocations, or when modifying the start and end times of an existing allocation. It is possible to override the configured policy for an individual command by specifying the **EnforcedDiscrete** option (e.g. `gdeposit --option name=EnforceDiscrete value=False`).

An allocation may have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the **Amount** field, the fund is like a debit account, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit account, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

It is possible for the allocation **Amount** or **CredLimit** to be set to Infinity (via a deposit). If the amount is infinite, debits will not decrease the balance. An infinite deposit will result in an infinite Allocated amount. If the credit limit is infinite, there will be no negative limit for debits. It is not possible to have infinite charges, liens, quotes, withdrawals, refunds, or transfers. However, it

is possible to have infinite allocation activations, deactivations, and deletions. This capability is only available when using a database that supports IEEE Standard 754 for Floating-Point Arithmetic (e.g. PostgreSQL).

Operations include querying, modifying, and deleting allocations. Allocations can be created by a fund deposit, creating a fund with allocation auto-generation enabled, refunding a usage record, or a transfer between funds. Allocations may also be indirectly modified via charges, withdrawals, transfers, or refunds. By default, a standard user may only query allocations which pertain to them.

Allocation queries allow the specification of filter options which filter the allocations to those with funds meeting the specified fund constraints. There are two allocation filter types that can be employed: `Exclusive` and `NonExclusive`. If an exclusive filter type is used, the query will return only allocations relating to funds for which the specified filters meet all constraints. For example, `Allocation Query FilterType:=Exclusive Filter:=User=scottmo` would not return an allocation for a fund with the sole constraint `Machine=blue`. If a non-exclusive filter type is used, the query will return all allocations relating to funds for which the filters do not specifically exclude the constraints. The query assumes that if constraints are not specified within the filters, they can be assumed as a wildcard and will return all allocations involving funds that are not specifically excluded by the filter. For example, `Allocation Query FilterType:=NonExclusive Filter:=User=scottmo` would return an allocation with a fund whose only constraint was `Machine=blue` but would not return an allocation with a fund with the constraint `User=bob`.

Creating Allocations

Allocations are normally created by making fund deposits via the `gdeposit` command (See [Making Deposits on page 2868](#)).

Querying Allocations

To display allocation information, use the command `glsalloc`:

```
glsalloc [-A | -I | {[-s start_time] [-e end_time]}] [-f fund_id]
[-X, --extension property=value]... [-u user_name] [-g group_
name] [-a account_name] [-o organization_name] [-c class_name]
[-m machine_name] [--filter filter_name=filter_value]... [--
filter-type Exclusive|NonExclusive] [--include-ancestors] [--
full] [--show attribute name,...] [--format csv|standard] [-h,
--hours] [--debug] [--site site_name] [--help] [--man] [--
quiet] [--version] [[-i] allocation_id]
```

Example 11-1: Listing allocations for fund 1

```
$ glsalloc -f 1
```

	Id	Fund	Active	StartTime	EndTime	InitialDeposit	Allocated	CreditLimit	Remaining
			PercentUsed						
	1	1	True	2015-01-01	2015-04-01	25000000	25000000	0	24974400
			0.10						
	2	1	False	2015-04-01	2015-07-01	25000000	25000000	0	25000000
			0.00						
	3	1	False	2015-07-01	2015-10-01	25000000	25000000	0	25000000
			0.00						
	4	1	False	2015-10-01	2016-01-01	25000000	25000000	0	25000000
			0.00

Modifying Allocations

To modify an allocation, use the command `gchalloc`:

```
gchalloc [-s start_time] [-e end_time] [-L credit_limit] [-d description] [-X, --extension property=value]... [-h, --hours] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] {[ -i] allocation_id}
```

Example 11-2: Changing the end time for an allocation

```
$ gchalloc -e "2016-01-01" 4
```

Successfully modified 1 allocation

Example 11-3: Changing the credit limit for an allocation

```
$ gchalloc -L 5000000000000 -i 2
```

Successfully modified 1 allocation

Allocation Auto-generation

It is possible to enable the auto-generation of allocations by setting the **AutoGen** property of the Allocation object to `True`. When creating a new fund, if allocation auto-generation is enabled, an allocation will automatically be created for the fund via a deposit. The deposit will use the default amount and default credit limit (defined in the **DefaultValue** property of the Allocation Amount and Allocation CreditLimit attributes). The default action for allocation auto-generation is to create an allocation with an infinite credit limit.

Example 11-6: Enable auto-generation of allocations

```
$ goldsh Object Modify Name==Allocation AutoGen=True
Successfully modify 1 object
```

Allocation Precedence

When issuing a charge (or a lien or quote) for the usage of a resource or service, the feasible allocations are sorted according to a weight given to them for that transaction. The weight for each allocation is calculated as follows: If the instance has a current lien against one or more allocations, these allocations are given a value of $10000000 + \text{int}((2147483647 - \text{<end_epoch_time>}) / 86400)$. Thus, these reserved allocations will generally have the highest precedence (subject to large fund priorities), with those that expire sooner being used first. For the remaining non-nested funds, allocations will be given a value of $100 * \text{int}((2147483647 - \text{<end_epoch_time>}) / 86400) + 10 * \text{<fund_priority>} + \text{<constraint_count>}$. Thus, sooner expiring allocations will be used before later expiring allocations, fund priority will be the next highest factor (assuming small priority values of 1-10), followed by the number of constraints on the fund (more specific funds will be used before more general funds). Of course, since priority is configurable, a sufficiently large priority (in the millions) can be used to override the precedence of earlier expiring allocations or even allocations with liens. Lastly,

nested funds that become feasible because of overflow to ancestor funds have a negative weighting and are used last, with the earliest expiring allocations being used before later expiring allocations and closer level ancestors being depleted before ancestor funds that are at more distant levels. These allocations are given a weight of $\langle distance * 100000 \rangle - \langle end_epoch_time \rangle$. After all feasible allocations are sorted according to the above rules, the charge (or lien or quote) will be applied against the allocations one by one in sorted order (highest value first) until the request is fulfilled, or until it fails due to insufficient funds. If a transaction is not able to be satisfied in whole, the entire transaction will fail and no partial debits will be applied.

Managing Liens

A lien is a hold placed against an allocation. Before usage of a resource or service begins, a lien is made against one or more allocations within the requesting user's applicable fund(s). Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Associated with a lien is the instance name (name of the item being used such as the job id), the usage record (which contains the item details), a start time and end time for the lien and a description. The lien will automatically expire and no longer count against the user's balance after the end time passes. Each lien will be associated with held amounts from one or more allocations. Operations include creating, querying, modifying, and deleting liens. By default, a standard user may only query liens attributed to them.

Lien queries allow the specification of filter options which narrow down the liens that will be returned. There are two lien filter types that can be employed:

AttributedTo and **ImpingesUpon**. If **ImpingesUpon** is used, the query will return all liens associated with funds satisfying the filters. For example, `Lien Query FilterType:=ImpingesUpon Filter:=User=scottmo` will return all liens impinging on Funds usable by `scottmo`. If **AttributedTo** is used, the query will return all liens associated with usage records satisfying the filters. For example, `Lien Query FilterType:=AttributedTo Filter:=User=scottmo` will return all liens for resources or services allocated to `scottmo`.

When a lien is created via the UsageRecord Reserve action (such as via `greserve`), if another lien exists with the same instance name, the default behavior is to leave the old lien in place (and create the new one alongside it). This behavior assumes that the other lien is probably a separate lien created by a resource or service manager that reuses instance ids. However, alternate behaviors may be specified via the mutually exclusive **Modify** or **Replace** options. If the **Replace** option is specified, any pre-existing liens with matching instance names will first be deleted, thereby ensuring only one lien per instance name at a time. If the **Modify** option is specified, a pre-existing lien with matching instance name will be modified to have the new properties (but keeping the same lien id), and can be used to extend a lien. This might be used with incremental charging to dynamically stretch liens along a little at a time as needed. (See [Making a Usage Lien on page 2894](#) for a description of the action using these options).

Liens may be granted a grace period (in seconds), which is defined as the difference between the validity period of the lien (end time minus start time) and the expected duration of the usage. The purpose of a grace period is to

account for the fact that we may not know precisely when the usage will begin and the lien needs to remain in force during the lifetime of the usage. One can apply a desired grace period for a lien by setting the end time longer than the specified duration. Alternatively, a grace duration option can be specified with the duration when creating a lien via `greserve` as a helper to computing a relatively adjusted end time.

Creating Liens

Liens are normally created with the `greserve` command (See [Making a Usage Lien on page 2894](#)).

However, it is also possible to create a manual lien against specified allocations using the `gmklie` command. A lien object and its allocation associations will be created. Unlike `greserve`, no calculated lien amount will be returned nor will a usage record be created or updated with the lien. Furthermore, `gmklie` will not perform any checking to ensure that the specified allocations have a sufficient active balance to support the lien.

```
gmklie [-J instance_name|job_id] [-s start_time] {-e end_time |
-t lien_duration} [-d description] [-X, --extension
property=value]... {-A allocation_id<-fund_id=sublien
amount,...}... [--debug] [--site site_name] [--help] [--man]
[--quiet] [--verbose] [--version]
```

Example 12-1: Creating a manual lien

```
$ gmklie -J weekend_run -t 84600 -A "5<-2=3600"
Successfully created 1 lien
```

 Use of the `gmklie` command bypasses the normal mechanisms that prevent more liens from being placed against an allocation than it can support. Use `greserve` instead if you wish to avoid the possibility of oversubscribing the allocations.

Modifying Liens

To modify a lien, use the command `gchlien`:

```
gchlien [-s start time] [-e end time] [-t lien duration] [-d
description] [-X, --extension property=value]... [--debug] [--
site site_name] [--help] [--man] [--quiet] [--verbose] [--
version] {[-l] lien_id}
```

Example 12-4: Changing the expiration time of a lien

```
$ gchlien -e "2015-06-06 14:43:02" 1
Successfully modified 1 lien
```

Deleting Liens

To delete a lien, use the command `grmlien`:

```
grmlien {-I | {-J instance_name} | {[-l] lien_id}} [--debug] [--
site site_name] [--help] [--man] [--quiet] [--verbose] [--
version]
```

Example 12-5: Deleting a lien by instance (or job id)

```
$ grmlien -J PBS.1234.0  
Successfully deleted 1 lien
```

Example 12-6: Deleting a lien by Lien Id

```
$ grmlien 1  
Successfully deleted 1 lien
```

Example 12-7: Purging stale liens

```
$ grmlien -I  
Successfully deleted 2 liens
```

Managing Quotes

A quotation provides a way to determine beforehand how much would be charged for a job. When a guaranteed quote is requested, the charge rates applicable to the usage request are saved and a quote id is returned. Charge rates may be specified with the quote or the standard rates may be used in the quote calculation. When the lien and the final charge are issued, the quote id can be referenced to ensure that the saved quote charge rates are used instead of current standard values. A quotation has an expiration time after which it cannot be used. A quotation may also be used to verify that the given job has sufficient funds and meets the policies necessary for the charge to succeed.

Associated with a quote is the id, the instance name (name of the item being used such as the job id), the amount quoted (assuming full use of the quoted resources or services), the usage record (which contains the usage details), a start and end time for the quote, a duration (how long the item is expected to be used), a boolean indicating whether the quote is pinned or unpinned, and a description. Each guaranteed quote will be associated with one or more saved charge rates. Operations include creating, querying, modifying and deleting quotes. By default, a standard user may only query quotes attributed to them.

Quote queries allow the specification of filter options which narrow down the quotes that will be returned. The query will return all quotes associated with usage records satisfying the filters. For example, `Quote Query`

`Filter:=User=scottmo` will return all quotes for resources or services allocated to `scottmo`.

A quote may be pinned (restricted to a particular instance) or unpinned (allowed to be used by any number of different instances). If a quote is pinned and has not been tied to a particular instance when initially created, it will be tied to the first instance that claims it. Once pinned to an instance, it can then be used repeatedly by that same instance until the quote expires, but not by any other instance. If a quote is not pinned, any instances may use the quoted rates while the quote is active.

A quote may be granted a grace period, which is defined as the difference between the validity period of the quote (end time minus start time) and the expected duration of the usage in seconds. The purpose of a grace period is to account for the fact that we may not know precisely when the usage will begin and the quote needs to be valid during the time of completion of the usage in order for the guaranteed charge rates to be applied. One can apply a desired grace period for a quote by setting the end time longer than the specified duration. Alternatively, a grace duration option can be specified with the duration when creating a quote via `gquote` as a helper to computing a relatively adjusted end time.

A distinction may be made between quotes and quote templates, both of which use the Quote object. A quote will always return a cost estimate and will be associated with a specific usage record. A quote template provides a way to bundle together a package of special charge rates that can be applied to quotes, liens, and charges. Quote templates use the same Quote object as regular quotes but they are not associated with a usage record and do not generate a quote amount.

In calculating a price, a quote will use (in order of lower to higher precedence) the standard charge rates, the charge rates from a specified quote template, the specified override charge rates, or an externally specified charge amount. In saving guaranteed charge rates, the standard charge rates pertaining to the specified usage record properties will be used unless overridden by a specified quote template or specified charge rates.

There are several key purposes for using quotes and quote templates. First, a quote may be requested to discover the cost of using a resource or service. If this is your sole purpose, then you may want to use the `gquote` command with the `--costOnly` option. Second, a quote can be used to check whether the requestor has sufficient access and funds to use the requested resource. This may be accomplished by invoking the `gquote` command without the `--costOnly` option. Third, a quote or a quote template can be used to lock-in current or specified charge rates for use in future liens and charges. If the details of the usage are known and you would like to get a quote amount with a quote id that can be referenced to guarantee the quoted charge rates, you may use the `gquote` command with the `--guarantee` option. Override charge rates may be factored in to the cost estimate of the quote by using the `gquote` command with the `--rate` option. If specific override charge rates need to be saved or guaranteed for future use within a quote, lien, or charge without generating a cost estimate, create a pinned quote template by using the `gmquote` command with the `--pin` and `-R` options. If it is necessary to create a quote template that can be used to override the standard charge rates for multiple instances, use the `gmquote` command with the `--nopin` and `-R` options.

Creating Quotes

Quotes are normally generated by the resource management system with the `gquote` command before an instance uses requested resources or services (see [Obtaining Usage Quotes on page 2893](#)).

Creating Quote Templates

Quote templates may be created by using the `gmquote` command. Quote templates provide a way to bundle together a package of special charge rates that can be applied to quotes, liens, and charges.

```
gmkquote [--pin] [-J instance_name|job_id] | --nopin] [-s
start_time] {-e end_time | -t quote_duration} [-d description]
[-X, --extension property=value]... {-R charge_rate_name
[{charge_rate_value}]=charge_rate amount,...}... [--debug] [--
site site_name] [--help] [--man] [--quiet] [--verbose] [--
version]
```

Example 13-1: Creating a pinned quote template

```
$ gmkquote --pin -J vpc.1 -t 86400 -R
Processors=1.5/s,QualityOfService{Premium}=*1.7
Successfully created 1 quote template with id 17
```

Example 13-2: Creating an unpinned quote template

```
$ gmkquote --nopin -t 86400 -R Disk=2.5/s,License{Matlab}=4/s
Successfully created 1 quote template with id 18
```

i Use of the `gmkquote` command will not result in a cost estimate or the creation of a usage record. Use `gquote` instead if you wish to obtain a quote for usage.

Managing Usage Records

Moab Accounting Manager can track the usage of resources and services on your system, recording the charge and the details of the usage in a usage record. A usage record is created when a resource or service manager requests a guaranteed quote for usage, places a lien for usage, or charges for the usage of an item. Usage records can also be created directly via UsageRecord Create (`gmkusage`). A refund can be invoked to credit a charge amount back to the originating fund. Usage records can also be queried, modified, or deleted. By default, a standard user may only query usage records attributed to them.

In a typical use case, a quote might be used to discover how much it would cost to use an item (resource or service) and to verify the user had sufficient access to the item and funds to cover the requested usage. Just before the item is about to be used, a lien (or hold) might be placed against the user's allocated credits for the requested usage. After the usage is complete, a charge for the actual usage can be debited from their fund and the lien removed.

As is the case for other Moab Accounting Manager objects, usage records are highly customizable. One may remove most usage record properties and add new usage record properties. Refer to the section [Customizing the Usage Record Object on page 2897](#) for examples of customizing usage records.

Creating a Usage Record

In most cases, usage records will be created by the resource management system via the API or with the `gquote`, the `greserve` or the `gcharge` command.

However, it is also possible to create usage records directly using the `gmkusage` command:

```
gmkusage [-T usage_record_type] [-S service_id] [-u user_name]
[-g group_name] [-a account_name] [-o organization_name] [-c
class_name] [-Q quality_of_service] [-m machine_name] [-N
nodes] [-P processors] [-C cpu_time] [-M memory] [-D disk] [-t
usage_duration] [-s start_time] [-S service_id] [-e end_time]
[-d description] [-X | --extension property=value]... [--
debug] [--site site_name] [--help] [--man] [--quiet] [--
verbose] [--version] {[-J instance_name|job_id]}
```

Example 14-1: Creating a usage record

```
$ gmkusage -u jsmith -a chem -m cluster -X Charge=2468 -P 2 -t 1234 -J PBS.1234.0
Successfully created 1 usage record with id 246
```

i The fields which are displayed by default by this command can be customized by setting the **usagerecord.show** configuration parameter in `gold.conf`.

i Use of the `gmksusage` command to record usage will not result in the debiting of a user's allocation. Use `gcharge` instead if you wish to charge for the usage.

[gmkusage](#) on page 3141

Obtaining Usage Quotes

Usage quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed. A breakdown of the charges in the

quote can be returned by specifying the `--itemize` option with the `--verbose` option.

To request a usage quote, use the command `gquote`:

```
gquote [-T usage_record_type] [-S service_id] [-u user_name] [-g group_name] [-a account_name] [-o organization] [-c class_name] [-Q quality_of_service] [-m machine_name] [-N nodes] [-P processors] [-C cpu_time] [-M memory] [-D disk] [-X, --extension property=value]... [-t quote_duration] [-G grace_duration]] [-s quote_start_time] [-e quote_end_time] [-d quote_description] [-z quote_amount] [--cost-only | --guarantee] [-R charge_rate_name[{charge_rate_value}]=charge_rate_amount,...]... [-h, --hours] [--itemize] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] [[-j] usage_record_id] [-q quote_template_id] [-J instance_name|job_id]
```

Example 14-5: Requesting a quote

```
$ gquote -a chemistry -u amy -m colony -P 2 -t 3600
Successfully quoted 7200 credits
```

Example 14-6: Requesting a guaranteed quote

```
$ gquote -a chemistry -u amy -m colony -P 16 -t 3600 --guarantee
Successfully quoted 57600 credits with quote id 1 and usage record id 86

$ glsquote
```

Id	Amount	UsageRecord	StartTime	EndTime	Duration	Used	Cha
rgesRates		Description					
1	57600	86	2015-04-06 10:09:58	2015-04-06 11:09:58	3600	0	Processors:1/s

i It is possible to establish a system default machine, project or user to be used in job functions (charge, reserve or quote) when left unspecified (see [Server Configuration](#) on page 2956).

Related Topics

[gquote](#) on page 3151

Making a Usage Lien

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The `replace` option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The `modify` option

may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one. See [Managing Liens on page 2883](#) for more information about these options.

To create a usage lien use the command `greserve`:

```
greserve [-T usage_record_type] [-S service_id] [-u user_name]
[-g group_name] [-a account_name] [-o organization] [-c class_name]
[-Q quality_of_service] [-m machine_name] [-N nodes] [-P processors]
[-C cpu_time] [-M memory] [-D disk] [-X, --extension property=value]...
[-t lien_duration] [-G grace_duration]] [-s lien_start_time] [-e lien_end_time]
[-d lien_description] [-z lien_amount] [--modify|--replace] [-R charge_rate name
[{charge_rate_value}]=charge_rate amount,...]... [-h, --hours] [--itemize]
[--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose]
[--version] [[-j] usage_record_id] [-q quote_id] {-J instance_name|job_id}
```

Example 14-7: Creating a lien

```
$ greserve -J PBS.1234.0 -a chemistry -u amy -m colony -P 2 -t 3600
```

```
Successfully reserved 7200 credits with lien id 37 for instance PBS.1234.0 and created
usage record id 87
```

Related Topics

[greserve on page 3163](#)

Charging for Usage

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors (see [Managing Charge Rates on page 2905](#)). By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed. If a usage record already exists for the instance being charged it will be updated with the data properties passed in with the charge request, otherwise a new usage record will be created.

A quote id can be specified to use a previously quoted set of charge rates. This will also ensure the charge will update the usage record instantiated with the quote. A lien id can be specified to help match up a charge with its lien (this may assist in deleting the correct lien if instance ids are not unique). This will also ensure the charge will update the usage record that may have been instantiated by the lien.

Although, by default, Moab Accounting Manager will calculate the charge for the usage using its default charge rates or using the charge rates saved by a referenced quote or quote template, it is possible to specify override charge

rates via the rate option. Alternatively, it is possible to designate an externally calculated charge by specifying the charge amount with the Charge option (-z option to `gcharge`).

To charge for a usage use the command `gcharge`:

```
gcharge [-T usage_record_type] [-S service_id] [-u user_name] [-g group_name] [-a account_name] [-o organization_name] [-c class_name] [-Q quality_of_service] [-m machine_name] [-N nodes] [-P processors] [-C cpu_time] [-M memory] [-D disk] [-x usage_state] [-X, --extension property=value]... [-t charge_duration] [-s charge_start_time] [-e charge_end_time] [-d charge_description] [-z charge_amount] [-f fund_id] [--incremental] [-R charge_rate_name[{charge_rate_value}]=charge_rate_amount,...]... [-h, --hours] [--itemize] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] [[-j] usage_record_id] [-q quote_id] [-l lien_id] {-J instance_name|job_id}
```

Example 14-8: Issuing a usage charge

```
$ gcharge -J PBS.1234.0 -a chemistry -u amy -m colony -P 2 -t 1234
Successfully charged 2468 credits for instance PBS.1234.0
1 lien was removed
```

Related Topics

[gcharge on page 2982](#)

Issuing Usage Refunds

A charged amount can be credited back in part or in whole by issuing a usage refund. This action attempts to lookup the referenced usage record to ensure that the refund does not exceed the original charge and so that the charge entry can be updated. If multiple matches are found (such as the case when instance names (such as job ids) are non-unique), this command will return the list of matched usage records with unique ids so that the correct usage record can be specified for the refund.

To issue a refund for a usage charge, use the command `grefund`:

```
grefund [-z amount] [-f fund_id] [-d description] [-A] [--filter filter_name=filter_value]... [--filter-type Exclusive|NonExclusive] [-h, --hours] [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] {-J instance_name|job_id | [-j] usage_record_id}
```

Example 14-9: Issuing a usage refund

```
$ grefund -J PBS.1234.0
Successfully refunded 19744 credits for instance PBS.1234.0
```

Customizing the Usage Record Object

The usage record object as natively defined can be customized with the attributes you want to track in your use cases. The chapter on [Customizing Objects on page 2937](#) goes into some detail on the customization syntax. However, since this may be a common requirement, this section will provide a few examples on modifying, adding and deleting usage record attributes and getting them to be tracked and show up in queries.

Usage record discriminators are those properties which are considered primary differentiators between usage, lien, and quote records. Usage record discriminators are used in the dynamic web portal as filters for the listing, modification, and deletion of usage records, liens, and quotes. The default usage record discriminators are Type, User, Group, Account, Organization, Class, QualityOfService, and Machine. Any new attributes added to the usage record object will become usage record discriminators. Removing a discriminator attribute from the usage record object will necessarily remove it as a usage record discriminator as well. It will be necessary to log out and back in after adding or removing a discriminator in order for it to be reflected in the web GUI.

Example 14-10: Setting VM as the default Usage Record Type

As installed, the usage record type defaults to `Job`. The default value can be set to `NULL` if there should be no default value, or to any other default value. This example will demonstrate how to set the default usage record type to `VM`.

```
$ goldsh Attribute Modify Object=UsageRecord Name=Type DefaultValue=VM
Successfully modified 1 attribute
```

Example 14-11: Adding a UsageRecord Application Field (and discriminator)

Let's say you would like to track the application run by your usage scenarios. First, you would add **Application** as an Attribute of the UsageRecord Object.

```
$ goldsh Attribute Create Object=UsageRecord Name=Application DataType=String
Successfully created 1 attribute
```

If you want the new attribute to show up in `glsusage`, you must add it to the **usagerecord.show** string in `gold.conf`.

```
$ vi /opt/mam/etc/gold.conf

usagerecord.show =
Id,Instance,User,Group,Organization,Account,QualityOfService,Machine,Stage,Charge,Processors,Nodes,Application,Duration,StartTime,EndTime,Description
```

If you want to filter the usage records by **Application**, (such as listing all usage records associated with the specified application), use the `-X` (or `--extension`) option in `glsusage`.

```
$ glsusage -X Application=foo --show=Type,Instance,Charge,User,Application
```

Type	Instance	Charge	User	Application
Job	PBS.1234.0	19744	amy	foo

You could also use **Application** as the basis of a `ChargeRate`. See the [Managing Charge Rates on page 2905](#) chapter for details on how to do this.

Although the initial step above allows the application value to be tracked in the usage record, it is also possible to add it as an attribute of the `Transaction` table so that it will be automatically populated from actions having assignments, conditions, options and data values referring to the **Application**.

```
$ goldsh Attribute Create Object=Transaction Name=Application DataType=String
Successfully created 1 attribute
```

Additionally, the `gstatement` client command can show `Application` as one of its discriminators (which are `Account`, `User`, and `Machine` by default) in its debit detail. These statement discriminators are specified by the `--show` argument to `gstatement` and can be configured with the **statement.show** configuration parameter in `gold.conf`.

Example 14-12: Removing the UsageRecord Class Field

Let's say you were not interested in tracking the class. First, you would delete **Class** as an Attribute of the `UsageRecord` Object.

```
$ goldsh Attribute Delete Object==UsageRecord Name==Class
Successfully deleted 1 attribute
```

Next, we need to make sure `glsusage` doesn't try to list the class.

```
$ vi /opt/mam/etc/gold.conf

usagerecord.show =
Id,Instance,User,Account,Machine,QualityOfService,Stage,Charge,Processors,Nodes,Application,Duration,StartTime,EndTime,Description
```

If the attribute you want to delete is also an attribute in the `Transaction` table, you could delete it from there as well.

Usage Record Property Verification

If a usage record property has an object associated with it, you may want to verify that when that usage record property is specified in a scheduling action (`Charge`, `Reserve`, `Quote`), it verifies that that property is a valid instance of its object type. You can apply a simple verification to a usage record property by

setting the property's **Values** attribute to an @ sign followed by the name of the object.

Example 14-13: Ensure that an organization specified in a charge actually exists

```
$ goldsh Attribute Modify Object==UsageRecord Name==Organization Values=@Organization  
Successfully modified 1 attribute
```

See [Managing Attributes on page 2940](#) for more information about setting the **Values** attribute.

Usage Record Property Defaults

It is possible to set defaults for usage record properties when they are not specified in the usage data for a charge, lien, or quote. There are two cases which must be considered — when the property has an object associated with it and when the property does not.

If a property does not have an object associated with it, simply set the **DefaultValue** attribute for the property's UsageRecord Attribute object to the desired value.

Example 14-14: Setting a system-wide simple default class of batch for usage functions

```
$ goldsh Attribute Modify Object==UsageRecord Name==Class DefaultValue=batch  
Successfully modified 1 attribute
```

If a property does have an object associated with it, you will need to both set the **DefaultValue** attribute for the property's **UsageRecord** Attribute object to the desired value AND set the **DefaultValue** attribute for the corresponding object to the desired value.

Example 14-15: Setting a system-wide simple default user of anonymous for usage functions

```
$ goldsh Attribute Modify Object==UsageRecord Name==User DefaultValue=anonymous  
Successfully modified 1 attribute
```

See [Global Object-Based Defaults on page 2940](#) for more information about setting default values for objects. See [Local Attribute-Based Defaults on page 2944](#) for more information about setting default values for attributes.

Usage Record Property Auto-Generation

It is possible for usage record properties which have object definitions to automatically create the referenced objects the first time they are encountered in a usage function (charge, reserve or quote). To do this, the referenced object must be set to `AutoGen=True` and the **Values** attribute for the UsageRecord attribute corresponding to the object must be set to a string consisting of the @ sign followed by the object name.

Example 14-16: Setting the Usage Record Type to auto-generate Items for usage functions

For example, let's assume there were many usage record types that could be charged for (Food, Book, Haircut) and that you had already created an Item object. It would be possible to automatically generate a new Item instance each time a new usage record type was referenced in a charge operation.

```
$ goldsh Object Modify Name==Item AutoGen=True
Successfully modified 1 object

See [Object Auto-Generation on page 2939](#) for more information about the auto-generation of objects.

Usage Record Property Instantiators

It is possible to establish a dynamic correlation between usage record properties in which one usage record property can instantiate another. For example, if a user is specified in a charge but no account is specified then the user's default account should be applied to the fund constraints and logged; or if an account is specified in a charge but not its organization then the organization corresponding to that account should be looked up and applied to the fund constraints and logged. Three usage record property instantiator types are currently supported and are configured by prefixing the property instance's Values foreign object reference with the appropriate characters: Assign if not defined (@?=), Assign if not different (@!=), Assign always (@:=). We shall look at each of these individually and in different terms.

Applying a correlated default (@?=) — If property X is specified with the value *x* in the usage record and property Y is not specified in the usage record and if the object instance referred to by *x* has a correlated default value of *y* for property Y, then *y* will be applied as the default value for property Y in the usage record. For example, we could establish the notion of a default account for a user.

Example 14-17: Establishing a default account for a user

First we add a `DefaultAccount` attribute (the name is arbitrary) to the User object and give it a **Values** property of `@?=Account`.

```
$ goldsh Attribute Create Object=User Name=DefaultAccount DataType=String
Values="@?=Account\" Description=\"Default Account\"
Successfully created 1 attribute
```

Then we can establish the default account for user `scottmo` to be `chemistry`.

```
User Modify Name==scottmo DefaultAccount=chemistry
Successfully modified 1 user
```

Subsequently, when a Charge, Lien, or Quote is issued that specifies the User `scottmo` but does not specify the Account, the `chemistry` Account will be applied to the charge as if originally specified in the usage record charge data.

Applying a correlated verification (@!=) — If property X is specified with the value `x` in the usage record and property Y is specified with the value `y` in the usage record and if the object instance referred to by `x` has a correlated verification value of `y'` for the property Y' and if `y'` does not equal `y`, then fail with an error message. Additionally, if property X is specified with the value `x` in the usage record and property Y is not specified in the usage record and if the object instance referred to by `x` has a correlated verification value of `y'` for property Y', then `y'` will be applied as the default value for property Y in the usage record. For example, we could establish a parent-child relationship between organizations and accounts in which explicitly specified incongruities result in a failure.

Example 14-18: Establishing an override hierarchy with accounts and organizations

First we add a `VerifyOrganization` attribute (the name is arbitrary) to the Account object and give it a **Values** property of `@!=Organization`.

```
$ goldsh Attribute Create Object=Account Name=VerifyOrganization DataType=String  
Values="@!=Organization\" Description="@Verify Organization\"
```

```
Successfully created 1 attribute
```

Then we can establish the verify organization for account `chemistry` to be `sciences`.

```
$ goldsh Account Modify Name==chemistry VerifyOrganization=sciences
```

```
Successfully modified 1 account
```

Subsequently, when a Charge, Lien, or Quote is issued that specifies the Account `chemistry` and specifies the wrong Organization (e.g. `arts`), the transaction will fail with an error message. Additionally, when a Charge, Lien, or Quote is issued that specifies the Account `chemistry` but does not specify the Organization, the Organization `sciences` will be applied to the charge as if originally specified in the usage record charge data.

Applying a correlated override (@:=) — If property X is specified with the value `x` in the usage record and if the object instance referred to by `x` has a correlated override value of `y'` for property Y', then `y'` will be applied as the override value for property Y in the usage record. For example, we could establish a parent-child relationship between organizations and accounts in which explicitly specified incongruities are silently overridden with the value from the child.

Example 14-19: Establishing an override hierarchy with accounts and organizations

First we add an `OverrideOrganization` attribute (the name is arbitrary) to the Account object and give it a **Values** property of `@:=Organization`.

```
$ goldsh Attribute Create Object=Account Name=OverrideOrganization DataType=String  
Values="\":=Organization\" Description=\"Override Organization\"
```

```
Successfully created 1 attribute
```

Then we can establish the override organization for account `chemistry` to be `sciences`.

```
$ goldsh Account Modify Name==chemistry OverrideOrganization=sciences
```

```
Successfully modified 1 account
```

Subsequently, when a Charge, Reserve or Quote is issued that specifies the Account `chemistry` and specifies either the wrong Organization (e.g. `arts`) or no Organization, the Organization `sciences` will be silently applied to the charge as if originally specified in the usage record charge data.

Managing Itemized Charges

The itemized charge table provides an ability to display the components of a composite charge in a line item format. Each charge transaction will write the components of its charge into the charge record so that you can get a line-item breakdown of each charge for usage including the names, values, rates, scaling factors, charge amounts and details listed for each component of the charge. This capability is enabled by setting `charge.itemization = true` in the `goldd.conf` (it is `false` by default).

Itemized charges may only be queried. They are created automatically in charge transactions and there are no command line clients to change or remove them.

Additionally, an `itemize` option can be specified for quotes, liens, and charges to include an itemized charge breakdown in the response data instead of a single line with the amount.

Querying Itemized Charges

To display itemized charge information, use the command `glscharge`:

```
glscharge [-j usage_record_id] [-J instance_name] [-n usage
property_name] [-s start_time] [-e end_time] [--full] [--show
attribute_name,...] [--format csv|standard] [-h, --hours] [--
debug] [--site site_name] [--help] [--man] [--quiet] [--
version]
```

Example 15-1: Listing all itemized charge information

```
$ glscharge
```

UsageRecord nTime	Instance Name Description		Value	Duration	Rate	ScalingFactor	Amount	Creatio
24 04-05 17:49:41	job.1 Storage		100	86400	1.157e-07	1	1	2015-
25 04-05 17:49:42	job.2 Processors	4	86400	5.787e-07	1		20	2015-
25 04-05 17:49:42	job.2 Memory	4096	86400	1.13e-08	1		4	2015-
26 04-05 17:49:43	job.3 Processors	1	86400	5.787e-05	1		5	2015-
26 04-05 17:49:43	job.3 Memory	1004	86400	1.13e-08	1		1	2015-

Displaying Itemized Charges for a Transaction

In addition to the itemized charge table, Moab Accounting Manager captures the itemized charges for usage record charges, liens, and guaranteed quotes in the details of the transaction. The itemized charges show the details for the formula used to calculate the charge for the transaction. To display the itemized charges for a scheduling transaction, parse the details from the command `glstxn --full -A Charge|Reserve|Quote:`

Example 15-2: Extract the itemized charges for a job charge

```
$ glstxn -A Charge -J PBS.1234.1 -q --show Details | perl -pe 's/.*(ItemizedCharges
[^,]*)\.*/\1/'
ItemizedCharges:=4 [Processors] * 5.787e-05 [ChargeRate{Processors}] * 86400
[Duration] + 4096 [Memory] * 1.13e-08 [ChargeRate{Memory}] * 86400 [Duration] = 24
```

Managing Charge Rates

Charge rates establish how much to charge for usage. A charge rate consists of its name, an optional value, and the amount. Charge rates are applied when usage properties matching the charge rate names are found in the usage data. In order for a charge rate of a given name to be applied, a usage record attribute of the same name must exist. For example, a charge rate having the name Processors will be applied if Processors is defined as a Usage Record attribute and the incoming usage data for the charge request contains a property called Processors that matches the value specified in the charge rate.

There are two basic types of charge rates: Name-valued charge rates and Numeric-valued charge rates.

- Name-valued charge rates are used for usage properties that take strings for values (e.g. `QualityOfService=premium` or `Account=chemistry`). The charge rate that is applied will be determined by a lookup of the usage property value to see if there is a matching charge rate value. A default rate may be specified by creating a name-valued charge rate with an empty charge rate value. Multiple values may be assigned to the same rate via separate charge rate definitions or by combining the values in a single charge rate value separated by commas.
- Numeric-valued charge rates are used for usage properties that take numbers for values (e.g. `Processors=2` or `CpuTime=12.67`). The charge rate amount that is applied will be multiplied by the usage property value. The charge rate value is commonly left blank to be taken as the default rate for the full range of usage property values. A particular value may also be specified as the charge rate value which means that that rate will only be used if the usage property value exactly matches the charge rate value. A half-bounded expression may be used by specifying a less than or greater than sign with an optional equal sign, followed by the number. For example, the charge rate value `<=4` would match a usage property value of `x` if `x <= 4`. A charge rate value may also be specified as a range (of the form `<number>[-<number>]`). For example, the range `1-4` would be match a usage property value of `x` if `1 <= x <= 4`. If you need to be more specific about the boundedness of the ranges, you may replace the dash with a less than sign with an optional equal sign on either side of it to indicate whether the endpoints are included. For example, the range `1<4` would match if `1 < x < 4`, `1=<4` would match if `1 <= x < 4`, `1<=4` would match if `1 < x <=4` and `1=<=4` would match if `1 <= x <= 4`. So you might use ranges like `1=<2`, `2=<4`, `4=<8`, and `>=8`. Multiple values or value ranges having the same charge rate may be specified in a single expression separated by commas.

A charge rate amount may have an operation modifier which dictates the way the rate is factored into the charge calculation. For example, consumption-

based charge rates or usage fees will often be additive in nature while quality-based charge rates may be multiplicative. The additive charge rates may be further distinguished by whether they should be added before or after the multiplicative charge rates are applied. The charge formula can be represented in the following form: $(S(\text{Pre-Additive Rates}) * P(\text{Multiplicative Rates})) + S(\text{Post-Additive Rates})$. Thus, there are three operation modifiers: Pre-Additive, Multiplicative and Post-Additive.

Composite type	Description
Pre-Additive	Pre-additive modifiers are applied to charge rates that should be added together before any charge multipliers are applied. A pre-additive modifier is specified by prepending a plus sign '+' to the charge rate amount. Since pre-additive is the most commonly specified operation modifier, a charge rate amount without an operation modifier will be assumed to be pre-additive by default.
Multiplicative	Multiplicative modifiers are applied to charge rates that should be multiplied together with other multiplicative charge rates and with the sum of the pre-additive charge rates. A multiplicative modifier is specified by prepending an asterisk '*' to the charge rate amount.
Post-Additive	Post-additive modifiers are applied to charge rates that should be added together after any charge multipliers are applied. A post-additive modifier is specified by appending a plus sign '+' to the charge rate amount.

A pre-additive charge rate may have a time-based modifier which dictates that the charge should be multiplied by the amount of time the feature was used. For example, it is common for the processor charge to be multiplied by the amount of time the processors were used. A time-based modifier is specified by appending a forward slash '/' to the charge rate amount, followed by one of the following time designators: s (per-second), m (per-minute), h (per-hour), d (per-day), W (per-week), M (per-month), Y (per-year). As an example, a per-hour time-based modifier is specified by appending '/h' to the charge rate amount and will cause a charge to be multiplied by the number of hours the feature was used. Technically, a rate with a time-based modifier will be multiplied by the number of seconds the feature was used, then divided by the number of seconds corresponding to the time designator (e.g. 3600), and will ultimately be rounded to the number of decimal places in the currency precision.

A pre-additive charge rate may have a divisor modifier which dictates that the charge should be divided by the specified integer. A divisor modifier is specified by appending a forward slash '/' to the charge rate amount, followed by an integer number. A divisor modifier can be used in lieu of expressing a small decimal fraction charge rate such as when converting a value from MegaBytes to GigaBytes. If a divisor modifier is used in conjunction with a time-based modifier, the divisor modifier must precede the time-based modifier.

A charge rate may have one or more conditions which dictates additional qualifications that must be met in order for the charge rate to be applied. A condition is specified by prepending `<propertyName>=<propertyValue>` followed by a question mark '?' to the value field of the charge rate. If you want Processors to apply a special charge rate (e.g. .5/s) for user amy, the charge rate value should consist of the string "User=amy?". Additionally, you may combine charge rate conditions with either a pipe symbol '|' for or, or an ampersand symbol '&' for and. For example, User=amy|User=dave? or User=amy&Project=chemistry?. You may not combine ands and ors in the same charge rate value.

Creating Charge Rates

To create a new charge rate, use the command `gmkrate`:

```
gmkrate -n charge_rate_name [-x charge_rate_value] [-d
description] [--debug] [--site site_name] [--help] [--man] [--
quiet] [--verbose] [--version] {[-z] charge_rate_amount}
```

i If a usage record attribute does not exist for the name of the charge rate you are creating, you must first create the corresponding usage record property. See [Customizing the Usage Record Object](#) on page 2897.

Example 16-1: Creating a numeric-valued pre-additive charge rate with a divisor and a time-based modifier

```
$ gmkrate -n Memory -z 1/1024/s
Successfully created 1 charge rate
```

Example 16-2: Creating a name-valued pre-additive charge rate

```
$ gmkrate -n License -x Matlab -z 5
Successfully created 1 charge rate
```

Example 16-3: Creating a numeric-valued pre-additive charge rate without a time-based modifier

```
$ gmkrate -n CpuTime -z 1
Successfully created 1 charge rate
```

Example 16-4: Creating a numeric-valued multiplicative charge rate

```
$ gmkrate -n Discount -z *1
Successfully created 1 charge rate
```

Example 16-5: Creating a couple of name-valued multiplicative charge rates and a default rate

```
$ gmkrate -n QualityOfService -x Premium -z *2
Successfully created 1 charge rate
```

```
$ gmkrate -n QualityOfService -J BottomFeeder -z *0.5  
Successfully created 1 charge rate
```

```
$ gmkrate -n QualityOfService -z *1  
Successfully created 1 charge rate
```

Example 16-6: Creating a numeric-valued post-additive charge rate

```
$ gmkrate -n Shipping -z 25+  
Successfully created 1 charge rate
```

Example 16-7: Creating a name-valued post-additive charge rate

```
$ gmkrate -n Zone -x Asia -z 200+  
Successfully created 1 charge rate
```

Example 16-8: Creating a couple of conditional numeric-valued pre-additive charge rates

```
$ gmkrate -n Disk -x User=dave? -z 0.2/s  
Successfully created 1 charge rate
```

```
$ gmkrate -n Disk -x User=mike? -z 0.5/s  
Successfully created 1 charge rate
```

Example 16-9: Creating some numeric-valued pre-additive charge rate ranges and a default

```
$ $ gmkrate -n Processors -x 1-4 -z 2/s  
Successfully created 1 charge rate
```

```
$ gmkrate -n Processors -x 5-8 -z 1.5/s  
Successfully created 1 charge rate
```

```
$ gmkrate -n Processors -z 1/s  
Successfully created 1 charge rate
```

Example 16-10: Creating some numeric-valued pre-additive rate ranges for floating point values (without time-based modifiers)

```
$ $ gmkrate -n Power -x '<2' -z 0.005  
Successfully created 1 charge rate
```

```
$ $ gmkrate -n Power -x '2=<4' -z 0.004  
Successfully created 1 charge rate
```

```
$ $ gmkrate -n Power -x '>=4' -z 0.003  
Successfully created 1 charge rate
```

Example 16-11: Assigning multiple classes to run for free

```
$ $ gmkrate -n Class -x dev,test -z *0  
Successfully created 1 charge rate
```

Querying Charge Rates

To display charge rate information, use the command `glstrate`:

```
glstrate [-n charge_rate_name] [-x charge_rate_value] [--full] [-  
-show attribute_name,...] [--format csv|standard] [--debug] [-  
-site site_name] [--help] [--man] [--quiet] [--version]
```

Example 16-12: Listing all charge rates

```
$ glstrate
```

Name	Value	Amount	Description
Class	dev,test	*0	
CpuTime		1	
Discount		*1	
Disk	User=dave?	0.2/s	
Disk	User=mike?	0.5/s	
License	Matlab	5/s	
Memory		1/1024/s	
Power	<2	0.005	
Power	2=<4	0.004	
Power	>=4	0.003	
Processors		1/s	
Processors	1-4	2/s	
Processors	5-8	1.5/s	
QualityOfService		*1	
QualityOfService	BottomFeeder	*0.5	
QualityOfService	Premium	*2	
Shipping		25+	
Zone	Asia	200+

Modifying Charge Rates

To modify a charge rate, use the command `gchrates`:

```
gchrates [-n charge_rate_name] [-x charge_rate_value] [-z charge_  
rate_amount] [-d description] [--debug] [--site site_name] [--  
help] [--man] [--quiet] [--verbose] [--version]
```

Example 16-13: Changing a charge rate

```
$ gchrates -n License -x Matlab -z 4/s  
Successfully modified 1 charge rate
```

Related Topics

[gchrates on page 3013](#)

Deleting Charge Rates

To delete a charge rate, use the command `grmrate`:

```
grmrate -n charge_rate_name [-x charge_rate_value] [--debug] [--  
site site_name] [--help] [--man] [--quiet] [--verbose] [--  
version]
```

Example 16-14: Deleting a charge rate

```
$ grmrate -n Memory  
Successfully deleted 1 charge rate
```

Related Topics

[grmrate on page 3189](#)

Managing Transactions

Moab Accounting Manager logs all modifying transactions in a detailed transaction journal (queries are not recorded). Previous transactions can be queried but not modified or deleted. By default, a standard user may only query transactions performed by them.

Querying Transactions

To display transaction information, use the command `glstrans`:

```
glstrans [-O object] [-A action] [-k primary key value] [-U actor] [-f fund id] [-i allocation id] [-u user name] [-a account name] [-m machine name] [-j usage record id] [-J instance name|job id] [-s start time] [-e end time] [-T transaction id] [-R request id] [-X, --extension property=value]... [--full] [--show attribute name,...] [--format csv|standard] [-h, --hours] [--debug] [--site site name] [--help] [--man] [--quiet] [--version]
```

Example 17-1: List all deposits made in 2015

```
$ glstrans -A Deposit -s 2015-01-01 -e 2016-01-01
```

Example 17-2: List everything done by amy since the beginning of 2015

```
$ glstrans -U amy -s 2015-01-01
```

Example 17-3: List all transactions related to job moab.1

```
$ glstrans -J moab.1
```

Example 17-4: List all transactions affecting charge rates

```
$ glstrans -O ChargeRate
```

Related Topics

[glstrans on page 3092](#)

Customizing the Transaction Object

The transaction record as natively defined can be customized with the attributes you want to track in your use cases. It is possible to add additional attributes to the Transaction table so that it will be automatically populated from actions having assignments, conditions, options and data values referring to the attribute.

Transaction discriminators are those properties which are considered primary differentiators between transaction records (besides the metadata differentiators of object, action, and instance). Transaction discriminators are used in the dynamic web portal as filters for the listing of transaction records. Any new attributes added to the Transaction object will become transaction discriminators. Removing a discriminator attribute from the transaction object will necessarily remove it as a transaction discriminator as well. It will be necessary to log out and back in after adding or removing a discriminator in order for it to be reflected in the web GUI.

Example 17-5: Adding an Organization field to the Transaction record (which also makes it a discriminator)

```
$ goldsh Attribute Create Object=Transaction Name=Organization DataType=String  
Successfully created 1 attribute
```

Modifying Events

To modify an event, use the command `gchevent`:

```
gchevent --fire-command fire_command [-s fire_time] [-e end_time]
[--rearm-period rearm_period] [--rearm-on-failure True|False]
[--failure-command failure_command] [--notify notification_url]
[--catch-up (True)|False] [-d description] [--debug] [--site site_name]
[--help] [--man] [--quiet] [--verbose] [--version] {[-E] event_id}
```

Example 18-1: Changing an event's rearm period to be monthly

```
$ gchevent --rearm-period "1 month" 1
Successfully modified 1 event
```

Related Topics

[gchevent on page 2991](#)

Creating Events

To create a new event, use the command `gmkevent`:

```
gmkevent --fire-command goldsh_command [-s fire_time] [-e end_time]
[--rearm-period rearm_period] [--rearm-on-failure True|False]
[--failure-command failure_command] [--notify notification_url]
[--catch-up (True)|False] [-d description] [--debug] [--site site_name]
[--help] [--man] [--quiet] [--verbose] [--version]
```

Example 18-2: Creating an automatic allocation renewal event

```
$ gmkevent --fire-command "Fund Reset" -s "2016-01-01" --rearm-period "3 months^"
Successfully created 1 event
```

Managing Notifications

When event commands are executed (asynchronously), the success or failure of the operation is communicated back to the initiator via a notification. When an event is created, you may specify the Notify option which will associate a notification method with the event. Currently there is only one **DeliveryMethod** implemented which is `Store`. With the Store delivery method, command response information is stored as instances of the Notification object. These messages can later be retrieved by the initiator via a Notification Query. Payments can also route a notification method down to their associated events via a Notify option.

The notification attributes include **Id** (auto-generated), **Type**, **Event**, **Status**, **Code**, **Message**, **Key**, **Recipient**, **EndTime** and **CreationTime**. Stored notifications can be queried on any of these conditions. The notification type distinguishes what type of command resulted in the notification (Fire or Failure). The notification key is the value of the primary key of the object instance that the command acted on (e.g. the Payment Id). The recipient could be a user name or any tag that identifies the intended reader for the notification. The Notification Query supports a **Delete** option, which if set to `True`, will delete the notifications after they have been queried. Additionally, stored notifications have an EndTime after which they are automatically deleted by Gold. The Notification actions include Send, Refresh, Create, Query, Delete and Modify.

There are two server configuration parameters which affect notifications: **notification.deliverymethod** which dictates which deliverymethod is used by default if unspecified and **notification.duration** which defines how long notifications stick around if the Store delivery method is used.

Querying Notifications

To display notification information, use the command `glsnot`:

```
glsnot [-E event_id] [-T notification_type] [-k primary_key_value] [-u recipient] [-x status] [-s start_time] [-e end_time] [--delete] [--full] [--show attribute_name,...] [--format csv|standard] [--debug] [--site site_name] [--help] [--man] [--quiet] [--version] [[-N] notification_id]
```

Example 19-1: Listing all failure notifications

```
$ glsnot -x Failure

Managing Roles

Moab Accounting Manager uses instance-level role-based access controls to determine what users can perform what functions. Named roles are created, actions are associated with the roles, and users are assigned to these roles.

The actions for a role consist of a set of tuples of object, action and instance permitted by the role. In other words, each role action defines an object (whether specific or `ANY`), the action that can be taken on that object (whether specific or `ANY`) and the instance of the object that action can be taken on (whether specific or `ANY`).

In the base configuration, there are three default roles: `SystemAdmin`, `Anonymous` and `OVERRIDE`. Other configurations, such as the bank configuration, add additional roles. Roles can be added as desired. The three base roles are required for proper function of Moab Accounting Manager and should not be deleted. By default, the `SystemAdmin` role can perform any action on any object. This role is usually assigned to the super user. The `Anonymous` role is intended to define the actions available to your standard unprivileged user. This may include the ability to set your password, query certain public objects and modify objects that belong to you (implemented via the `OVERRIDE` role). The `OVERRIDE` role is a special role type that defines those actions that should use special business logic intrinsic to the routine that handles that object and action. For example, in the bank configuration, the `OVERRIDE` logic for the Account Query routine will only allow the standard user to see information about accounts for which he or she is a member. A given user's privileges will be the superset of the actions of all roles that apply to that user.

The instance indicates which specific instances of the object the action can be performed on. There are several special instance types that can be used in certain situations. The `ANY` instance is supported by all objects and permits the specified action on all instances of the specified object. The `SELF` instance applies to the user's own instance if the object is `User`, or to objects that have a `User` attribute associated with the user. The `MEMBERS` instance applies to objects for which the user is a direct member. The `ADMIN` instance applies to objects for which the user is designated as an administrator. Unless otherwise specified, the instance will default to a value of `ANY`.

Creating Roles

To create a new role, use the command `gmkrrole`. Users and actions may be associated with the role at creation time. When assigning actions to a role, the object, action and instance must be specified in the form shown. Multiple actions or users may be specified for the role.

```
gmkrole [-d description] [-u user_name,...]... [-A object_name-
>action_name[{instance_name}],...]... [--debug] [--site site
name] [--help] [--man] [--quiet] [--verbose] [--version] {[-r]
role_name}
```

Example 20-1: Creating a Manager role

```
$ gmkrole -r Manager -d "Manages Roles and Responsibilities"
Successfully created 1 role
```

Related Topics

[gmkrole on page 3138](#)

Querying Roles

To display the role information, use the command `glsrole`:

```
glsrole [--full] [--show attribute_name,...] [--long] [--wide]
[--format csv|standard] [--debug] [--site site_name] [--help]
[--man] [--quiet] [--version] {[-r] role_name}
```

Example 20-2: Listing all roles along with users and descriptions

```
$ glsrole --show=Name,Users,Description
```

Name	Users	Description
AccountAdmin		Can update or view an account they are admin for
Anonymous	ANY	Things that can be done by anybody
OVERRIDE	ANY	A custom authorization method will be invoked
Schedule	root	Scheduler relevant Transactions
SystemAdmin	scottmo	Can update or view any object
UserServices		User Services

Example 20-3: Listing information about the scheduler role

```
$ glsrole --long Scheduler
```

Name	Users	Actions	Description
Scheduler	root	UsageRecord->Create (ANY) UsageRecord->Quote (ANY) UsageRecord->Reserve (ANY) UsageRecord->Charge (ANY) Lien->Delete (ANY)	Scheduler relevant Transactions

Related Topics

[glsrole on page 3089](#)

Modifying Roles

To modify a role, use the command `gchrole`:

```
gchrole [-d description] [--add-user(s) user_name,...]... [--  
add-action(s) object_name->action_name[{instance  
name}],...]}... [--del-user(s) user_name,...]... [--del-action  
(s) object_name->action_name[{instance_name}],...]}... [--  
debug] [--site site_name] [--help] [--man] [--quiet] [--  
verbose] [--version] {[-r] role_name
```

Users may be added to a role or removed from a role. Actions also may be added to a role or removed from a role. When specifying actions, the instance will default to a value of `ANY`.

Example 20-4: Adding a user to a role

Let's add `dave` to our new `Manager` role:

```
$ gchrole --add-user dave -r Manager  
Successfully added 1 user
```

Example 20-5: Associating an action with a role

Allow the `Manager` to change role responsibilities:

```
$ gchrole --add-action "RoleAction->ANY" Manager -v  
Successfully added 1 action
```

Related Topics

[gchrole on page 3016](#)

Deleting Roles

To delete a role, use the command `grmrole`:

```
grmrole [--debug] [--site site_name] [--help] [--man] [--quiet]  
[--verbose] [--version] {[-r] role_name}
```

Users may be added to a role or removed from a role. Actions also may be added to a role or removed from a role. When specifying actions, the instance will default to a value of `ANY`.

Example 20-6: Deleting the `Manager` role

Let's add `dave` to our new `Manager` role:

```
$ grmrole Manager  
Successfully deleted 1 role and 2 associations
```

Managing Passwords

Passwords must be established for each user who wishes to use the web-based GUI. Passwords must be at least eight characters and are stored in encrypted form. A `gchpasswd` command line client exists to aid a user or administrator in setting or changing a password. Other operations (deleting or listing password entries) must be performed using the interactive control program (`goldsh`). By default, a standard user may only set or change his or her own password. A system administrator may set or change any user's password.

Because Moab Accounting Manager caches password information for faster responsiveness, it will be necessary to restart the server after running `gchpasswd` for the GUI to accept that password change.

Setting Passwords

To set a new password, use the command `gchpasswd`. If the user name is not specified via an option or as the unique argument, then the invoking user will be taken as the user whose password will be set. The invoker will be prompted for the new password.

```
gchpasswd [--debug] [--site site_name] [--help] [--man] [--quiet] [--verbose] [--version] {[-u] user_name}
```

Example 21-1: Setting a password

```
$ gchpasswd amy
Enter your new password:
Successfully created 1 password
```

Related Topics

[gchpasswd on page 3008](#)

Querying Passwords

To display password information, use the command `goldsh Password Query`:

```
goldsh Password Query [Show:=<"Field1,Field2,...">] [User==<User Name>] [ShowUsage:=True]
```

Example 21-2: List the users who have set passwords

```
$ goldsh Password Query Show:=User
User
-----
amy
gold
```

Deleting Passwords

To delete a password, use the command `goldsh Password Delete:`

```
goldsh Password Delete User==<User Name>]
```

i The `goldsh` control program allows you to make powerful and sweeping modifications to Moab Accounting Manager objects. Misuse of this command could result in the inadvertent deletion of all passwords.

Example 21-3: Deleting a password

```
$ goldsh Password Delete User==amy
User      Password
-----
amy      HZYzWD20o1XIE/gxRYyFKP2sumkCluHm
Successfully deleted 1 password
```

Using the Gold Shell (goldsh)

`goldsh` is an interactive control program that can access all of the advanced functionality in Moab Accounting Manager.

i The `goldsh` control program allows you to make powerful and sweeping modifications to many objects with a single command. Inadvertent mistakes could result in modifications that are very difficult to reverse.

Usage

Goldsh commands can be invoked directly from the command line as arguments, or read from stdin (interactively or redirected from a file).

```
goldsh [--debug] [--site site_name] [--help] [--man] [--format  
csv|standard] [--quiet] [--verbose] [--version] [command]
```

Example 22-1: Specifying the command as direct arguments

```
$ goldsh System Query
```

Name	Version	Description
Moab Accounting Manager	8.1.0.0	Commercial Release

Example 22-2: Using the interactive prompt

```
$ goldsh
gold> System Query
```

Name	Version	Description
Moab Accounting Manager	8.1.0.0	Commercial Release

```
gold> quit
```

Example 22-3: Reading commands from a file

```
$ cat >commands.gold <<EOF
System Query
quit
EOF
$ goldsh <commands.gold
```

Name	Version	Description
Moab Accounting Manager	8.1.0.0	Commercial Release

Command Syntax

goldsh commands are of the form:

```
<Object> [=<Alias>] [, <Object> [=<Alias>]...] <Action> [  
  [<Conjunction>] [<Open_Parenthesis>...] [<Object>.]  
  <Name> <Operator> [<Subject>.] <Value> [<Close_Par-  
  enthesis>...] ...]
```

The basic form of a command is `<Object> <Action>`

`[<Name><Operator><Value>]*`. When an action is performed on more than one object, such as in a multi-object query, the objects are specified in a comma-separated list. Commands may accept zero or more predicates which may function as fields to return, conditions, update values, processing options, etc. Predicates, in their simplest form, are expressed as Name, Operator, Value tuples. Predicates may be combined via conjunctions with grouping specified with parentheses. When performing multi-object queries, names and values may need to be associated with their respective objects.

Valid conjunctions include:

Conjunction	Meaning
&&	and
 	or
&!	and not
 !	or not

Open parentheses may be any number of literal open parentheses '('.

Name is the name of the condition, assignment, or option. When performing a multi-object query, a name may need to be prepended by its associated object separated by a period.

Valid operators include:

Operator	Meaning
==	equals
<	less than

Operator	Meaning
>	greater than
<=	less than or equal to
>=	greater than or equal to
!=	not equal to
~	matches
=	is assigned
+=	is incremented by
-=	is decremented by
:=	option
:!	not option

Value is the value of the selection list, condition, assignment, or option. When performing a multi-object query, a value may need to be prepended by its associated object (called the subject) separated by a period.

Close parentheses may be any number of literal closing parentheses ')'.

Valid Objects

To list the objects available for use with commands in goldsh commands, use the goldsh command: `Object Query`

Example 22-4: Listing all objects

```
gold> Object Query Show:"Sort (Name) "  
Name  
-----  
Account  
AccountUser  
Action  
Allocation  
Attribute  
ChargeRate  
Constrainst  
Fund  
FundFund  
Lien  
LienAllocation  
Object  
Organization  
Password  
Quote  
QuoteChargeRate  
Role  
RoleAction  
RoleUser  
System  
Transaction  
UsageRecord  
User
```

Valid Actions for an Object

To list the actions that can be performed on an object, use the goldsh command: `Action Query`

Example 22-5: Listing all actions associated with the Fund object

```
gold> Action Query Object==Fund Show:"Sort (Name) "  
Name  
-----  
Create  
Delete  
Deposit  
Modify  
Query  
Transfer  
Undelete  
Withdraw
```

Valid Predicates for an Object and Action

By appending the option `ShowUsage:=True` to a command, the syntax of the command is returned, expressed in SSSRMAP XML Message Format.

Example 22-6: Show the usage for Allocation Query

```
gold> Allocation Query ShowUsage:=True

<Request action="Query">
  <Object>Allocation<Object>
    [<Get name="Id" [op="Sort|Tros|Count|GroupBy|Max|Min"]></Get>]
    [<Get name="Fund" [op="Sort|Tros|Count|GroupBy|Max|Min"]></Get>]
    [<Get name="StartTime" [op="Sort|Tros|Count|GroupBy|Max|Min"]></Get>]
    [<Get name="EndTime" [op="Sort|Tros|Count|GroupBy|Max|Min"]></Get>]
    [<Get name="Amount" [op="Sort|Tros|Count|GroupBy|Max|Min|Sum|Average"]></Get>]
    [<Get name="CreditLimit" [op="Sort|Tros|Count|GroupBy|Max|Min|Sum|Average"]
  ></Get>]
  [<Get name="InitialDeposit" [op="Sort|Tros|Count|GroupBy|Max|Min|Sum|Average"]
  ></Get>]
  [<Get name="Allocated" [op="Sort|Tros|Count|GroupBy|Max|Min|Sum|Average"]></Get>]
  [<Get name="Active" [op="Sort|Tros|Count|GroupBy"]></Get>]
  [<Get name="Description" [op="Sort|Tros|Count|GroupBy|Max|Min"]></Get>]
  [<Where name="Id" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>Integer Number}</Where>]
  [<Where name="Fund" [op="EQ|NE|GT|GE|LT|LE|Match|NotMatch (EQ)"] [conj="And|Or
  (And)"] [group="<Integer Number>Fund Name}</Where>]
  [<Where name="StartTime" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>YYYY-MM-DD[ hh:mm:ss]|-infinity|infinity|now}</Where>]
  [<Where name="EndTime" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>YYYY-MM-DD[ hh:mm:ss]|-infinity|infinity|now}</Where>]
  [<Where name="Amount" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>Decimal Number}</Where>]
  [<Where name="CreditLimit" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>Decimal Number}</Where>]
  [<Where name="InitialDeposit" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>Decimal Number}</Where>]
  [<Where name="Allocated" [op="EQ|NE|GT|GE|LT|LE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>Decimal Number}</Where>]
  [<Where name="Active" [op="EQ|NE (EQ)"] [conj="And|Or (And)"]
  [group="<Integer Number>True|False}</Where>]
  [<Where name="Description" [op="EQ|NE|GT|GE|LT|LE|Match|NotMatch (EQ)"]
  [conj="And|Or (And)"] [group="<Integer Number>Description}</Where>]
  [<Option name="Filter">True|False (False)</Option>]
  [<Option name="FilterType">Exclusive|NonExclusive (NonExclusive)</Option>]
  [<Option name="IncludeAncestors">True|False (False)</Option>]
  [<Option name="Time">YYYY-MM-DD[ hh:mm:ss]</Option>]
  [<Option name="Unique">True|False (False)</Option>]
  [<Option name="Limit">{Integer Number}</Option>]
  [<Option name="Offset">Integer Number}</Option>]
  [<Option name="ShowHidden">True|False (False)</Option>]
  [<Option name="ShowUsage">True|False (False)</Option>]
</Request>
```

Common Options

There are a number of options that may be specified for all commands. These options include: *ShowUsage*

ShowUsage — This option may be included with any command to cause the command to return a usage message in SSSRMAP XML Message Format.

Common Actions Available for Most Objects

There are a number of actions that are available for most objects. These actions include Query, Create, Modify, Delete, and Undelete. Commands involving these actions inherit some common structure unique to the action type.

Query Action

The Query action is used to query objects. It accepts selections that describe the attributes (fields) to return (including aggregation operations on those attributes), conditions that select which objects to return the attributes for, and other options unique to queries.

Selections

Selections use the `Show` option to specify a list of the attributes to return for the selected object. If selections are not specified, a default set of attributes (defaulting to those not marked as hidden) will be returned.

Name = Show

Op = :=

Value = "attribute1,attribute2,attribute3,..."

Aggregation operators may be applied to attributes by enclosing the target attribute in parenthesis and prepending the name of the desired operator. The aggregation operators that can be applied depend on the datatype of the attribute.

Valid selection operators include:

Sort — Ascending sort

Tros — Descending sort

Count — Count

Max — Maximum value

Min — Minimum value

Average — Average value

Sum — Sum

GroupBy — Group other aggregations by this attribute

Additionally, aliases can be applied to selections so that columns can be renamed as desired. Aliases are expressed by adding `=<Alias>` to the target attribute name (and after the trailing parenthesis of the aggregation, if specified).

For example: `Allocation Query Show:="GroupBy) Fund) , Sum (Amount) =Total"`

Conditions	<p>Conditions are used to select which objects the action is to be performed on.</p> <p>Name = Name of the attribute to be tested</p> <p>Op = conditional operator</p> <p>Value = The object or value against which the attribute is tested</p> <p>Valid condition operators include:</p> <p>== Equal to</p> <p>!= Not equal to</p> <p>< Less than</p> <p>> Greater than</p> <p><= Less than or equal to</p> <p>>= Greater than or equal to</p> <p>~ Matches</p> <p>!~ Does not match</p> <p>Matching uses the wildcards * and ? (equivalent to SQL % and _ respectively) in a manner similar to file globbing. * matches zero or more unspecified characters and ? matches exactly one unspecified character. For example <code>mscf*</code> matches objects having the specified attributes whose values start with the letters <code>mscf</code>, while <code>mscf?</code> matches objects having the specified attributes whose values start with <code>mscf</code> and have a total of exactly five characters.</p>
Options	<p>Options indicate processing options that affect the result.</p> <p>Name = Name of the option</p> <p>Op = :=</p> <p>Value = Value of the option</p> <p>Valid options for query actions include:</p> <p>ShowHidden:=True False (False) Includes hidden attributes in the result</p> <p>Time:=YYYY-MM-DD[hh:mm:ss] Run the command as if it were the specified time</p> <p>Unique:=True False (False) Display only unique results (like DISTINCT in SQL)</p> <p>Limit:={Integer Number} Limit the results to the number of objects specified</p>

Example 22-7: Return the number of inactive liens

```
gold> Lien Query EndTime<now Show:="Count(Id) "
Id
---
8
```

Create Action

The Create action is used to create a new object. It accepts assignments that describe the values of the attributes to be set.

Assignments	<p>Assignments specify values to be assigned to attributes in the new object.</p> <p>Name = Name of the attribute being assigned a value</p> <p>Op = = (is assigned)</p> <p>Value = The new value being assigned to the attribute</p>
-------------	---

Example 22-8: Add a new account member

```
gold> AccountUser Create Account=chemistry Name=scottmo
```

Account	Name	Active	Admin
chemistry	scottmo	True	False

```
Successfully created 1 accountUser
```

Modify Action

The Modify action is used to modify existing objects. It accepts conditions that select which objects will be modified and predicates that describe the values of the attributes to be set.

Assignments	<p>Assignments specify values to be assigned to attributes in the selected objects.</p> <p>Name = Name of the attribute being assigned a value</p> <p>Op = assignment operators {=, +=, -=}</p> <p>Value = The value being assigned to the attribute</p> <p>Valid assignment operators include:</p> <p>= is assigned</p> <p>+= is incremented by</p> <p>-= is decremented by</p>
-------------	--

Conditions	<p>Conditions are used to select which objects the action is to be performed on.</p> <p>Name = Name of the attribute to be tested</p> <p>Op = conditional operator</p> <p>Value = The object or value against which the attribute is tested</p> <p>Valid condition operators include:</p> <p>== Equal to</p> <p>!= Not equal to</p> <p>< Less than</p> <p>> Greater than</p> <p><= Less than or equal to</p> <p>>= Greater than or equal to</p> <p>~ Matches</p> <p>!~ Does not match</p> <p>Matching uses the wildcards * and ? (equivalent to SQL % and _ respectively) in a manner similar to file globbing. * matches zero or more unspecified characters and ? matches exactly one unspecified character. For example <code>mscf*</code> matches objects having the specified attributes whose values start with the letters <code>mscf</code>, while <code>mscf?</code> matches objects having the specified attributes whose values start with <code>mscf</code> and have a total of exactly five characters.</p>
------------	--

Example 22-9: Change/set *scottmo*'s phone number and email address

gold> User Modify Name==scottmo PhoneNumber="(509) 376-2204" EmailAddress="scottmo@adaptivecomputing.com"				
Name	Active	CommonName	PhoneNumber	EmailAddress
		DefaultAccount	Description	

scottmo	True	Jackson, Scott M.	(509) 376-	
2204		scottmo@adaptivecomputing.com		
Successfully modified 1 user				

Example 22-10: Extend all liens against account *chemistry* by 10 days

gold> Lien Modify EndTime+=864000 Instance=="job.1"								
Id	Fund	Amount	Instance	UsageRecord	User	Project	Machine	EndTime
			Description					
1	2	57600	PBS.1234.0	1	amy	chemistry	colony	2015-04-16 10:47:30
Successfully modified 1 lien								

Delete Action

The Delete action is used to delete objects. It accepts conditions that select which objects are to be deleted.

Conditions

Conditions are used to select which objects the action is to be performed on.

Name = Name of the attribute to be tested

Op = conditional operator

Value = The object or value against which the attribute is tested

Valid condition operators include:

== Equal to

!= Not equal to

< Less than

> Greater than

<= Less than or equal to

>= Greater than or equal to

~ Matches

!~ Does not match

Matching uses the wildcards * and ? (equivalent to SQL % and _ respectively) in a manner similar to file globbing. * matches zero or more unspecified characters and ? matches exactly one unspecified character. For example `mscf*` matches objects having the specified attributes whose values start with the letters `mscf`, while `mscf?` matches objects having the specified attributes whose values start with `mscf` and have a total of exactly five characters.

Example 22-11: Get rid of the pesky Jacksons

```
gold> User Delete CommonName~"Jackson*"
```

Name	Active	CommonName	PhoneNumber	EmailAddress
		DefaultAccount	Description	
scottmo	True	Jackson, Scott M.	(509) 376-	
2204		scottmo@adaptivecomputing.gov		

Successfully deleted 1 user and 1 association

Undelete Action

The Undelete action is used to restore deleted objects. It accepts conditions that select which objects are to be undeleted.

Conditions	<p>Conditions are used to select which objects the action is to be performed on.</p> <p>Name = Name of the attribute to be tested</p> <p>Op = conditional operator</p> <p>Value = The object or value against which the attribute is tested</p> <p>Valid condition operators include:</p> <p>== Equal to</p> <p>!= Not equal to</p> <p>< Less than</p> <p>> Greater than</p> <p><= Less than or equal to</p> <p>>= Greater than or equal to</p> <p>~ Matches</p> <p>!~ Does not match</p> <p>Matching uses the wildcards * and ? (equivalent to SQL % and _ respectively) in a manner similar to file globbing. * matches zero or more unspecified characters and ? matches exactly one unspecified character. For example <code>mscf*</code> matches objects having the specified attributes whose values start with the letters <code>mscf</code>, while <code>mscf?</code> matches objects having the specified attributes whose values start with <code>mscf</code> and have a total of exactly five characters.</p>
------------	--

Example 22-12: Resurrect the deleted users that were active

```
gold> User Undelete Active==True
```

Name	Active	CommonName	PhoneNumber	EmailAddress
		DefaultAccount	Description	
scottmo	True	Jackson, Scott M.	(509) 376-	
2204		scottmo@adaptivecomputing.com		

Successfully undeleted 1 user and 1 association

Multi-Object Queries

Goldsh supports multi-object queries (table joins). Multiple objects are specified via a comma-separated list and attributes need to be prefixed by the associated object.

Example 22-13: Print the sums for active balance and allocated amounts grouped by account

```
gold> Allocation,Constraint Query
Show:="GroupBy (Constraint.Value)=Account, Sum (Allocation.Amount)=Balance, Sum
(Allocation.Deposited)=Allocation"
Constraint.Fund==Allocation.Fund Constraint.Name==Account
Allocation.Active==True
```

Account	Balance	Allocation
biology	193651124	360000000
chemistry	296167659	360000000

Example 22-14: Show all active accounts for amy's privileges

```
gold> RoleUser,RoleAction Query
Show:="RoleAction.Object,RoleAction.Name=Action"
RoleUser.Role==RoleAction.Role && ( RoleUser.Name==amy ||
RoleUser.Name==ANY ) Unique:=True
```

Object	Action
Account	Query
AccountUser	Query
Action	Query
Allocation	Query
Attribute	Query
ChargeRate	Query
Constraint	Query
Fund	Query
FundFund	Query
Lien	Query
LienAllocation	Query
Object	Query
Organization	Query
Password	ANY
Quote	Query
QuoteChargeRate	Query
Role	Query
RoleAction	Query
RoleUser	Query
System	Query
Transaction	Query
UsageRecord	Query
User	Query

i Although the forgoing was a good example of a join request, it should be understood that it is not a straightforward way to determine the full extent of a user's privileges. Some of the actions may be tied to specific object instances and many of them are associated with an override method which may not actually permit the user access to any instances of the object.

Using

Show:="RoleUser.Role,RoleUser.Name=User,RoleAction.Object,RoleAction.Name=Action,RoleAction.Instance" may be revealing in this regard. See the chapter on **Managing Roles** on page 2919 for more information about managing roles.

Customizing Objects

Moab Accounting Manager provides the ability to dynamically create new objects or customize or delete existing objects through the interactive control program (goldsh).

i The object customizations described in this chapter will be noticeable in subsequent goldsh queries (and in the web GUI after a fresh login). Client commands may need to be modified to properly interact with changed objects or attributes.

i The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. Inadvertent mistakes could result in modifications that are very difficult to reverse.

Managing Objects

In Moab Accounting Manager, Objects correspond to tables in the repository which have Attributes (such as Name and Color) and Actions (such as Query and Modify). A specific instance of an object is described as an Instance and has Properties (the specific values of the attributes for that object). The instance is uniquely referred to via its primary key(s) (such as its Name or Id).

An object must have a name and may have a description. An object may be set to auto-generate its instances when first seen (see [Object Auto-Generation on page 2939](#)) and/or a default value may be designated for the object (see [Global Object-Based Defaults on page 2940](#)).

Objects may reference other objects. If a single instance of an object references only a single instance of another object (for example, a usage record may only have one user), then it is sufficient for the first object to have an attribute field for the second object (the UsageRecord object has an attribute called User). However, if there may be a many-to-many relationship between objects (for example, an account may have multiple users and a user may belong to multiple accounts), then it is necessary to maintain a separate object as an association table (e.g. AccountUser). When creating an association object, the object should be given an appropriate name (e.g. AccountUser), it should be marked as an association (`Association=True`), and an object needs to be designated for the parent (e.g. Account) and the child (e.g. User). The association object itself may have additional attributes that provide qualitative information about the association (e.g. a particular AccountUser association may be active or be an administrator).

Creating a Custom Object

To create a new object, use the command `goldsh Object Create`. When an object is created, the 5 default actions are automatically created for the object: Create, Delete, Modify, Query and Undelete. A number of default metadata attributes are created as well: CreationTime, ModificationTime, Deleted, RequestId and TransactionId. These attributes are normally hidden in regular queries.

```
goldsh Object Create Name=<Object Name> [AutoGen=True|False]
[DefaultValue=<Default Value>] [Description=<Description>]
[Association=True|False] [Child=<Child Object>]
[Parent=<Parent Object>] [ShowUsage:=True]
```

Example 23-1: Creating a Node Object

```
$ goldsh Object Create Name=Node Description=\"Node Information\"
Successfully created 1 object and 5 actions
```

Example 23-2: Add a node name attribute

```
$ goldsh Attribute Create Object=Node Name=Name DataType=String PrimaryKey=True
Successfully created 1 attribute
```

Example 23-3: Add a processor count attribute

```
$ goldsh Attribute Create Object=Node Name=Processors DataType=Integer
Successfully created 1 attribute
```

Querying Objects

To display object information, use the command `goldsh Object Query`.

```
goldsh Object Query [Name=<Object Name>]
[Show:=Name,AutoGen,DefaultValue,Description,Association,Parent,Child]
[ShowUsage:=True]
```

Example 23-4: List Information for the Node Object

```
$ goldsh Object Query Name==Node
```

Name	Association	Parent	Child	DefaultValue	AutoGen	Description
Node	False				False	Node Information

Modifying an Object

It is possible to modify an object by using the command `goldsh Object Modify`.

```
goldsh Object Query [Name=<Object Name>] [AutoGen=True|False]
[DefaultValue=Default Value] [Description=Description]
```

```
[Association=True|(False)] [Child=Child Object>]  
[Parent=Parent Object>] [ShowUsage:=True]
```

Example 23-5: Changing the Node object's description

```
$ goldsh Object Modify Name==Node Description="\Host Information\  
Successfully modified 1 object
```

Deleting an Object

To delete an object, use the command `goldsh Object Delete`. When an object is deleted, all associated attributes, actions and other associations are automatically deleted as well.

```
goldsh Object Delete [Name=<Object Name>] [ShowUsage:=True]
```

Example 23-6: Deleting the Node Object

```
$ goldsh Object Delete Name==Node  
Successfully deleted 1 object
```

i This is a very dangerous operation and could result in the deletion of all object definitions requiring database repair. The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. Be sure to specify conditions for the object you want to delete.

Object Auto-Generation

It is possible to have object instances be automatically generated the first time they are referenced in designated contexts. For example, you might want a user be auto-generated when newly added to an account. You could have an organization auto-generated when specified as the default for a user. You could have a cost-center be auto-generated when referenced in a usage record. To do this, the referenced object must be set to `AutoGen=True` and the **Values** property for the attribute that you want to trigger the auto-generation must be set to a string consisting of the @ sign followed by the object name.

Example 23-7: Auto-generate an account's organization

For example, let's assume that your accounts belong to specific organizations that you may want to run a report against but you don't want to define all of the organizations up front. It would be possible to automatically generate a new organization instance each time an undefined organization is specified for an account.

```
$ goldsh Object Modify Name==Organization AutoGen=True  
Successfully modified 1 object
```

```
$ goldsh Attribute Modify Object==Account Name==Organization Values=@Organization
Successfully modified 1 attribute
```

See [Usage Record Property Auto-Generation on page 2899](#) for a discussion of auto-generating objects referenced in usage records.

Global Object-Based Defaults

It is possible to set a global default for an object that will be applied to all attributes referencing this object. When a new instance of an object is being created which has an attribute referring to another object via its **Values** property, if that attribute has not been specified and you want it to default to the global default, you will need to set the **DefaultValue** attribute for the referenced object to the desired value.

Example 23-8: Setting a system-wide simple default organization called general

```
$ goldsh Object Modify Name==Organization DefaultValue=general
Successfully modified 1 object
```

Thereafter each (non-association) object which has an attribute with a **Values** property set to @Organization will default to general if that attribute is not specified. Perhaps we would want the default value to be taken for the organization when a new account is created.

```
$ goldsh Attribute Modify Object==Account Name==Organization Values=@Organization
Successfully modified 1 attribute
```

See [Local Attribute-Based Defaults on page 2944](#) for more information about setting default values for attributes. See [Usage Record Property Defaults on page 2899](#) for more information about setting default values for usage record properties.

Managing Attributes

Objects can have any number of fields called Attributes. When an object is first created, a number of attributes are created for the object by default. These are: **CreationTime** (time the object was first created), **ModificationTime** (time the object was last updated), **Deleted** (whether the object is deleted or not), **RequestId** (request id that resulted in the last modification of the object), **TransactionId** (transaction id that resulted in the last modification of the object).

An attribute must have a name and be associated with an object.

An attribute will have a data type which can be one of (**AutoGen**, **TimeStamp**, **Boolean**, **Float**, **Integer**, **Currency**, **String**) and defaults to String. A data type of AutoGen means the field will be a primary key of type integer which will assume the next auto-incremented value from the g_key_generator table.

TimeStamps are epoch times stored in integer format. Booleans are strings constrained to the values of `True` or `False` (or unset). Float is used to store decimal or floating point values. Currency is like Float but may have special business logic for handling currency values.

An object may have zero or more attributes which are primary keys (`PrimaryKey==True`), the combination of which are used to uniquely identify an object instance. Moab Accounting Manager will try to ensure that there can only be one object instance with the exact same set of values of its primary keys.

A required attribute (`Required==True`), must be either specified or be derived via a default value or other dynamic mechanism when the object is created. It can also not be unset.

A fixed attribute (`Fixed==True`), may not be changed from its initial value.

An attribute may be constrained to certain values via the **Values** attribute. The values may be constrained to members of a list expressed as a parenthesized comma-delimited list of strings (i.e. `Values="(Brazil,China,France,Russia,USA)"`). Alternatively, the values may be constrained to be an instance of a particular object type (like a foreign key constraint) by assigning to the Values attribute the name of an object prefixed by the `@` sign (e.g. `Values="@Account"` -- which would constrain the value of this attribute to be a valid account name). Stronger versions of the `@`-prefixed object-constrained values may be used in Quote, Reserve and Charge actions to enforce dynamic interactions between usage record properties such as to assign default values if not defined (e.g. `Values="@?=Account"`), verification values which evoke an error if they differ (e.g. `Values="@!=Account"`), or designated values which always overwrite the value (e.g. `Values="@:=Account"`). See [Usage Record Property Instantiators on page 2900](#) for more information.

A default value may be assigned to an attribute via the **DefaultValue** attribute. When a new instance of an object is created, if a property is not specified for the attribute, the default value will be used.

The **Sequence** attribute determines which order an object's attributes will be listed in for queries if no selection list is specified in the query. Attributes with smaller sequence numbers will appear before attributes with larger sequence numbers. The Sequence attribute is also used to enforce a proper attribute display ordering in the web GUI.

The **Hidden** attribute specifies whether an attribute should be shown in a query by default or not. Hidden attributes can be seen in queries by specifying the **ShowHidden** option with a value of `True`.

The **Description** field is a location to describe the meaning of the attribute and is used in the GUI for field descriptions.

Adding an Attribute to an Object

To create a new attribute for an object, use the command `goldsh Attribute Create`:

```
goldsh Attribute Create Object=<Object Name> Name=<Attribute Name>
[DataType=AutoGen|TimeStamp|Boolean|Float|Integer|Currency|
(String)] [PrimaryKey=True|(False)] [Required=True|(False)]
[Fixed=True|(False)] [Values=<Foreign Key or List of Values>]
[DefaultValue=<Default Value>] [Sequence=<Integer Number>]
[Hidden=<True|(False)>] [Description=<Description>]
[ShowUsage:=True]
```

Example 23-9: Adding a Country Attribute to User

```
$ goldsh Attribute Create Object=User Name=Country Values="\
(Brazil,China,France,Russia,USA)\\"" DefaultValue=USA
Successfully created 1 attribute
```

Example 23-10: Tracking Submission Time in Usage records

```
$ goldsh Attribute Create Object=UsageRecord Name=SubmissionTime DataType=TimeStamp
Successfully created 1 attribute
```

Querying Attributes

To display attribute information, use the command `goldsh Attribute Query`:

```
goldsh Attribute Query Object=<Object Name> Name=<Attribute Name>
[Show:=Object,Name,DataType,PrimaryKey,Required,Fixed,Values,D
efaultValue,Sequence,Hidden,Description] [ShowHidden:=True]
[ShowUsage:=True]
```

Example 23-11: List the attributes of the Node object

```
$ goldsh Attribute Query Object==Node
```

Object Name	DataType	PrimaryKey	Required	Fixed	Values	DefaultValue	Sequence	Hidden	Description
Node Processors	Integer	False	False	False			20	False	
Node Name	String	True	True	True			10	False	
Node TransactionId	Integer	False	False	True			990	True	Last Modifying Transaction Id
Node RequestId	Integer	False	False	True			980	True	Last Modifying Request Id
Node Deleted	Boolean	False	False	True			970	True	Is this object deleted?
Node ModificationTime	TimeStamp	False	False	True			960	True	Last Updated
Node CreationTime	TimeStamp	False	False	True			950	True	First Created

Modifying an Attribute

To modify an attribute, use the command `goldsh Attribute Modify`:

```
goldsh Attribute Modify Object==<Object Name> Name==<Attribute Name>
[Required=True|(False)] [Fixed=True|(False)] [Values=<Foreign
Key or List of Values>] [DefaultValue=<Default Value>]
[Sequence=<Integer Number>] [Hidden=<True|(False)>]
[Description=<Description>] [ShowUsage:=True]
```

i The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. A mistake made using this command could result in the inadvertent modification of all attributes.

Example 23-12: Change Account Organization values to not be restricted to the set of organization instances

```
$ goldsh Attribute Modify Object==Account Name==Organization Values=NULL
Successfully modified 1 attribute
```

Removing an Attribute From an Object

To delete an attribute, use the command `goldsh Attribute Delete`:

```
goldsh Attribute Delete Object==<Object Name> Name==<Attribute Name>
[ShowUsage:=True]
```

i The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. A mistake made using this command could result in the inadvertent deletion of all attributes.

i When using Moab Accounting Manager as an accounting manager, certain objects and attributes are assumed to exist. For example, a call to `UsageRecord Charge` would fail if you had deleted the **Allocation Amount** attribute. The `Attribute Undelete` command might come in useful in such a case.

Example 23-13: Removing the Organization attribute from Account

```
$ goldsh Attribute Delete Object==Account Name==Organization
Successfully deleted 1 attribute
```

Example 23-14: Perhaps we don't care to track the QualityOfService attribute in a Usage record

```
$ goldsh Attribute Delete Object==UsageRecord Name==QualityOfService
Successfully deleted 1 attribute
```

Local Attribute-Based Defaults

It is possible to set a specific default for an object attribute that will be applied when an instance of that object is created but the attribute is not specified. This type of default is intended for attributes which do not refer to another object or which should vary from the object global default. This default value is assigned to an attribute via the **DefaultValue** attribute. When a new instance of the associated object is created, if a property is not specified for the attribute, the specified default value will be used. A local attribute default will have precedence over a global object default.

```
goldsh Attribute Delete Object==<Object Name> Name==<Attribute Name> [ShowUsage:=True]
```

Example 23-15: Setting a default organization just for the account object

```
$ goldsh Attribute Modify Object==Account Name==Organization DefaultValue=university
Successfully modified 1 attribute
```

Example 23-16: Setting a default phone for the user object

```
$ goldsh Attribute Modify Object==User Name==PhoneNumber DefaultValue="\NoPhone\"
Successfully modified 1 attribute
```

See [Global Object-Based Defaults on page 2940](#) for more information about setting default values for objects.

See [Usage Record Property Defaults on page 2899](#) for more information about setting default values for usage record properties.

Managing Actions

Moab Accounting Manager defines which actions can be performed by which objects. When an object is first created, five basic actions are created for the object by default. These are: Create, Modify, Query, Delete and Undelete. Specific code must exist in Moab Accounting Manager modules in order for objects to support additional actions.

An action is uniquely specified by its name and the object with which it is associated. An action also has a description and a boolean display attribute which governs whether this action should be displayed in the web GUI or not.

Adding an Action to an Object

To specify that an action is allowed for an object, use the command `goldsh Action Create`:

```
goldsh Action Create Object=<Object Name> Name=<Action Name>
[Display=True|False] [Description=<Description>]
[ShowUsage:=True]
```

Example 23-17: Adding a Modify Action to Transaction

```
$ goldsh Action Create Object=Transaction Name=Modify Description=Modify
Successfully created 1 action
```

Querying Actions

To display action information, use the command `goldsh Action Query`:

```
goldsh Action Query [Object==<Object Name>] [Name==<Attribute
Name>] [Show:=Object,Name,Display,Description]
[ShowUsage:=True]
```

Example 23-18: List the actions of the Node object

```
$ goldsh Action Query Object==Node
```

Object	Name	Display	Description
Node	Create	False	Create
Node	Delete	False	Delete
Node	Modify	False	Modify
Node	Query	False	Query
Node	Undelete	False	Undelete

Modifying an Action

To modify an action, use the command `goldsh Action Modify`:

```
goldsh Action Modify [Object==<Object Name>] [Name==<Attribute
Name>] [Display=True|(False)] [Description=<Description>]
[ShowUsage:=True]
```

i The `goldsh` control program allows you to make powerful and sweeping modifications to many objects with a single command. A mistake made using this command could result in the inadvertent modification of all actions.

Example 23-19: Display all Node actions but Undelete in the web GUI

```
$ goldsh Action Modify Object==Node Name!=Undelete Display=True
Successfully modified 4 actions
```

Removing an Action From an Object

To delete an action from an object, use the command `goldsh Action Delete`:

```
goldsh Action Delete [Object==<Object Name>] [Name==<Attribute
Name>] [ShowUsage:=True]
```

 The goldsh control program allows you to make powerful and sweeping modifications to many objects with a single command. A mistake made using this command could result in the inadvertent modification of all actions.

 When using Moab Accounting Manager as an accounting manager, certain actions are assumed to exist. Be careful what you delete!

Example 23-20: Do not allow accounts to be deleted

```
$ goldsh Action Delete Object==Account Name==Delete
Successfully deleted 1 action
```

Examples Creating Custom Objects

Creating a custom object normally involves defining a new object and adding attributes to the object.

Example 23-21: Creating a License object to track license usage and charges.

Invoke the Moab Accounting Manager control program in interactive mode.

```
$ goldsh
```

Create the License Object.

```
gold> Object Create Name=License Description=License
Successfully created 1 object and 5 actions
```

Next, define its attributes. Give each record a unique id (so the record can be more easily modified), a license type that can be one of (Matlab,Mathematica,Compiler,AutoCAD,Oracle), the user who is using it, the start and end time, how many instances of the license were used, and how much was charged.

```

gold> Attribute Create Object=License Name=Id DataType=AutoGen PrimaryKey=True
Description="Record Id"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=Type DataType=String Required=True Values="
(Matlab,Mathematica,Compiler,AutoCAD,Oracle)" Fixed=True Description="License Type"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=User Required=True Values="@User"
Description="User Name"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=StartTime DataType=TimeStamp
Description="Start Time"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=EndTime DataType=TimeStamp Description="End
Time"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=Count DataType=Integer Description="Number
of Licenses Used"

Successfully created 1 attribute

gold> Attribute Create Object=License Name=Charge DataType=Currency
Description="Amount Charged"

Successfully created 1 attribute

```

Finally, since we would like to manage licenses from the web GUI, set `Display=True`.

```

gold> Action Modify Object==License Name!=Undelete Display=True

Successfully modified 4 actions

```

When done, exit the goldsh prompt.

```

gold> quit

```

That's about it. Licenses should now be able to be managed via the GUI and goldsh. The data source will need to use one of the methods of interacting with Moab Accounting Manager (see [Methods of Interacting with Moab Accounting Manager on page 2952](#)) in order to push license record usage info to Moab Accounting Manager.

Apart from being used as an accounting manager, Moab Accounting Manager can be used as a generalized information service. It can be used to manage just about any object-oriented information over the web. For example, Moab Accounting Manager could be used to provide meta-schedulers with machine/user mappings, or node/resource information.

Example 23-22: Using Moab Accounting Manager as a Grid Map File.

Invoke the goldsh control program in interactive mode.

```
$ goldsh
```

Create the GridMap Object.

```
gold> Object Create Name=GridMap Description="Online Grid Map File"
```

```
Successfully created 1 object and 5 actions
```

Next, define its attributes. Each entry will consist of a userid (which will serve as the primary key) and a required public X.509 certificate.

```
gold> Attribute Create Object=GridMap Name=User PrimaryKey=True Values=@User  
Description="User Name"
```

```
Successfully created 1 attribute
```

```
gold> Attribute Create Object=GridMap Name=Certificate DataType=String Required=True  
Description="X.509 Public Key"
```

```
Successfully created 1 attribute
```

Exit the goldsh prompt.

```
gold> quit
```

From this point, a peer service will need to use one of the methods of interacting with Moab Accounting Manager (see Interaction Methods) in order to query the GridMap information.

Integration

This chapter provides information on integrating with the resource management system (Moab Workload Manager) and Moab Web Services. It also contains as methods for interacting with Moab Accounting Manager.

- [Integrating with Moab Workload Manager on page 2949](#)
- [Integrating with Moab Web Services on page 2951](#)
- [Methods of Interacting with Moab Accounting Manager on page 2952](#)

Integrating with Moab Workload Manager

Moab Workload Manager can be configured to interact with Moab Accounting Manager to track and charge for resources utilized by jobs and reservations. You will need to use Moab HPC Suite — Enterprise Edition in order to have support for Moab Accounting Manager.

Select an Appropriate Accounting Management Interface Type

There are two accounting manager interface types that Moab can use to interact with Moab Accounting Manager: MAM, which makes direct calls to MAM over the SSS wire protocol, and Native, in which customizable scripts are invoked to communicate with Moab Accounting Manager. The MAM accounting manager interface is the default as it is usually faster. The Native accounting manager interface can be used if higher customizability is needed, or if you need to interface with a third party accounting or allocation system. See [Accounting Manager Interface Types on page 533](#) in the Moab Workload Manager documentation for more information. Choose the accounting manager interface type that is right for your needs and remember it. This information will be used in a later step.

Run Configure --with-am

It may be necessary or advantageous when installing Moab Workload Manager to run configure with certain accounting related options.

Configure Moab to use the Moab Accounting Manager by running `./configure` with the applicable options when installing Moab:

- `--with-am[=TYPE]` - Enable accounting management with the specified accounting manager interface type (mam or native) [mam].
- `--with-am-dir=DIR` - Uses the specified prefix directory for the accounting manager if installed in a non-default location.

The `--with-am` option specifies the accounting manager interface type that you want to use as either `mam`, which is the default, or `native`. Specifying this option will add essential entries into Moab configuration files. Although these entries may be added manually later, this step facilitates configuration by adding parameters appropriate for your selected accounting manager interface type.

Use `--with-am-dir` to specify the prefix directory for Moab Accounting Manager if it has been installed in a non-default location. This value is used to help the native accounting manager scripts find the Moab Accounting Manager libraries and server connection information.

Example 24-1: Configuring Moab to Use the Direct Accounting Manager Interface

```
$ ./configure --with-am
```

Edit the Moab Server Configuration File

Add or uncomment the essential `AMCFG` lines in the `moab.cfg` file.

Example 24-2: Configuring Moab to Use the MAM Accounting Manager Interface

If you are using the direct (MAM) accounting manager interface, at a minimum, you must tell Moab to use `AMCFG [] TYPE=MAM`. Additionally, if your Moab Accounting Manager server is running on a different host than the Moab Workload Manager server, you must specify the hostname via the `AMCFG [] HOST` parameter.

```
$ vi /opt/moab/etc/moab.cfg
AMCFG[mam] TYPE=MAM HOST=localhost
```

Example 24-3: Configuring Moab to Use the Native Accounting Manager Interface

If you are using the script (Native) accounting manager interface, at a minimum, you must tell Moab to use `AMCFG [] TYPE=NATIVE`. Moab Workload Manager will default to using a set of stock scripts to interact with Moab Accounting Manager.

```
$ vi /opt/moab/etc/moab.cfg
AMCFG[mam] TYPE=NATIVE
```

Edit the Moab Private Configuration File

If you have chosen to use the direct MAM accounting manager interface type, you will need to configure Moab to have Moab Accounting Manager's symmetric key for secure authentication. This step is not necessary when using the Native accounting manager interface type since the secret key can be securely derived from Moab Accounting Manager and used via the connection libraries.

Example 24-4: Configuring Moab to Communicate Securely with Moab Accounting Manager

Add or uncomment a `CLIENTCFG[AM:mam] KEY` parameter line in `moab-private.cfg`. Copy the **token.value** parameter in `/opt/mam/etc/site.conf` into the KEY value in `/opt/moab/etc/moab-private.cfg`.

```
# vi /opt/moab/etc/moab-private.cfg
CLIENTCFG[AM:mam] KEY=UiW7EihzKyUyVQg6dKirDhV3
```

Restart Moab Workload Manager

Restart Moab in order for the configuration changes to take effect.

Example 24-5: Restarting Moab

```
# service moab restart
```

Integrating with Moab Web Services

Moab Web Services can be configured to interact with Moab Accounting Manager order to be able to perform RESTful web service queries against accounting objects in Moab Accounting Manager.

Edit the MWS HPC Configuration File

Uncomment and set the following parameters in `/opt/mws/etc/mws.d/mws-config-hpc.groovy`:

- **mam.secretKey** - Set to the value of the token.value parameter in `/opt/mam/etc/site.conf`
- **mam.server** - Set to the hostname of the MAM server
- **mam.port** - Set to the port of the MAM server (defaults to 7112)

Example 24-6: Configuring Moab Web Services to Communicate with MAM Accounting Manager

```
$ vi /opt/mws/etc/mws.d/mws-config-hpc.groovy

mam.secretKey = "UiW7EihzKyUyVQg6dKirDhV3"
mam.server = "localhost"
mam.port = 7112
```

Restart Moab Web Services

Restart tomact in order for the MWS configuration changes to take effect.

Example 24-7: Restarting Moab Web Services

```
# service tomcat6 restart
```

Methods of Interacting with Moab Accounting Manager

There are essentially five ways of interacting with Moab Accounting Manager. Let's consider a simple usage charge in each of the different ways.

Using the Appropriate Command-line Client

From inside a script, or by invoking a system command, you can use a command-line client (one of the "g" commands in the bin directory).

Example 24-8: To issue a charge at the completion of job usage, you could use gcharge:

```
gcharge -J Moab.1234 -a chemistry -u amy -m colony -P 2 -t 3600 -X Duration=3600
```

Using the Interactive Control Program

The interactive control program, goldsh, will issue a charge for a job expressed in xml.

Example 24-9: To issue a charge you must invoke the Charge action on the Job object:

```
goldsh UsageRecord Charge
Data:="<UsageRecord><Instance>Moab.1234</Instance><Account>chemistry</Account><User>amy</User><Machine>colony</Machine><Processors>2</Processors><Duration>3600</Duration></UsageRecord>" Duration:=3600
```

Use the Perl API

The Perl API exposes the full functionality of Moab Accounting Manager. The client commands can be examined as sample code. Use perldoc on the modules in lib/Gold for function documentation.

Example 24-10: To make a charge via this interface you might do something like:

```
use Gold;

my $request = new Gold::Request(object => "UsageRecord", action => "Charge");
my $usageRecord = new Gold::Datum("UsageRecord");
$usageRecord->addProperty("Instance", "Moab.1234");
$usageRecord->addProperty("Account", "chemistry");
$usageRecord->addProperty("User", "amy");
$usageRecord->addProperty("Machine", "colony");
$usageRecord->addProperty("Processors", "2");
$usageRecord->addProperty("Duration", "3600");
$request->setDatum($usageRecord);
$request->setOption("Duration", "3600");
my $response = $request->getResponse();
print $response->getStatus(), ": ", $response->getMessage(), "\n";
```

Use the Java API

Although deprecated, the Java API may still be usable to interact with Moab Accounting Manager. The javadoc command can be run on the

contrib/java/gold directory to generate documentation for the gold java classes.

Example 24-11: To make a charge via this interface you might do something like:

```
import java.util.*;
import gold.*;

public class Test
{
    public static void main(String [] args) throws Exception
    {
        Gold.initialize();
        Request request = new Request("UsageRecord", "Charge");
        Datum usageRecord = new Datum("UsageRecord");
        usageRecord.addProperty("Instance", "Moab.1234");
        usageRecord.addProperty("Account", "chemistry");
        usageRecord.addProperty("User", "amy");
        usageRecord.addProperty("Machine", "colony");
        usageRecord.addProperty("Processors", "2");
        usageRecord.addProperty("Duration", "3600");
        request.setDatum(usageRecord);
        request.setOption("Duration", "3600");
        Response response = request.getResponse();
        System.out.println(response.getStatus() + ": " + response.getMessage() + "\n");
    }
}
```

Communicating via the SSSRMAP Protocol

Finally, it is possible to interact with Moab Accounting Manager by directly using the SSSRMAP Wire Protocol and Message Format over the network (see [SSS Resource Management and Accounting documentation](#)). This will entail building the request body in XML, appending an XML digital signature, combining these in an XML envelope framed in an HTTP POST, sending it to the server, and parsing the similarly formed response. The Moab Workload Manager communicates with Moab Accounting Manager via this method.

Example 24-12: The message might look something like:

```
POST /SSSRMAP HTTP/1.1
Content-Type: text/xml; charset="utf-8"
Transfer-Encoding: chunked

190
<?xml version="1.0" encoding="UTF-8"?>
<Envelope>
  <Body>
    <Request action="Charge" actor="scottmo">
      <Object>UsageRecord</Object>
      <Data>
        <UsageRecord>
          <Instance>Moab.1234</Instance>
          <Account>chemistry</Account>
          <User>amyh</User>
          <Machine>colony</Machine>
          <Processors>2</Processors>
          <Duration>3600</Duration>

Configuration Files

Moab Accounting Manager uses four configuration files: one for the connection information (`site.conf`), one for the server (`goldd.conf`), one for the clients (`gold.conf`) and one for the graphical user interface (`goldg.conf`). For configuration parameters that have hard-coded defaults, the default value is specified within brackets.

Site Configuration

The site configuration file specifies the connection information for the current site such as the server host name, port, backup server, default security method and the symmetric key. Optionally, it may also have blocks that specify connection information for other sites. This file should be readable only by the accounting admin user.

Example 25-1: The following is an example `site.conf` file

```
server.host = red-head1
backup.host = red-head2
server.port = 7071
token.type = Symmetric
token.value = pBaIapJqbfLd8NiyzTJefFXW

[white]
server.host = white-head1
server.port = 7071
token.value = Fl7wOkioUpyjdqJ8ckvWK_ta

[blue]
server.host = blue-head1
server.port = 7071
token.value = gVSeQ8Diz5O3pzj01y4inGWq
```

The following configuration parameters may be set in the site configuration file (`site.conf`).

backup.host — The hostname of the backup server. Each site can have both a primary server and a hot-standby backup server. They should either point to the same database or separate instances of replicated database. If `backup.host` is specified, clients will try communicating with the primary server first, and if the connection fails, they will try communicating with the backup server.

server.host — The hostname of the server

server.port [7112] — The port that the server listens on

token-type [Symmetric] — Indicates the default security token type to be used in both authentication and encryption. Valid token types include `Password` and `Symmetric`. The default is `Symmetric`.

token.value — When using the `Symmetric` token type, `token.value` is the secret key. It is a base64-encoded symmetric key used between clients and the server for authentication and encryption.

Server Configuration

The following configuration parameters may be set in the server configuration file (`goldd.conf`).

Parameter	Description
accounting.mode [<code>strict-allocation</code>]	The accounting mode can be one of <code>usage-tracking</code> , <code>notional-charging</code> , <code>fast-allocation</code> , or <code>strict-allocation</code> . If <code>usage-tracking</code> is specified, charges will simply result in the creation of usage records with no charge value. No charge will be calculated and allocations will not be debited. If <code>notional-charging</code> is specified, a charge will be calculated and recorded with the usage record, but allocations are not debited. If <code>fast-allocation</code> is specified, usage records will be updated with charge amounts and allocations will be debited, but liens will not be used to protect the allocation from simultaneous use. If <code>strict-allocation</code> is specified, usage records will be updated with charge amounts and allocations will be debited, and liens will be used to protect the allocation from simultaneous use.
currency.itemization [<code>false</code>]	Enables (<code>true</code>) or disables (<code>false</code>) the storing of itemized charges to the Charge table for charge transactions.
currency.precision [<code>0</code>]	Indicates the number of decimal places in the resource credit currency. For example, if you will be dealing with an integer billable unit like processor-seconds, use 0 (which is the default). If you will be charging dollars and cents, then use 2. This parameter should be the same in the <code>goldd.conf</code> and <code>gold.conf</code> files.
database.datasource [<code>DBI:Pg:dbname=mam;host=localhost</code>]	The Perl DBI data source name for the database you wish to connect to
database.password	The password to be used for the database connection (if any)
database.user	The username to be used for the database connection (if any)
event.scheduler [<code>false</code>]	Specifies whether the event scheduler is enabled (<code>true</code>) or not (<code>false</code>)

Parameter	Description
event.pollinterval [5]	The period in minutes that the event scheduler uses to check and fire events. The poll interval must divide evenly into the number of minutes in a day (1440).
log4perl.appender.Log.filename	Used by <code>log4perl</code> to set the base name of the log file
log4perl.appender.Log.max	Used by <code>log4perl</code> to set the number of rolling backup logs
log4perl.appender.Log.size	Used by <code>log4perl</code> to set the size the log will grow to before it is rotated
log4perl.appender.Log.Threshold	Used by <code>log4perl</code> to set the debug level written to the log. The logging threshold can be one of TRACE, DEBUG, INFO, WARN, ERROR, and FATAL
log4perl.appender.Screen.Threshold	Used by <code>log4perl</code> to set the debug level written to the screen. The logging threshold can be one of TRACE, DEBUG, INFO, WARN, ERROR, and FATAL
notification.deliverymethod [store]	Specifies which delivery method is used by default if unspecified
notification.duration [1209600]	Defines how long in seconds that stored notifications persist before being automatically deleted. The default is two weeks.
response.chunksize [0]	Indicates the line length in the data response that will trigger message segmentation (or truncation). A value of 0 (zero) means unlimited, i.e. that the server will not truncate or segment large responses unless overridden by a chunksize specification in a client request. The response chunksize will be taken to be the smaller of the client and server chunksize settings.
security.authentication [true]	Indicates whether incoming message authentication is required
security.encryption [false]	Indicates whether incoming message encryption is required
super.user [root]	The primary Moab Accounting Manager system admin which by default can perform all actions on all objects. The super user is sometimes used as the actor in cases where an action is invoked from within another action.
user.firstaccountdefault [true]	If set to true, the first account that a user is added to will become the default account for that user. This default value is true.

Client Configuration

The following configuration parameters may be set in the client configuration file (`gold.conf`):

Parameter	Description
account.show [Name,Active,Users,Organization,Description]	The default fields shown by <code>glsaccount</code>
accounting.context [hpc]	By specifying the accounting context (either <code>hpc</code> or <code>cloud</code>), the behavior of some client commands are adjusted to show the proper fields for that context. The default is <code>hpc</code> .
accounting.mode [strict-allocation]	The accounting mode can be one of <code>usage-tracking</code> , <code>notional-charging</code> , <code>fast-allocation</code> , or <code>strict-allocation</code> . The value of this parameter may modify the default fields displayed by certain commands such as <code>glsusage</code> .
allocation.enforcedisdiscrete [true]	If enabled (the default), new allocations will be prevented from overlapping existing ones. This policy helps to improve clarity when reporting on allocation usage during a particular period.
allocation.show [Id,Fund,StartTime,EndTime,InitialDeposit,Allocated,CreditLimit,Remaining,PercentUsed]	The default fields shown by <code>glsalloc</code>
balance.show [Id,Name,Balance,Reserved,Effective,CreditLimit,Available]	The default fields shown by <code>gbbalance</code>
currency.precision [0]	Indicates the number of decimal places in the credit currency. For example, if you will be dealing with integer billable units like processor-seconds, use 0 (which is the default). If you will be charging dollars and cents, then use 2. This parameter should be the same in the <code>goldd.conf</code> and <code>gold.conf</code> files.

Parameter	Description
event.show	[Id,FireCommand,FireTime,ArmTime,RearmPeriod,EndTime,Notify,RearmOnFailure,FailureCommand,CatchUp,CreationTime,Description] -- The default fields shown by <code>glsevent</code>
fund.show [Id,Name,Constraints,Allocated,Balance,DefaultDeposit,Description]	The default fields shown by <code>glsfund</code>
lien.show [Id,Instance,Amount,StartTime,EndTime,UsageRecord,Funds,Description]	The default fields shown by <code>glslie</code>
log4perl.appender.Log.filename	Used by log4perl to set the base name of the log file
log4perl.appender.Log.max	Used by log4perl to set the number of rolling backup logs
log4perl.appender.Log.size	Used by log4perl to set the size the log will grow to before it is rotated
log4perl.appender.Log.Threshold	Used by log4perl to set the debug level written to the log. The logging threshold can be one of TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.
log4perl.appender.Screen.Threshold	Used by log4perl to set the debug level written to the screen. The logging threshold can be one of TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.
notification.show	[Id,Event,Type,Status,Code,Message,Key,Recipient,EndTime,CreationTime] --The default fields shown by <code>glshot</code>
organization.show [Name,Description]	The default fields shown by <code>glstorg</code>
quote.show [Id,Amount,Pinned,Instance,UsageRecord,StartTime,EndTime,Duration,Cha	The default fields shown by <code>glstquote</code>

Parameter	Description
response.chunking [false]	Indicates whether large responses should be chunked (segmented). If set to false, large responses will be truncated
response.chunksize [1000]	Indicates the line length in the data response that will trigger message segmentation (or truncation). A value of 0 (zero) means unlimited, i.e., that the client will accept the chunksize set by the server. The response chunksize will be taken to be the smaller of the client and server chunksize settings.
security.authentication [true]	Indicates whether outgoing message are signed
security.encryption [false]	Indicates whether outgoing messages are encrypted

Parameter	Description
security.promotion [suidperl]	When using the symmetric key for security authentication or encryption, since the <code>site.conf</code> file is readable only by the accounting admin user, a method must be employed to temporarily elevate privileges in order to encrypt the communication with the symmetric key. One of two security promotion methods may be selected: <code>suidperl</code> or <code>gauth</code> . Suiperl allows a Perl script to temporarily elevate privileges to the owner of the script if the <code>setuid</code> bit is set on the file. This method is recommended when <code>suidperl</code> can be installed on the system. If you prefer not to use <code>suidperl</code> or if it is not available for your system (such as with Perl 5.12 and higher), you will need to use the <code>gauth</code> security promotion method. <code>Gauth</code> is a <code>setuid</code> binary that allows the request body to be passed in as standard input and returns the authenticated digest and signature. Currently, only <code>suidperl</code> can be used for encryption of client communication. The security promotion method should be configured at install time by specifying the <code>--with-promotion</code> configuration parameter and defaults to <code>suidperl</code> when it is available.
statement.show [Account,User,Machine]	The default discriminator fields in <code>gstatement</code>
transaction.show [Id,Object,Action,Actor,Name,Child,Instance,Count,Amount,Delta,Balance,User	The default fields shown by <code>glstrans</code>
usagerecord.show [Id,Type,Instance,Charge,Stage,Quote,User-Group,Account,Organization,Class,QualityOfService,Machine,Not	The default fields shown by <code>glusage</code>
user.show [Name,Active,CommonName,PhoneNumber,EmailAddress,DefaultAccount,Descript	The default fields shown by <code>gluser</code>

GUI Configuration

The following configuration parameters may be set in the GUI configuration file (`goldg.conf`).

Parameter	Description
currency.enablehours [false]	If set to true, the graphical user interface will include a ShowHours radio button (defaulting to <code>True</code>) for certain panels (e.g. Fund Deposit, Query, Statement, Transfer, Withdraw) that will allow the currency inputs or outputs to be divided by 3600.
currency.precision [0]	Indicates the number of decimal places in the credit currency. For example, if you will be dealing with integer billable units like processor-seconds, use 0 (which is the default). If you will be charging dollars and cents, then use 2. This parameter should be the same in the <code>goldd.conf</code> and <code>gold.conf</code> files.
gui.style [viewpoint]	Modifies the appearance and behavior of the web GUI to be consistent with use within viewpoint or for standalone use. Valid values are <code>legacy</code> or <code>viewpoint</code> . The default is <code>viewpoint</code> .
log4perl.appender.Log.filename	Used by log4perl to set the base name of the log file
log4perl.appender.Log.max	Used by log4perl to set the number of rolling backup logs
log4perl.appender.Log.size	Used by log4perl to set the size the log will grow to before it is rotated
log4perl.appender.Log.Threshold	Used by log4perl to set the debug level written to the log. The logging threshold can be one of TRACE, DEBUG, INFO, WARN, ERROR, and FATAL.
response.chunking [false]	Indicates whether large responses should be chunked (segmented). If set to false, large responses will be truncated.
response.chunksize [1000]	Indicates the line length in the data response that will trigger message segmentation (or truncation). A value of 0 (zero) means unlimited, i.e. that the client will accept the chunksize set by the server. The response chunksize will be taken to be the smaller of the client and server chunksize settings.
security.authentication [true]	Indicates whether outgoing message are signed
security.encryption [false]	Indicates whether outgoing messages are encrypted

Parameter	Description
security.promotion [suidperl]	When using the symmetric key for security authentication or encryption, since the <code>site.conf</code> file is readable only by the accounting admin user, a method must be employed to temporarily elevate privileges in order to encrypt the communication with the symmetric key. One of two security promotion methods may be selected: <code>suidperl</code> or <code>gauth</code> . Suidperl allows a Perl script to temporarily elevate privileges to the owner of the script if the <code>setuid</code> bit is set on the file. This method is recommended when <code>suidperl</code> can be installed on the system. If you prefer not to use <code>suidperl</code> , or if it is not available for your system (such as with Perl 5.12 and higher), you will need to use the <code>gauth</code> security promotion method. <code>Gauth</code> is a <code>setuid</code> binary that allows the request body to be passed in as standard input and returns the authenticated digest and signature. Currently, only <code>suidperl</code> can be used for encryption of client communication. The security promotion method should be configured at install time by specifying the <code>--with-promotion</code> configuration parameter and defaults to <code>suidperl</code> when it is available.
statement.discriminators	The Fund Statement page will group summary entries in the debit detail by these transaction properties.

Appendices

Appendix A: Commands Reference

Moab Accounting Manager provides a server daemon and client commands for use by administrators and end users.

Common Command Options

Most Moab Accounting Manager commands support the following common options.

Option	Description
--help	Brief command option summary
--man	Full command documentation
--site	Obtain response from specified site
--version	Display product version

List of Commands

Command	Description
<u>gbalance</u>	Display balance information
<u>gchaccount</u>	Modify an account
<u>gchalloc</u>	Modify an allocation
<u>gcharge</u>	Create a usage charge
<u>gchevent</u>	Modify an event
<u>gchfund</u>	Modify a fund

Command	Description
<u>gchlien</u>	Modify a lien
<u>gchorg</u>	Modify an organization
<u>gchpasswd</u>	Set a user password
<u>gchquote</u>	Modify a quote
<u>gchrates</u>	Modify a charge rate
<u>gchrole</u>	Modify a role
<u>gchusage</u>	Modify a usage record
<u>gchuser</u>	Modify a user
<u>gdeposit</u>	Issue a deposit
<u>glsaccount</u>	Query accounts
<u>glsalloc</u>	Query allocations
<u>glscharge</u>	Query charges
<u>glsconfig</u>	Query configuration
<u>glsevent</u>	Query events
<u>glsfund</u>	Query funds
<u>glslien</u>	Query liens
<u>glsnot</u>	Query stored notifications
<u>glsorg</u>	Query organizations
<u>glsquote</u>	Query quotes
<u>glstrate</u>	Query charge rates

Command	Description
<u>glsrole</u>	Query roles
<u>glstrans</u>	Query transactions
<u>glsusage</u>	Query usage records
<u>glsuser</u>	Query users
<u>gmkaaccount</u>	Create a new account
<u>gmkevent</u>	Create a new event
<u>gmkfund</u>	Create a new fund
<u>gmklie</u>	Create a lien
<u>gmkorg</u>	Create a new organization
<u>gmkquote</u>	Create a quote template
<u>gmkrate</u>	Create a new charge rate
<u>gmkrole</u>	Create a new role
<u>gmkusage</u>	Create a new usage record
<u>gmkuser</u>	Create a new user
<u>gquote</u>	Quote for usage
<u>grefund</u>	Issue a usage refund
<u>greserve</u>	Reserve for usage
<u>grmaaccount</u>	Delete an account
<u>grmallo</u>	Delete an allocation or purge stale allocations
<u>grmevent</u>	Delete an event

Command	Description
<u>grmfund</u>	Delete a fund
<u>grmlien</u>	Delete a lien
<u>grmnot</u>	Delete a stored notification
<u>grmorg</u>	Delete an organization
<u>grmquote</u>	Delete a quote
<u>grmrates</u>	Delete a charge rate
<u>grmrole</u>	Delete a role
<u>grmusage</u>	Delete a usage record
<u>grmuser</u>	Delete a user
<u>gstatement</u>	Display fund statement
<u>gtransfer</u>	Issue a transfer
<u>gwithdraw</u>	Issue a withdrawal
<u>goldsh</u>	Interactive shell for gold
<u>goldd</u>	Moab Accounting Manager server
<u>mybalance</u>	Display personal balance information

gbalance

Synopsis

```
gbalance [-u <user_name>] [-g <group_name>] [-a <account_name>]
[-o <organization_name>] [-c <class_name>] [-m <machine_name>]
[--filter <filter_name>=<filter_value>]... [--filter-type
<filter_type>] [--ignore-ancestors] [--full] [--show
<attribute_name>,...] [--long] [--wide] [--format <output_
```

```
type>] [-h, --hours] [--debug] [--site <site_name>] [--help]
[--man] [--quiet] [--version]
```

Overview

`gbalance` displays balance information for funds having active allocations.

Options

-a

Format	<code>-a <account_name></code>
Default	---
Description	Displays the balance available to the specified account.

-c

Format	<code>-c <class_name></code>
Default	---
Description	Displays the balance available to the specified class.

-g

Format	<code>-g <group_name></code>
Default	---
Description	Displays the balance available to the specified group.

-h, --hours

Format	<code>-h</code> or <code>--hours</code>
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-m	
Format	-m <machine_name>
Default	---
Description	Display the s balance available to the specified machine.

-o	
Format	-o <organization_name>
Default	---
Description	Displays the balance available to the specified organization.

-u	
Format	-u <user_name>
Default	---
Description	Displays the balance available to the specified user.

--debug	
Format	--debug
Default	---
Description	Logs debugging information to the screen.

--filter	
Format	--filter <filter_name>=<filter_value>
Default	---

--filter	
Description	Displays the balance for funds where constraints do not conflict with the specified filters. You can use multiple filter options by logically ANDing them together.

--filter-type	
Format	--filter-type <filter_type>
Default	NonExclusive
Description	Selects the filtering type. If you use the exclusive filter type, a fund will only be matched if the specified filters meet all constraints. If you use the non-exclusive filter type, a fund will be matched as long as the specified filters do not conflict with the constraints.

--format	
Format	--format <output_type>
Default	standard
Description	Data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--ignore-ancestors	
Format	--ignore-ancestors
Default	---
Description	Does not include hierarchical ancestor funds in the result.

--long	
Format	--long
Default	---
Description	Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays the full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show

Description

Valid attributes include the following:

- **Allocated** – Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
- **Available** – Total amount currently available for charging (Balance - Reserved + CreditLimit).
- **Balance** – Sum of active allocation amounts remaining within this fund. It does not take into account current liens.
- **Capacity** – Total expendable amount (Allocated + CreditLimit).
- **Constraints** – Constraints on fund usage.
- **CreationTime** – Time this fund was created.
- **CreditLimit** – Sum of active credit limits within this fund.
- **Deleted** – Boolean indicating whether this fund is deleted.
- **Description** – Fund description
- **Effective** – Effective allocation total not blocked by liens (Balance - Reserved).
- **Id** – Fund id.
- **ModificationTime** – Time this fund was last modified.
- **Name** – Fund name.
- **PercentRemaining** – Percentage of allocation remaining (Balance * 100 / Capacity).
- **PercentUsed** – Percentage of allocation used (Used * 100 / Capacity).
- **RequestId** – Id of the last modifying request.
- **Reserved** – Sum of active lien amounts against this fund.
- **TransactionId** – Id of the last modifying transaction.
- **Used** – Total amount used from this allocation (Allocated - Balance).

--site

Format

--site <site_name>

Default

Description

Obtains a response from specified site.

--wide

Format

--wide

Default

Description

Displays multi-valued fields in a single-line, comma-separated format.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchaccount

Synopsis

```
gchaccount [-A | -I] [-o <organization name>] [-d <description>]
[-X, --extension <property>=<value>]... [--add-user(s) [^|!]
[+|-]<user_name>, ...]... [--del-user(s) <user_name>, ...]... [-
-mod-user(s) [^|!][+|-]<user_name>, ...]... [--debug] [--site
<site_name>] [--help] [--man] [--quiet] [--verbose] [--
version] {[-a] <account_name>}
```

Overview

gchaccount modifies an account.

Options

-a	
Format	[-a] <account_name>
Default	---
Description	Specifies the name of the account to modify.

-A	
Format	-A

-A	
Default	---
Description	Activates the account.

-d	
Format	-d <description>
Default	---
Description	Modifies the account description.

-I	
Format	-I
Default	---
Description	Deactivates the account.

-o	
Format	-o <organization_name>
Default	---
Description	Modifies the name of the organization to which the account belongs.

-X, --extension	
Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--add-user	
Format	<code>--add-user [^ !][+ -]<user_name>[, [^ !][+ -]<user_name>...]</code>
Default	---
Description	Adds user members of the account. The optional caret or exclamation symbol indicates whether the user should be created as an administrator (^) or not (!) for the account. The optional plus or minus signs can precede each member to indicate whether the member should be created in the active (+) or inactive (-) state. By default, a user will be created in the active state but not an administrator. You can pass multiple users to the --add-user option in a comma-delimited list or you can specify multiple --add-user options.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--del-user	
Format	<code>--del-user <user_name>[, <user_name>...]</code>
Default	---
Description	Removes user members from the account. You can pass multiple users to the --del-user option in a comma-delimited list or specify multiple --del-user options.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--mod-user	
Format	--mod-user [[^] !] ⁺ [-]<user_name>[, [[^] !] ⁺ [-]<user_name>...]
Default	---
Description	Modifies user members of the account. The caret symbol or exclamation symbol indicates the user should be changed to become an administrator ([^]) or not (!) for the account. The plus or minus signs indicate whether the user should be changed to become active (+) or inactive (-). If you do not specify an active or admin modifier, that aspect of the user member will remain unchanged. You can pass multiple users to the --mod-user option in a comma-delimited list or you can specify multiple --mod-user options.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchalloc

Synopsis

```
gchalloc [-s <start_time>] [-e <end_time>] [-L <credit_limit>] [-d <description>] [-X, --extension <property>=<value>]... [-h, --hours] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-i] <allocation_id>}
```

Overview

`gchalloc` modifies an allocation. This includes changing the credit limit or description or adjusting the start time or end time.

Options

-d	
Format	-d <description>

-d	
Default	---
Description	Modifies the allocation description.

-e	
Format	-e <end_time>
Default	---
Description	Specifies a new end time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-h, --hours	
Format	-h or --hours
Default	---
Description	Treats currency as specified in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), this option allows you to specify the credit limit in resource hours.

-i	
Format	[-i]<allocation_id>
Default	---
Description	The ID of the allocation to modify.

-L	
Format	-L <credit_limit>
Default	---
Description	Specifies a new credit limit.

-s	
Format	-s <start_time>
Default	---
Description	Specifies a new start time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-X, --extension <property>	
Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---

--man	
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gcharge

Synopsis

```
gcharge [-T <usage_record_type>] [-S <service_id>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o <organization_name>] [-c <class_name>] [-Q <quality_of_service>] [-m <machine_name>] [-N <nodes>] [-P <processors>] [-C <cpu_time>] [-M <memory>] [-D <disk>] [-x <usage_state>] [-X, --extension <property>=<value>]... [-t <charge_duration>] [-s <charge_start_time>] [-e <charge_end_time>] [-d <charge_description>] [-z <charge_amount>] [-f <fund_id>] [--incremental] [-R <charge_rate_name>[<charge_rate_value>]] [=<charge_rate_amount>,...]... [-h, --hours] [--itemize] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] [[-j] <usage_record_id>] [-q <quote_id>] [-l <lien_id>] {-J <instance_name>|<job_id>}
```

Overview

gcharge charges for resource or service usage.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies the account to charge.

-c	
Format	-c <class_name>
Default	---
Description	Specifies the class of queue used.

-C	
Format	-C <cpu_time>
Default	---
Description	Specifies the CPU time used.

-d	
Format	-d <charge_description>
Default	---
Description	Specifies an explanatory message for the charge. You can pass the overall usage description via the extension property option (-X Description=<description>).

-D	
Format	-D <disk>
Default	---
Description	Specifies the amount of disk space used.

-e	
Format	-e <charge_end_time>
Default	Now
Description	Specifies an end time for the charge in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now You can pass the overall usage end time via the extension property option (-X EndTime=<end_time>).

-f	
Format	-f <fund_id>

-f	
Default	---
Description	Specifies the fund ID to charge.

-g	
Format	-g <group_name>
Default	---
Description	Specifies the name of the group to charge.

-h, --hours	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-j	
Format	[-j] <usage_record_id>
Default	---
Description	Specifies the usage record id for the charge (if already created with <code>gmkusage</code> , <code>gquote</code> , <code>greserve</code> or a previous <code>gcharge</code>). Use <code>-j</code> to charge an existing usage record if the instance name (such as a job ID) is ambiguous or if a usage has already been debited and you want to charge an additional amount to the same usage record.

-J	
Format	-J <instance_name> <job_id>
Default	---

-J

Description	Specifies the instance name or job ID for the charge if known. This can sometimes be non-unique, such as when a resource manager recycles job IDs, and does not always unambiguously identify a usage record to charge. In such cases, look up and specify the usage record ID for the charge.
--------------------	--

-l

Format	<code>-l <lien_id></code>
Default	---
Description	Specifies the lien ID, which MAM will use to match up the right usage record ID and remove the correct lien, if ambiguous.

-m

Format	<code>-m <machine_name></code>
Default	---
Description	Specifies the name of the cluster, cloud, or system used.

-M

Format	<code>-M <memory></code>
Default	---
Description	Specifies the amount of memory used.

-N

Format	<code>-N <nodes></code>
Default	---
Description	Specifies the number of nodes used.

-o	
Format	-o <organization_name>
Default	---
Description	Specifies the organization name.

-P	
Format	-P <processors>
Default	---
Description	Specifies the number of processors used.

-q	
Format	-q <quote_id>
Default	---
Description	Specifies the quote MAM should use to determine charge rates.

-Q	
Format	-Q <quality_of_service_name>
Default	---
Description	Specifies the quality of service used.

-R	
Format	-R <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount> [,<charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>...]
Default	---

-R	
Description	Specifies the charge rates in the charge. The specified rates override the general rates or rates guaranteed through a quote. You can pass multiple charge rates <code>-R</code> option in a comma-delimited list or specify multiple <code>-R</code> options.

-s	
Format	<code>-s <charge_start_time></code>
Default	Now - <duration>
Description	Specifies a start time for the charge in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now You can pass the overall usage end time via the extension property option (<code>-X StartTime=<start_time></code>).

-S	
Format	<code>-S <service_id></code>
Default	---
Description	Specifies the root service ID (cloud).

-t	
Format	<code>-t <charge_duration></code>
Default	---
Description	Specifies the wallclock duration for the charge in seconds. You can pass the total wallclock time for the lifetime usage via the extension property option (<code>-X Duration=<duration_in_seconds></code>).

-T	
Format	<code>-T <usage_record_type></code>

-T	
Default	---
Description	Specifies the usage record type (Job, Reservation, etc.).

-u	
Format	-u <user_name>
Default	---
Description	Specifies the user name.

-x	
Format	-x <usage_state>
Default	---
Description	Specifies the final status of the usage.

-X, --extension	
Format	-X or --extension <property>=<value>
Default	---
Description	Specifies an extension property. You can specify any number of extra field assignments.

-z	
Format	-z <charge_amount>
Default	---
Description	Specifies the charge amount if calculated externally.

--debug	
Format	--debug
Default	---
Description	Logs debugging information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--incremental	
Format	--incremental
Default	---
Description	Debits any associated liens instead of removing them.

--itemize	
Format	--itemize
Default	---
Description	Returns the composite charge information in the response data. This must be used in conjunction with the --verbose flag to display the data.

--man	
Format	--man
Default	---

--man	
Description	Displays the full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchevent

Synopsis

```
gchevent [--fire-command <fire_command>] [-s <fire_time>] [-e
<end_time>] [--rearm-period <rearm_period>] [--rearm-on-
failure <boolean>] [--failure-commmand <failure_command>] [--
notify <notification_url>] [--catch-up <boolean>] [-d
<description>] [--debug] [--site <site_name>] [--help] [--man]
[--quiet] [--verbose] [--version] {[-E] <event_id>}
```

Overview

gchevent modifies an event.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-e	
Format	-e <end_time>
Default	---
Description	Specifies the time this event becomes inactive.

-E	
Format	-E <event_id>
Default	---
Description	Specifies the ID of the event to modify.

-s	
Format	<code>-s <fire_time></code>
Default	---
Description	Specifies a new target time for the event to be triggered by the event scheduler. The actual fire time may be dependent on the state of the server and will be recorded in the CreationTime property of the corresponding "Event Fire" Transaction. An event may also be fired manually with the goldsh Event Fire action.

--catch-up	
Format	<code>--catch-up <boolean></code>
Default	True
Description	If you set the --catch-up boolean to True and the server was down during the time this event should have fired, the event scheduler will attempt to make up for the past due events by progressively firing them (rearming based on previous arm time) until it catches up to the present. The actions will still show as having occurred in the present rather than in the past. If set to False and the server is brought back up after an outage, the event scheduler will still fire immediately for a past due event, but it will only fire once and then rearm relative to the current time.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debugging information to the screen.

--failure-command	
Format	<code>--failure-command <goldsh_command></code>
Default	---
Description	Specifies a new command MAM should execute if the fired command results in an unsuccessful response status. This command is expressed in a serialized form of the request identical to the syntax used in the interactive control program (goldsh). The option argument will need to be appropriately quoted and/or escaped in order to avoid misinterpretation or alteration by the shell.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays the full documentation.

--notify	
Format	--notify [+ =] [<delivery_method>:][recipient]
Default	Logs all event statuses to the Notification table.
Description	A Notification method logs the result of the fired command. If the term is a -, the notification is sent only on failure. If the term is a +, the notification is sent only on success. Otherwise the notification is always sent. See Managing Notifications on page 2915 for more information about delivery method and recipient.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--rearm-on-failure	
Format	--rearm-on-failure <boolean>

--rearm-on-failure	
Default	False
Description	If you set the <code>--rearm-on-failure</code> boolean to <code>False</code> , MAM will not rearm the event if the command was unsuccessful. If you set it to <code>True</code> , MAM will evaluate the event for rearming even if the command response has a status of <code>Failure</code> .

--rearm-period	
Format	<code>--rearm-period <period>[[@instant][~ ^]!]</code>
Default	---
Description	<p>The <code>--rearm-period</code> is a time period expression specifying when MAM will rearm the event. This period expression is of the form:</p> <pre><period>[[@instant][~ ^]!]</pre> <p>where <code><period></code> may be something like 1 day, 2 hours, or 5 minutes. <code>Instant</code> locks the period to a specific instant within the time period such as 1 day @ hour 12 or 1 month @ day 3. The modifiers indicate whether the time period should be relative to now (!), or relative to the start of this (~) designator (month, minute, or other unit), or relative to the start of the first (^) designator (month, minute, or other unit). For example, assuming the fire time was 7:15, if you specified 4 hours ! as the rearm period, MAM would rearm it at 11:15; if you specified 4 hours ~ as the rearm period, MAM would rearm it at 11:00; and if you specified 4 hours ^ as the rearm period, MAM would rearm it at 8:00.</p>

--site	
Format	<code>--site <site_name></code>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	<code>--verbose</code>
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchfund

Synopsis

```
gchfund { { [-n <fund_name>] [--priority <fund_priority>] [--
default-deposit <deposit_amount>] [-d <description>] [-X, --
extension <property>=<value>]... [--add-constraint
<constraint_name>=[!]<constraint_value>,...]... [--del-
constraint(s) <constraint_name>[=<constraint_value>],...]...
[--parent <parent_fund_id>] } | { --reset [--all]} } [-u
<user_name>] [-g <group_name>] [-a <account_name>] [-o
<organization_name>] [-c <class_name>] [-m <machine_name>] [--
filter <filter_name>=<filter_value>]... [--filter-type
<filter_type>] [--debug] [--site <site_name>] [--help] [--man]
[--quiet] [--verbose] [--version] [[-f] <fund_id>]
```

Overview

gchfund modifies a fund. This includes adding to or deleting from constraints for the account. After applying all filter options, if there is exactly one applicable fund, that fund will be modified. Otherwise, a list of funds will be displayed for the specified filters and you will be prompted to rerun **gchfund** against one of the enumerated funds.

Options

-a	
Format	-a <account_name>

-a	
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given account.

-c	
Format	-c <class_name>
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given class.

-d	
Format	-d <description>
Default	---
Description	Specifies a new description

-f	
Format	[-f] <fund_id>
Default	---
Description	Specifies the ID of the fund to modify.

-g	
Format	-g <group_name>
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given group.

-m	
Format	<code>-m <machine_name></code>
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given machine.

-n	
Format	<code>-n <fund_name></code>
Default	---
Description	Specifies a new fund name.

-o	
Format	<code>-o <organization_name></code>
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given organization.

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Specifies that the fund to modify should be restricted to one usable by the given user.

-X, --extension	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--add-constraint

Format	<code>--add-constraint <constraint_name>=[!]<constraint_value>[,<constraint_name>=[!]<constraint_value>...]</code>
Default	---
Description	Adds a constraint to the fund. The constraint value may be a perl5 regular expression. You can prepend an exclamation point to the constraint value to express a negation of the constraint. You can pass multiple constraints to the <code>--add-constraint</code> option in a comma-delimited list or specify multiple <code>--add-constraint</code> options.

--all

Format	<code>--all</code>
Default	---
Description	Specifies that you want to reset all active allocations for all funds when you use it with the <code>--reset</code> option.

--debug

Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--default-deposit

Format	<code>--default-deposit <deposit_amount></code>
Default	---
Description	Specifies the default amount for any deposit that is made to this fund that does not specify a deposit amount.

--del-constraint	
Format	<code>--del-constraint <constraint_name>=<constraint_value>[,<constraint_name>=<constraint_value>]...</code>
Default	---
Description	Removes a constraint from the fund. You can pass multiple constraints to the <code>--del-constraint</code> option in a comma-delimited list or by specifying multiple <code>--del-constraint</code> options.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Restricts the fund to one without constraints that conflict with the specified filters. For example, <code>gchfund --filter User=amy</code> will restrict the fund to one usable by the user amy. You can specify multiple filter options by logically ANDing them together.

--filter-type	
Format	<code>--filter-type <filter_type></code>
Default	NonExclusive
Description	Selects the filtering type. If you use the exclusive filter type, a fund will only be matched if the specified filters meet all constraints. If you use the non-exclusive filter type, a fund will be matched as long as the specified filters do not conflict with the constraints.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--parent	
Format	--parent <parent_fund_id>
Default	---
Description	Sets a new parent fund, replacing the current parent fund if one exists.

--priority	
Format	--priority <fund_priority>
Default	---
Description	Sets a new fund priority.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--reset	
Format	--reset
Default	---

--reset

Description	Ends all active allocations and initiates a new default deposit. If the default deposit amount is positive, MAM creates a new allocation with this amount, otherwise no deposit is made and the fund becomes inactive. You may reset the allocations for a specified fund using the [-f] fund_id option, all funds using the --all option, or use filtering options to filter the funds to be reset. Do not use this option with any other modifying option.
--------------------	--

--site

Format	<code>--site <site_name></code>
Default	---
Description	Obtains a response from specified site.

--verbose

Format	<code>--verbose</code>
Default	---
Description	Displays modified object details.

--version

Format	<code>--version</code>
Default	---
Description	Displays the product version.

gchlien

Synopsis

gchlien [[-s](#) <start_time>] [[-e](#) <end_time>] [[-t](#) <lien_duration>]
[[-d](#) <description>] [[-X](#), --extension <property>=<value>]... [[--debug](#)]
[[--site](#) <site_name>] [[--help](#)] [[--man](#)] [[--quiet](#)] [[--verbose](#)]
[[--version](#)] {[[-l](#)] <lien_id>}

Overview

gchlien modifies a lien.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-e	
Format	-e <end_time>
Default	---
Description	Specifies a new expiration time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-l	
Format	[-l] <lien_id>
Default	---
Description	Specifies the ID of the lien to modify.

-s	
Format	<code>-s <start_time></code>
Default	---
Description	Specifies a new start time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-t	
Format	<code>-t <lien_duration></code>
Default	---
Description	Specifies the duration of the lien in seconds. Although the lien start time and end time are enforced, the duration is not authoritative. If the time frame between the end time and the start time is greater than the duration, the difference is the allotted grace period (which defaults to 10 minutes).

-X, --extension <property>	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>

--help	
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchorg

Synopsis

```
gchorg [-d <description>] [-X, --extension
<property>=<value>]... [--debug] [--site <site_name>] [--help]
[--man] [--quiet] [--verbose] [--version] {[-o] <organization_
name>}
```

Overview

gchorg modifies an organization.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-o	
Format	-o <organization_name>
Default	---

-o	
Description	Specifies the name of the organization to modify.

-X, --extension <property>	
Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchpasswd

Synopsis

```
gchpasswd [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] [[-u] <user_name>]
```

Overview

`gchpasswd` sets a user password. If the user name is not specified via an option or as the unique argument, then the invoking user will be taken as the user whose password will be set. The invoker will be prompted for the new password.

Options

-u	
Format	<code>[-u] <user_name></code>
Default	---
Description	Specifies the name of user whose password is to be set. If no user is specified, the invoking user will be taken as the user whose password will be set.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

Synopsis

```
gchquote [-s <start_time>] [-e <end_time>] [-d <description>] [-X, --extension <property>=<value>]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-q] <quote_id>}
```

Overview

gchquote modifies a quote.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-e	
Format	-e <end_time>
Default	---
Description	Specifies a new expiration time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-q	
Format	[-q] <quote_id>
Default	---

-q

Description	Specifies the ID of the quote to modify.
--------------------	--

-s

Format	<code>-s <start_time></code>
---------------	------------------------------------

gchrate

Synopsis

```
gchrate -n <charge_rate_name> [-x <charge_rate_value>] [-z
<charge_rate_amount>] [-d <description>] [--debug] [--site
<site_name>] [--help] [--man] [--quiet] [--verbose] [--
version]
```

Overview

`gchrate` modifies a charge rate. Only the amount or the description of a charge rate may be modified.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-n	
Format	-n <charge_rate_name>
Default	---
Description	Specifies the name of the charge rate to change.

-x	
Format	-x <charge_rate_value>
Default	---

-X	
Description	Specifies the charge rate value expression to change. If you do not specify a value, an empty value is assumed.

-Z	
Format	<code>-z <charge_rate_amount></code>
Default	---
Description	Specifies a new amount for the charge rate. The amount is an integer or decimal and may include operators indicating how to apply the charge rate as well as divisors and time-based units. See Managing Charge Rates on page 2905 for more information.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchrole

Synopsis

```
gchrole [-d <description>] [--add-user(s) <user_name>,...]... [--add-action(s) <object_name>-><action_name>[{<instance_name>}],...}]... [--del-user(s) <user_name>,...]... [--del-action(s) <object_name>-><action_name>[{<instance_name>}],...}]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-r] <role_name>}
```

Overview

gchaccount modifies a role. This can include adding or removing users from a role and adding removing actions from a role.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-r	
Format	[-r] <role_name>
Default	---
Description	Specifies the name of the role to modify.

--add-action	
Format	--add-action <object_name>-><action_name>[{<instance_name>}],<object_name>-><action_name>[{<instance_name>}]...
Default	---

--add-action

Description	Adds actions to the role. You must specify the object, action and instance in the form shown. Unless specified, the instance will default to a value of ANY. You may pass multiple actions to the --add-action option in a comma-delimited list or by specifying multiple --add-action options.
--------------------	---

--add-user

Format	--add-user <user_name>[, <user_name>...]
Default	---
Description	Adds users to the role. You may pass multiple users to the --add-user option in a comma-delimited list or by specifying multiple --add-user options.

--debug

Format	--debug
Default	---
Description	Logs debug information to the screen.

--del-action

Format	--del-action <object_name>-><action_name>[{<instance_name>}] [, <object_name>-><action_name>[{<instance_name>}]...]
Default	---
Description	Removes actions from a role. You must specify the object and action; however, the instance is optional. You may pass multiple actions to the --del-action option in a comma-delimited list or by specifying multiple --del-action options.

--del-user

Format	--del-user <user_name>[, <user_name>...]
Default	---

--del-user

Description	Removes users from the role. You may pass multiple users to the <code>--del-user</code> option in a comma-delimited list or by specifying multiple <code>--del-user</code> options.
--------------------	---

--help

Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man

Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet

Format	<code>--quiet</code>
Default	---
Description	Suppresses headers and success messages.

--site

Format	<code>--site <site_name></code>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---

gchusage

Synopsis

```
gchusage [-T <usage_record_type>] [-S <service_id>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o <organization_name>] [-c <class_name>] [-Q <quality_of_service>] [-m <machine_name>] [-N <nodes>] [-P <processors>] [-C <cpu_time>] [-M <memory>] [-D <disk>] [-t <usage_duration>] [-s <start_time>] [-e <end_time>] [-d <description>] [-X, --extension <property>=<value>]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] { [-j <usage_record_id> | -J <instance_name> | <job_id> }
```

Overview

gchusage modifies a usage record.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies a new account name.

-c	
Format	-c <class_name>
Default	---
Description	Specifies a new class or queue.

-C	
Format	-C <cpu_time>
Default	---
Description	Specifies a new CPU time used.

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-D	
Format	-D <disk>
Default	---

-D	
Description	Specifies a new amount of disk used.

-e	
Format	-e <end_time>
Default	---
Description	Specifies a new date and time the usage ended in the format YYYY-MM-DD[hh:mm:ss]

-g	
Format	-g <group_name>
Default	---
Description	Specifies a new group name.

-j	
Format	[-j] <usage_record_id>
Default	---
Description	Specifies the ID of the usage record to modify. Instance names can be non-unique (resource managers often recycle job IDs). This option allows you to specify a usage record uniquely using the unique gold identifier.

-J	
Format	[-J] <instance_name> <job_id>
Default	---
Description	Specifies the instance name of the usage record(s) to modify. If there is exactly one matching usage record, MAM will modify that usage record. Otherwise, MAM will display a list of usage records for the specified instance and you will be prompted to rerun <code>gchusage</code> against one of the enumerated usage records.

-m	
Format	-m <machine_name>
Default	---
Description	Specifies the new name of the cluster, cloud, or system used.

-M	
Format	-M <memory>
Default	---
Description	Specifies the new amount of memory used.

-N	
Format	-N <nodes>
Default	---
Description	Specifies a new number of nodes used.

-O	
Format	-o <organization_name>
Default	---
Description	Specifies a new organization name.

-P	
Format	-P <processors>
Default	---
Description	Specifies a new number of processors used.

-Q	
Format	-Q <quality_of_service>
Default	---
Description	Specifies a new quality of service used.

-s	
Format	-s <start_time>
Default	---
Description	Specifies a new date and time the usage started in the format YYYY-MM-DD[hh:mm:ss]

-S	
Format	-S <service_id>
Default	---
Description	Specifies a new root service ID (cloud).

-t	
Format	-t <usage_duration>
Default	---
Description	Specifies a new amount of time used in seconds.

-T	
Format	-T <usage_record_type>
Default	---
Description	Specifies the usage record type (Job or Reservation, for example).

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Specifies a new user name.

-X, --extension	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gchuser

Synopsis

gchuser [-A | -I] [-n <common_name>] [-F <phone_number>] [-E <email_address>] [-a <default_account>] [-d <description>] [-X, --extension <property>=<value>]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-u] <user_name>}

Overview

gchuser modifies a user.

Options

-a	
Format	-a <default_account>
Default	---
Description	Specifies the account MAM will charge when no account is specified.

-A	
Format	-A
Default	---
Description	Activates the user.

-d	
Format	-d <description>
Default	---
Description	Specifies a new description.

-E	
Format	-E <email_address>
Default	---
Description	Specifies a new email address.

-F	
Format	-F <phone_number>
Default	---
Description	Specifies a new phone number.

-I	
Format	-I
Default	---
Description	Deactivates the user.

n	
Format	-n <common_name>
Default	---
Description	Specifies the common name for the user.

-u	
Format	[-u] <user_name>
Default	---
Description	Specifies the name of the user to modify.

-X, --extension <property>

Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug

Format	--debug
Default	---
Description	Logs debug information to the screen.

--help

Format	--help
Default	---
Description	Displays a brief help message.

--man

Format	--man
Default	---
Description	Displays full documentation.

--quiet

Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gdeposit

Synopsis

```
gdeposit [-L <credit_limit>] [-s <start_time>] [-e <end_time>]
[-d <description>] [-f <fund_id>] [-i <allocation_id>] [-u
<user_name>] [-g <group_name>] [-a <account_name>] [-o
<organization_name>] [-c <class_name>] [-m <machine_name>] [--
filter <filter_name>=<filter_value>]... [--filter-type
<filter_type>] [--create-fund=<boolean>] [--reset] [-h, --
hours] [--debug] [--site <site_name>] [--help] [--man] [--
quiet] [--verbose] [--version] [[-z] <amount>]
```

Overview

`gdeposit` makes time-bound deposits into funds. After applying all filter options, if there is exactly one debitable fund for the specified criteria, MAM makes a deposit into that fund. If multiple funds match the specified criteria, MAM displays a list of matching funds and prompt you to respecify the deposit against one of the enumerated funds. If no funds match your criteria, if auto-generation is turned on for the fund object, or the `--create-fund` flag is asserted, MAM creates a fund and make a deposit into it; otherwise, the deposit fails (the fund will need to be created with [gmkgfund](#)).

Options

-a	
Format	<code>-a <account_name></code>
Default	---
Description	Restricts the fund for the deposit to one usable by the specified account.

-c	
Format	<code>-c <class_name></code>
Default	---
Description	Restricts the fund for the deposit to one usable by the specified class.

-d	
Format	<code>-d <description></code>
Default	---
Description	Specifies the reason for the deposit. The annotation applies to the transaction description (seen via glstrans), not the allocation description.

-e	
Format	<code>-e <end_time></code>

-e	
Default	Infinity
Description	Specifies the end time for the allocation to be credited in the format: YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-f	
Format	-f <fund_id>
Default	Infinity
Description	Specifies the ID of the fund into which the deposit will be made.

-g	
Format	-g <group_name>
Default	---
Description	Specifies that the fund for the deposit should be restricted to one usable by the specified group.

-h	
Format	-h or --hours
Default	---
Description	Treats currency as specified in hours. In systems where the currency is measured in resource-seconds (like processor-seconds), this option allows you to specify the amount and credit limit in resource-hours.

-i	
Format	-i <allocation_id>

-i	
Default	---
Description	Specifies the allocation in which to make the deposit. This option is incompatible with the -L option.

-L	
Format	-L <i><credit_limit></i>
Default	---
Description	Creates a new allocation with the specified credit limit. This option is incompatible with the -i option.

-m	
Format	-m <i><machine_name></i>
Default	---
Description	Restricts the fund for the deposit to one usable by the specified machine.

-o	
Format	-o <i><organization_name></i>
Default	---
Description	Restricts the fund for the deposit to one usable by the specified organization.

-s	
Format	-s <i><start_time></i>
Default	Infinity
Description	Specifies the start time for the allocation to be credited in the format: YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-u	
Format	-u <user_name>
Default	---
Description	Restricts the fund for the deposit to one usable by the specified user.

-z	
Format	[-z] <amount>
Default	---
Description	Specifies the amount to deposit.

--create-fund	
Format	--create-fund <boolean>
Default	---
Description	Overrides the fund auto-generation setting. Setting this option to <code>True</code> creates a default fund for this deposit. Setting this option to <code>False</code> inhibits the creation of a default fund for this deposit.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--filter	
Format	--filter <filter_name>=<filter_value>
Default	---

--filter	
Description	Restricts the fund to one where constraints do not conflict with the specified filters. For example, <code>gchfund --filter User=amy</code> restricts the fund to one usable by the user <code>amy</code> . You may specify multiple filter options by logically ANDing them together.

--filter-type	
Format	<code>--filter-type <filter_type></code>
Default	<code>NonExclusive</code>
Description	Specifies the filtering type. If you use the exclusive filter type, MAM will only match a fund if the specified filters meet all constraints. If you use the non-exclusive filter type, MAM will match a fund as long as the specified filters do not conflict with the constraints.

--help	
Format	<code>--help</code>
Default	<code>---</code>
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	<code>---</code>
Description	Displays full documentation.

--quiet	
Format	<code>--quiet</code>
Default	<code>---</code>
Description	Suppresses headers and success messages.

--reset	
Format	--reset
Default	---
Description	Ends the current allocation and creates a new allocation with the deposit.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

glsaccount

Synopsis

glsaccount [-A | -I] [-o <organization_name>] [-X, --extension <property>=<value>]... [-u <user_name>] [--full] [--show <attribute_name>,...] [--long] [--wide] [--format <output_type>] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--version] [[-a] <account_pattern>]

Overview

glsaccount displays account information.
You can customize the fields this command displays by default by setting the **account.show** configuration parameter in gold.conf.

Options

-a	
Format	[-a] <account_pattern>
Default	---
Description	Displays only accounts matching the pattern. If no pattern is specified then all accounts are displayed.

-A	
Format	-A
Default	---
Description	Displays only active accounts.

-I	
Format	-I
Default	---
Description	Displays only inactive accounts.

-o	
Format	<code>-o <organization_name></code>
Default	---
Description	<p>Displays only accounts belonging to the specified organization. The following wildcards are supported:</p> <ul style="list-style-type: none"> • * – matches any number of characters • ? – matches a single character

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Displays only accounts that have the specified user as a member.

-X	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--format	
Format	<code>--format <output_format></code>

--format	
Default	standard
Description	Specifies the data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--long	
Format	--long
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Active – Boolean indicating whether this account is active or not. • CreationTime – Time this account was created. • Deleted – Boolean indicating whether this account is deleted or not. • Description – Account description. • ModificationTime – Time this account was last modified. • Name – Account name. • Organization – Organization to which the account belongs. • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction. • Users – List of users belonging to the account. A caret prefixing a user name indicates that the user is an account admin. A minus sign prefixing a user name indicates that the user is an inactive member of the account.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version

--version	
Default	---
Description	Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line, comma-separated format.

glsalloc

Synopsis

```
glsalloc [-A | -I | {[ -s <start_time>] [-e <end_time>]}] [-f
<fund_id>] [-X, --extension <property>=<value>]... [-u <user_
name>] [-g <group_name>] [-a <account_name>] [-o
<organization_name>] [-c <class_name>] [-m <machine_name>] [--
filter <filter_name>=<filter_value>]... [--filter-type
<filter_type>] [--include-ancestors] [--full] [--show
<attribute_name>,...] [--format <output_type>] [-h, --hours]
[--debug] [--site <site_name>] [--help] [--man] [--quiet] [--
version] [[-i] <allocation_id>]
```

Overview

`glsalloc` displays allocation information.

You can customize the fields this command displays by default by setting the **allocation.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only allocations usable by the specified account.

-A	
Format	-A
Default	---
Description	Displays only active allocations.

-c	
Format	-c <class_name>
Default	---
Description	Displays only allocations usable by the specified class.

-e	
Format	-e <end_time>
Default	---
Description	Displays only allocations that start before the specified end time.

-f	
Format	-f <fund_id>
Default	---

-f

Description	Displays only the allocations associated with the specified fund.
--------------------	---

-g

Format	<code>-g <group_name></code>
---------------	------------------------------------

Default	---
----------------	-----

Description	Displays only allocations usable by the specified group.
--------------------	--

-h

Format	<code>-h</code> or <code>--hours</code>
---------------	---

Default	---
----------------	-----

Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.
--------------------	--

-i

Format	<code>[-i] <allocation_id></code>
---------------	---

Default	---
----------------	-----

Description	Displays only the allocation with the specified ID.
--------------------	---

-I

Format	<code>-I</code>
---------------	-----------------

Default	---
----------------	-----

Description	Displays only inactive allocations.
--------------------	-------------------------------------

-m	
Format	-m <machine_name>
Default	---
Description	Displays only allocations usable by the specified machine.

-o	
Format	-o <organization_name>
Default	---
Description	Displays only accounts usable to the specified organization.

-s	
Format	-s <start_time>
Default	---
Description	Displays only allocations that end after the specified start time.

-u	
Format	-u <user_name>
Default	---
Description	Displays only allocations usable by the specified user.

-X	
Format	-X or --extension <property>=<value>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--filter	
Format	--filter <filter_name>=<filter_value>
Default	---
Description	Displays allocations where fund constraints comply with the specified filters. For example, <code>gls-fund --filter User=amy</code> displays funds usable by the user amy. You can specify multiple filter options by logically ANDing them together.

--filter-type	
Format	--filter-type <filter_type>
Default	NonExclusive
Description	Specifies the filtering type. If you use exclusive filter type, MAM only matches a fund if the specified filters meet all constraints. If you specify the non-exclusive filter type, MAM matches a fund as long as the specified filters do not conflict with the constraints.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full

--full	
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--include-ancestors	
Format	--include-ancestors
Default	---
Description	Includes ancestors of the selected allocations.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Valid attributes include the following:</p> <ul style="list-style-type: none"> • Active – Boolean indicating whether this allocation is active or not. • Adjustments – Total of subsequent adjustments to the initial deposit via deposits, withdrawals or transfers (Allocated - InitialDeposit). • Allocated – Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers. • Available – Amount currently available for charging. If the allocation is active, this is Remaining - Reserved + CreditLimit. If the allocation is inactive, this is zero. • Balance – Active allocation balance. If the allocation is active, this is the remaining allocation amount (Remaining). If the allocation is inactive, this is zero. • Capacity – Total expendable amount (Allocated + CreditLimit). • CreationTime – Time this allocation was created. • CreditLimit – Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens). • Deleted – Boolean indicating whether this allocation is deleted or not. • Description – Allocation description. • Effective – Effective balance not blocked by liens. If the allocation is active, this is Remaining - Reserved. If the allocation is inactive, this is zero. • EndTime – Time this allocation becomes inactive. • Fund – Fund ID. • FundName – Fund name. • Id – Allocation ID. • InitialDeposit – Amount of the first deposit into this allocation. • ModificationTime – Time this allocation was last modified. • PercentRemaining – Percentage of allocation remaining (remaining * 100 / Capacity). • PercentUsed – Percentage of allocation used (Used * 100 / Capacity). • Remaining – Remaining allocation amount. • Reserved – Sum of active lien amounts against this allocation. • RequestId – ID of the last modifying request. • StartTime – Time this allocation becomes active. • TransactionId – ID of the last modifying transaction. • Used – Amount used from this allocation (Allocated - Remaining).

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

glscharge

Synopsis

```
glscharge [-j <usage_record_id>] [-J <instance_name>] [-n
<usage_property_name>] [-s <start_time>] [-e <end_time>] [--
full] [--show <attribute_name>,...] [--format <output_type>]
[-h, --hours] [--debug] [--site <site_name>] [--help] [--man]
[--quiet] [--version]
```

Overview

glscharge displays allocation information.

Options

-e	
Format	-e <end_time>

-e	
Default	---
Description	Displays charges occurring before the specified time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-j	
Format	-j <usage_record_id>
Default	---
Description	Displays only charges associated with the specified usage record.

-J	
Format	-J <instance_name>
Default	---
Description	Displays only charges against the specified instance (such as a job ID).

-n	
Format	-n <usage_record_property_name>
Default	---
Description	Displays only charges against the specified usage property.

-s	
Format	<code>-s <start_time></code>
Default	---
Description	Displays charges occurring after the specified time in the format <code>YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now</code>

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--format	
Format	<code>--format <output_format></code>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	<code>--full</code>
Default	---
Description	Displays all attributes.

--help	
Format	<code>--help</code>
Default	---

--help

Description	Displays a brief help message.
--------------------	--------------------------------

--man

Format	--man
---------------	-------

Default	---
----------------	-----

Description	Displays full documentation.
--------------------	------------------------------

--quiet

Format	--quiet
---------------	---------

Default	---
----------------	-----

Description	Suppresses headers and success messages.
--------------------	--

--show

Format	--show <attribute_name>[,<attribute_name>...]
---------------	---

Default	---
----------------	-----

--show

Description

Displays only the specified attributes in the order specified. Valid attributes include the following:

- **Amount** – Amount charged.
- **CreationTime** – Time this charge was created.
- **Deleted** – Boolean indicating whether this allocation is deleted or not.
- **Description** – Charge description.
- **Details** – Details of the formula used in calculating the charge.
- **Duration** – Amount of time the item was used in seconds.
- **Instance** – Instance name (such as job ID) for the charge.
- **ModificationTime** – Time this charge was last modified.
- **Name** – Usage record property name (also charge rate name).
- **Rate** – Base charge rate.
- **RequestId** – ID of the last modifying request.
- **ScalingFactor** – Product of all applicable multipliers (discounts and premiums) applied to the base rate.
- **TransactionId** – ID of the last modifying transaction.
- **UsageRecord** – Usage record ID.
- **Value** – Usage record property value.

--site

Format

--site <site_name>

Default

Description

Obtains a response from specified site.

--version

Format

--version

Default

Description

Displays the product version.

glsconfig

Synopsis

glsconfig [[-c on page 3052](#) | [-s on page 3052](#) | [-g on page 3052](#)] [[-p parameter_pattern](#)] [[--help](#)] [[--man](#)] [[--quiet](#)] [[--version](#)]

Overview

`glsconfig` is used to display configuration information. It will only display enabled (uncommented) parameter values. If neither `-c`, `-s` nor `-g` are specified, configuration parameters from all configuration files will be displayed.

Options

-c	
Format	-c
Default	---
Description	Display only client configuration parameters.

-g	
Format	-g
Default	---
Description	Display only GUI configuration parameters.

-s	
Format	-s
Default	---
Description	Display only server configuration parameters.

-p	
Format	-p <parameter_pattern>
Default	---
Description	Display only configuration parameters matching the specified pattern. The following wildcards are supported: * – Matches any number of characters ? – Matches a single character

--help	
Format	--help
Default	---
Description	Brief help message.

--man	
Format	--man
Default	---
Description	Full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppress headers and parameter names.

--version	
Format	--version

--version	
Default	---
Description	Display product version.

glsevent

Synopsis

```
glsevent [-s <start_time>] [-e <end_time>] [--full] [--show
<attribute_name>,...] [--format <output_type>] [--debug] [--
site <site_name>] [--help] [--man] [--quiet] [--version] [[-E]
<event_id>]
```

Overview

`glsevent` displays event information.

You can customize the fields this command displays by default by setting the **event.show** configuration parameter in `gold.conf`.

Options

-e	
Format	-e <end_time>
Default	---
Description	Displays events with a prospective fire time occurring before the specified time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-E	
Format	[-E] <event_id>
Default	---

-E	
Description	Displays only the event with the specified ID.

-s	
Format	-s <start_time>
Default	---
Description	Displays events with a prospective fire time occurring after the specified time in the format YYYY-MM-DD [hh:mm:ss] -Infinity Infinity Now

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

Description

Displays only the specified attributes in the order specified. Valid attributes include the following:

- **ArmTime** – Time the event was last armed or fired. This field is used as a reference time to be able to derive how long the event has been waiting to happen. This field will be initially set to mark the moment the first FireTime is set and updated thereafter to indicate the last time the event was fired. In the case where an event does not have a FireTime set, this field may be set manually and used in a similar manner. If we consider the time between event firings as "laps," this could be thought of as the Lap Start Time.
- **CatchUp** – If set to `True` and Gold was down during the time this event should have fired, Gold will attempt to make up for the past due events by progressively firing them (rearming based on previous arm time) until catching up to the present. The actions will still show as having occurred in the present rather than in the past. If set to `False`, and Gold is brought back up after an outage, Gold will still fire immediately for a past due event, but it will only fire once and then rearm relative to the current time.
- **CreationTime** – Time this event was created.
- **Deleted** – Boolean indicating whether this event is deleted or not.
- **Description** – Event description.
- **EndTime** – Time after which an event having a rearm period will be deleted.
- **FailureCommand** – Serialized Gold request string to be executed if the fired command results in an unsuccessful response status. They syntax is the same as used to invoke commands within the goldsh prompt.
- **FireCommand** – Serialized Gold request string to be executed when the event is fired. They syntax is the same as used to invoke commands within the goldsh prompt.
- **FireTime** – Target time for the event to be triggered. The actual fire time may be dependent on the state of the server and will be recorded in the CreationTime property of the corresponding "Event Fire" Transaction.
- **Id** – Event ID.
- **ModificationTime** – Time this event was last modified.
- **Notify** – Expression specifying where to send a notification of the response for the fire command and the failure command. The notification expression is of the form: `[+==] [delivery_method:] [recipient] [, [+==] [delivery_method:] [recipient]] *` (For example, `-store:amy`). If the term is a `-`, the notification is sent only on failure. If the term is a `+`, the notification is sent only on success. Otherwise the notification is always sent. There can be multiple notify expressions separated by a comma.
- **RearmPeriod** – Time period expression specifying when the event will be rearmed. This period expression is of the form: `period[@instant] [~|^] !!` where period may be something like 1 day, 2 hours, or 5 minutes. Instant locks the period to a specific instant within the time period such as 1 day @ hour 12 or 1 month @ day 3. The modifiers indicate whether the time period should be relative to now (!), or relative to the start of this (~) designator (month or minute, etc.), or relative to the start of the first (^) designator (month or minute, etc.).
- **RearmOnFailure** – If set to `False`, the event will not be rearmed if the command was unsuccessful. If set to `True`, the event will be evaluated for rearming even if the command response has a status of Failure. The standard default value for this boolean is `False`.
- **RequestId** – ID of the last modifying request.

--show

- **TransactionId** – ID of the last modifying transaction.

--site

Format	<code>--site <site_name></code>
Default	---
Description	Obtains a response from specified site.

--version

Format	<code>--version</code>
Default	---
Description	Displays the product version.

glsfund

Synopsis

```
glsfund [-A | -I] [-n <fund_name>] [-X, --extension  
<property>=<value>]... [-u <user_name>] [-g <group_name>] [-a  
<account_name>] [-o <organization_name>] [-c <class_name>] [-m  
<machine_name>] [--filter <filter_name>=<filter_value>]... [--  
filter-type <filter_type>] [--full] [--show <attribute_  
name>,...] [--long] [--wide] [--format <output_type>] [-h, --  
hours] [--debug] [--site <site_name>] [--help] [--man] [--  
quiet] [--version] [-f <fund_id>]
```

Overview

glsfund displays fund information.

You can customize the fields this command displays by default by setting the **fund.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only funds valid toward the specified account.

-A	
Format	-A
Default	---
Description	Displays funds with active allocations.

-c	
Format	-c <class_name>
Default	---
Description	Displays only funds usable by the specified class.

-f	
Format	[-f] <fund_id>
Default	---
Description	Displays only the funds with the specified ID.

-g	
Format	-g <group_name>
Default	---
Description	Displays only funds usable by the specified group.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-I	
Format	-I
Default	---
Description	Displays only funds with inactive allocations.

-m	
Format	-m <machine_name>
Default	---
Description	Displays only funds valid toward the specified machine.

-n	
Format	-n <fund_name>
Default	---

-n	
Description	Displays only funds with the specified name.

-o	
Format	-o <organization_name>
Default	---
Description	Displays only funds valid toward the specified organization.

-u	
Format	-u <user_name>
Default	---
Description	Displays only funds valid toward the specified user.

-X	
Format	-X or --extension <property>=<value>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Displays funds where constraints do not conflict with the specified filters. For example, <code>glsfund -f User=amy</code> displays funds usable by the user amy. You may specify multiple filter options by logically ANDing them together.

--filter-type	
Format	<code>--filter-type <filter_type></code>
Default	NonExclusive
Description	Selects the filtering type. If you use the exclusive filter, MAM only matches a fund if the specified filters meet all constraints. If you use the non-exclusive filter type, MAM will match a fund as long as the specified filters do not conflict with the constraints.

--format	
Format	<code>--format <output_format></code>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	<code>--full</code>
Default	---
Description	Displays all attributes.

--help	
Format	<code>--help</code>

--help	
Default	---
Description	Displays a brief help message.

--long	
Format	--long
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show

Description

Displays only the specified attributes in the order specified. Valid attributes include the following:

- **Allocated** – Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
- **Allocations** – Lists the active allocations in this fund in the format `id:amount:start_time:end_time`.
- **Balance** – Sum of active allocation amounts within this fund.
- **Children** – Lists the children funds in the format `id[(deposit_share)][^]` where the carat symbol (^) is displayed if Overflow is True.
- **Constraints** – Constraints on fund usage.
- **CreationTime** – Time this fund was created.
- **CreditLimit** – Sum of active credit limits within this fund.
- **DefaultDeposit** – Used for the deposit amount if a deposit is made without specifying an amount.
- **Deleted** – Boolean indicating whether this fund is deleted or not.
- **Description** – Fund description.
- **Id** – Fund ID.
- **InitialDeposit** – Initial deposit for current allocation.
- **ModificationTime** – Time this fund was last modified.
- **Name** – Fund name.
- **Parent** – Displays the parent fund in the format `id[(deposit_share)][^]` where the carat symbol (^) is displayed if Overflow is True.
- **Priority** – Fund priority.
- **RequestId** – ID of the last modifying request.
- **TransactionId** – ID of the last modifying transaction.

--site

Format

`--site <site_name>`

Default

Description

Obtains a response from specified site.

--version

Format

`--version`

Default

--version	
Description	Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line comma-separated format.

glslien

Synopsis

```
glslien [-A|-I] [-J <instance_pattern>] [-X, --extension
<property>=<value>]... [-u <user_name>] [-g <group_name>] [-a
<account_name>] [-o <organization_name>] [-c <class_name>] [-m
<machine_name>] [--filter <filter_name>=<filter_value>]... [--
filter-type <filter_type>] [--full] [--show <attribute
name>,...] [--long] [--wide] [--format <output_type>] [-h,--
hours] [--debug] [--site <site_name>] [--help] [--man] [--
quiet] [--version] [[-l] <lien_id>]
```

Overview

glslien displays lien information.

You can customize the fields this command displays by default by setting the **lien.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>

-a	
Default	---
Description	Displays only liens against the specified account.

-A	
Format	-A
Default	---
Description	Displays only unexpired liens.

-c	
Format	-c <class_name>
Default	---
Description	Displays only liens against the specified class.

-g	
Format	-g <group_name>
Default	---
Description	Displays only liens against the specified group.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-I	
Format	-I
Default	---
Description	Displays only expired liens.

-J	
Format	-J <i><instance_pattern></i>
Default	---
Description	Displays only liens with the instance names (or job IDs) matching the pattern.

I	
Format	[-I] <i><lien_id></i>
Default	---
Description	Displays only the specified lien.

-m	
Format	-m <i><machine_name></i>
Default	---
Description	Displays only liens against the specified machine.

-O	
Format	-O <i><organization_name></i>
Default	---
Description	Displays only liens against the specified organization.

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Displays only liens against the specified user.

-X	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Displays liens where constraints do not conflict with the specified filters. For example, <code>glslien -f User=amy</code> will display liens usable by the user <code>amy</code> . You may specify multiple filter options by logically ANDing them together.

--filter-type	
Format	<code>--filter-type <filter_type></code>

--filter-type	
Default	AttributedTo
Description	Selects the filtering type. If you use the <code>AttributedTo</code> filter type, the query returns all liens associated with usage records satisfying the filters. If you use the <code>ImpingesUpon</code> filter type, the query returns all liens affecting the balances of funds satisfying the filters.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--long	
Format	--long
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Funds – List of funds that the lien has holds against. • Allocations – List of allocations that the lien has holds against in the format <allocation_id><-<fund_id>=<reserved_amount>. • Amount – Reserved amount. • CreationTime – Time this lien was created. • Deleted – Boolean indicating whether this lien is deleted or not. • Description – Lien description. • Duration – Expected duration of the reserved usage in seconds. • EndTime – Time the lien becomes inactive. • Id – Lien ID. • Instance – The lien is against the specified instance (for instance, job ID). • ModificationTime – Time this lien was last modified. • RequestId – ID of the last modifying request. • StartTime – Time the lien becomes active. • TransactionId – ID of the last modifying transaction. • UsageRecord – ID of the usage record associated with the lien and containing the usage properties.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line comma-separated format.

glsnot

Synopsis

```
glsnot [-E <event_id>] [-T <notification_type>] [-k <primary_key_value>] [-u <recipient>] [-x <status>] [-s <start_time>] [-e <end_time>] [--delete] [--full] [--show <attribute_name>, ...] [--format <output_type>] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--version] [[-N] <notification_id>]
```

Overview

glsnot displays stored notification information.

You can customize the fields this command displays by default by setting the **notification.show** configuration parameter in `gold.conf`.

Options

-e	
Format	<code>-e <end_time></code>
Default	---
Description	Displays the notifications sent before the specified time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now.

-E	
Format	<code>-E <event_id></code>
Default	---
Description	Displays only the notifications associated with the specified event ID.

-k	
Format	<code>-k <primary_key_value></code>
Default	---
Description	Displays only the notifications associated with the specified primary key value. This value of the primary key of the object instance that the command acted on.

-N	
Format	<code>[-N] <notification_id></code>
Default	---
Description	Displays only the notifications with the specified ID.

-s	
Format	-s <start_time>
Default	---
Description	Displays notifications sent after the specified time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now

-x	
Format	-x <status>
Default	---
Description	Displays notifications having the specified status (such as Success or Failure).

-T	
Format	-T <notification_type>
Default	---
Description	Displays notifications of the specified type (such as Fire or Failure).

-u	
Format	-u <recipient>
Default	---
Description	Displays notifications having the specified recipient. This could be a user name or any tag that identifies the intended reader of this notification.

--debug	
Format	--debug

--debug	
Default	---
Description	Logs debug information to the screen.

--delete	
Format	--delete
Default	---
Description	Deletes a notification after it has been queried.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Code – Event command exit code. • CreationTime – Time this notification was created. • Deleted – Boolean indicating whether this notification is deleted or not. • EndTime – Time after which a notification will be detected. • Event – Event ID. • Key – Object primary key value. • Id – Notification ID. • Message – Event command message. • ModificationTime – Time this notification was last modified. • Recipient – Recipient to notify. • Status – Event command status. • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction. • Type – Displays the type of notification. Notifications may be created by event "Fire" commands or by event "Failure" commands.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

glsorg

Synopsis

```
glsorg [-X, --extension <property>=<value>]... [--full] [--show
<attribute_name>,...] [--format <output_type>] [--debug] [--
site <site_name>] [--help] [--man] [--quiet] [--version] [[-o]
<organization_pattern>]
```

Overview

glsorg displays organization information.

You can customize the fields this command displays by default by setting the **organization.show** configuration parameter in `gold.conf`.

Options

-o	
Format	-o <organization_pattern>

-O	
Default	---
Description	Displays only organizations matching the pattern. If no pattern is specified then all organizations are displayed. The following wildcards are supported: * – matches any number of characters ? – matches a single character

-X	
Format	-X or --extension <i><property>=<value></i>
Default	---
Description	Extension property. You may specify any number of extra custom conditions may be specified.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <i><output_format></i>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---

--full	
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show	
Description	Displays only the specified attributes in the order specified. Valid attributes include the following: <ul style="list-style-type: none"> • CreationTime – Time this organization was created. • Deleted – Boolean indicating whether this organization is deleted or not. • Description – Organization description. • ModificationTime – Time this organization was last modified. • Name – Organization name. • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

format <output_type>] [-h,--hours] [--debug] [--site <site_
```

```
name>] [--help] [--man] [--quiet] [--version] [[-q] <quote_id>]
```

Overview

`glquote` displays quote information.

You can customize the fields this command displays by default by setting the **quote.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only quotes for the specified account.

-A	
Format	-A
Default	---
Description	Displays only unexpired quotes.

-c	
Format	-c <class_name>
Default	---
Description	Displays only quotes for the specified class.

-g	
Format	-g <group_name>

-g	
Default	---
Description	Displays only quotes for the specified group.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-l	
Format	-l
Default	---
Description	Displays only expired quotes.

-J	
Format	-J <instance_name>
Default	---
Description	Displays only quotes with the specified instance name or job ID.

-m	
Format	-m <machine_name>
Default	---
Description	Displays only quotes for the specified machine.

-o	
Format	<code>-o <organization_name></code>
Default	---
Description	Displays only quotes for the specified organization.

-q	
Format	<code>[-q] <quote_id></code>
Default	---
Description	Displays only information for the specified quote.

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Displays only quotes for the specified user.

-X	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Displays quotes where constraints do not conflict with the specified filters. For example, <code>glsquote --filter User=amy</code> will display funds usable by the user amy. You may specify multiple filter options by logically ANDing them together.

--format	
Format	<code>--format <output_format></code>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	<code>--full</code>
Default	---
Description	Displays all attributes.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--long	
Format	<code>--long</code>

--long	
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show

Description

Displays only the specified attributes in the order specified. Valid attributes include the following:

- **Amount** – Quoted amount.
- **ChargeRate** – Saved charge rates to be used when the quote is referenced. These are displayed in the format `<charge_rate_name>[{<charge_rate_value>}]`
=`<charge_rate_amount>`
- **CreationTime** – Time this quote was created.
- **Deleted** – Boolean indicating whether this quote is deleted or not.
- **Description** – Quote description.
- **Duration** – Expected duration of the quoted usage in seconds.
- **EndTime** – Time the quote becomes inactive.
- **Id** – Quote ID.
- **Instance** – The quote may only be used by the specified instance.
- **ModificationTime** – Time this quote was last modified.
- **Pinned** – Boolean indicating whether the quote is pinned or not.
- **RequestId** – ID of the last modifying request.
- **StartTime** – Time the quote becomes active.
- **TransactionId** – ID of the last modifying transaction.
- **UsageRecord** – ID of the usage record associated with the quote and containing the usage properties.

--site

Format

`--site <site_name>`

Default

Description

Obtains a response from specified site.

--version

Format

`--version`

Default

Description

Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line comma-separated format.

Related Topics

glstrate

Synopsis

```
glstrate [-n <charge_rate_name>] [-x <charge_rate_value>] [--full] [--show <attribute_name>,...] [--format <output_type>] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--version]
```

Overview

glstrate displays charge rate information.

Options

-n	
Format	-n <charge_rate_name>
Default	---
Description	Displays only charge rates of the specified name.

-x	
Format	-x <charge_rate_value>
Default	---

-X	
Description	Displays only charge rates having the specified value.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <i><output_format></i>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Amount – Charge rate amount. The amount is an integer or decimal number and may include operators indicating how to apply the charge rate as well as divisors and time-based units. See Managing Charge Rates on page 2905 for more information. • CreationTime – Time this charge rate was created. • Deleted – Boolean indicating whether this charge rate is deleted or not. • Description – Charge rate description. • ModificationTime – Time this charge rate was last modified. • Name – Charge rate name (such as Processors or License). • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction. • Value – Charge rate value. For name-valued charge rates this is the usage property value corresponding to the rate. For numeric-valued charge rates this is the range of values corresponding to the rate. A blank value will function as a default charge rate. See Managing Charge Rates on page 2905 the for more information.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

glrole

Synopsis

```
glrole [--full] [--show <attribute_name>,...] [--long] [--wide]
[--format <output_type>] [--debug] [--site <site_name>] [--
help] [--man] [--quiet] [--version] [[-r] <role_name>]
```

Overview

glrole displays role information.

Options

-r	
Format	[-r] <role_name>
Default	---
Description	Displays information for only the specified role.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--long	
Format	--long
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Actions – List of actions permitted by the role. Actions are displayed in the format <code>object->action{instance}</code> • CreationTime – Time this role was created. • Deleted – Boolean indicating whether this role is deleted or not. • Description – Role description. • ModificationTime – Time this role was last modified. • Name – Role name. • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction. • Users – List of users granted access to the role.

--site	
Format	--site <site_name>
Default	---

--site	
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line comma-separated format.

glstrans

Synopsis

```
glstrans [-O <object>] [-A <action>] [-k <primary_key_value>] [-U
<actor>] [-f <fund_id>] [-i <allocation_id>] [-u <user_name>]
[-a <account_name>] [-m <machine_name>] [-j <usage_record_id>]
[-J <instance_name>|<job_id>] [-s <start_time>] [-e <end_
time>] [-T <transaction_id>] [-R <request_id>] [--filter
<filter_name>=<filter_value>] [-X, --extension
<property>=<value>]... [--full] [--show <attribute_name>,...]
[--long] [--wide] [--format <output_type>] [-h,--hours] [--
debug] [--site <site_name>] [--help] [--man] [--quiet] [--
version]
```

Overview

glstrans displays transaction information.

You can customize the fields this command displays by default by setting the **transaction.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only transactions involving the specified account.

-A	
Format	-A <action>
Default	---
Description	Displays only transactions invoking the specified action.

-e	
Format	-e <end_time>
Default	---
Description	Displays transactions occurring before the specified time in the format YYYY-MM-DD [hh:mm:ss] -Infinity Infinity Now

-f	
Format	-f <fund_id>
Default	---
Description	Displays only transactions involving the specified fund.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-i	
Format	-i <allocation_id>
Default	---
Description	Displays only transactions logged against the specific allocation.

-j	
Format	-j <usage_record_id>
Default	---
Description	Displays only transactions affecting the given usage record.

-J	
Format	-J <instance_name job_id>
Default	---
Description	Displays only transactions affiliated with the given instance name or job ID.

-k	
Format	-k <primary_key_value>
Default	---

-k

Description	Displays only transactions involving the objects having the specified primary key value (i.e. having the specified Id or Name) or associations with the given parent name.
--------------------	--

-m

Format	<code>-m <machine_name></code>
---------------	--------------------------------------

Default	---
----------------	-----

Description	Displays only transactions involving the specified machine.
--------------------	---

-O

Format	<code>-O <object></code>
---------------	--------------------------------

Default	---
----------------	-----

Description	Displays only transactions performing actions on the given object type.
--------------------	---

-R

Format	<code>-R <request_id></code>
---------------	------------------------------------

Default	---
----------------	-----

Description	Displays only transactions with the specified request ID. A unique request ID is associated with each request, while each request may be associated with more than one transaction.
--------------------	---

-S

Format	<code>-s <start_time></code>
---------------	------------------------------------

Default	---
----------------	-----

Description	Displays transactions occurring after the specified time in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now
--------------------	---

-T	
Format	-T <transaction_id>
Default	---
Description	Displays only transactions with the specified transaction ID. A transaction occurs when an action is invoked on an object. A complex request may involve multiple transactions.

-u	
Format	-u <user_name>
Default	---
Description	Displays only transaction involving the specified user.

-U	
Format	-U <actor>
Default	---
Description	Displays only transactions invoked by the specified user.

-X	
Format	-X or --extension <property>=<value>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	--debug
Default	---

--debug	
Description	Logs debug information to the screen.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show

Description

Valid attributes include the following:

- **Account** – Account name associated with the transaction.
- **Action** – Action name.
- **Actor** – User that performed the action.
- **Allocation** – Allocation ID associated with the transaction.
- **Amount** – Amount.
- **Balance** – Effective active balance. If the allocation is active, this is the same as the remaining allocation amount (Remaining). If the allocation is inactive, this is zero.
- **Child** – If the transaction object is an association, this is the value of the child.
- **Count** – Number of objects affected by the transaction.
- **CreationTime** – Time this transaction was created.
- **Deleted** – Boolean indicating whether this transaction is deleted or not.
- **Delta** – Change (positive or negative) to the effective active balance of an allocation (Balance). This may differ in some cases from the change in the actual allocation amount (Remaining). For example, if an allocation expires, a negative Delta will be recorded for the event, while the remaining allocation amount has not changed. On the other hand, a modification of the amount in an expired allocation will be recorded as a Delta of zero.
- **Description** – Transaction description.
- **Details** – Additional assignments, conditions, options, and other details of the transaction are recorded here when there is no applicable transaction property to store them in.
- **Duration** – Expected duration of the transaction in seconds.
- **Fund** – Fund ID associated with the transaction.
- **Id** – Transaction ID.
- **Instance** – Instance name.
- **Key** – If the transaction object is an association, this is the value of the parent, otherwise this is the value of the primary key (ID or name) of the object.
- **Machine** – Machine name associated with the transaction.
- **ModificationTime** – Time this transaction was last modified.
- **Object** – Object name.
- **Remaining** – Remaining allocation amount. If an allocation amount has the potential for being affected by this transaction, this field stores the remaining allocation amount after the transaction completed. Note that for expired allocations, this will still record the allocation's actual remaining amount, even though the allocation's effective active balance (Balance) may be zero. Thus it is possible for the Remaining amount to change even though the Delta is zero or the Remaining amount to remain unchanged even though the Delta is non-zero.
- **RequestId** – ID of the last modifying request.
- **TransactionId** – ID of the last modifying transaction.
- **UsageRecord** – ID of the usage record associated with the transaction.
- **User** – User name associated with the transaction.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

glsusage

Synopsis

```
glsusage [-T <usage_record_type>] [-J <instance_name
pattern>|<job_id_pattern>] [-S <service_id>] [-u <user_name>]
[-g <group_name>] [-a <account_name>] [-o <organization_name>]
[-c <class_name>] [-Q <quality_of_service>] [-m <machine
name>] [--stage <stage>] [-s <start_time>] [-e <end_time>] [-
X, --extension <property>=<value>]... [--full] [--show
<attribute_name>,...] [--format <output_type>] [-h,--hours] [-
debug] [--site <site_name>] [--help] [--man] [--quiet] [--
version] [[-j] <usage_record_id>]
```

Overview

glsusage displays usage record information.

You can customize the fields this command displays by default by setting the **usagerecord.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only usage records affiliated with the specified account.

-c	
Format	-c <class_name>
Default	---
C	Specifies the class or queue name.

-e	
Format	-e <end_time>
Default	---
Description	Ended before the specified time.

-g	
Format	-g <group_name>
Default	---
Description	Displays only usage records affiliated with the specified group

-h	
Format	-h or --hours
Default	---

-h	
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-j	
Format	<code>[-j] <usage_record_id></code>
Default	---
Description	Displays the usage record with the specified ID.

-J	
Format	<code>-J <instance_name> <job_pattern></code>
Default	---
Description	Displays only usage records matching the specified instance name or job id pattern. The following wildcards are supported: <ul style="list-style-type: none"> • * – matches any number of characters • ? – matches a single character

-m	
Format	<code>-m <machine_name></code>
Default	---
Description	Displays only usage records affiliated with the specified machine.

-o	
Format	<code>-o <organization_name></code>
Default	---
Description	Displays only usage records affiliated with the specified organization.

-Q	
Format	<code>-Q <quality_of_service></code>
Default	---
Description	Displays only usage records affiliated with the given quality of service .

-S	
Format	<code>-s <start_time></code>
Default	---
Description	Started after the specified time.

--stage	
Format	<code>--stage <stage></code>
Default	---
Description	Last stage completed by the usage (Quote, Create, Reserve, Charge).

-S	
Format	<code>-S <service_id></code>
Default	---
Description	Display on usage records associated with the specified root service ID (cloud).

-T	
Format	<code>-T <usage_record_type></code>
Default	---
Description	Displays only usage records associated with the specified type (such as Job or Reservation).

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Displays only usage records affiliated with the given user.

-X	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--format	
Format	<code>--format <output_format></code>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	<code>--full</code>
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---

--show

Description

Displays only the specified attributes in the order specified. Valid attributes include the following:

- **Account** – Account name associated with the usage.
- **Charge** – Cumulative amount charged.
- **Class** – Class or queue name associated with the usage.
- **CPUTime** – CPU time used.
- **CreationTime** – Time this usage record was created.
- **Deleted** – Boolean indicating whether this usage record is deleted or not.
- **Description** – Usage description.
- **Disk** – Amount of disk used.
- **Duration** – Expected duration of the usage.
- **EndTime** – Overall end time of the usage.
- **Id** – Usage record ID.
- **Instance** – Instance name (job ID).
- **JobTemplate** – Job template name (cloud).
- **Machine** – Cluster name (HPC) or virtual or physical machine name (cloud).
- **Memory** – Amount of memory used.
- **ModificationTime** – Time this usage record was last modified.
- **Nodes** – Number of nodes used (HPC).
- **Organization** – Organization name associated with the usage.
- **Processors** – Number of cores or processors used.
- **QualityOfService** – Quality of service associated with the usage.
- **Quote** – Associated quote ID.
- **RequestId** – ID of the last modifying request.
- **Service** – Root service ID (cloud).
- **ServiceComponent** – Leaf service ID (cloud).
- **Stage** – Last affecting action (Create, Quote, Reserve, Query).
- **StartTime** – Overall start time of the usage.
- **TransactionId** – ID of the last modifying transaction.
- **Type** – Usage record type.
- **User** – User name associated with the usage.

--site

Format

--site <site_name>

Default

Description

Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

gluser

Synopsis

```
gluser [-A|-I] [-X, --extension <property>=<value>]... [-a
<account_name>] [--full] [--show <attribute_name>,...] [--
long] [--wide] [--format <output_type>] [--debug] [--site
<site_name>] [--help] [--man] [--quiet] [--version] [[-u]
<user_pattern>]
```

Overview

gluser displays user information.

You can customize the fields this command displays by default by setting the **user.show** configuration parameter in `gold.conf`.

Options

-a	
Format	-a <account_name>
Default	---
Description	Displays only users affiliated with the specified account.

-A	
Format	-A
Default	---
Description	Displays only active users.

-I	
Format	-I
Default	---
Description	Displays only inactive users.

-u	
Format	<code>[-u] <user_pattern></code>
Default	---
Description	<p>Displays only users matching the pattern. If you do not specify a pattern then all users are displayed. The following wildcards are supported:</p> <ul style="list-style-type: none"> • * – matches any number of characters • ? – matches a single character

-X	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--debug	
Format	--debug

--debug	
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <output_format>
Default	standard
Description	Specifies a data output format. Valid values include standard and csv.

--full	
Format	--full
Default	---
Description	Displays all attributes.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--long	
Format	--long
Default	---
Description	Long format. Displays multi-valued fields in a multi-line format.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--show	
Format	--show <attribute_name>[,<attribute_name>...]
Default	---
Description	<p>Displays only the specified attributes in the order specified. Valid attributes include the following:</p> <ul style="list-style-type: none"> • Active – Boolean indicating whether this user is active or not. • CommonName – Common name for the user. • CreationTime – Time this user was created • Deleted – Boolean indicating whether this user is deleted or not. • DefaultAccount – Default account. • Description – User description. • EmailAddress Email address. • ModificationTime – Time this user was last modified. • Name – User name. • PhoneNumber – Phone number. • Accounts – List of accounts to which the user belongs. • RequestId – ID of the last modifying request. • TransactionId – ID of the last modifying transaction.

--site	
Format	--site <site_name>

--site	
Default	---
Description	Obtains a response from specified site.

--version	
Format	--version
Default	---
Description	Displays the product version.

--wide	
Format	--wide
Default	---
Description	Wide format. Displays multi-valued fields in a single-line comma-separated format.

gmkaaccount

Synopsis

```
gmkaaccount [-A|-I] [-o <organization_name>] [-d <description>]
[-X, --extension <property>=<value>]... [-u [^|!][+|-]<user_
name>,...]... [--create-fund=<boolean>] [--debug] [--site
<site_name>] [--help] [--man] [--quiet] [--verbose] [--
version] [[-a] <account_pattern>]
```

Overview

`gmkaaccount` creates a new account. Users may be associated with the account. If you turn on auto-generation for the Fund object or assert the `--create-fund` flag, a fund will automatically be created for the account.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies the name of the new account

-A	
Format	-A
Default	---
Description	Activates the account

-d	
Format	-d <description>
Default	---
Description	Specifies an account description.

-I	
Format	-I
Default	---
Description	Deactivates the account.

-o	
Format	-o <organization_name>
Default	---

-o

Description	Specifies the name of the organization to which the account belongs.
--------------------	--

-u

Format	<code>-u [^ !][+ -]<user_name>[, [^ !][+ -]<user_name>...]</code>
---------------	---

Default	---
----------------	-----

Description	Defines user members of the account. The optional caret or exclamation symbol indicates whether the user should be created as an admin (^) or not (!) for the account. The optional plus or minus sign can precede each member to indicate whether the member should be created in the active (+) or inactive (-) state. By default, a user will be created in the active state but not an admin. You may pass multiple users may be passed to the <code>-u</code> option in a comma-delimited list or by specifying multiple <code>-u</code> options.
--------------------	--

-X

Format	<code>-X or --extension <property>=<value></code>
---------------	---

Default	---
----------------	-----

Description	Specifies an extension property. You can specify any number of extra custom conditions.
--------------------	---

--create-fund

Format	<code>--create-fund <boolean></code>
---------------	--

Default	---
----------------	-----

Description	Overrides the fund auto-generation setting. Setting this option to <code>True</code> creates a default fund for this account. Setting this option to <code>False</code> inhibits the creation of a default fund for this account.
--------------------	---

--debug

Format	<code>--debug</code>
---------------	----------------------

Default	---
----------------	-----

--debug

Description	Logs debug information to the screen.
--------------------	---------------------------------------

--help

Format	--help
---------------	--------

Default	---
----------------	-----

Description	Displays a brief help message.
--------------------	--------------------------------

--man

Format	--man
---------------	-------

Default	---
----------------	-----

Description	Displays full documentation.
--------------------	------------------------------

--quiet

Format	--quiet
---------------	---------

Default	---
----------------	-----

Description	Suppresses headers and success messages.
--------------------	--

--site

Format	--site <site_name>
---------------	--------------------

Default	---
----------------	-----

Description	Obtains a response from specified site.
--------------------	---

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

Related Topics

[Creating Accounts on page 2855](#)

[Appendix A: Commands Reference on page 2965](#)

gmkevent

Synopsis

```
gmkevent --fire-command <fire_command> [-s <fire_time>] [-e
<end_time>] [--rearm-period <rearm_period>] [--rearm-on-
failure <boolean>] [--failure-command <failure_command>] [--
notify <notification_url>] [--catch-up <boolean>] [-d
<description>] [--debug] [--site <site_name>] [--help] [--man]
[--quiet] [--verbose] [--version]
```

Overview

gmkevent creates a new event.

Options

-d	
Format	-d <description>

-d	
Default	---
Description	Specifies an event description.

-e	
Format	<code>-e <end_time></code>
Default	---
Description	Specifies the time that this event becomes inactive.

-s	
Format	<code>-s <fire_time></code>
Default	---
Description	Specifies the target time for the event scheduler to trigger the event. The actual fire time may be dependent on the state of the server and will be recorded in the CreationTime property of the corresponding "Event Fire" Transaction. An event may also be fired manually with the goldsh Event Fire action.

--catch-up	
Format	<code>--catch-up <boolean></code>
Default	True
Description	If you set <code>--catch-up</code> to <code>True</code> and the server was down during the time this event should have fired, the event scheduler will attempt to make up for the past-due events by progressively firing them (rearming based on previous arm time) until it catches up to the present. The actions will still appear to have occurred in the present rather than in the past. If you set it to <code>False</code> and the server is brought back up after an outage, the event scheduler will still fire immediately for a past due event, but it will only fire once and then rearm relative to the current time.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--failure-command	
Format	--failure-command <goldsh_command>
Default	---
Description	Specifies the command MAM should execute if the fired command results in an unsuccessful response status. This command is expressed in a serialized form of the request identical to the syntax used in the interactive control program (goldsh). You must appropriately quote and/or escape the option argument to avoid misinterpretation or alteration by the shell.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--notify	
Format	--notify [+ =] [<delivery_method>:] [<recipient>]

--notify	
Default	Log all event statuses to the Notification table.
Description	Causes MAM to log the result of the fired command. If the term is a -, the notification is sent only on failure. If the term is a +, the notification is sent only on success. Otherwise the notification is always sent. See the Managing Notifications on page 2915 for more information about delivery method and recipient.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--rearm-on-failure	
Format	--rearm-on-failure <Boolean>
Default	False
Description	If you set --rearm-on-failure to False, MAM will not rearm the event if the command was unsuccessful. If you set it to True, the event will be evaluated for rearming even if the command response has a status of Failure.

--rearm-period	
Format	--rearm-period <period>[[@instant][~ ^]!]
Default	---
Description	Specifies when the event will be rearmed. This period expression is of the form <period> [[@instant][~ ^]!], where <period> may be something like 1 day, 2 hours, or 5 minutes. Instant locks the period to a specific instant within the time period such as 1 day @ hour 12 or 1 month @ day 3. The modifiers indicate whether the time period should be relative to now (!), relative to the start of this (~) designator (month, minute, or other unit), or relative to the start of the first (^) designator (month, minute, or other unit). For example, assuming the fire time was 7:15, if you specified 4 hours ! as the rearm period it would be rearmed at 11:15; if you specified 4 hours ~ as the rearm period, it would be rearmed at 11:00; and if you specified 4 hours ^ as the rearm period it would be rearmed at 8:00.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkgfund

Synopsis

```
gmkgfund [-n <fund_name>] [--priority <fund_priority>] [--
default-deposit <deposit_amount>] [-d <description>] [-X, --
extension <property>=<value>]... [-u <user_name>,...]... [-g
<group_name>,...]... [-a <account_name>,...]... [-o
<organization_name>,...]... [-c <class_name>,...]... [-m
<machine_name>,...]... [--constraint <constraint_name>=(!]
<constraint_value>,...]... [--parent <parent_fund_id>] [--
debug] [--site <site_name>] [--help] [--man] [--quiet] [--
verbose] [--version]
```

Overview

`glsfund` creates new funds. MAM automatically generates a new ID for the fund. It essentially creates a new container into which time-bounded credits valid toward a specific set of constraints can be later credited and debited.

Options

-a	
Format	<code>-a <account_name>[,<account_name>...]</code>
Default	---
Description	Specifies the account required by the fund. You may pass multiple accounts to the <code>-a</code> option in a comma-delimited list or by specifying multiple <code>-a</code> options may be specified.

-c	
Format	<code>-c <class_name>[,<class_name>...]</code>
Default	---
Description	Specifies the class or queue required by the fund. You may pass multiple classes may be passed to the <code>-c</code> option in a comma-delimited list or by specifying multiple <code>-c</code> options.

-d	
Format	<code>-d <description></code>
Default	---
Description	Specifies a fund description.

-g	
Format	<code>-g <group_name>[,<group_name>...]</code>
Default	---

-g

Description	Specifies the group required by the fund. You can pass multiple groups to the <code>-g</code> option in a comma-delimited list or by specifying multiple <code>-g</code> options.
--------------------	---

-m

Format	<code>-m <machine_name>[, <machine_name>...]</code>
Default	---
Description	Specifies the machine (cluster or cloud) the fund requires. You may pass multiple machines to the <code>-m</code> option in a comma-delimited list or by specifying multiple <code>-m</code> options .

-n

Format	<code>-n <fund_name></code>
Default	---
Description	Specifies the fund name.

-o

Format	<code>-o <organization_name>[, <organization_name>...]</code>
Default	---
Description	Specifies the organization the fund requiresd. You may pass multiple organizations may be passed to the <code>-o</code> option in a comma-delimited list or by specifying multiple <code>-o</code> options.

-u

Format	<code>-u <user_name>[, <user_name>...]</code>
Default	---
Description	Specifies the user required by the fund. You may pass multiple users may be passed to the <code>-u</code> option in a comma-delimited list or by specifying multiple <code>-u</code> options.

-X, --extension	
Format	<code>-X</code> or <code>--extension</code> <i><property>=<value></i>
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

--constraint	
Format	<code>--constraint</code> <i><constraint_name>=<constraint_value></i> [, <i><constraint_name>=<constraint_value>...</i>]
Default	---
Description	Specifies a constraint for the fund. The constraint value may be a perl5 regular expression. You may prepend an exclamation point to the constraint value to express a negation of the constraint. You may specify multiple constraint options. For example, <code>--constraint User=amy --constraint Machine=colony</code> will make the credits in this fund valid only for the user amy on the machine colony. You may pass multiple constraints to the <code>--constraint</code> option in a comma-delimited list or specify multiple <code>--constraint</code> .

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--default-deposit	
Format	<code>--default-deposit</code> <i><default_amount></i>
Default	---
Description	Sets the default amount for any deposit that is made to this fund that does not specify a deposit amount.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--parent	
Format	--parent <parent_fund_id>
Default	---
Description	Associates the newly created fund as a child of the specified parent fund.

--priority	
Format	--priority <fund_priority>
Default	---
Description	Specifies the fund priority.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkljen

Synopsis

```
gmkljen [-J <instance_name>|<job_id>] [-s <start_time>] {[-e
<end_time>] | -t <lien_duration>}] [-d <description>] [-X, --
extension <property>=<value>]... {-A <allocation_id><-<fund
id>=<sublien_amount>,...}>... [--debug] [--site <site_name>] [-
help] [--man] [--quiet] [--verbose] [--version]
```

Overview

`gmklie`n creates a lien against specified allocations. MAM will create a lien object and its allocation associations. Unlike [greserve](#), MAM will not return a calculated lien amount or create a usage record with the lien.

 This command bypasses the normal mechanisms that prevent more liens from being placed against an allocation than it can support.

Options

-A	
Format	<code>-A <allocation_id><-<fund_id>=<sublien_amount>[,<allocation_id><-<fund_id>=<sublien_amount>...]</code>
Default	---
Description	Creates subliens against the specified allocations. You must specify at least one allocation expression with the lien. You may pass multiple allocation expressions to the <code>-A</code> option in a comma-delimited list or by specifying multiple <code>-A</code> options.

-d	
Format	<code>-d <description></code>
Default	---
Description	Specifies a description for the lien.

-e	
Format	<code>-e <end_time></code>
Default	Now
Description	Specifies the expiration time for the lien in the format <code>YYYY-MM-DD [hh:mm:ss] -Infinity Infinity Now</code> .

-J	
Format	<code>[-J] <instance_name> <job_id></code>
Default	---
Description	Specifies the instance name or job ID for the lien.

-S	
Format	<code>-s <start_time></code>
Default	Now
Description	Specifies a new start time for the lien in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now.

-t	
Format	<code>-t <lien_duration></code>
Default	Lien end time minus start time
Description	Specifies the duration of the lien in seconds.

-X, --extension	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	<code>--debug</code>
Default	---

--debug	
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkgorg

Synopsis

```
gmkgorg [-d <description>] [-X, --extension
<property>=<value>]... [--debug] [--site <site_name>] [--help]
[--man] [--quiet] [--verbose] [--version] {[-o] <organization_
name>}
```

Overview

gmkgorg creates a new organization.

Options

-d	
Format	-d <description>
Default	---

-d	
Description	Specifies a description for the organization.

-o	
Format	<code>-o <organization_name></code>
Default	---
Description	Specifies the name of the organization.

-X, --extension <property>	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkgquote

Synopsis

```
gmkgquote [[--pin] [-J <instance_name>|<job_id>] | --nopin] [-s
<start_time>] {-e <end_time> | -t <quote_duration>} [-d
<description>] [-X, --extension <property>=<value>]... {-R
<charge_rate_name>[{<charge_rate_value>}]=<charge_rate_
amount>,...}... [--debug] [--site <site_name>] [--help] [--
man] [--quiet] [--verbose] [--version]
```

Overview

gmkgquote creates a new chargeable quote template. MAM will create a quote object and its associated charge rates. Instances referencing the quote will use the override charge rates specified in the command. Unlike gquote, gmkgquote will not return a calculated quote amount or create a usage record with the quote.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a description of the quote.

-e	
Format	-e <end_time>
Default	---
Description	Specifies the expiration time for the quote template in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now. The rates associated with this quote may not be claimed after this time. If you do not specify an end time but did specify a duration, MAM will calculate the end time as start time + duration. If you specify both end time and duration but they are inconsistent, MAM will ignore the duration specification.

-J	
Format	<code>-J <instance_name> <job_id></code>
Default	---
Description	Specifies the instance name, such as a job ID, for the quote. You cannot specify an instance name if the quote is unpinned.

-R	
Format	<code>-R <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>[,<charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>...]</code>
Default	---
Description	Associates the specified charge rates with the quote. You must specify at least one charge rate expression with the quote. You may pass multiple charge rate expressions to the <code>-R</code> option in a comma-delimited list or specify multiple <code>-R</code> options.

-S	
Format	<code>-s <start_time></code>
Default	Now
Description	Specifies a beginning time for the quote template in the format <code>YYYY-MM-DD[hh:mm:ss]</code> <code>-Infinity</code> <code>Infinity</code> <code>Now</code> . The rates associated with this quote may not be claimed before this time.

-t	
Format	<code>-t <quote_duration></code>
Default	---
Description	Specifies the amount of time in seconds the rates in the quote template may be used. MAM uses the duration to calculate an end time (start time + duration) as an alternative to specifying the end time.

-X, --extension <property>	
Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--nopin	
Format	--nopin
Default	Not set

--nopin

Description	Indicates that the quote is not to be pinned to a specific instance. An instance may use an unpinned quote while the quote is active.
--------------------	---

--pin

Format	--pin
Default	Set
Description	Indicates that the quote will be pinned to a specific instance. If you do not specify the instance when you create the quote, the first instance to claim it will become the pinned instance. Once a quote is pinned to a particular instance, no other instances may use the quote.

--quiet

Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site

Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose

Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkrate

Synopsis

```
gmkrate -n <charge_rate_name> [-x <charge_rate_value>] [-d
<description>] [--debug] [--site <site_name>] [--help] [--man]
[--quiet] [--verbose] [--version] {[ -z] <charge_rate_amount>}
```

Overview

gmkrate creates a new charge rate.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies a charge rate description.

-n	
Format	-n <charge_rate_name>
Default	---

-n	
Description	Specifies the name of the usage record property for which the rate is charging, such as Processors or QualityOfService.

-x	
Format	-x <charge_rate_value>
Default	---
Description	Specifies charge rate value. For name-valued charge rates, this is the usage property value corresponding to the rate. For numeric-valued charge rates, this is the range of values corresponding to the rate. A blank value will function as a default charge rate. See Managing Charge Rates on page 2905 for more information.

-z	
Format	-z <charge_rate_amount>
Default	---
Description	Specifies the rate for the charge. This is an integer or decimal number and may include operators that indicate how the charge is applies as well as divisors and time-based units. See Managing Charge Rates on page 2905 for more information.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---

--help	
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkrrole

Synopsis

```
gmkrrole [-d <description>] [-u <user_name>, ...]... [-A <object_name>-><action_name>[{{<instance_name>}}], ...]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] [{[-r] <role_name>}]
```

Overview

gmkrrole creates a new role. You can associate users and actions with the role at creation time.

Options

-A	
Format	-A <object_name>-><action_name>[{{<instance_name>}}] [, <object_name>-><action_name>[{{<instance_name>}}] ...]
Default	ANY
Description	Adds actions to the role. You must specify the object, action and instance in the form shown. You may pass multiple actions to the -A option in a comma-delimited list or specify multiple -A options.

-d	
Format	-d <description>

-d	
Default	---
Description	Specifies a role description.

-r	
Format	<code>[-r] <role_name></code>
Default	---
Description	Specifies the name of the new role.

-u	
Format	<code>-u <user_name>[, <user_name>...]</code>
Default	---
Description	Adds users to the role. You may pass multiple users to the <code>-u</code> option in a comma-delimited list or specify multiple <code>-u</code> options.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkusage

Synopsis

```
gmkusage [-T <usage_record_type>] [-S <service_id>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o <organization_name>] [-c <class_name>] [-Q <quality_of_service>] [-m <machine_name>] [-N <nodes>] [-P <processors>] [-C <cpu_time>] [-M <memory>] [-D <disk>] [-t <usage_duration>] [-s <start_time>] [-e <end_time>] [-d <description>] [-X, --extension <property>=<value>]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-J <instance_name>|<job_id>}
```

Overview

gmkusage creates a new usage record.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies an account name.

-c	
Format	-c <class_name>
Default	---
Description	Specifies a class or queue.

-C	
Format	-C <i><cpu_time></i>
Default	---
Description	Specifies CPU time used.

-d	
Format	-d <i><description></i>
Default	---
Description	Specifies a description.

-D	
Format	-D <i><disk></i>
Default	---
Description	Specifies the amount of disk used.

-e	
Format	-e <i><end_time></i>
Default	---
Description	Specifies the date and time the usage ended.

-g	
Format	-g <i><group_name></i>
Default	---
Description	Specifies a group name.

-J	
Format	<code>[-J] <instance_name> <job_id></code>
Default	---
Description	Specifies the instance name or job ID of the new usage record.

-m	
Format	<code>-m <machine_name></code>
Default	---
Description	Specifies the name of the cluster, cloud, or system used.

-M	
Format	<code>-M <memory></code>
Default	---
Description	Specifies the amount of memory used.

-N	
Format	<code>-N <nodes></code>
Default	---
Description	Specifies the number of nodes used.

-O	
Format	<code>-o <organization_name></code>
Default	---
Description	Specifies an organization name.

-P	
Format	<code>-P <processors></code>
Default	---
Description	Specifies the number of processors used.

-Q	
Format	<code>-Q <quality_of_service></code>
Default	---
Description	Specifies the quality of service used.

-s	
Format	<code>-s <start_time></code>
Default	---
Description	Specifies the date and time the usage started.

-S	
Format	<code>-S <service_id></code>
Default	---
Description	Specifies the root service ID (cloud).

-t	
Format	<code>-t <usage_duration></code>
Default	---
Description	Specifies the amount of time used in seconds.

-T	
Format	-T <usage_record_type>
Default	---
Description	Specifies the usage record type (Job or reservation, for example).

-u	
Format	-u <user_name>
Default	---
Description	Specifies the user name.

-X, --extension	
Format	-X or --extension <property>=<value>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gmkuser

Synopsis

```
gmkuser [-A|-I] [-n <common_name>] [-F <phone_number>] [-E <email_address>] [-a <default_account>] [-d <description>] [-X, --extension <property>=<value>]... [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-u] <user_name>}
```

Overview

gmkuser creates a new user.

Options

-a	
Format	-a <default_account>
Default	---
Description	Specifies the account MAM will charge when no account is specified.

-A	
Format	-A
Default	---
Description	Activates the user.

-d	
Format	-d <description>
Default	---

-d	
Description	Specifies a user description.

-E	
Format	-E <i><email_address></i>
Default	---
Description	Specifies an email address.

-F	
Format	-F <i><phone_number></i>
Default	---
Description	Specifies a phone number.

-I	
Format	-I
Default	---
Description	Deactivates the user.

n	
Format	-n <i><common_name></i>
Default	---
Description	Specifies the common name for the user.

-u	
Format	<code>[-u] <user_name></code>
Default	---
Description	Specifies the new user's ID or name.

-X, --extension <property>	
Format	<code>-X or --extension <property>=<value></code>
Default	---
Description	Modifies an extension property. You can specify any number of extra field assignments.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gquote

Synopsis

```
gquote [-T <usage_record_type>] [-S <service_id>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o <organization_name>] [-c <class_name>] [-Q <quality_of_service>] [-m <machine_name>] [-N <nodes>] [-P <processors>] [-C <cpu_time>] [-M <memory>] [-D <disk>] [-X, --extension <property>=<value>]... [-t <quote_duration>] [-G <grace_duration>]] [-s <quote_start_time>] [-e <quote_end_time>] [-d <quote_description>] [-z <quote_amount>] [--cost-only | --guarantee] [-R <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>, ...]... [-h, --hours] [--itemize] [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] [[-j <usage_record_id>] [-q <quote_template_id>] [-J <instance_name>|<job_id>]
```

Overview

gquote obtains a quote for usage. This command and its options can estimate the cost of using resources or services, validate that a requester has sufficient access and funds to use the requested resources or services, and guarantee that the charge rates used to generate the quote do not change when applying subsequent liens and charges.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies the account name.

-c	
Format	-c <class_name>
Default	---
Description	Specifies the class or queue used.

-C	
Format	<code>-C <cpu_time></code>
Default	---
Description	Specifies the estimated CPU time used.

-d	
Format	<code>-d <quote_description></code>
Default	---
Description	Specifies an explanatory message for the quote. You can pass overall usage description via the extension property option (<code>-X Description=<description></code>).

-D	
Format	<code>-D <disk></code>
Default	---
Description	Specifies the amount of disk used.

-e	
Format	<code>-e <quote_end_time></code>
Default	---
Description	Specifies the end time for the quote in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now.

-g	
Format	<code>-g <group_name></code>

-g	
Default	---
Description	Specifies the group name.

-G	
Format	-G <i><grace_duration></i>
Default	---
Description	Specifies a grace period in seconds. If you specify the quote duration but not the quote end time, MAM will calculate the quote end time as the quote start time plus the quote duration plus the grace duration.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-j	
Format	[-j] <i><usage_record_id></i>
Default	---
Description	Usage record ID for the quote if already created with <code>gmkusage</code> or a previous <code>gquote</code> .

-J	
Format	-J <i><instance_name job_id></i>
Default	---
Description	Instance name or the job ID of the quote if known.

-m	
Format	-m <machine_name>
Default	---
Description	Specifies the name of the cluster, cloud, or system used.

-M	
Format	-M <memory>
Default	---
Description	Specifies the amount of memory used.

-N	
Format	-N <nodes>
Default	---
Description	Specifies the number of nodes used.

-O	
Format	-o <organization_name>
Default	---
Description	Specifies the organization name.

-P	
Format	-P <processors>
Default	---
Description	Specifies the number of processors used.

-q	
Format	<code>-q <quote_template_id></code>
Default	---
Description	Specifies quote template used to override standard charge rates.

-Q	
Format	<code>-Q <quality_of_service></code>
Default	---
Description	Specifies the quality of service used.

-R	
Format	<code>-R <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>[, <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>...]</code>
Default	---
Description	Uses the specified charge rates in the quote. The specified rates override the general rates. If you specify the <code>--guarantee</code> option, these charge rates will be saved and used when this quote is referenced in a charge action. You may pass multiple charge rates to the <code>-R</code> option in a comma-delimited list or you can specify multiple <code>-R</code> options.

-S	
Format	<code>-s <quote_start_time></code>
Default	---
Description	Specifies the start time for the quote in the format <code>YYYY-MM-DD[hh:mm:ss]</code> <code>-Infinity</code> <code>Infinity</code> <code>Now</code> . You can pass the overall usage start time via the extension property option (<code>-X StartTime=<start_time></code>).

-S	
Format	<code>-S <service_id></code>
Default	---
Description	Specifies the root service ID (cloud).

-t	
Format	<code>-t <quote_duration></code>
Default	---
Description	Specifies the wallclock duration for the quote in seconds. You can pass the estimated wallclock time for the total lifetime usage via the extension property option (<code>-X Duration=<usage_duration></code>).

-T	
Format	<code>-T <usage_record_type></code>
Default	---
Description	Specifies the usage record type, such as job, service, or reservation.

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Specifies the user name.

-X	
Format	<code>-X or --extension <property>=<value></code>

-X	
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

-z	
Format	-z <quote_amount>
Default	---
Description	Specifies the quote amount if calculated externally.

--cost-only	
Format	--cost-only
Default	---
Description	Returns the cost, ignoring all balance and validity checks. This option is mutually exclusive with --guarantee.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--guarantee	
Format	--guarantee
Default	---
Description	Guarantees the quote and returns a quote ID to secure the current charge rates. This results in the creation of a quote record and a permanent usage record. This option is mutually exclusive with --cost-only .

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--itemize	
Format	--itemize
Default	---
Description	Returns the composite charge information in the response data. You must use this in conjunction with the --verbose flag to display the data.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---

--site	
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grefund

Synopsis

```
grefund [-z <amount>] [-f <fund_id>] [-d <description>] [-A] [--filter <filter_name>=<filter_value>]... [--filter-type <filter_type>] [-h, --hours] [--debug] [--site <site_name>] [-help] [--man] [--quiet] [--verbose] [--version] {-J <instance_name>|<job_id> | [-j] <usage_record_id>}
```

Overview

grefund issues a refund for the specified usage. The command will return a list of usage records if the usage search does not yield a unique match. If you do not specify an amount, MAM will credit the appropriate allocations for the full amount the overall usage was charged. You may specify a lesser amount for a partial refund.

Options

-A	
Format	-A
Default	---
Description	When you use filters to select the fund to be refunded, specifies that only active allocations should be considered.

-d	
Format	-d <description>
Default	---
Description	Specifies an explanatory message for the refund.

-f	
Format	-f <fund_id>
Default	---
Description	Specifies the fund to be refunded to. If you omit this, MAM will look in the transaction table to determine to which fund it should deposit the refund.

-h, --hours	
Format	-h or --hours
Default	---
Description	Treats currency as specified in hours. In systems where the currency is measured in resource-seconds (like processor-seconds), this option allows the amount to be specified in resource-hours.

-j	
Format	<code>[-j] <usage_record_id></code>
Default	---
Description	Specifies the unique usage record identifier the accounting manager assigns to distinguish between usage with non-unique instance names.

-J	
Format	<code>-J <instance_name> <job_id></code>
Default	---
Description	Specifies the name of the instance (such as a job ID assigned by the local resource manager). This ID might not be unique among the historical list of usage records the accounting manager manages.

-z	
Format	<code>-z <amounts></code>
Default	---
Description	Specifies the amount to refund. This amount must be non-negative and less than or equal to the amount charged for the overall usage.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>

--filter	
Default	---
Description	By default, MAM refunds amounts to the same fund from which it took them. If you want to override this, by specifying filters you may restrict the fund to be refunded to one whose constraints are consistent with the specified filters. For example, <code>grefund --filter User=amy</code> will refund the amount to the fund usable by the user <code>amy</code> . You may specify multiple filter options by logically ANDing them together.

--filter-type	
Format	<code>--filter-type <filter_type></code>
Default	<code>NonExclusive</code>
Description	Selects the filtering type. If you use the <code>Exclusive</code> filter type, a fund will only be matched if the specified filters meet all constraints. If you use the <code>NonExclusive</code> filter type, a fund will be matched as long as the specified filters do not conflict with the constraints.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	<code>--quiet</code>

--quiet	
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

greserve

Synopsis

```
greserve [-T <usage_record_type>] [-S <service_id>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o
```

```
<organization_name>] [-c <class_name>] [-Q <quality_of
service>] [-m <machine_name>] [-N <nodes>] [-P <processors>]
[-C <cpu_time>] [-M <memory>] [-D <disk>] [-X, --extension
<property>=<value>]... [-t <lien_duration> [-G <grace
duration>]] [-s <lien_start_time>] [-e <lien_end_time>] [-d
<lien_description>] [-z <lien_amount>] [--modify|--replace] [-R
<charge_rate_name>[{{<charge_rate_value>}}]=<charge_rate
amount>, ...]... [-h, --hours] [--itemize] [--debug] [--site
<site_name>] [--help] [--man] [--quiet] [--verbose] [--
version] [-j] <usage_record_id>] [-q <quote_id>] [-J
<instance_name>|<job_id>]
```

Overview

greserve obtains a lien for usage.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies the account name.

-c	
Format	-c <class_name>
Default	---
Description	Specifies the class or queue used.

-C	
Format	-C <cpu_time>
Default	---
Description	Specifies the estimated CPU time used.

-d	
Format	<code>-d <lien_description></code>
Default	---
Description	Specifies an explanatory message for the lien. You can pass overall usage description via the extension property option (<code>-X Description=<description></code>).

-D	
Format	<code>-D <disk></code>
Default	---
Description	Specifies the amount of disk used.

-e	
Format	<code>-e <lien_end_time></code>
Default	<i>Now</i>
Description	Specifies the end time for the lien in the format YYYY-MM-DD [hh:mm:ss] -Infinity Infinity Now.

-g	
Format	<code>-g <group_name></code>
Default	---
Description	Specifies the group name.

-G	
Format	<code>-G <grace_duration></code>

-G	
Default	---
Description	Specifies a grace period in seconds. If you specify the lien duration but not the lien end time, MAM will calculate the lien end time as the lien start time plus the lien duration plus the grace duration.

-h	
Format	-h or --hours
Default	---
Description	Displays time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-j	
Format	[-j] <usage_record_id>
Default	---
Description	Usage record ID for the lien if already created with gmkusage , gquote , or a previous greserve . This places a hold against an existing usage record if the instance name (such as a job ID) is ambiguous or if usage has already been debited and you want to reserve an additional amount associated with the same usage record.

-J	
Format	-J <instance_name job_id>
Default	---
Description	Instance name or the job ID of the lien if known. This can sometimes be non-unique, such as when a resource manager recycles job ids, and does not always unambiguously identify a usage record to reserve. In such cases, look up and specify the usage record ID for the lien.

-m	
Format	-m <machine_name>
Default	---
Description	Specifies the name of the cluster, cloud, or system used.

-M	
Format	-M <memory>
Default	---
Description	Specifies the amount of memory used..

-N	
Format	-N <nodes>
Default	---
Description	Specifies the number of nodes used.

-O	
Format	-o <organization_name>
Default	---
Description	Specifies the organization name.

-P	
Format	-P <processors>
Default	---
Description	Specifies the number of processors used.

-q	
Format	<code>[-q] <quote_id></code>
Default	---
Description	Specifies the quote used to determine charge rates.

-Q	
Format	<code>-Q <quality_of_service></code>
Default	---
Description	Specifies the quality of service used.

-R	
Format	<code>-R <charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount></code> <code>[,<charge_rate_name>[{<charge_rate_value>}]=<charge_rate_amount>...]</code>
Default	---
Description	Uses the specified charge rates in the lien. The specified rates override the general rates or rates guaranteed through a quote. You may pass multiple charge rates to the <code>-R</code> option in a comma-delimited list or specify multiple <code>-R</code> options.

-s	
Format	<code>-s <lien_start_time></code>
Default	---
Description	Specifies the start time for the lien in the format <code>YYYY-MM-DD[hh:mm:ss]</code> <code>-Infinity</code> <code>Infinity</code> <code>Now</code> . You can pass the overall usage start time via the extension property option (<code>-X StartTime=<start_time></code>).

-S	
Format	-S <service_id>
Default	---
Description	Specifies the root service ID (cloud).

-t	
Format	-t <lien_duration>
Default	---
Description	Specifies the wallclock duration for the lien in seconds. You can pass the estimated wallclock time for the total lifetime usage via the extension property option (-X Duration=<usage_duration>).

-T	
Format	-T <usage_record_type>
Default	---
Description	Specifies the usage record type, such as job, service, or reservation.

-u	
Format	-u <user_name>
Default	---
Description	Specifies the user name.

-X	
Format	-X or --extension <property>=<value>

-X	
Default	---
Description	Specifies an extension property. You can specify any number of extra custom conditions.

-z	
Format	-z <lien_amount>
Default	---
Description	Specifies the lien amount if calculated externally.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--itemize	
Format	--itemize
Default	---
Description	Returns the composite charge information in the response data. You must use this in conjunction with the --verbose flag to display the data.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--modify	
Format	--modify
Default	---
Description	Causes the reserve operation to augment existing liens instead of creating new ones. This new option is mutually exclusive with the <code>--replace</code> option which deletes existing matching liens and recreates a new one. The default action is to create a new lien even if a lien for an instance of the same name exists. The modify behavior supports extending liens out dynamically and is often used with incremental charging.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--replace	
Format	--replace
Default	---
Description	If you specify this option, MAM will delete similarly named liens before creating this lien. The default action is to create a new lien while leaving any existing liens for instances of the same name. The replace option should be specified if you want this lien to replace existing liens for instances of the same name such as when a system reuses instance names. This new option is mutually exclusive with the <code>--modify</code> option which modifies any existing matching lien instead of creating a new one.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmaccount

Synopsis

```
grmaccount [--debug] [--site <site_name>] [--help] [--man] [--quiet]
[--verbose] [--version] { [-a] <account_name> }
```

Overview

grmaccount deletes an account.

Options

-a	
Format	<code>[-a] <account_name></code>
Default	---
Description	Specifies the name of the account to be deleted.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	<code>--quiet</code>
Default	---

--quiet	
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmalloc

Synopsis

```
grmalloc (-I |{[-i] allocation_id}) [--debug] [--site <site_name>]
[--help] [--man] [--quiet] [--verbose] [--version]
```

Overview

`grmalloc` deletes an allocation or purges stale allocations.

Options

-i

Format	<code>[-i] <allocation_id></code>
Default	---
Description	Specifies the allocation to be deleted.

-I

Format	<code>-I</code>
Default	---
Description	Deletes inactive allocations.

--debug

Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help

Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmevent

Synopsis

```
grmevent [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-E] <event_id>}
```

Overview

grmevent deletes an event.

Options

-E	
Format	[-E] <event_id>
Default	---
Description	Specifies the ID of the event to be deleted.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmfund

Synopsis

```
grmfund [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] { [-f] <fund_id> }
```

Overview

grmfund deletes a fund.

Options

-f	
Format	[-f] <fund_id>
Default	---
Description	Specifies the fund to be deleted.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version

grmlien

Synopsis

```
grmlien { -I | { -J <instance_name> } | { [-l] <lien_id> } } [--debug]  
[--site <site_name>] [--help] [--man] [--quiet] [--verbose] [-  
version]
```

Overview

grmlien deletes a lien or purges stale liens.

Options

-I	
Format	-I
Default	---
Description	Deletes expired liens.

-J	
Format	-J <instance_name>
Default	---
Description	Specifies that the liens with the specified instance name,, or job ID, will be deleted.

-l	
Format	[-l] <lien_id>
Default	---
Description	Specifies the lien to be deleted.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmnot

Synopsis

```
grmnot [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {\[-N\] <notification_id>}
```

Overview

grmnot deletes a stored notification.

Options

-N	
Format	-N <notification_id>
Default	---
Description	Deletes expired liens.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmorg

Synopsis

```
grmorg [--debug] [--site <site_name>] [--help] [--man] [--quiet]
[--verbose] [--version] {[-o] <organization_name>}
```

Overview

grmorg deletes an organization.

Options

-o	
Format	[-o] <organization_name>
Default	---
Description	Specifies the organization to delete.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

grmquote

Synopsis

```
grmquote { -I | { [-q] <quote_id> } } [--debug] [--site <site name>] [--help] [--man] [--quiet] [--verbose] [--version]
```

Overview

`grmquote` deletes a quote or purges expired quotes.

Options

-I	
Format	-I
Default	---
Description	Deletes expired quotes.

-q	
Format	<code>[-q] <quote_id></code>
Default	---
Description	Specifies the quote to be deleted.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	<code>--quiet</code>
Default	---
Description	Suppresses headers and success messages.

Synopsis

```
grmrate -n <charge_rate_name> [-x <charge_rate_value>] [--debug]
[--site <site_name>] [--help] [--man] [--quiet] [--verbose] [-
version]
```

Overview

`grmrate` deletes a charge rate.

Options

-n	
Format	-n <charge_rate_name>
Default	---
Description	Specifies the charge rate to delete.

-x	
Format	-x <charge_rate_value>
Default	---
Description	Specifies the charge rate value to delete. If you do not specify a value, MAM will only delete a charge rate with an empty value.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

grmrole

Synopsis

```
grmrole [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] { [-r] <role_name> }
```

Overview

grmrole deletes a role.

Options

-r	
Format	[-r] <role_name>
Default	---
Description	Specifies the role to delete.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

grmusage

Synopsis

```
grmusage [--debug] [--site <site_name>] [--help] [--man] [--quiet] [--verbose] [--version] {[-j] <usage_record_id>|-J <instance_name>}
```

Overview

grmusage deletes a usage record.

Options

-j	
Format	[-j] <usage_record_id>
Default	---
Description	Specifies the ID of the usage record to delete. Instance names can be non-unique, because resource managers often recycle job IDs). This option enables specifying a unique usage record using the unique identifier.

-J	
Format	-J <instance_name>
Default	---
Description	Specifies the instance name to delete. Since instance names are assigned by externally and may be non-unique (such as job IDs assigned by a resource manager), all usage records with the specified instance name will be deleted.

--debug	
Format	--debug

--debug	
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

grmuser

Synopsis

```
grmuser [--debug] [--site <site_name>] [--help] [--man] [--quiet]
[--verbose] [--version] [-u] <user_name>
```

Overview

grmuser deletes a user.

Options

-u	
Format	[-u] <user_name>
Default	---
Description	Specifies the name of the user to delete.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Display modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gstatement

Synopsis

```
gstatement [[-f] <fund_id>] [-n <fund_name>] [-u <user_name>] [-g <group_name>] [-a <account_name>] [-o <organization_name>] [-c <class_name>] [-m <machine_name>] [--filter <filter_name>=<filter_value>]... [--filter-type <filter_type>] [-s <start_time>] [-e <end_time>] [--summarize] [-h, --hours] [--debug] [--site <site_name>] [--help] [--man] [--version]
```

Overview

`gstatement` displays a fund statement. For a specified time frame it displays the beginning and ending balances as well as the total credits and debits to the fund over that period. This is followed by an itemized report of the debits and credits. You can use filters to select the funds you would like to review.

Options

-a	
Format	-a <account_name>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this account. Note that the statement may include information from other accounts if multiple accounts share the included funds.
-c	
Format	-c <class_name>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this class. Note that the statement may include information from other classes if multiple classes share the included funds.
-e	
Format	-e <end_time>
Default	Now
Description	Specifies the end of the reporting period in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now.
-f	
Format	[-f] <fund_id>
Default	Infinity
Description	Specifies that MAM should make the fund statement for the specified fund.

-g	
Format	<code>-g <group_name></code>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this group. Note that the statement may include information from other groups if multiple groups share the included funds.

-h	
Format	<code>-h</code> or <code>--hours</code>
Default	---
Description	Specifies that MAM should display time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), the currency is divided by 3600 to display resource-hours.

-m	
Format	<code>-m <machine_name></code>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this machine. Note that the statement may include information from other machines if multiple machines share the included funds.

-n	
Format	<code>[-n] <fund_name></code>
Default	---
Description	Specifies that MAM will display the fund statement for funds with the given name.

-o	
Format	-o <organization_name>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this organization. Note that the statement may include information from other organizations if multiple organizations share the included funds.

-s	
Format	-s <start_time>
Default	-Infinity
Description	Specifies the beginning of the reporting period in the format YYYY-MM-DD[hh:mm:ss] -Infinity Infinity Now.

-u	
Format	-u <user_name>
Default	---
Description	Specifies that the statement will represent a combination of information for all the funds available for this user. Note that the statement may include information from other users if multiple machines share the included users.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Restricts the fund to one where constraints do not conflict with the specified filters. For example, <code>gstatement --filter User=amy</code> will restrict the fund to one usable by the user amy. You may specify multiple filter options that are logically ANDed together.

--filter-type	
Format	<code>--filter-type <filter_type></code>
Default	NonExclusive
Description	Specifies the filtering type. If you use the <code>Exclusive</code> filter type, MAM will only match a fund if the specified filters meet all constraints. If you use the <code>NonExclusive</code> filter type, MAM will match a fund as long as the specified filters do not conflict with the constraints.

--help	
Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man	
Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet	
Format	<code>--quiet</code>

--quiet	
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--summarize	
Format	--summarize
Default	---
Description	Displays transaction summaries only. Deposits, Refunds, Charges, and other properties will be shown as total as opposed to being itemized.

--version	
Format	--version
Default	---
Description	Displays the product version.

gtransfer

Synopsis

gtransfer {[--from-fund](#) <source_fund_id> &| [--from-allocation](#) <source_allocation_id> &| [--from-filter](#) <filter_name>=<filter_value>...} {[--to-fund](#) <destination_fund> &| [--to-allocation](#) <destination_allocation_id> &| [--to-filter](#) <filter_name>=<filter_value>...} [[--filter-type](#) <filter_type>] [[-d](#) <description>] [[-h](#), [--hours](#)] [[--debug](#)] [[--site](#) <site_name>] [[-help](#)] [[--man](#)] [[--quiet](#)] [[--verbose](#)] [[--version](#)] {[\[-z\]](#) <amount>}

Overview

gtransfer issues a transfer between funds.

Options

-d	
Format	-d <description>
Default	---
Description	Specifies the reason for the transfer. The annotation applies to the transaction description (seen via glstrans), not the allocation description.
-h	
Format	-h or --hours
Default	---
Description	Treats currency as specified in hours. In systems where the currency is measured in resource-seconds (like processor-seconds), this option allows the amount to be specified in resource-hours.
-z	
Format	[-z] <amount>
Default	---

-z	
Description	Specifies the amount to transfer.

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--filter-type	
Format	--filter-type <filter_type>
Default	NonExclusive
Description	Specifies the filtering type. If you use the <code>Exclusive</code> filter type, MAM will only match a fund if the specified filters meet all constraints. If you use the <code>NonExclusive</code> filter type, MAM will match a fund as long as the specified filters do not conflict with the constraints.

--from-allocation	
Format	--from-allocation <source_allocation_id>
Default	---
Description	Transfers credits from the specified allocation ID only. If you omit the allocation, only credits from active allocations will transfer in the order of earliest expiring first.

--from-filter	
Format	--from-fund <filter_name=<filter_value>
Default	---

--from-filter

Description	If you specify one or more source filters and there is exactly one matching fund, MAM makes the transfer from that fund. Otherwise, it displays a list of funds for the specified filters and you will be prompted to respecify the transfer against one of the enumerated funds. You can specify multiple <code>--from-filter</code> options by logically ANDing them together.
--------------------	--

--from-fund

Format	<code>--from-fund <source_fund_id></code>
Default	---
Description	Specifies the fund to be debited.

--help

Format	<code>--help</code>
Default	---
Description	Displays a brief help message.

--man

Format	<code>--man</code>
Default	---
Description	Displays full documentation.

--quiet

Format	<code>--quiet</code>
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--to-allocation	
Format	--to-allocation <destination_allocation_id>
Default	---
Description	Transfers credits to the specified allocation ID only. If you omit the allocation, MAM transfers the credits to the allocation having the same start and end time as the source allocation the funds are taken from, or, if such an allocation is non-existent, MAM will create a new allocation in the target fund having the same start and end time.

--to-filter	
Format	--to-filter <filter_name>--<filter_value>
Default	---
Description	If you specify one or more destination filters and there is exactly one matching fund, a transfer will be made to that fund. Otherwise, MAM displays a list of funds for the specified filters and you will be prompted to respecify the transfer against one of the enumerated funds. You may specify multiple --to-filter options by logically ANDing them together.

--to-fund	
Format	--to-fund <destination_fund_id>
Default	---
Description	Specifies the fund to be credited.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

gwithdraw

Synopsis

```
gwithdraw [-f <fund_id>] [-i <allocation_id>] [-u <user_name>]
[-g <group_name>] [-a <account_name>] [-o <organization_name>]
[-c <class_name>] [-m <machine_name>] [--filter <filter_
name>=<filter_value>]... [--filter-type <filter_type>] [-d
<description>] [-h, --hours] [--debug] [--site <site_name>] [-
-help] [--man] [--quiet] [--verbose] [--version] {[-z]
<amount>}
```

Overview

gwithdraw makes a withdrawal from the specified fund.

Options

-a

Format	<code>-a <account_name></code>
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified account.

-c

Format	<code>-c <class_name></code>
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified class.

-d

Format	<code>-d <description></code>
Default	---
Description	Specifies the reason for the withdrawal. The annotation applies to the transaction description (seen via glstrans), not the allocation description.

-f

Format	<code>-f <fund_id></code>
Default	---
Description	Specifies the ID of the fund from which MAM will make the withdrawal.

-g

Format	<code>-g <group_name></code>
---------------	------------------------------------

-g	
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified group.

-h	
Format	-h or --hours
Default	---
Description	Specifies that MAM should display time-based credits in hours. In cases where the currency is measured in resource-seconds (like processor-seconds), this option allows the amount to be specified in resource-hours.

-i	
Format	-i <allocation_id>
Default	---
Description	Withdraws credits from the specified allocation ID only. If you omit the allocation, MAM only withdraws credits from active allocations in the order of earliest expiring first.

-m	
Format	-m <machine_name>
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified machine

-o	
Format	-o <organization_name>
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified organization.

-u	
Format	<code>-u <user_name></code>
Default	---
Description	Specifies that the fund for the withdrawal should be usable by the specified user.

-z	
Format	<code>[-z] <amount></code>
Default	---
Description	Specifies the amount to withdraw. You may also specify the amount as the sole argument.

--debug	
Format	<code>--debug</code>
Default	---
Description	Logs debug information to the screen.

--filter	
Format	<code>--filter <filter_name>=<filter_value></code>
Default	---
Description	Restricts the fund to one where constraints do not conflict with the specified filters. For example, <code>gwithdraw --filter User=amy</code> will restrict the fund to one usable by the user <code>amy</code> . You may specify multiple filter options that are logically ANDed together.

--filter-type	
Format	<code>--filter-type <filter_type></code>

--filter-type	
Default	NonExclusive
Description	Specifies the filtering type. If you use the Exclusive filter type, MAM will only match a fund if the specified filters meet all constraints. If you use the NonExclusive filter type, MAM will match a fund as long as the specified filters do not conflict with the constraints.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

goldsh

Synopsis

```
goldsh [--debug] [--site <site_name>] [--help] [--man] [--
format <output_type>] [--quiet] [--verbose] [--version]
[<command>]
```

Overview

goldsh is an interactive control program that can access all functionality available in Gold. You can invoke commands directly from the command line, or an interpreter can parse commands from stdin.

Commands follow the form:

```
<Object>[,<Object>...] <Action> [<Predicate>]...
```

<Predicate> follows the form:

```
[<Conjunction>] [<OpenParentheses>] [<Object>.]<Name Operator>
[<Subject>.]<Value> [<CloseParentheses>]
```

Where

- *<Conjunction>* defaults to "And" and includes:
 - && – and
 - || – or
 - &! – and not
 - |! – or not
- *<OpenParentheses>* can be any number of literal open parentheses '('.
- *<Name>* is the name of the condition, assignment or option.
- *<Operator>* is one of:
 - == – equals
 - < – less than
 - > – greater than
 - <= – less than or equal to
 - >= – greater than or equal to
 - != – not equal to
 - ~ – matches
 - !~ – does not match
 - = – assignment
 - += – increment
 - -= – decrement
 - := – option
 - :! – negated option
- *<Value>* is the value of the condition, assignment, or option and may be enclosed in double quotes to enclose spaces or special characters.
- *<CloseParentheses>* can be any number of literal close parentheses ')'.

You can specify the desired selections (columns to be displayed) in a query via a pseudo Show option with a value of comma-separated attribute names. It can optionally include an object, operator and alias. It will follow the form:

```
Show:="[operator()][object.]name[=alias]()[],[operator()][object.]name[=alias]()[)]..."
```

See [Using the Gold Shell \(goldsh\) on page 2925](#) for more information on constructing requests.

Options

--debug	
Format	--debug
Default	---
Description	Logs debug information to the screen.

--format	
Format	--format <standard csv>
Default	standard
Description	Specifies the data output format. Valid values include standard and csv.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--quiet	
Format	--quiet
Default	---

--quiet	
Description	Suppresses headers and success messages.

--site	
Format	--site <site_name>
Default	---
Description	Obtains a response from specified site.

--verbose	
Format	--verbose
Default	---
Description	Displays modified object details.

--version	
Format	--version
Default	---
Description	Displays the product version.

goldd

Synopsis

```
goldd [-k, --stop] [-r, --restart] [-s, --start] [-l, --status]
[--help] [--man] [-d, --debug [<debug_level>]] [--version]
```

Overview

`goldd` is a forking server that listens for and services Moab Accounting Manager client requests. It handles the startup and daemonization, shutdown and restart of the application.

Options

`-k, --stop`

Format	<code>-k</code> or <code>--stop</code>
Default	---
Description	Shuts down the server.

`-l, --status`

Format	<code>-l</code> or <code>--status</code>
Default	---
Description	Displays the status of the server, indicating whether it is running or has stopped.

`-r, --restart`

Format	<code>-r</code> or <code>--restart</code>
Default	---
Description	Restarts the server.

`-s, --start`

Format	<code>-s</code> or <code>--start</code>
Default	---
Description	Starts the server. This option is assumed in the absence of a stop or restart flag and may be omitted in a start request.

-d, --debug	
Format	-d or --debug [<debug_level>]
Default	DEBUG
Description	Logs debug information to the screen. You can supply an optional debug level parameter to indicate the logging threshold. It can be one of TRACE, DEBUG, INFO, WARN, ERROR and FATAL.

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

--version	
Format	--version
Default	---
Description	Displays the product version.

mybalance

Synopsis

mybalance [-h, --hours] [--help] [--man]

Overview

mybalance displays balance information for the invoking user.

Options

-h, --hours	
Format	-h or --hours
Default	---
Description	Displays balance in processor-hours (instead of processor-seconds).

--help	
Format	--help
Default	---
Description	Displays a brief help message.

--man	
Format	--man
Default	---
Description	Displays full documentation.

About Viewpoint

Viewpoint is a web application that, interacting with Moab Workload Manager, allows users to manage jobs and resources without the complexities of maintaining Moab via the command line. Viewpoint uses a customizable portal which enables users to view and configure jobs and to compute node resources, principals, and roles. Viewpoint permissions allow administrators to specify which pages, tools, and settings certain users or groups are permitted to use, manage, and view.

About Viewpoint

Viewpoint is a web application that, interacting with Moab Workload Manager, allows users to manage jobs and resources without the complexities of maintaining Moab via the command line. Viewpoint uses a customizable portal which enables users to view and configure jobs and to compute node resources, principals, and roles. Viewpoint permissions allow administrators to specify which pages, tools, and settings certain users or groups are permitted to use, manage, and view.

Configuration

About Configuration

You can configure Viewpoint entirely within the user interface using the Configuration page. Only users with the Configuration page permission can access the Configuration page.

There are many parts of the Viewpoint configuration that you only need to perform one time during the initial Viewpoint setup. However, these configuration options are available for modification if the need arises.

On the Configuration page, you can select from three different configuration pages.

- **[MWS Configuration Page on page 3222](#)** (default display)
- **[Role Management Page on page 3227](#)**
- **[Principal Management Page on page 3240](#)**

Associated Tasks

The following topics offer details on how to configure the Viewpoint connection to Moab Web Services, and how to set up roles and principals. There is also detailed information about the fields you will use when completing configuration tasks.

- [Setting Up the Connection to MWS on page 3221](#)
- [MWS Configuration Page on page 3222](#)
- [Configuring Viewpoint to Use SSL on page 3225](#)
- [Creating or Editing a Role on page 3229](#)
- [Creating or Editing a Principal on page 3241](#)
- [OAuth Configuration Using mws-config.groovy on page 1582](#)
- [PAM \(Pluggable Authentication Module\) Configuration Using mws-config.groovy on page 1581](#)
- [LDAP Configuration Using mws-config.groovy on page 1576](#)

Setting Up the Connection to MWS

You can set your Viewpoint connection to Moab Web Services on the MWS Configuration page. You will do this once when you first install or upgrade Viewpoint and any time you need to make a change to your MWS-Viewpoint connection.

First-Time Login Requirements

The MWS configuration is crucial to the functionality of Viewpoint. The first time you launch Viewpoint, you will have to log in as the moab-admin user and configure a connection to Moab Web Services. The default password is *changeme!* for the moab-admin user. Once you log in, you need to set up the connection with MWS. No other Viewpoint pages will function properly until the connection with MWS is successfully made.

Required Before Configuring Viewpoint to Connect to MWS

i You must configure OAuth in MWS. See [OAuth Configuration Using mws-config.groovy on page 1582](#) for details.

To Set Up Your MWS Configuration

1. As an administrator with Viewpoint configuration privileges, log in to Viewpoint. The MWS Configuration page should display as the default. If the

MWS Configuration page is not displayed, select **Configuration** from the navigation menu bar.

2. Complete the fields as necessary. See [MWS Configuration Page on page 3222](#) for more information.
3. To test whether the connection information is successful before saving your settings, click **Test**.

i If the server path is valid, a green tick mark is displayed next to the Server field.

4. To save your MWS configuration settings, click **Save**.

i Any time you make changes to the MWS configuration, you will need to sign out of Viewpoint and then log back in.

Related Topics

[Configuring Viewpoint to Use SSL on page 3225](#)

[Configuring Moab Web Services on page 1570](#)

MWS Configuration Page

Path: Configuration > MWS Configuration

The MWS Configuration page lets you set up a connection to Moab Web Services.

The screenshot shows the Moab Viewpoint MWS Configuration page. The header includes the Moab Viewpoint logo and user information: "Welcome, moab-admin", "Sign Out", and settings icons. The navigation bar has tabs for HOME, WORKLOAD, NODES, and CONFIGURATION. The left sidebar lists MWS Configuration, Roles, and Principals. The main content area is titled "MWS Configuration" and contains the following fields and options:

- Server:
- Username:
- Password:
- Path:
- Client Id:
- Client Secret:
- ☐ Use Google Analytics to help improve this product
- ☐ Reset Permissions
- SAVE button
- TEST button

i The MWS configuration is crucial to the functionality of Viewpoint. The first time you launch Viewpoint, the system automatically directs to the MWS Configuration page to set up your MWS connection. No other Viewpoint pages are available to you until you make a successful connection. Likewise, if there are external changes to your MWS instance and the MWS-Viewpoint connection is broken, the next time you log in to Viewpoint, the system again directs you to the MWS Configuration page to make updates and re-establish the MWS connection.

Fields

The following fields are available to help you set up the connection to MWS.

Field	Description
Server	Full URL of the server hosting Moab Web Services (for example, "http://server:8080"). If your MWS web server is configured to use HTTPS, you must specify "https" in the URL. See the Setting up MWS Security on page 1585 section of the Moab Web Services Reference Guide for more information.
Username	Name of the administrative account that communicates with Moab Web Services (for example, "moab-admin").
Password	Password being used to communicate with Moab Web Services.
Path	Path prefix of the Moab Web Services URL. This will almost always be "/mws/".
Client ID	MWS configured OAuth client ID. Values are in the <code>mws-config.groovy</code> file (default location: <code>/opt/mws/etc/mws-config.groovy</code>). See the OAuth Configuration Using mws-config.groovy on page 1582 section in the Moab Web Services Reference Guide for more information.
Client Secret	MWS configured OAuth client secret. See the OAuth Configuration Using mws-config.groovy on page 1582 section in the Moab Web Services Reference Guide for more information.
Use Google Analytics to help improve this product	Indicates whether you want to track usage through Google Analytics.
Reset Permissions	Indicates whether you want to reset roles and permissions back to default settings. Resetting permissions is required the first time you connect Viewpoint to MWS to create the page permissions. Without resetting, a non moab-admin user does not have permission to see any pages. Resetting permissions also grants the HPCAdmin and HPCUser roles the appropriate permissions.

Field	Description
Save	Saves the changes to the MWS Configuration settings.
Test	Tests the connection to Moab Web Services before saving.

Sample Configuration

For this configuration, let's say MWS was set up as:

```
grails.plugin.springsecurity.oauthProvider.clients = [
  [
    clientId:"MY_CLIENT_ID",
    clientSecret:"MY_CLIENT_SECRET",
    authorizedGrantTypes:["password"]
  ]
]
```

An example configuration would then be:

[Configuring Moab Web Services on page 1570](#)

[Setting up MWS Security on page 1585](#)

[Configuring Viewpoint to Use SSL on page 3225](#)

Configuring Viewpoint to Use SSL

This topic explains how to enable SSL for Viewpoint. It contains the following sections:

- [Creating a Self-Signed Certificate on page 3225](#)
- [Enabling SSL for Viewpoint on page 3226](#)
- [Connecting Viewpoint To MWS over HTTPS on page 3227](#)

Creating a Self-Signed Certificate

To Create a Self-Signed Certificate

1. Generate a private key.

```
[root]# openssl genrsa -out server.key 1024
```

i This will create the private key unencrypted. It is important to keep it private and have only root privileges.

If you want to add a passphrase to the private key you can do the following:

```
[root]# openssl genrsa -des3 -out server.key 1024
```

2. Generate certificate signing request from the private key (what is used to create a self-signed certificate).

```
[root]# openssl req -new -key server.key -out server.csr
```

i It will prompt for passphrase if private key has it.

You will be prompted for the certificate metadata.

```
...
Country Name (2 letter code) [XX]:US
State or Province Name (full name) []:Utah
Locality Name (eg, city) [Default City]:Provo
Organization Name (eg, company) [Default Company Ltd]:Adaptive Computing
Enterprises, Inc.
Organizational Unit Name (eg, section) []:Engineering
Common Name (eg, your name or your server's hostname)
[]:test1.adaptivecomputing.com
...
```

3. Generate the self-signed certificate from the CSR.

```
[root]# openssl x509 -req -in server.csr -signkey server.key -out server.crt
```

i You should have both a private key (server.key) and a certificate (server.crt)

Enabling SSL for Viewpoint

To Enable SSL for Viewpoint

1. Install the Apache SSL Module.
Example for CentOS 6:

```
[root]# yum install mod_ssl
```

2. Install the key and certificate.

```
[root]# chmod 400 server.key server.crt
[root]# chown root:root server.key server.crt
[root]# cp -p server.key server.crt /etc/httpd
```

3. Edit /etc/httpd/conf.d/viewpoint.conf so it looks like this:

```
Listen 443
LoadModule ssl_module modules/mod_ssl.so

<VirtualHost *:443>

    SSLEngine On
    SSLCertificateKeyFile /etc/httpd/server.key
    SSLCertificateFile /etc/httpd/server.crt

    WSGIScriptAlias / /opt/iris/iris/wsgi.py
    DocumentRoot "/opt/iris/"

    Alias /static/ /opt/iris/static/
    Alias /logs/ /opt/iris/logs/

    <Directory /opt/iris/static/>
        Order deny,allow
        Allow from all
    </Directory>

    <Directory /opt/iris/logs/>
        Order deny,allow
        Allow from all
    </Directory>

</VirtualHost>
```

i Viewpoint needs its own VirtualHost on its own port. Therefore, if Apache is serving pages or applications besides Viewpoint over SSL, choose a port for Viewpoint besides 443.

4. Start or restart Apache.

Example for CentOS 6:

```
[root]# service httpd restart
```

Connecting Viewpoint To MWS over HTTPS

This section shows how to connect Viewpoint to MWS over HTTPS (Hypertext Transfer Protocol Secure).

1. Configure the MWS Server for HTTPS. See [Securing Client Connections to MWS on page 1587](#).
2. Import the MWS Server Certificate. If the MWS server is using a certificate signed by a certificate authority, skip this step. Otherwise, import the MWS server certificate by running the following command on the Viewpoint server. In this example, the MWS host name and secure port number are mws.example.com and 8443, respectively.

```
[root]# openssl s_client -showcerts -connect mws.example.com:8443 < /dev/null 2>
/dev/null |
    sed -n -e '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' \
    >> $(python -m requests.certs)
```

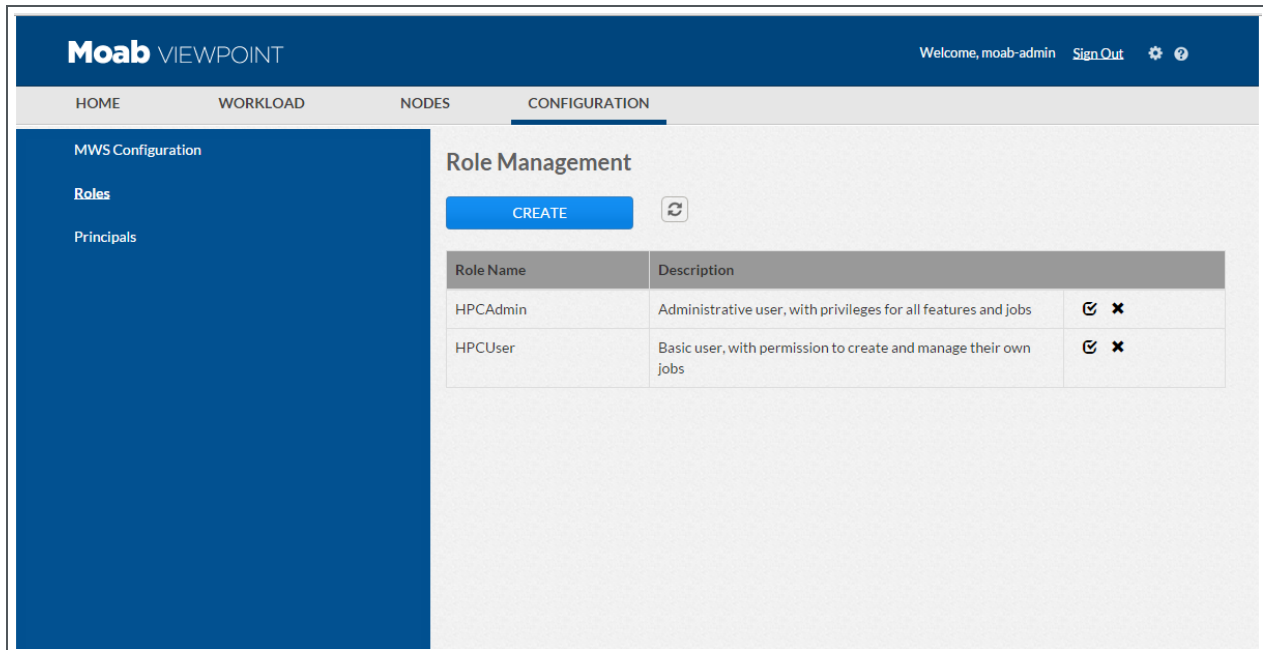

3. Configure Viewpoint.
 - a. On the MWS Configuration page of Viewpoint, specify the secure URL for MWS. For example: https://mws.example.com:8443
 - b. Fill out the rest of the MWS Configuration page as usual; note that:
 - The host name must match the Common Name (CN) of the MWS server certificate.
 - The Viewpoint server must be able to resolve the host name using /etc/hosts or DNS.

Roles

Role Management Page

Path: Configuration > Roles

The Role Management page allows administrators to create, edit, or remove user roles.

A role in Viewpoint is simply a collection of permissions. Once permissions are assigned, a role is assigned to users or user groups in a principal. This means that each user in the principal will be bound by the role permissions. See [Principal Management Page on page 3240](#) for more information.

Viewpoint is delivered with these default roles:

- **HPCAdmin** - This role is a global role that enables all possible permissions.

i It is recommended that users with the HPCAdmin role be granted ADMIN[1] permission in the Moab configuration file (`moab.cfg`). Otherwise Moab Workload Manager may reject the user's attempt to perform certain operations even though the user has the appropriate MWS domain permissions. See [ADMINCFG\[X\] on page 1071](#) for more information.

- **HPCUser** - This role is a global role that enables permissions for users to create and manage jobs.

See [Permissions on page 3230](#) for a full list of the permissions contained in each role.

You can edit, create, or delete any of the delivered default roles. However, if you ever want to revert to the default roles, reset the roles from the MWS Configuration page by selecting the **Reset Permissions** box. See [Resetting Default Roles and Permissions on page 3239](#) for more information.

Role Tasks:

- [Creating or Editing a Role](#) on page 3229
- [Deleting a Role](#) on page 3230

Creating or Editing a Role

1. On the Role Management page, click **Create** to add a new role or click the edit icon (✎) next to the role you want to edit. The Roles page displays.

Permissions

Path: Configuration > Roles > click **Create**, when adding a new role; or click the edit icon () , when modifying an existing role.

This topic lists all the permissions you can set when you configure roles in Viewpoint. See [Role Management Page on page 3227](#) for more information.

Permissions are stored in Moab Web Services. Any new permission you want to add to Viewpoint you must add through Moab Web Services. See [Permissions on page 1802](#) (resource section of the *Moab Web Services Reference Guide*) for more information.

Permissions are grouped in these categories:

- [Domain Permissions](#) on page 3231
- [Viewpoint Permissions](#) on page 3238

Each table lists the permission name and describes what the permission does. By default, domain permissions are added to the delivered HPCAdmin role.

At any time, you can reset the default permissions to the delivered roles on the Configuration page. See [Resetting Default Roles and Permissions](#) on page 3239 for more information.

Domain Permissions

The Domain Permissions are explained in the following tables.

- [Accounting/accounts](#) on page 3232
- [Credentials](#) on page 3233
- [Diag](#) on page 3233
- [Events](#) on page 3233
- [Insight](#) on page 3233

Name	Description	Action	Resource	Scope
create-principals	Permission to create principals.	create	principals	global
delete-principals	Permission to delete principals.	delete	principals	global
read-principals	Permission to read principals.	read	principals	global
update-principals	Permission to update principals.	update	principals	global

Table 26-16: Priority

Name	Description	Action	Resource	Scope
read-priority	Permission to read the priority of a job.	read	priority	global
update-priority	Permission to update the priority of a job.	update	priority	global

Table 26-17: Reports

Name	Description	Action	Resource	Scope
create-reports	Permission to create reports.	create	reports	global
delete-reports	Permission to delete reports.	delete	reports	global
read-reports	Permission to read reports.	read	reports	global
update-reports	Permission to update reports.	update	reports	global
read-report-datapoints	Permission to read datapoints.	read	reports/datapoints	global

Table 26-18: Reservations

Name	Description	Action	Resource	Scope
create-reservations-all	Permission to create all reservations.	create	reservations	global
delete-reservations-all	Permission to delete all reservations.	delete	reservations	global

Name	Description	Action	Resource	Scope
read-reservations-all	Permission to read all reservations.	read	reservations	global
update-reservations-all	Permission to update all reservations.	update	reservations	global

Table 26-19: Resource-types

Name	Description	Action	Resource	Scope
read-resource-types	Permission to read resource types.	read	resource-types	global

Table 26-20: Roles

Name	Description	Action	Resource	Scope
create-roles	Permission to create roles.	create	roles	global
delete-roles	Permission to delete roles.	delete	roles	global
read-roles	Permission to read roles.	read	roles	global
update-roles	Permission to update roles.	update	roles	global

Table 26-21: Standing-reservations

Name	Description	Action	Resource	Scope
read-standing-reservations	Permission to read standing reservations.	read	standing-reservations	global

Table 26-22: Tenants

Name	Description	Action	Resource	Scope
create-tenants	Permission to create tenants.	create	tenants	global
read-tenants	Permission to read tenants.	read	tenants	global
update-tenants	Permission to update tenants.	update	tenants	global

Name	Description	Action	Resource	Scope
delete-tenants	Permission to delete tenants.	delete	tenants	global

Table 26-23: VCs

Name	Description	Action	Resource	Scope
create-vcs	Permission to create virtual containers.	create	vcs	global
delete-vcs	Permission to delete virtual containers.	delete	vcs	global
read-vcs	Permission to read virtual containers.	read	vcs	global
update-vcs	Permission to update virtual containers.	update	vcs	global

Viewpoint Permissions

When you reset roles and permissions, Viewpoint creates the following permissions in Moab Web Services:

Name	Description	Action	Resource	Scope
Configuration	Permission to view and make changes to the configuration.	read	--	None
Principal and Roles	Permission to view, create, edit and delete roles and principals.	read	--	None
Workload	Permission to see all jobs as admin or individual jobs as user.	read	--	None
Job Details	Permission to see job details.	read	--	None
Job Edit-user	Permission to edit non-admin fields.	read	--	None
Job Edit-admin	Permission to edit admin fields.	read	--	None
Resources	Permission to see resources (read list of nodes).	read	--	None

Name	Description	Action	Resource	Scope
Resource Edit	Permission to update node features and power on/off a node.	read	--	None
Reservation	Permission to create, view, and delete reservations.	read	--	None
Credential Pages	Permission to see credential information.	read	--	None
Policy Pages	Permission to see policy information.	read	--	None
Job View All	Permission to see all jobs. <div>  Even a non-admin user with this permission will be able to see all the jobs. </div>	read	--	None

[Resetting Default Roles and Permissions on page 3239](#)

Resetting Default Roles and Permissions

Viewpoint offers the ability to reset the default HPCAdmin and HPCUser roles with permissions back to their original default settings, which creates the Viewpoint page permissions and adds them to the correct roles. Without page permissions, a non-backdoor moab-admin user cannot access any Viewpoint pages.

Viewpoint must have a valid MWS connection configured in order for reset of permissions to work. See [Setting Up the Connection to MWS on page 3221](#) for additional information.

To Reset Default Roles and Permissions

1. On the MWS Configuration page, select the **Reset Permissions** check box.
2. Click **Save**.

Any changes made to default roles and permissions will be overwritten.

i Default roles and permissions are not set up on initial log in. The Reset Permissions box must be selected the first time. See [Setting Up the Connection to MWS on page 3221](#) for additional information.

Principals

Principal Management Page

Path: Configuration > Principals

The Principal Management page allows administrators to specify LDAP/PAM users, groups, or **OUs**¹ and it allows administrators to assign users, groups, or OUs a user role (or roles). Any LDAP/PAM entity (user, group, or OU) with an assigned role (or roles) is called a principal.

The screenshot displays the Moab Viewpoint web interface. The top navigation bar includes the Moab Viewpoint logo, user information 'Welcome, moab-admin', and links for 'Sign Out', settings, and help. Below this is a secondary navigation bar with tabs for 'HOME', 'WORKLOAD', 'NODES', and 'CONFIGURATION'. The 'CONFIGURATION' tab is active, and a left sidebar shows 'MWS Configuration', 'Roles', and 'Principals'. The 'Principals' section is selected, leading to the 'Principal Management' page. This page features a 'CREATE' button, a refresh icon, and a table listing existing principals.

Principal Name	Description	
PrincipalForHPCUser	This principal created for HPC user	

¹organizational unit for LDAP

i PAM or LDAP must be configured in MWS. See [PAM \(Pluggable Authentication Module\) Configuration Using mws-config.groovy](#) on page 1581 and [LDAP Configuration Using mws-config.groovy](#) on page 1576 for details.

Principal Management Tasks:

- [Creating or Editing a Principal](#) on page 3241
- [Deleting a Principal](#) on page 3242

Creating or Editing a Principal

1. On the Principal Management page, click **Create** to add a principal or click the edit icon (✎) next to the principal you want to edit. The Principals page displays.

Moab VIEWPOINT Welcome, moab-admin [Sign Out](#) ⚙️ ⓘ

HOME WORKLOAD NODES **CONFIGURATION**

MWS Configuration

Roles

Principals

Principals

A principal's resources and access is based on the role(s) they are granted. Each role has a list of permissions that can be configured in the Roles tab.

Name: Description:

Roles

HPCAdmin	<input type="checkbox"/>
HPCUser	<input type="checkbox"/>

Principal Entity Type +

2. Complete the fields as necessary.

Field	Description
Name	Lets you specify the name of the principal.
Description	(Optional) Lets you specify a text description of the principal.

Field	Description
Roles	Lets you specify the role(s) of the principal. This is a list of suggest roles from those you have already created (Configuration > Roles).

3. Add or remove LDAP or PAM entities to the principal.

- Click the Add icon () to add.
- Click the Delete icon () to remove.

4. Complete the fields as necessary.

Field	Description
Principal Entity	Lets you specify the name of the LDAP or PAM entity. For a User type, this is simply the name (for example, "jdoe"). If the type is LDAP Group or OU, you must provide the entire distinguished name. PAM group names represent the UNIX group on the underlying server.
Type	Lets you specify the type of LDAP or PAM entity you are adding. This can be a user, OU , or group. Possible values are LDAP, LDAPGROUP, LDAPOU, PAM, and PAMGROUP.

5. Click **Done**.

Deleting a Principal

On the Principal Management page, click the Delete icon () next to the principal you want to remove.

Viewpoint Basics

Logging In/Signing Out

Context

Regardless of the configured security type, you must log in to Viewpoint to use it. For security purposes, it is important to log out of Viewpoint after each use.

To Log In to Viewpoint

1. In a web browser, navigate to Viewpoint.

You are automatically taken to the login page.

2. Enter your **Username** and **Password** into the respective fields.

- **Username** - Enter the username for a valid LDAP or PAM user or for the backdoor moab-admin user. If using an LDAP or PAM user, this user should have been attached to a principal that has permission to view Viewpoint pages. To see how to attach an LDAP or PAM user to a principal, see [Principal Management Page on page 3240](#).
- **Password** - The password for the username entered in the username field. Note that the default password for the backdoor moab-admin user is *changeme!*.

3. Click **Login** to log in.

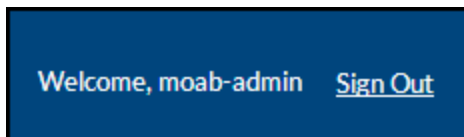

You will be redirected to the Viewpoint homepage.

Troubleshooting

A user's ability to see a particular page is dependent on which permissions are granted to that user according to Moab Web Services. To find out specifically which permissions a user has, see [Get a User's Permissions on page 1804](#).

To Sign Out of Viewpoint

1. From any Viewpoint page, locate the Sign Out link in the top right corner of the page.

2. Click the **Sign Out** link to sign out.

You will be redirected to the login page.

Navigating Viewpoint

The navigation menu bar in Viewpoint lets you easily get to the page you want to see. This navigation menu bar is fixed at the top of every page in Viewpoint so that you can easily navigate to where you want to go from anywhere. See [Menu Navigation on page 3243](#) for a list of default navigation links.

If the logged-in user does not have permissions to access a particular page, the navigation link will not appear in the menu. If a user tries to access a page (by entering a URL) that he/she does not have permissions to see, Viewpoint disallows access.

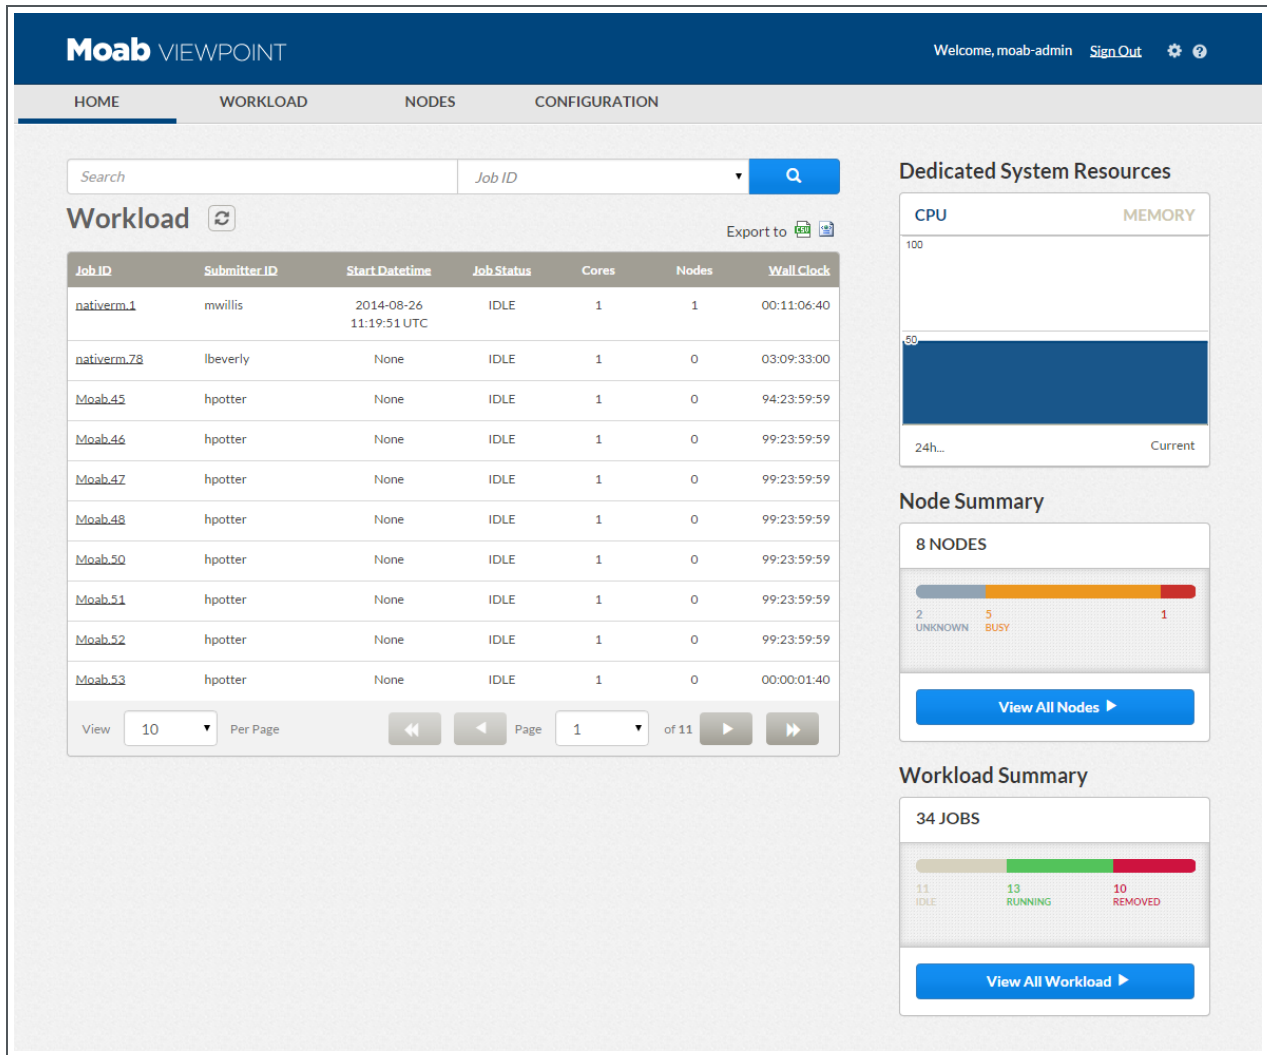

You can also use Homepage gadgets to navigate to certain pages in Viewpoint. See [Viewpoint Home Page on page 3244](#) for more information.

- [Workload Summary Gadget on page 3247](#)

Workload Gadget

Refresh

At any time you can click the refresh icon () to refresh the information displayed.

Search Options

To filter the content of the Workload job list, insert the Job ID you're looking for and click the magnifying glass to commence the search.

Export Options

There are two options for exporting a Workload job list: (1) via a Comma Separated Values (CSV) file and (2) via Extensible Markup Language (XML). Use either option to import data into a spreadsheet or a database application.

Workload Gadget Fields

Field	Description
Job ID	The ID given by the Moab Workload Manager (or resource manager). You can use the  icon to change the status of a job; the updated job status is displayed under the job status column.
Submitter ID (Name)	The user that created a job.
Start Datetime	The date and time when the job started.
Job Status	The current state of the job; COMPLETED, RUNNING, IDLE are examples.
Cores	The number of cores the job is running on.

Field	Description
Nodes	The number of compute nodes the job is running on (or ran on).
Wall Clock	The amount of time required for the job. This represents the maximum amount of time the job is expected to run and is specified when the job is submitted. Wall clock time does not represent the amount of time the job actually ran for, if the job finished. Wall clock time uses the following format: (Days:Hours:Minutes:Seconds). For example, 01:00:01:30 means the owner of the job requested the job run for one day one minute and thirty seconds.

Dedicated System Resources Gadget

The dedicated system resources graph shows the ratio of resources dedicated to jobs to total resources.

CPU

The percentage of processors dedicated to running jobs over the total processors in the cluster. For example if your cluster has 5,000 processors and 4,500 of those processors are dedicated to jobs, your CPU utilization is 90%.

Memory

The percentage of memory dedicated to running jobs over the total amount of memory in the cluster. For example, if your cluster has 1,000 GB of memory and 850 GB of memory is dedicated to jobs, then your memory utilization is 85%.

Node Summary Gadget

The node summary gadget shows the number of nodes in each state, such as nodes that are idle, down, or running.

Workload Summary Gadget

The workload summary gadget shows the number of jobs in each state, such as jobs that are idle, completed, or running.

Threshold Settings

Insight currently supports 50K weekly job submissions and 400 nodes. Job submission rates or cluster sizes beyond these numbers are not supported at this time.

This topic contains instructions on how to configure Insight and Viewpoint settings to adjust the amount of data displayed by Viewpoint.

- By default, Insight archives job data older than 7 days. This limitation helps to keep page load times short. If your environment is running significantly fewer than 50k jobs per week, and you would like to look at more than 7 days in the UI, you can configure Insight to wait longer to archive. See the Job Archiving section in [Tuning Insight](#).

i Use caution when changing the archive period. Once data is archived, it cannot be easily unarchived.

- The Resource Job Timeline View, by default, is set to show the last 24 hours and the next 4 hours when you first visit the page. Depending on how many jobs run in your cluster per day, and how many nodes you are viewing, that time window might contain too many objects for the browser to display.
 - You can change the default time window by editing PAST_HOURS and FUTURE_HOURS in /opt/iris/iris/settings.py.
 - You can change the default limit on the number of objects to display by editing RJTV_THRESHOLD in /opt/iris/config/config.json.

Workload

Workload Page

The Workload page is a list view of jobs in your cluster. This page helps you determine if your jobs are running correctly.

Searching and Filtering

Searching by Job ID or Submitter ID

The Workload page has filtering options to help you find what you need and to organize what you see. The search tool allows you to create your own filters.

To search, select the column you want to filter by from the drop-down box. In the Narrow Search field, enter text that should appear in the selected column for the desired job. For example, if you want to find all jobs submitted by user "tgates", select **Submitter ID** (from the drop-down box) and enter **tgates**. When you add multiple search criteria, only jobs that match all search criteria display.

Filtering by Job State

You can also filter out all jobs that are not in a particular state. To show only IDLE jobs, for example, simply select **IDLE** from the Select Job State drop-down box.

Filtering by Start Date

To show only jobs with a start date in a given range, select **Start Date** from the Select drop-down box on the bottom right side of the page. Two additional fields appear representing minimum and maximum start date. Enter data for the minimum and maximum, then click **Filter**. Only jobs with a start date between your minimum and maximum start dates display.

Filtering by Wall Clock

To show only jobs with requested wall clock duration in a given range, select **Wall Clock** from the Select drop-down box on the bottom right side of the page. Two additional panels appear allowing you to specify a minimum and maximum wall clock. Enter the minimum and maximum wall clock, then click **Filter**. Only jobs with wall clock in between your minimum and maximum display.

To remove the filter selection and display the default Workload page, click **Reset**.

You can update the information on the Workload page manually by clicking the refresh icon .

Columns

Job ID

The ID given to a job by Moab Workload Manager (or the resource manager) . For each ID displayed, you can also:

- Click on the ID to view details about the job. See [Job Details Page on page 3252](#) for more information.
- Use the  icon to change the status of a non-completed job (as displayed in the Job Status column). See [Changing the Job Status on page 3256](#) for more information.

Submitter ID (Name)

The user that submitted a job.

Start Datetime

The date and time when the job started.

Job Status

The current state of the job; COMPLETED, RUNNING, IDLE are examples.

Cores

The number of cores on which the job is running.

Node

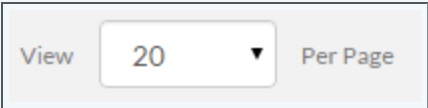

The number of compute nodes on which the job is running (or ran).

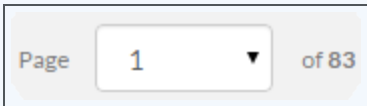

Wall Clock

The amount of time requested for the job. This represents the maximum amount of time the job is expected to run and is specified when the job is submitted. Wall clock time does not represent the amount of time the job actually ran for, if the job finished. Wall clock time uses the following format: (Days:Hours:Minutes:Seconds). For example, 01:02:03:04 means the owner of the job requested the job run for one day, two hours, three minutes, and four seconds. Jobs that exceed their wall clock limits are subject to the corrective action specified in the [WCVIOLATIONACTION on page 1224](#) parameter.

Page Controls

The Workload page allows you to customize how many jobs appear per page, and it allows you to select which page to display.

	Shows how many jobs you want displayed on the page. To change this, select the number of jobs that you want to appear on each page from the drop-down box.
	Displays the first page of jobs that match the current search.

	Displays the previous page of jobs that match the current search.
	Allows you to select which page of jobs you want to see. All jobs will match the current search.
	Displays the next page of jobs that match the current search.
	Displays the last page of jobs that match the current search.

Fields

Job Information

- **Job ID** - The ID given to the job by the resource manager.
- **Status** - The current state of the job, such as COMPLETED, RUNNING, or IDLE.

i The fields displayed on the Job Details page will vary based on the status of the job.

Time Frame

Field	Description
Start Time	The date and time that the job started.
Duration	The amount of time requested for the job in seconds. This represents the maximum amount of time the job is expected to run and is specified when the job is submitted. This does not represent the amount of time the job actually ran if the job is completed. Jobs that exceed their wallclock limits are subject to the corrective action specified in the WCVIOLATIONACTION on page 1224 parameter.
Completion Time	The date and time that the job completed.
Actual Duration	The amount of time the job has been running (or ran if the job is completed).

Credentials

Field	Description
User	The user that submitted a job.
Group	Displays the group credential, which represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
Account	Displays the account credential. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
Class	Displays the job class. The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
Quality of Service	Displays the quality of service assigned to the job.

Job Priority

Field	Description
Partition Access List	The partition access list of the job.
Start Count	The number of times the job has started.
User Job Priority	User priority allows the end user's priority to be a factor in the overall start priority calculation. See Job Priority Factors on page 459 for more details.
System Priority	Allows an administrator to override Moab Workload Manager's start priority to allow jobs to start sooner than they would ordinarily. See mjobctl on page 289 for more details.

Resource

Field	Description
Required Node List/Allocated Node List	<p>If the job is idle, the Required Node List field shows the compute nodes on which the job is required to run.</p> <p>If the job is already running or has completed, the Allocated Node List field shows the nodes that Moab assigned to the job.</p>
Allocated Partition	The partition where the job is running.

Requirements

Field	Description
Required Features	Features that are required to be found on the node(s) that the job runs on. See Node Attributes on page 684 for more details.
Processors per Task	The number of processors per task that the job requires. For the total number of processors required by the job, multiply this number by the Required Minimum Tasks.
Operating System	The operating system that the job requires.
Required Minimum Tasks	The minimum number of tasks the job requires. To determine the total number of processors the job requires, multiply this field by Processor per Task.

Controls

- **Return to earlier search** - Clicking this link on the top right of the page takes you to the Workload page, showing the earlier filtered and searched results.
- **Cancel** - Cancel any changes made to the resource and return to [Workload Page on page 3248](#).
- **Done** - Submit any changes made to the job to Moab Workload Manager and return to the Workload page.
- **Apply** - Submit any changes made to the resource to Moab Workload Manager and stay on the Job Details page.

Changing the Job Status

The existing jobs in Viewpoint are displayed under the Job ID column of the Home page and the Workload page. You can change the status of an existing job either from the Home page or the Workload page.

To Change the Job Status

1. On the Home page or the Workload page, hover your mouse over the Job ID and click the  icon. Depending on the current status of the job, the available statuses for the job appear in a pop-up menu. For example, hover your mouse over the Job ID with job status as IDLE, and click the  icon. The available job statuses Hold and Cancel are displayed.
2. Select the desired job status from the available status options. For this example, select **Hold**. The job status is updated and displayed under the Job Status column on the Home page and the Workload page.

Nodes

Nodes Page

You can view all the nodes reported to Moab by your resource manager on the Nodes page. The Nodes page offers a place to determine the status of your compute nodes, how many jobs are running on each node, what features are on each node, and other information.

The screenshot displays the Moab Viewpoint interface for the Nodes page. The top navigation bar includes 'HOME', 'WORKLOAD', 'NODES' (selected), and 'CONFIGURATION'. The right side of the header shows 'Welcome, moab-admin', a 'Sign Out' link, and settings/help icons.

The main content area is titled 'Nodes' with a refresh icon. It features a table of node information and a sidebar with search and filter options.

Node ID	Status	Class	Feature	Procs Available/Configured	Jobs	CPU Utilization	Memory Utilization
node-0...	BUSY	batch	InfiniBand	0/8	103	100	0
node-0...	BUSY	batch	InfiniBand	0/8	138	100	0
node-0...	BUSY	batch	InfiniBand	0/4	81	100	0
node-0...	BUSY	batch	InfiniBand	0/4	84	100	0
node-0...	BUSY	batch	InfiniBa...	0/4	59	100	0
node-0...	BUSY	batch	InfiniBa...	0/4	107	100	0
node-0...	BUSY	batch	InfiniBand	0/4	75	100	0
node-0...	BUSY	batch	InfiniBand	0/4	76	100	0
node-0...	BUSY	batch	InfiniBand	0/8	151	100	0
node-0...	RUNNING	batch	InfiniBand	2/4	98	50	0
node-0...	BUSY	batch	InfiniBand	0/4	66	100	0
node-0...	BUSY	batch	InfiniBa...	0/4	53	100	0
node-0...	BUSY	batch	InfiniBand	0/8	118	100	0
node-0...	BUSY	batch	InfiniBand	0/8	117	100	0
node-0...	BUSY	batch	InfiniBand	0/8	103	100	0
node-0...	BUSY	batch	InfiniBa...	0/8	94	100	0
node-0...	BUSY	batch	InfiniBand	0/4	85	100	0
node-0...	BUSY	batch	InfiniBand	0/8	130	100	0
node-0...	BUSY	batch	InfiniBand	0/4	76	100	0
node-0...	BUSY	batch	InfiniBand	0/4	74	100	0

At the bottom of the table, there is a 'View' dropdown set to '20' and 'Per Page' controls. The pagination shows 'Page 1 of 3' with navigation arrows.

The right sidebar contains a 'Current Search' dropdown set to '- Select -', a 'Narrow Search' input field with a search icon, and a 'Filters' section. The filters include a 'Select Status' dropdown and four range selectors for 'Processors', 'Jobs', 'CPU Utilization', and 'Memory Utilization', each with '0' and '∞' values and up/down arrows. 'Reset' and 'Filter' buttons are at the bottom of the filter section.

Nodes Page Toolbar

The Nodes page has a toolbar with links to other pages.

- The first icon is the Nodelist page. This is the default Nodes page view.
- The second icon is the Resource Job Timeline page. For more information, see [Resource Job Timeline Page on page 3262](#).

Searching and Filtering

Searching by NodeID, Class, or Features

The Nodes page has filtering options to help you find specific nodes or groups of nodes.

To search, select the column you want to filter by from the drop-down box. In the Narrow Search field, enter text that should appear in the selected column for the desired node. For example, if you want to find all nodes with the GigE feature, select **Features** and enter **GigE**.

You can add multiple search criteria. Only the nodes that match all search criteria will be shown.

Filtering by Status

You can also filter all nodes that are not in a particular state. For example, to show only busy nodes, select **BUSY** from the Select Status drop-down box.

Filtering by Processors, Jobs, CPU Utilization, or Memory Utilization

You can also show only nodes with a numeric attribute in a given range. Select the minimum and maximum values for this filter next to the name of the attribute you want to filter. The minimum value text field is always directly to the left of the accompanying maximum value text field. For example, to see only nodes with 2, 3, or 4 processors, select **2** as the minimum and **4** as the maximum, and click **Filter**.

Click the refresh icon () to refresh the information on the Nodes page, .

Click **Reset** to remove the filter selection and display the default Nodes page.

Columns

Node ID

The identifier of the node.

Status

The state of the node.

Class

The class of the jobs that are running on this node.

Feature

The current features available on this node.

Procs

The number of processors on this node. The number of Available and Configured Procs are displayed in this column.

Jobs

The number of jobs running on this node.

CPU Utilization

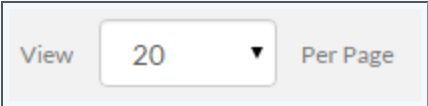

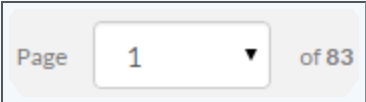

The percentage of this node's processors that are dedicated to currently running jobs.

Memory Utilization

The percentage of this node's memory that is dedicated to currently running jobs.

Page Controls

The Nodes page allows you to customize how many nodes appear per page and to select which page to display.

	Shows how many nodes you want displayed on the page. To change this, select the number of nodes that you want to appear on each page from the drop-down box.
	Displays the first page of nodes that match the current search.
	Displays the previous page of nodes that match the current search.
	Allows you to select which page of nodes you want to see. All nodes will match the current search.

	Displays the next page of nodes that match the current search.
	Displays the last page of nodes that match the current search.

Node Details

Field	Description
Name	The ID of the node.
State	The current state of the node or resource, such as BUSY, IDLE, DOWN, and so forth.
Power	The power state of the node, such as ON or OFF.
Image	The name of the operating system currently running on this node.
Resource Managers	The resource manager that is reporting the node.
Jobs	The number of jobs running.
Reservations	The reservations that include this node.

Resources

Field	Description
Real processors	The number of processors on the node.
Available processors	The number of processors that are not dedicated to currently running jobs.
Real memory (GB)	The amount of memory on the node in GB.
Available memory (GB)	The amount of memory that is available on the node in GB.
CPU utilization	The current CPU utilization of the node.
Generic Resource with Count	The generic resources required by the node or resource.

Features

Field	Description
Reported features	Features reported by the resource manager or configured in the Moab configuration file .
Configurable features	<p>Features that have been added by the UI or through Moab Web Services. By clicking the + button, you can add or remove configurable features from this node.</p> <p>The configurable feature selector will only allow you to select configurable features that exist on at least one node. You cannot create new configurable features using Viewpoint. Therefore, you must first create configurable features (also known as custom features) and add them to a node using an MWS node modification REST call as described in Modify Node on page 1788.</p>

Controls

- **Return to earlier search** - Clicking this link on the top right of the page takes you to the Nodes page, showing the earlier filtered and searched results.
- **Cancel** - Cancel any changes made to the node or resource and return to the Nodes page.
- **Done** - Submit any changes made to the node or resource to Moab Workload Manager and return to the Nodes page.
- **Apply** - Submit any changes made to the node or resource to Moab Workload Manager and stay on the Node Details page.

Related Topics

[Nodes Page on page 3257](#)

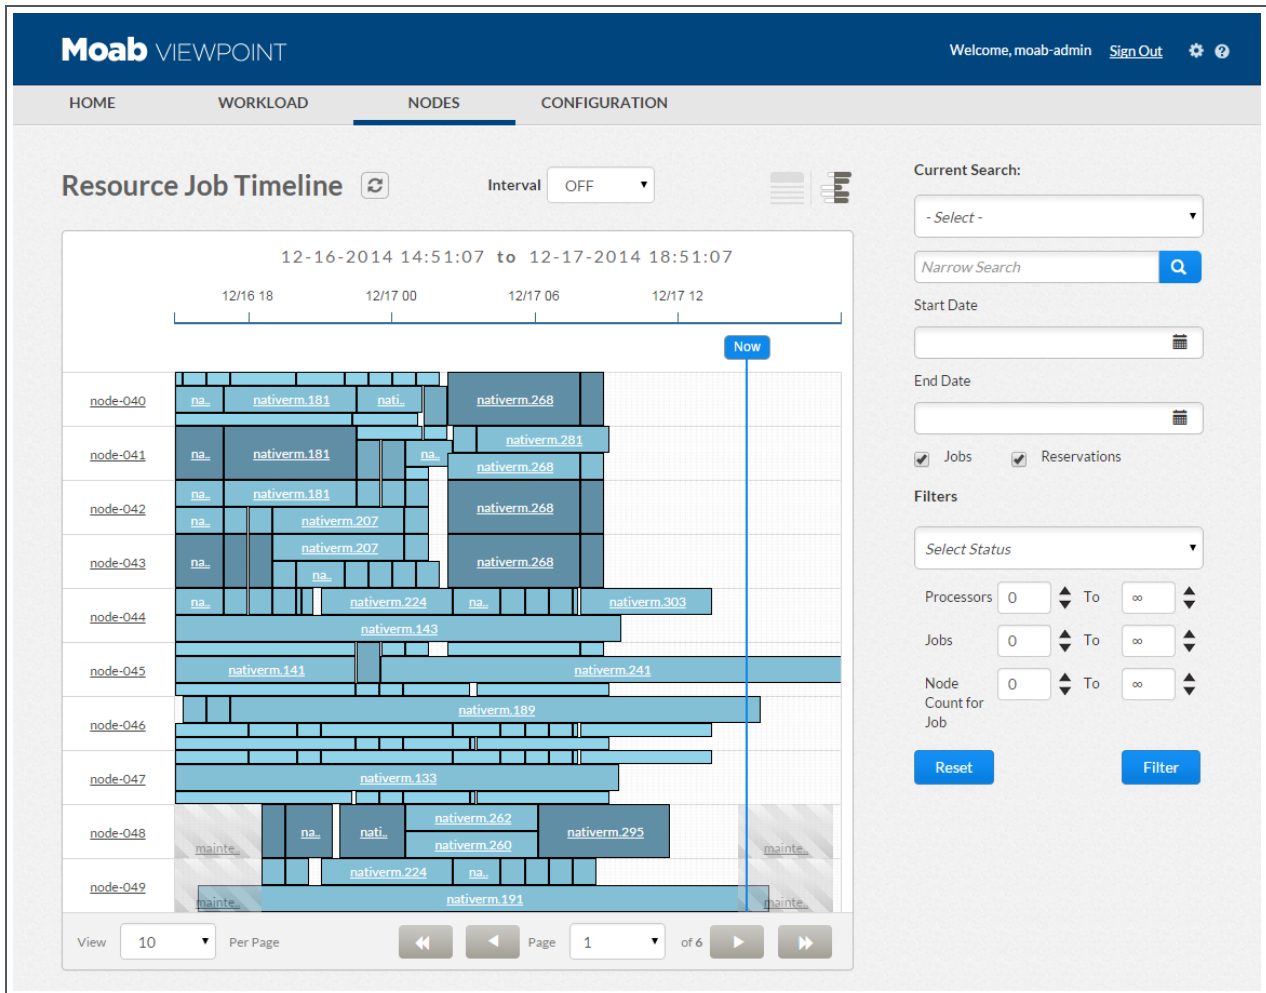

[Resource Job Timeline Page on page 3262](#)

Resource Job Timeline Page

Path: Nodes > click the Resource Job Timeline icon on the top right ().

To return to the Nodes page, click the Nodelist icon on the top right ().

The Resource Job Timeline page displays information about the jobs and reservations that are running on a set of nodes graphically, in the timeline window of the page.

The Resource Job Timeline View, by default, is set to show the last 24 hours and the next 4 hours when you first visit the page. Depending on how many jobs run in your cluster per day, and how many nodes you are viewing, that time window might contain too many objects for the browser to display. You can change the default setting. See [Threshold Settings on page 3247](#) more information.

Refreshing the Resource Job Timeline

You can refresh the information displayed on the Resource Job Timeline page with the latest details about the jobs running on the nodes. You can specify an automatic refresh interval and you can manually update the information as desired.

- **Automatic Refresh Interval** - To set an automatic refresh duration, select the time interval from the Interval drop-down box. Valid values are

OFF, 30s, 60s, 5m, 10m, 15m. For example, if you want to update the information after every 60 seconds, select **60s**.

- **Manual Refresh** - At any time you can click the refresh icon () to refresh the information displayed .

Displaying Jobs and Reservations

You can select the information to be displayed on the timeline using the Jobs and Reservations check boxes placed to the right of the page.

 The Jobs check box is selected, by default.

To view only the Reservations on the timeline, clear the Jobs check box, select the Reservations check box, and then click **Filter**. To view both the Jobs and Reservations on the timeline, select both the Jobs and Reservations check boxes, and then click **Filter**.

 When both the Reservations check box and the Jobs check box are selected, and Jobs and Reservations co-exist in the same time frame and on the same node, the Reservation block overlaps the Job block on the timeline.

Searching and Filtering

Searching by Node Name, Job Name, and Reservation ID:

The Resource Job Timeline page has filtering options to help you find a specific node or a specific job or a Reservation ID.

 When you select the Reservation ID from the drop-down box and click the search icon, the Reservations check box is selected by default.

To search, select the option you want to filter by from the drop-down box. In the Narrow Search field, enter text that should appear in the search result. For example, if you want to find a node with node name "node-020", select **Node Name** from the drop-down box and enter **node-020**.

You can add multiple search criteria. For example, if you want to search for a job with job name "nativerm.536" that is running on node-014. Select **Job Name** from the drop-down box and in the Narrow Search field, enter **nativerm.536**. Click the search icon () . The timeline shows the nativerm.536 job running on separate nodes. Now, select **Node Name** from the drop down box and in the Narrow Search field, enter **node-014**. Click the search icon () . The search is narrowed down and the nativerm.536 job, which is running on node-014, is displayed on the timeline.

Filtering by Date Range

To show jobs or reservations with a date in a given range, select the date and time in the Start Date and To fields by clicking the calendar icon. Click **Filter**. Only the Jobs and Reservations with a start date between your minimum and maximum start dates display.

Filtering by Status

You can filter all nodes that are in a particular state. For example, to show only busy nodes, select **BUSY** from the Select Status drop-down box and click **Filter**.

Filtering by Processors, Jobs, or Node Count for Job

You can show nodes with a numeric attribute that is in a given range. Select the minimum and maximum values for this filter next to the name of the attribute you want to filter. The minimum value text field is always directly to the left of the accompanying maximum value text field. For example, to see jobs with 2, 3, or 4 processors, select **2** as the minimum and **4** as the maximum next to the Processors box, and click **Filter**.

Click **Reset** to remove the filter selection and display the default Resource Job Timeline page.

Resource Job Timeline

The Resource Job Timeline page displays the details of the jobs and reservations running on a node. The following information is displayed on the graphical timeline:

Node ID

The node ID is displayed on the vertical axis on the left. Hovering the mouse over the node ID displays the number of processors configured on the node. You can also click on the node ID to view the Node Details page, which displays additional information about that node (see [Node Details Page on page 3260](#)).

Time Span

The time span is displayed on the horizontal axis at the top. The vertical blue line with the Now label  on the timeline denotes the current time.

i The default time span displayed on the timeline is 24 hours in the past and 4 hours in the future.

Jobs

The jobs are displayed on the timeline only if the Jobs check box is selected from the right of the page. A job that is running on a particular node is

displayed against the node on the timeline as blocks in shades of blue. The color shade of the job block indicates the number of processors used for the job. The darker shade indicates more processors and the lighter shade indicates fewer processors being used for the job (relative to your cluster's average job size). The vertical height of the block indicates the number of processors that the job is using on a particular node. For example, if a job is using 2 out of 4 processors on a particular node, then the job will take up 50 percent of the height of the Node ID row.

Job Details

You can view the information about a job displayed on the Resource Job Timeline by hovering your mouse over the individual job block.

 The Job ID is displayed on the Job block only if the length of the block allows it.

Hovering the mouse over the job block displays the following information for that specific job:

- **Job ID** - The ID given to the job by Moab.
- **Start Time** - The date and time when the job started.
- **End Time** - The date and time when the job ended. This field will be null if the job is still running.
- **Processors On Node** - The number of processors that the specific job is occupying on that specific node. It does not display information on other jobs on that node or the other nodes occupied by that job.
- **Wallclock Limit Seconds** - The amount of time requested for the job, in seconds. This represents the maximum amount of time the job is expected to run and is specified when the job is submitted.

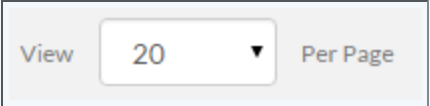

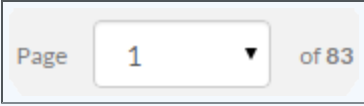

You can also click on the Job block in the timeline to view the Job Details page, which displays additional information about that job (see [Job Details Page on page 3252](#)).

Reservations

The Reservations are displayed on the timeline only if the Reservations check box is selected from the right of the page. A Reservation on a particular node is displayed against that node on the timeline in the form of gray blocks. If a job and a reservation co-exist in the same time frame and for the same node, then the Reservation block is displayed over the Job block.

Page Controls

The Resource Job Timeline page allows you to customize how many jobs/reservations appear per page and to select which page to display.

	Shows how many job/reservations you want displayed on the page. To change this, select the number of jobs/reservations that you want to appear on each page from the drop-down box.
	Displays the first page of jobs/reservations that match the current search.
	Displays the previous page of jobs/reservations that match the current search.
	Allows you to select which page of jobs/reservations you want to see. All jobs will match the current search.
	Displays the next page of jobs/reservations that match the current search.
	Displays the last page of jobs/reservations that match the current search.

Moab Insight Overview

Insight is an optional component of the Moab HPC Suite, Enterprise or Basic Edition, that lets you create, analyze, and report dashboards that represent the current and historical state of your cluster. It collects the data that Moab emits on its message queue. The message queue is efficient and reliable and gracefully tolerates disconnections or restarts on either side.

You should install Insight if you want to do either of the following: 1) Use Moab Viewpoint 8.1.0 or 2) Run reports and analyze events within the cluster using standard relational database tools such as Crystal Reports.

Moab produces a large, coherent snapshot of its object model at the end of each scheduling iteration and event-based updates as they occur; for instance, whenever a job starts or finishes. Insight constantly collects this data and writes it to the database. In the background, it runs an "archiver." Every so often, the archiver takes a sample of the current state of the cluster and copies it to historical tables. Insight periodically prunes the database to eliminate data that has become stale or expired. When Moab and Insight experience periods of disconnection for any reason, Moab uses a buffer to temporarily save that data. You can configure the sampling, pruning, and the buffer to suit the needs of your environment.

Associated tasks

The following sections describe how to configure, customize, and use Insight.

- [Installing Insight on page 114](#)
- [Writing a Report on page 3269](#)
- [Adding a New Table, View, or Index to the Schema on page 3269](#)
- [Tuning the Insight Archiver Sample Rate on page 3271](#)
- [Changing the Pruning Policy on page 3272](#)
- [Configuring Reliable Message Delivery on page 3275](#)

References

The following sections contain detailed information about the use of Insight.

- [The Insight Archiver Sample Rate on page 3275](#)
- [The Insight Pruning Policy on page 3276](#)
- [Troubleshooting on page 3277](#)

How-to

Writing a Report

To write a report

1. Choose a reporting tool such as Crystal Reports, Stonefield, Cognos, Jasper.
2. Define a JDBC connection with the Postgres database. For more information, see "[Connecting to the Database](#)" in the PostgreSQL documentation. It is recommended that you create a new read-only user for the PostgreSQL `moab_insight` database for all reporting tools.
3. Enter your query. For example:

```
SELECT job.state, count(*) AS count, "user".name AS user_name
FROM job INNER JOIN "user" ON job.user_id = "user".credential_id
GROUP BY job.state, "user".name;
```

i The above query is just an example and may not be applicable for your configuration.

Related Topics

[Adding a New Table, View, or Index to the Schema on page 3269](#)

Adding a New Table, View, or Index to the Schema

To add a new table, view, or index to the schema

1. Open PostgreSQL and switch to the `moab_insight` database.

```
$ sudo -u postgres psql -d moab_insight
```

2. Run the `CREATE TABLE` or `CREATE VIEW` command, ensuring that your table or view name begins with `x_`. This convention tells Insight that your table or view is an extension that it should protect on upgrade and that it should not directly manage it.

```
> CREATE TABLE x_my_table
```

Related Topics

[Writing a Report on page 3269](#)

Tuning Insight for your System

Insight is by default configured for smaller systems in order to prevent undesired memory or CPU usage. This section provides information to tune your configuration to keep pace with Moab Workload Manager.

Available Hardware

We recommend configuration based on the hardware available to Insight. The parameters listed below should be uncommented and tuned in the `/opt/insight/etc/config.groovy` configuration file.

- `messageQueue.workerCount = <processor count * 4> // i.e. 64 for a 16 core machine`
- `messageQueue.parserCount = 4 // Smaller systems may use less`
- `messageQueue.workerQueueCapacity = <workerCount * 25> // i.e. 1600 for a workerCount value of 64`
- `jdbc.c3p0.maxPoolSize = <workerCount + 6> // i.e. 70 for a workerCount value of 64`

i Please note that the **maxPoolSize** configuration parameter must be less than the maximum connections allowed by PostgreSQL or else errors will occur. This configuration parameter may be changed in PostgreSQL if it needs to be increased.

- `jdbc.c3p0.maxStatements = <workerCount * 512> // i.e. 32768 for a workerCount value of 64`

Job Archiving Schedule

Insight will periodically move the records of jobs that have completed into archive tables. This keeps job-related database tables small enough that inserts and queries do not become slow. By default, job archiving will start every day at midnight and will archive all jobs that have been completed (or canceled) for seven or more days. This includes data in tables related to jobs (for example, job reservations and job state transitions will also be archived). Running and idle jobs will not be archived (irregardless of the job date).

If it appears that Insight is not keeping pace with Moab, you may want to configure the archiver to run more aggressively. This is most likely to be the case *only* if you have a large cluster with high numbers of jobs. One indication that you may want to do this is that the data in Insight is out of date by several RM poll intervals. See [RMPOLLINTERVAL on page 1184](#) to specify the interval between RM polls.

To Customize the Archiver Settings

Add or adjust the following parameters in the `/opt/insight/etc/config.groovy` configuration file.

Parameter	Default	Description
<code>archiver.jobArchiving.maxAgeDays</code>	7	Jobs that have been completed longer than this many days will be archived.
<code>archiver.jobArchiving.schedule</code>	"0 0 0 * * *" // Every day at midnight	Job archiving will happen according to this schedule, which is described in cron job syntax .

For example:

```
archiver.jobArchiving.maxAgeDays = 3
archiver.jobArchiving.schedule = "0 */6 * * * *" // Every 6 hours starting at midnight
```

i For archiving purposes, the job's age is the number of days it has been completed rounded down to the nearest integer value. For example, if a job has been completed for 3 1/2 days the archiver will consider the job's age to be 3.

Tuning the Insight Archiver Sample Rate

Context

Insight always captures the current snapshot of jobs; however, you can configure it to track statistics, usage, and trends in a more granular or relaxed fashion according to your needs.

To tune the Insight sample rate

Open the Insight configuration file (`/opt/insight/etc/config.groovy`) and uncomment and change the default **archiver.schedule** parameter.

- Default

```
// Archiver configuration - the archiver creates samples or historical data from
current state data
//archiver.schedule = "0 *0-59 * * * *" // Run once a minute
```

- Example

```
// Archiver configuration - the archiver creates samples or historical data from
current state data
archiver.schedule = "*/10 * * * * *" // Run once every 10 minutes
```

Schedule value

The schedule value is a cron-like string. It is a string that contains six space-separated fields representing second, minute, hour, day, month, and weekday. You can give month and weekday names as the first three letters of the English names.

Example Patterns

0 0 * * * * – the top of every hour of every day
 */10 * * * * * – every ten seconds
 0 0 8-10 * * * – 8:00, 9:00 and 10:00 every day
 0 0/30 8-10 * * * – 8:00, 8:30, 9:00, 9:30 and 10:00 everyday
 0 0 9-17 * * MON-FRI – on the hour from 9:00 to 5:00 on weekdays
 0 0 0 25 12 ? – every Christmas at midnight

Related Topics

[The Insight Archiver Sample Rate on page 3275](#)

[Changing the Pruning Policy on page 3272](#)

Tuning your PostgreSQL Server

Adaptive Computing recommends you follow the PostgreSQL team's official documentation for tuning your server. Their tuning documentation can be found [here](#).

The following parameters are especially important to tune for use with Moab Insight:

- shared_buffers
- effective_cache_size
- checkpoint_segments
- checkpoint_completion_target
- work_mem

Changing the Pruning Policy

Context

The Insight data retention and pruning behavior control how large the database grows and how far back in time it stretches.

You can configure the pruning policy via configuration files (/opt/insight/etc/config-defaults.groovy and /opt/insight/etc/config.d/).

The following is a sample pruning configuration:

```
pruner {
  schedule = "*/10 * * * * *"
  policy = [
    [ // Last 3 minutes => Granularity 1 per minute
      'interval' : [ 'unit' : "MINUTE", 'count': 2 ],
      'granularity': [ 'unit': "MINUTE", 'each': 1 ]
    ],
    [ // Last 30 minutes => Granularity 10 per minute
      'interval' : [ 'unit' : "MINUTE", 'count': 30 ],
      'granularity': [ 'unit': "MINUTE", 'each': 10 ]
    ],
    [ // Last 2 hours => Granularity 1 per hour
      'interval' : [ 'unit' : "HOUR", 'count': 2 ],
      'granularity': [ 'unit': "HOUR", 'each': 1 ]
    ]
  ]
}
```

You can find the pruner policy within the policy section. The policy consists of several blocks enclosed with square brackets []. Each item contains two subsections: interval and granularity. The intervals described in this policy are applied one after another, beginning from the current moment. The order is important.

The `unit` fields can have one of the following values:

- MINUTE
- HOUR
- DAY
- WEEK
- MONTH
- YEAR
- INFINITY

`each` and `count` fields are unsigned integers.

The pruner policy is loaded and validated when Insight starts. If the given policy is invalid, Insight will fail to start.

Here is the list of rules which the pruning policy must satisfy:

- The policy cannot be empty. You must have at least one item with the interval and granularity set.
- When you go from the current time to the past, the granularity must not get smaller (for example, "Now I want 1 item per 10 minutes, but after an hour let it be 1 item per minute."). This would cause historical data loss, which is considered erroneous.

- The sample rate cannot be arbitrary.
- The set of valid granularity radices are: one minute, 10 minutes, hour, day, week.
- The set of valid sample rates is any number N that is a factor of all granularities greater than N and a multiple of all granularities less than N . So 2 is a valid sample rate, because 2 minutes is factor of all granularities greater than 2 and a multiple of 1; however, 3 is not a valid sample rate, because it doesn't divide evenly into 10.

One month is a valid granularity because it is divided by week radix and there is no greater radix it should divide.

20 minutes is a valid granularity because it is divided by 10 minutes radix and the greater radix – hour – is divided by 20 minutes.

11 minutes is not a valid granularity.

Pruning Schedule

In the sample configuration provided above there is a `schedule` field. This field controls the schedule when the corresponding pruner background thread gets invoked. This schedule impacts directly how often the sample data is aligned to the pruning policy.

The schedule value is a cron-like string. It is a string that contains six space-separated fields representing second, minute, hour, day, month, and weekday. You can give month and weekday names as the first three letters of the English names.

Example Patterns

0 0 * * * * – the top of every hour of every day
 */10 * * * * * – every ten seconds
 0 0 8-10 * * * – 8:00, 9:00 and 10:00 every day
 0 0/30 8-10 * * * – 8:00, 8:30, 9:00, 9:30 and 10:00 everyday
 0 0 9-17 * * MON-FRI – on the hour from 9:00 to 5:00 on weekdays
 0 0 0 25 12 ? – every Christmas at midnight

Configuring Reliable Message Delivery

Context

Moab and the Insight daemon gracefully handle disconnects or restarts. If you restart Moab, you do not have to restart Insight. To handle instances of disconnect, or downtime, Moab stores all data it attempts to send to Insight in memory and on disk. Once Moab generates enough data to meet the maximum storage size, it begins to delete the oldest data and make room for the new data. The size of the data on the disk is two times the maximum storage size. By default, the maximum storage size is 1 GB with 2 GB max on disk. You can customize the storage size for your unique environment.

To configure reliable message delivery

1. Open the Moab configuration file on the Moab head node and set the **INSIGHTSTORESIZE** and **INSIGHTSTOREDIR** configuration parameters. See [Appendix A: Moab Parameters on page 1069](#) in Moab Workload Manager for parameter information.

```
[moab]$ vi /opt/etc/moab
...
INSIGHTSTORESIZE 2048 # 2 GB store size with 4 GB on disk
INSIGHTSTOREDIR /tmp/insight_store
...
```

If **INSIGHTSTOREDIR** is a relative path, the Moab home directory is prepended to it. It uses the given path if it is an absolute path.

2. Restart Moab in order for the new configuration parameters to take effect.

References

The Insight Archiver Sample Rate

The sample rate is the rate at which Insight archives snapshots of statistical, usage, and trend data in the cluster. You can make the sample rate as granular as once per minute or as relaxed as once per hour. To maximize the usefulness of samples in statistical analysis and dashboards, ensure that your sample rate divides evenly into 10- and 60-minute intervals. Valid values include 2 minutes, 5 minutes, 10 minutes, 20 minutes, and 30 minutes, but values such as 3 minutes and 15 minutes are invalid.

Usually when you configure a more granular sample rate, Insight streams more data to the database and the reports and dashboards contain greater detail. However, if Moab has a long scheduling iteration, sampling may provide little benefit. This is because Moab emits a great deal of the data only once per cycle.

As you create samples, the database grows larger and running queries places a greater burden on the RAM and processors of the Insight machine. Note, however, that because Insight has a retention and pruning policy, it does not retain all samples forever. For more information, see [Changing the Pruning Policy on page 3272](#).

[The Insight Pruning Policy on page 3276](#)

The Insight Pruning Policy

A pruning or retention policy tells Insight how much data to retain. It is stored as a structure in the Insight configuration file that you define in terms of units at varying granularity. For example, a simple pruning policy could dictate that Insight should do the following: retain minute-by-minute samples of the cluster for one week and consider data older than that expired and prune it to avoid overwhelming the capacity of the database.

The pruning policy is the set of rules applied to `job_samples`, `node_samples`, and `reservation_samples` tables in the database. The pruner uses these rules to identify which historical records can be removed and which ones should be retained. The aim of the pruner is to retain a coherent historical view at the cluster and, at the same time, take care of the DB size growth.

The pruner policy rules are written in terms of granularity (i.e. the sampling rate or how often the records can appear) and the time interval to which the given granularity is applied.

During the last hour, the samples are retained with one-per-minute granularity; during the last day, with one-per-ten-minutes granularity; during the last week, with one-per-hour granularity; during the last month, with one-per-six-hours granularity; and finally, indefinitely, with one-per-day granularity.

The default insight pruning policy is complex and says the following: keep minute-by-minute samples back to the beginning of the previous hour; keep 10-minute samples back to the beginning of the previous day; keep hourly samples back to the beginning of the previous week; keep 6-hour samples back to the beginning of the previous day; and keep daily samples forever.

Troubleshooting

This topic contains information on troubleshooting and resolving issues.

- [liquibase.exception.LockException: Could not acquire change log lock on page 3277](#)
- [Job state is completed yet job has a null completion time on page 3279](#)

liquibase.exception.LockException: Could not acquire change log lock

Cause

This usually happens when Insight is prematurely terminated the first time it is run after being installed. The termination would have occurred during or right after Insight was setting up the database schema.

1. The main symptom of this problem is that whenever you start Insight you'll see the following error in the /opt/insight/log/insight.log and Insight will terminate abruptly several minutes after starting:

```
java.lang.RuntimeException: liquibase.exception.LockException: Could not acquire
change log lock. Currently locked by geminst02 (fe80:0:0:0:f816:3eff:fe12:44a9%2)
since 12/9/14 9:24 AM
at com.ace.insight.data.service.DbInitService.validateDbConsistency
(DbInitService.java:130) ~[insight-8.1.jar:8.1]
at
com.ace.insight.data.service.DbInitService$$FastClassBySpringCGLIB$$$91c2bfb8.invoke
(<generated>) ~[spring-core-4.0.3.RELEASE.jar:8.1]
at org.springframework.cglib.proxy.MethodProxy.invoke (MethodProxy.java:204) ~
[spring-core-4.0.3.RELEASE.jar:4.0.3.RELEASE]
at
org.springframework.aop.framework.CglibAopProxy$CglibMethodInvocation.invokeJoinpoi
nt (CglibAopProxy.java:711) ~[spring-aop-4.0.3.RELEASE.jar:4.0.3.RELEASE]
```

2. If the error displays, check the DATABASECHANGELOGLOCK table for entries where the locked column is set to 't'.

```
[root]# sudo su - postgres
[postgres]$ psql -d moab_insight_reference -c "select * from
DATABASECHANGELOGLOCK;"
 id | locked | lockgranted | lockedby
-----+-----+-----+-----
  1 | t      | 2014-12-09 09:24:29.538-07 | geminst02
(fe80:0:0:0:f816:3eff:fe12:44a9%2)
(1 row)
```

Prevention

To prevent this avoid doing anything that might terminate the Insight process until you see the following lines appear in the insight.log:

```
2014-12-11T17:28:57.920+0400    main    INFO
com.ace.insight.app.ApplicationListenerBean    0    The application has been started.
Insight version: master
2014-12-11T17:28:57.950+0400    main    INFO    com.ace.insight.app.Application
0    Started Application in 139.173 seconds (JVM running for 142.189)
```

These lines are an indication that Insight has set up the database and released the locks. The service can be shut down at this point.

Troubleshooting Methods

Method 1

Use this method first. This method is safe to use regardless of whether you have data in your moab_database as it will not disturb this moab_insight database.

Remove the lock line in the DATABASECHANGELOGLOCK table.

```
[postgres]$ psql -d moab_insight_reference -c "DELETE FROM DATABASECHANGELOGLOCK where
id>0;"
[postgres]$ exit
[root]# service insight start
```

If the issue still exists, follow the instructions for Method 2.

Method 2

This method assumes you do **not** have data in the database that you need to keep. This is likely only going to be the case if you have just barely installed Insight.

 This method will delete all data in your moab_insight database. If you **do** have data in the database, and you have already tried Method 1, do not use this method. Contact your Adaptive support representative.

Remove the Insight database and restart Insight.

1. Run the following:

```
[root]# service insight stop #Make sure Insight is not running
[root]# su - postgres -c "dropdb moab_insight"
[root]# su - postgres -c "dropdb moab_insight_reference"
[root]# su - postgres -c "createdb -O moab_insight moab_insight"
[root]# su - postgres -c "createdb -O moab_insight moab_insight_reference"
[root]# service insight start
```

2. Wait until you see the started message in the insight.log. Example:

```
2014-12-11T17:28:57.920+0400    main    INFO
com.ace.insight.app.ApplicationListenerBean    0    The application has been
started. Insight version: master
2014-12-11T17:28:57.950+0400    main    INFO    com.ace.insight.app.Application
0    Started Application in 139.173 seconds (JVM running for 142.189)
```

3. If you are using Viewpoint, you must manually grant SELECT permissions to the mws user.

```
[root]# su - postgres -c "psql -d moab_insight -c 'GRANT SELECT ON ALL TABLES IN
SCHEMA public TO mws;'"
```

Job state is completed yet job has a null completion time

Cause

If you notice that a job's state is completed, yet the job has a null completion time, it is likely that Insight did not process a job end event. For example:

```
[root]# su - postgres
[postgres]$ psql -d moab_insight -c "select job_id,job_name,job_state,wallclock_
seconds,job_start_datetime,completion_datetime from workload_view where job_
name='Moab.411'"
job_id | job_name | job_state | wallclock_seconds | job_start_datetime |
completion_datetime
-----+-----+-----+-----+-----+-----
403    | Moab.411 | COMPLETED | 3600 | 2015-01-19 10:30:00.000-07 |
```

Troubleshooting Method

To rectify this data inconsistency it is possible to insert a job end event into the Insight database manually. Do the following:

1. Notice what the UTC offset is. The UTC offset represents the difference in hours between local time and UTC time. There are many ways of determining this, but one way is to look at the trailing digits after the final dash in the `job_start_datetime`. Since the `job_start_datetime` in the example above is "2015-01-19 10:30:00.000-07", the UTC offset is "07".
2. Determine the job's completion time. Since the database does not have it, we first try querying `checkjob` on the machine running Moab Workload Manager. This may or may not be the same machine where your PostgreSQL database is.

```
[root]# checkjob Moab.411 | grep Completion
Completion Code: 0 Time: Mon Jan 19 11:28:00
```

If `checkjob` reports "ERROR: invalid job specified: Moab.411" this means that Moab has already purged the record of the job. You'll have to use the events file. Navigate to the `/opt/moab/stats` folder and search for `JOBEND`

events relating to Moab.411. This will also be on the machine running Moab Workload Manager.

```
[root]# cd /opt/moab/stats
[root]# grep -r 'Moab.411' * | grep JOBEND | cut -c1-100
events.Mon_Jan_19_2015:11:28:00 1421692080:372 job      Moab.411      JOBEND
0      1      bob
```

3. Create a primary key for the row you wish to insert. To do this create a row in the `job_state_journal_id` table and set the id in your newly created row to DEFAULT. If Moab and PostgreSQL are running on different machines, be sure to return to the machine running PostgreSQL. For example:

```
[postgres]$ psql -d moab_insight -c "INSERT INTO job_state_journal_id(id) VALUES
(DEFAULT) RETURNING id"
 id
----
522
(1 row)

INSERT 0 1
```

4. In the example above the primary key that was generated is 522. Now that we have a primary key, we can use it to manually insert the missing job end event into the `job_state_journal` table. We know from the events file that the job completed on January 19, 2015 at 11:28 AM. We also know from our earlier work that the UTC offset is 07. The date we wish to insert will be "2015-01-19 11:28:00.000-07".

```
[postgres]$ psql -d moab_insight -c "INSERT INTO job_state_journal(id,job_
id,state,timestamp_datetime) VALUES (522,403,'COMPLETED','2015-01-19 11:28:00.000-
07')"
```

TORQUE Resource Manager

Introduction

This section contains some basic introduction information to help you get started using TORQUE. It contains these topics:

- [What is a Resource Manager? on page 3280](#)
- [What are Batch Systems? on page 3281](#)
- [Basic Job Flow on page 3282](#)

What is a Resource Manager?

While TORQUE has a built-in scheduler, `pbs_sched`, it is typically used solely as a *resource manager* with a scheduler making requests to it. Resources managers

provide the low-level functionality to start, hold, cancel, and monitor jobs. Without these capabilities, a scheduler alone cannot control jobs.

What are Batch Systems?

While TORQUE is flexible enough to handle scheduling a conference room, it is primarily used in batch systems. Batch systems are a collection of computers and other resources (networks, storage systems, license servers, and so forth) that operate under the notion that the whole is greater than the sum of the parts. Some batch systems consist of just a handful of machines running single-processor jobs, minimally managed by the users themselves. Other systems have thousands and thousands of machines executing users' jobs simultaneously while tracking software licenses and access to hardware equipment and storage systems.

Pooling resources in a batch system typically reduces technical administration of resources while offering a uniform view to users. Once configured properly, batch systems abstract away many of the details involved with running and managing jobs, allowing higher resource utilization. For example, users typically only need to specify the minimal constraints of a job and do not need to know the individual machine names of each host on which they are running. With this uniform abstracted view, batch systems can execute thousands and thousands of jobs simultaneously.

Batch systems are comprised of four different components: (1) Master Node, (2) Submit/Interactive Nodes, (3) Compute Nodes, and (4) Resources.

Component	Description
Master Node	A batch system will have a master node where <code>pbs_server</code> runs. Depending on the needs of the systems, a master node may be dedicated to this task, or it may fulfill the roles of other components as well.
Submit/Interactive Nodes	Submit or interactive nodes provide an entry point to the system for users to manage their workload. For these nodes, users are able to submit and track their jobs. Additionally, some sites have one or more nodes reserved for interactive use, such as testing and troubleshooting environment problems. These nodes have client commands (such as <code>qsub</code> and <code>qhold</code>).
Computer Nodes	Compute nodes are the workhorses of the system. Their role is to execute submitted jobs. On each compute node, <code>pbs_mom</code> runs to start, kill, and manage submitted jobs. It communicates with <code>pbs_server</code> on the master node. Depending on the needs of the systems, a compute node may double as the master node (or more).
Resources	Some systems are organized for the express purpose of managing a collection of resources beyond compute nodes. Resources can include high-speed networks, storage systems, license managers, and so forth. Availability of these resources is limited and needs to be managed intelligently to promote fairness and increased utilization.

Basic Job Flow

The life cycle of a job can be divided into four stages: (1) creation, (2) submission, (3) execution, and (4) finalization.

Stage	Description
Creation	<p>Typically, a submit script is written to hold all of the parameters of a job. These parameters could include how long a job should run (walltime), what resources are necessary to run, and what to execute. The following is an example submit file:</p> <pre>#PBS -N localBlast #PBS -S /bin/sh #PBS -l nodes=1:ppn=2,walltime=240:00:00 #PBS -M user@my.organization.com #PBS -m ea source ~/.bashrc cd \$HOME/work/dir sh myBlast.sh -i -v</pre> <p>This submit script specifies the name of the job (localBlast), what environment to use (/bin/sh), that it needs both processors on a single node (nodes=1:ppn=2), that it will run for at most 10 days, and that TORQUE should email "user@my.organization.com" when the job exits or aborts. Additionally, the user specifies where and what to execute.</p>
Submission	A job is submitted with the <code>qsub</code> command. Once submitted, the policies set by the administration and technical staff of the site dictate the priority of the job and therefore, when it will start executing.
Execution	Jobs often spend most of their lifecycle executing. While a job is running, its status can be queried with <code>qstat</code> .
Finalization	When a job completes, by default, the <code>stdout</code> and <code>stderr</code> files are copied to the directory where the job was submitted.

Overview

This section contains some basic information about TORQUE, including how to install and configure it on your system. For details, see these topics:

- [TORQUE Installation Overview on page 3283](#)
- [Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#)
- [Advanced Configuration on page 3299](#)
- [Manual Setup of Initial Server Configuration on page 3314](#)
- [Server Node File Configuration on page 3315](#)
- [Testing Server Configuration on page 3317](#)

- [TORQUE on NUMA Systems on page 3319](#)
- [TORQUE Multi-MOM on page 3323](#)

TORQUE Installation Overview

This section contains information about TORQUE architecture and explains how to install TORQUE. It also describes how to install TORQUE packages on compute nodes and how to enable TORQUE as a service.

For details, see these topics:

- [TORQUE Architecture on page 3283](#)
- [Installing TORQUE on page 3283](#)
- [Compute Nodes on page 3289](#)
- [Enabling TORQUE as a Service on page 3290](#)

Related Topics

[Troubleshooting on page 3414](#)

TORQUE Architecture

A TORQUE cluster consists of one head node and many compute nodes. The head node runs the `pbs_server` daemon and the compute nodes run the `pbs_mom` daemon. Client commands for submitting and managing jobs can be installed on any host (including hosts not running `pbs_server` or `pbs_mom`).

The head node also runs a scheduler daemon. The scheduler interacts with `pbs_server` to make local policy decisions for resource usage and allocate nodes to jobs. A simple FIFO scheduler, and code to construct more advanced schedulers, is provided in the TORQUE source distribution. Most TORQUE users choose to use a packaged, advanced scheduler such as Maui or Moab.

Users submit jobs to `pbs_server` using the `qsub` command. When `pbs_server` receives a new job, it informs the scheduler. When the scheduler finds nodes for the job, it sends instructions to run the job with the node list to `pbs_server`. Then, `pbs_server` sends the new job to the first node in the node list and instructs it to launch the job. This node is designated the execution host and is called *Mother Superior*. Other nodes in a job are called *sister MOMs*.

[Installing TORQUE on page 3283](#)

Installing TORQUE

This topic contains instructions on how to install and start TORQUE.

In this topic:

- [Requirements on page 3284](#)
- [Prerequisites on page 3285](#)
- [Dependencies and Packages Installation on page 3285](#)
- [Installing TORQUE on page 3286](#)

Requirements

Supported Operating Systems

- CentOS 6.x
- Red Hat 6.x
- Scientific Linux 6.x
- SUSE Linux Enterprise Server 11

i CentOS 5.9, Red Hat 5.9 and Scientific Linux 5.9 are supported, largely to continue support for clusters where the compute nodes operating systems cannot be upgraded. We recommend that the TORQUE head node run on the supported operating systems listed above.

Software Requirements

- libxml2-devel package (package name may vary)
- openssl-devel package (package name may vary)
- Tcl/Tk version 8 or later if you plan to build the GUI portion of TORQUE or use a Tcl based scheduler
- If you use [cpuset](#), libhwloc 1.2 is required for TORQUE 5.1.0 or 5.0.x; 1.1 is required for TORQUE 4.2.9

If you intend to use TORQUE 5.1.0 with Moab Workload Manager, you must run Moab version 8.1.0 or 8.0.x. TORQUE 5.1.0 will not work with versions earlier than Moab 8.0.

If you build TORQUE from source (i.e. clone from github), the following additional software is required:

- gcc
- gcc-c++
- A posix compatible version of make
- libtool 1.5.22
- boost-devel 1.36.0

Prerequisites

- If using a firewall, open necessary ports.

TORQUE requires certain ports to be open for essential communication:

- For client and pbs_mom communication to pbs_server, the default port is 15001.
- For pbs_server communication to pbs_mom, the default port is 15002.
- For pbs_mom communication to pbs_mom, the default port is 15003.

To open ports in your firewall:

- Red Hat-based distributions using iptables:

```
[root]# iptables-save > /tmp/iptables.mod
[root]# vi /tmp/iptables.mod

# Add the following lines immediately *before* the line matching
# "-A INPUT -j REJECT --reject-with icmp-host-prohibited"

# Needed on the TORQUE server for client and MOM communication
-A INPUT -p tcp --dport 15001 -j ACCEPT

# Needed on the TORQUE MOM for server and MOM communication
-A INPUT -p tcp --dport 15002 -j ACCEPT
-A INPUT -p tcp --dport 15003 -j ACCEPT

[root]# iptables-restore < /tmp/iptables.mod
[root]# service iptables save
```

- SuSE-based distributions using SuSEfirewall2:

```
[root]# vi /etc/sysconfig/SuSEfirewall2

# Add the following ports to the FW_SERVICES_EXT_TCP parameter as required

# Needed on the TORQUE server for client and MOM communication
FW_SERVICES_EXT_TCP="15001"

# Needed on the TORQUE MOM for server and MOM communication
FW_SERVICES_EXT_TCP="15002 15003"

[root]# service SuSEfirewall2_setup restart
```

For more information on how to configure the ports that TORQUE uses for communication, see [Configuring Ports on page 3295](#).

- Make sure your host (with the correct IP address) is in your `/etc/hosts` file. To verify that the hostname resolves correctly, make sure that `hostname` and `hostname -f` report the correct name for the host.

Dependencies and Packages Installation

Install the `libxml2-devel`, `openssl-devel`, and `boost-devel` packages.

- **RHEL 6.x, CentOS 6.x, and Scientific Linux 6.x:**

```
[root]# yum install libtool openssl-devel libxml2-devel boost-devel gcc gcc-c++
```

- **SLES:**

```
[root]# zypper install libopenssl-devel libtool libxml2-devel boost-devel gcc
gcc-c++ make gmake
```

- **RHEL 5, CentOS 5, and Scientific Linux 5:**

```
[root]# yum install openssl-devel libtool-devel libxml2-devel gcc gcc-c++ wget
```

Use these instructions for installing `libtool`:

```
[root]# cd /tmp
[root]# wget http://ftpmirror.gnu.org/libtool/libtool-2.4.2.tar.gz
[root]# tar -xzf libtool-2.4.2.tar.gz
[root]# cd libtool-2.4.2
[root]# ./configure --prefix=/usr
[root]# make
[root]# make install
```

i TORQUE requires Boost version 1.36.0 or greater. The `boost-devel` package provided with RHEL 5, CentOS 5, and Scientific Linux 5 is older than this requirement. A new option, `--with-boost-path` has been added to `configure` (see **Customizing the Install** on page 3299 in the *TORQUE Administrator Guide* for more information). This allows you to point TORQUE to a specific version of boost during make. One way to compile TORQUE without installing Boost is to simply download the Boost version you plan to use from: <http://www.boost.org/users/history/>. Next, untar Boost—you do not need to build it or install it. When you run TORQUE `configure`, use the `--with-boost-path` option pointed to the extracted Boost directory.

Installing TORQUE

1. Switch the user to root.

```
[user]$ su -
```

2. Download the latest 5.1 build from the [Adaptive Computing](#) website. It can also be downloaded via command line (github method or the tarball distribution).

- **Clone the source from github.**

i If git is not installed:

```
# RHEL, CentOS, Scientific Linux:
[root]# yum install git

# SLES:
[root]# zipper install git
```

```
[root]# git clone https://github.com/adaptivecomputing/torque.git -b <version>
<version>
[root]# cd <version>
[root]# ./autogen.sh
```

- **Get the tarball source distribution.**

```
[root]# yum install wget
[root]# wget http://www.adaptivecomputing.com/download/torque/torque-
<version>.tar.gz -O torque-<version>.tar.gz

[root]# tar -xzf torque-<version>.tar.gz
[root]# cd torque-<version>/
```

3. Run each of the following commands in order.

```
[root]# ./configure
[root]# make
[root]# make install
```

For information on what options are available to customize the `./configure` command, see [Customizing the Install on page 3299](#).

4. Configure the `trqauthd` daemon to start automatically at system boot.

```
# RHEL, CentOS, Scientific Linux:
[root]# cp contrib/init.d/trqauthd /etc/init.d/
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start

# SLES:
[root]# cp contrib/init.d/suse.trqauthd /etc/init.d/trqauthd
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start
```

5. Verify that the `/var/spool/torque/server_name` file exists and contains the correct name of the server.

```
[root]# echo <pbs_server's_hostname> > /var/spool/torque/server_name
```

6. By default, TORQUE installs all binary files to `/usr/local/bin` and `/usr/local/sbin`. Make sure the path environment variable includes these directories for both the installation user and the root user.

```
[root]# export PATH=/usr/local/bin:/usr/local/sbin:$PATH
```

7. Initialize `serverdb` by executing the `torque.setup` script.

```
[root]# ./torque.setup root
```

8. Add nodes to the `/var/spool/torque/server_priv/nodes` file. For information on syntax and options for specifying compute nodes, see [Specifying Compute Nodes on page 3293](#).
9. Configure the MOMs if necessary (see [Configuring TORQUE on Compute Nodes on page 3295](#) in the TORQUE Administrator Guide).

i The `make packages` command can be used to create self-extracting packages that can be copied and executed on your nodes. For information on creating packages and deploying them, see [Compute Nodes on page 3289](#).

10. Configure `pbs_server` to start automatically at system boot, and then start the daemon.

- TORQUE Server on RHEL, CentOS, and Scientific Linux:

```
[root]# cp contrib/init.d/pbs_server /etc/init.d
[root]# chkconfig --add pbs_server
[root]# service pbs_server restart
```

- TORQUE Server on SLES:

```
[root]# cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
[root]# chkconfig --add pbs_server
[root]# service pbs_server restart
```

11. Configure `pbs_mom` to start automatically at system boot on each compute node, and then start the daemon.

There are several methods to get the following `inti.d` scripts on to each node. The following instructions assume the entire contents of `contrib/init.d` in the TORQUE git repository or source tarball are copied(`scp`)/cloned to the compute node.

i These options can be added to the self-extracting packages.

- TORQUE MOM on RHEL, CentOS, and Scientific Linux:

```
[root]# cp contrib/init.d/pbs_mom /etc/init.d
[root]# chkconfig --add pbs_mom
[root]# service pbs_mom start
```

- TORQUE MOM on SLES:

```
[root]# cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
[root]# chkconfig --add pbs_mom
[root]# service pbs_mom start
```

[Component Documentation on page 160](#)

Compute Nodes

Use the Adaptive Computing TORQUE package system to create self-extracting tarballs which can be distributed and installed on compute nodes. The TORQUE package are customizable. See the `INSTALL` file for additional options and features.

i If you installed TORQUE using the RPMs, you must install and configure your nodes manually by modifying the `/var/spool/torque/mom_priv/config` file of each one. This file is identical for all compute nodes and can be created on the head node and distributed in parallel to all systems.

```
[root]# vi /var/spool/torque/mom_priv/config

$pbsserver      headnode      # hostname running pbs server
$logevent       225           # bitmap of which events to log

[root]# service pbs_mom restart
```

To create TORQUE packages

1. Configure and make as normal, and then run `make packages`.

```
> make packages
Building ./torque-package-clients-linux-i686.sh ...
Building ./torque-package-mom-linux-i686.sh ...
Building ./torque-package-server-linux-i686.sh ...
Building ./torque-package-gui-linux-i686.sh ...
Building ./torque-package-devel-linux-i686.sh ...
Done.

The package files are self-extracting packages that can be copied and executed on
your production machines. Use --help for options.
```

2. Copy the desired packages to a shared location.

```
> cp torque-package-mom-linux-i686.sh /shared/storage/
> cp torque-package-clients-linux-i686.sh /shared/storage/
```

3. Install the TORQUE packages on the compute nodes.

Adaptive Computing recommends that you use a remote shell, such as SSH, to install TORQUE packages on remote systems. Set up shared SSH keys if you do not want to supply a password for each host.

i The only required package for the compute node is mom-linux. Additional packages are recommended so you can use client commands and submit jobs from compute nodes.

The following is an example of how to copy and install mom-linux in a distributed fashion.

```
> for i in node01 node02 node03 node04 ; do scp torque-package-mom-linux-i686.sh
${i}:/tmp/. ; done
> for i in node01 node02 node03 node04 ; do scp torque-package-clients-linux-
i686.sh ${i}:/tmp/. ; done
> for i in node01 node02 node03 node04 ; do ssh ${i} /tmp/torque-package-mom-linux-
i686.sh --install ; done
> for i in node01 node02 node03 node04 ; do ssh ${i} /tmp/torque-package-clients-
linux-i686.sh --install ; done
```

Alternatively, you can use a tool like xCAT instead of dsh.

To use a tool like xCAT

1. Copy the TORQUE package to the nodes.

```
> prcp torque-package-linux-i686.sh noderange:/destinationdirectory/
```

2. Install the TORQUE package.

```
> psh noderange /tmp/torque-package-linux-i686.sh --install
```

Although optional, it is possible to use the TORQUE server as a compute node and install a `pbs_mom` with the `pbs_server` daemon.

Enabling TORQUE as a Service

i Enabling TORQUE as a service is optional. In order to run TORQUE as a service, you must enable `trqauthd`. (see [Configuring trqauthd for Client Commands on page 3297](#)).

The method for enabling TORQUE as a service is dependent on the Linux variant you are using. Startup scripts are provided in the `contrib/init.d/` directory of the source package. To enable TORQUE as a service, run the following on the host for the appropriate TORQUE daemon:

- RedHat (as root)

```
> cp contrib/init.d/pbs_mom /etc/init.d/pbs_mom
> chkconfig --add pbs_mom
> cp contrib/init.d/pbs_server /etc/init.d/pbs_server
> chkconfig --add pbs_server
```

- SuSE (as root)

```
> cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
> insserv -d pbs_mom
> cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
> insserv -d pbs_server
```

- Debian (as root)

```
> cp contrib/init.d/debian.pbs_mom /etc/init.d/pbs_mom
> update-rc.d pbs_mom defaults
> cp contrib/init.d/debian.pbs_server /etc/init.d/pbs_server
> update-rc.d pbs_server defaults
```

 You will need to customize these scripts to match your system.

These options can be added to the self-extracting packages. For more details, see the `INSTALL` file.

[Configuring trqauthd for Client Commands on page 3297](#)

Initializing/Configuring TORQUE on the Server (pbs_server)

The TORQUE server (pbs_server) contains all the information about a cluster. It knows about all of the MOM nodes in the cluster based on the information in the `$TORQUE_HOME/server_priv/nodes` file (See [Configuring TORQUE on Compute Nodes on page 3295](#)). It also maintains the status of each MOM node through updates from the MOMs in the cluster (see [pbsnodes on page 3457](#)). All jobs are submitted via [qsub](#) to the server, which maintains a master database of all jobs and their states.

Schedulers such as Moab Workload Manager receive job, queue, and node information from pbs_server and submit all jobs to be run to pbs_server.

The server configuration is maintained in a file named `serverdb`, located in `$TORQUE_HOME/server_priv`. The `serverdb` file contains all parameters pertaining to the operation of TORQUE plus all of the queues which are in the configuration. For `pbs_server` to run, `serverdb` must be initialized.

You can initialize `serverdb` in two different ways, but the recommended way is to use the `./torque.setup` script:

- As root, execute `./torque.setup` from the build directory (see [./torque.setup](#) on page 3292).
- Use `pbs_server -t create` (see [Initializing/Configuring TORQUE on the Server \(pbs_server\)](#) on page 3291).

Restart `pbs_server` after initializing `serverdb`.

```
> qterm
> pbs_server
```

`./torque.setup`

The `torque.setup` script uses `pbs_server -t create` to initialize `serverdb` and then adds a user as a manager and operator of TORQUE and other commonly used attributes. The syntax is as follows:

`/torque.setup username`

```
> ./torque.setup ken
> qmgr -c 'p s'

#
# Create queues and set their attributes.
#
#
# Create and define queue batch
#
create queue batch
set queue batch queue_type = Execution
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server acl_hosts = kmn
set server managers = ken@kmn
set server operators = ken@kmn
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6
set server mom_job_sync = True
set server keep_completed = 300
```

pbs_server -t create

The `-t create` option instructs `pbs_server` to create the `serverdb` file and initialize it with a minimum configuration to run `pbs_server`.

```
> pbs_server -t create
```

To see the configuration and verify that TORQUE is configured correctly, use **qmgr**:

```
> qmgr -c 'p s'

#
# Set server attributes.
#
set server acl_hosts = kmn
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6
```

A single queue named `batch` and a few needed server attributes are created.

Related Topics

[Appendix C: Node Manager \(MOM\) Configuration on page 3539](#)

[Advanced Configuration on page 3299](#)

Specifying Compute Nodes

The environment variable `TORQUE_HOME` is where configuration files are stored. If you used the default locations during installation, you do not need to specify the `TORQUE_HOME` environment variable.

The `pbs_server` must recognize which systems on the network are its compute nodes. Specify each node on a line in the server's nodes file. This file is located at `TORQUE_HOME/server_priv/nodes`. In most cases, it is sufficient to specify just the names of the nodes on individual lines; however, various properties can be applied to each node.

i Only a root user can access the `server_priv` directory.

Syntax of nodes file:

```
node-name[:ts] [np=] [gpus=] [properties]
```

- The **node-name** must match the hostname on the node itself, including whether it is fully qualified or shortened.
- The **[ts]** option marks the node as timeshared. Timeshared nodes are listed by the server in the node status report, but the server does not allocate jobs to them.
- The **[np=]** option specifies the number of virtual processors for a given node. The value can be less than, equal to, or greater than the number of physical processors on any given node.
- The **[gpus=]** option specifies the number of GPUs for a given node. The value can be less than, equal to, or greater than the number of physical GPUs on any given node.
- The node processor count can be automatically detected by the TORQUE server if **auto_node_np** is set to TRUE. This can be set using this command:

```
qmgr -c set server auto_node_np = True
```

Setting **auto_node_np** to TRUE overwrites the value of np set in `TORQUE_HOME/server_priv/nodes`.

- The **[properties]** option allows you to specify arbitrary strings to identify the node. Property strings are alphanumeric characters only and must begin with an alphabetic character.
- Comment lines are allowed in the nodes file if the first non-white space character is the pound sign (**#**).

The following example shows a possible node file listing.

`TORQUE_HOME/server_priv/nodes`:

```
# Nodes 001 and 003-005 are cluster nodes
#
node001 np=2 cluster01 rackNumber22
#
# node002 will be replaced soon
node002:ts waitingToBeReplaced
# node002 will be replaced soon
#
node003 np=4 cluster01 rackNumber24
node004 cluster01 rackNumber25
node005 np=2 cluster01 rackNumber26 RAM16GB
node006
node007 np=2
node008:ts np=4
...

```

[Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#)

Configuring TORQUE on Compute Nodes

If using TORQUE self-extracting packages with default compute node configuration, no additional steps are required and you can skip this section.

If installing manually, or advanced compute node configuration is needed, edit the `TORQUE_HOME/mom_priv/config` file on each node. The recommended settings follow.

`TORQUE_HOME/mom_priv/config:`

```
$pbsserver    headnode    # hostname running pbs server
$logevent     225         # bitmap of which events to log
```

This file is identical for all compute nodes and can be created on the head node and distributed in parallel to all systems.

Related Topics

[Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#)

Configuring Ports

You can optionally configure the various ports that TORQUE uses for communication. Most ports can be configured multiple ways. The ports you can configure are:

- [pbs_server listening port](#)
- [pbs_mom listening port](#)
- [port pbs_server uses to communicate to the pbs_mom](#)
- [port pbs_mom uses to communicate to the pbs_server](#)
- [port client commands use to communicate to the pbs_server](#)
- [port trqauthd uses to communicate to the pbs_server](#)

i If you are running pbspro on the same system, be aware that it uses the same environment variables and `/etc/services` entries.

Configuring the pbs_server Listening Port

To configure the port the `pbs_server` listens on, follow any of these steps:

- Set an environment variable called `PBS_BATCH_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Start `pbs_server` with the `-p` option.

```
$ pbs_server -p port_num
```

- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`
- Start `pbs_server` with the `-H` option.

```
$ pbs_server -H server_name:port_num
```

Configuring the `pbs_mom` Listening Port

To configure the port the `pbs_mom` listens on, follow any of these steps:

- Set an environment variable called `PBS_MOM_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs_mom port_num/tcp`.
- Start `pbs_mom` with the `-M` option.

```
$ pbs_mom -M port_num
```

- Edit the `nodes` file entry for that list: add `mom_service_port=port_num`.

Configuring the Port `pbs_server` Uses to Communicate with `pbs_mom`

To configure the port the `pbs_server` uses to communicate with `pbs_mom`, follow any of these steps:

- Set an environment variable called `PBS_MOM_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs_mom port_num/tcp`.
- Start `pbs_mom` with the `-M` option.

```
$ pbs_server -M port_num
```

Configuring the Port `pbs_mom` Uses to Communicate with `pbs_server`

To configure the port the `pbs_mom` uses to communicate with `pbs_server`, follow any of these steps:

- Set an environment variable called `PBS_BATCH_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Start `pbs_mom` with the `-S` option.

```
$ pbs_mom -p port_num
```

- Edit the `nodes` file entry for that list: add `mom_service_port=port_num`.

Configuring the Port Client Commands Use to Communicate with pbs_server

To configure the port client commands use to communicate with `pbs_server`, follow any of these steps:

- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`

Configuring the Port trqauthd Uses to Communicate with pbs_server

To configure the port `trqauthd` uses to communicate with `pbs_server`, follow any of these steps:

- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`

Related Topics

[Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#)

[pbs_server](#)

[pbs_mom](#)

[trqauthd](#)

[client commands](#)

Configuring trqauthd for Client Commands

`trqauthd` is a daemon used by TORQUE client utilities to authorize user connections to `pbs_server`. Once started, it remains resident. TORQUE client utilities then communicate with `trqauthd` on port 15005 on the loopback interface. It is multi-threaded and can handle large volumes of simultaneous requests.

Running trqauthd

`trqauthd` must be run as root. It must also be running on any host where TORQUE client commands will execute.

By default, `trqauthd` is installed to `/usr/local/bin`.

`trqauthd` can be invoked directly from the command line or by the use of `init.d` scripts which are located in the `contrib/init.d` directory of the TORQUE source.

There are three `init.d` scripts for `trqauthd` in the `contrib/init.d` directory of the TORQUE source tree:

Script	Description
debian.trqauthd	Used for apt-based systems (debian, ubuntu are the most common variations of this)
suse.trqauthd	Used for suse-based systems
trqauthd	An example for other package managers (Redhat, Scientific, CentOS, and Fedora are some common examples)

i You should edit these scripts to be sure they will work for your site.

Inside each of the scripts are the variables `PBS_DAEMON` and `PBS_HOME`. These two variables should be updated to match your TORQUE installation. `PBS_DAEMON` needs to point to the location of `trqauthd`. `PBS_HOME` needs to match your TORQUE installation.

Choose the script that matches your dist system and copy it to `/etc/init.d`. If needed, rename it to **trqauthd**.

To start the daemon

```
/etc/init.d/trqauthd start
```

To stop the daemon

```
/etc/init.d/trqauthd stop
```

OR

```
service trqauthd start/stop
```

i If you receive an error that says "Could not open socket in trq_simple_connect. error 97" and you use a CentOS, RedHat, or Scientific Linux 6+ operating system, check your `/etc/hosts` file for multiple entries of a single host name pointing to the same IP address. Delete the duplicate(s), save the file, and launch `trqauthd` again.

Related Topics

[Initializing/Configuring TORQUE on the Server \(pbs_server\)](#) on page 3291

Finalizing Configurations

After configuring the `serverdb` and the `server_priv/nodes` files, and after ensuring minimal MOM configuration, restart the `pbs_server` on the server node and the `pbs_mom` on the compute nodes.

Compute Nodes:

```
> pbs_mom
```

Server Node:

```
> qterm -t quick
> pbs_server
```

After waiting several seconds, the `pbsnodes -a` command should list all nodes in state `free`.

Related Topics

[Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#)

Advanced Configuration

This section contains information about how you can customize the installation and configure the server to ensure that the server and nodes are communicating correctly. For details, see these topics:

- [Customizing the Install on page 3299](#)
- [Server Configuration on page 3307](#)

Related Topics

[Appendix B: Server Parameters on page 3520](#)

Customizing the Install

The TORQUE `configure` command has several options available. Listed below are some suggested options to use when running `./configure`.

- By default, TORQUE does not install the admin manuals. To enable this, use `--enable-docs`.
- By default, only children MOM processes use syslog. To enable syslog for all of TORQUE, use `--enable-syslog`.

Table 26-24: Optional Features

Option	Description
<code>--disable-clients</code>	Directs TORQUE not to build and install the TORQUE client utilities such as <code>qsub</code> , <code>qstat</code> , <code>qdel</code> , etc.
<code>--disable-FEATURE</code>	Do not include FEATURE (same as <code>--enable-FEATURE=no</code>).

Option	Description
--disable-lib-tool-lock	Avoid locking (might break parallel builds).
--disable-mom	Do not include the MOM daemon.
--disable-mom-check-spool	Don't check free space on spool directory and set an error.
--disable-posixmemlock	Disable the MOM's use of mlockall. Some versions of OSs seem to have buggy POSIX MEMLOCK.
--disable-priv-ports	Disable the use of privileged ports for authentication. Some versions of OSX have a buggy bind () and cannot bind to privileged ports.
--disable-qsub-keep-override	Do not allow the qsub -k flag to override -o -e.
--disable-server	Do not include server and scheduler.
--disable-shell-pipe	Give the job script file as standard input to the shell instead of passing its name via a pipe.
--disable-spool	If disabled, TORQUE will create output and error files directly in \$HOME/.pbs_spool if it exists or in \$HOME otherwise. By default, TORQUE will spool files in TORQUE_HOME/spool and copy them to the users home directory when the job completes.
--disable-xopen-net-working	With HPUX and GCC, don't force usage of XOPEN and libxnet.
--enable-acct-x	Enable adding x attributes to accounting log.
--enable-array	Setting this under IRIX enables the SGI Origin 2000 parallel support. Normally autodetected from the /etc/config/array file.
--enable-blcr	Enable BLCR support.
--enable-cpa	Enable Cray's CPA support.

Option	Description
--enable-cpu-set	<p>Enable Linux 2.6 kernel cpusets.</p> <div>  It is recommended that you turn on this feature to prevent a job from expanding across more CPU cores than it is assigned. </div>
--enable-debug	Prints debug information to the console for pbs_server and pbs_mom while they are running. (This is different than --with-debug which will compile with debugging symbols.)
--enable-dependency-tracking	Do not reject slow dependency extractors.
--enable-fast-install[=PKGS]	Optimize for fast installation [default=yes].
--enable-FEATURE [=ARG]	Include FEATURE [ARG=yes].
--enable-file-sync	Open files with sync on each write operation. This has a negative impact on TORQUE performance. This is disabled by default.
--enable-force-nodefile	Forces creation of nodefile regardless of job submission parameters. Not on by default.
--enable-gcc-warnings	Enable gcc strictness and warnings. If using gcc, default is to error on any warning.
--enable-geometry-requests	TORQUE is compiled to use procs_bitmap during job submission.
--enable-gui	Include the GUI-clients.
--enable-main-tainer-mode	This is for the autoconf utility and tells autoconf to enable so called rebuild rules. See main-tainer mode for more information.

Option	Description
--enable-maxdefault	<p>Turn on the RESOURCEMAXDEFAULT flag.</p> <div> <p>i Versions of TORQUE earlier than 2.4.5 attempted to apply queue and server defaults to a job that didn't have defaults specified. If a setting still did not have a value after that, TORQUE applied the queue and server maximum values to a job (meaning, the maximum values for an applicable setting were applied to jobs that had no specified or default value).</p> <p>In TORQUE 2.4.5 and later, the queue and server maximum values are no longer used as a value for missing settings. To re-enable this behavior in TORQUE 2.4.5 and later, use <code>--enable-maxdefault</code>.</p> </div>
--enable-nochildsignal	Turn on the NO_SIGCHLD flag.
--enable-nodemask	Enable nodemask-based scheduling on the Origin 2000.
--enable-pemask	Enable pemask-based scheduling on the Cray T3e.
--enable-plock-daemons[=ARG]	Enable daemons to lock themselves into memory: logical-or of 1 for pbs_server, 2 for pbs_scheduler, 4 for pbs_mom (no argument means 7 for all three).
--enable-quick-commit	Turn on the QUICKCOMMIT flag.
--enable-shared[=PKGS]	Build shared libraries [default=yes].
--enable-shell-use-argv	Enable this to put the job script name on the command line that invokes the shell. Not on by default. Ignores --enable-shell-pipe setting.
--enable-sp2	Build PBS for an IBM SP2.
--enable-srfs	Enable support for SRFS on Cray.
--enable-static[=PKGS]	Build static libraries [default=yes].

Option	Description
--enable-sys-log	Enable (default) the use of syslog for error reporting.
--enable-tcl-qstat	Setting this builds qstat with Tcl interpreter features. This is enabled if Tcl is enabled.
--enable-unix-sockets	Enable the use of Unix Domain sockets for authentication.

Table 26-25: Optional Packages

Option	Description
--with-blcr=DIR	BLCR installation prefix (Available in versions 2.5.6 and 3.0.2 and later).
--with-blcr-include=DIR	Include path for libcr.h (Available in versions 2.5.6 and 3.0.2 and later).
--with-blcr-lib=DIR	Lib path for libcr (Available in versions 2.5.6 and 3.0.2 and later).
--with-blcr-bin=DIR	Bin path for BLCR utilities (Available in versions 2.5.6 and 3.0.2 and later).

Option	Description
--with-boost-path=DIR	<p>Set the path to the Boost header files to be used during make. This option does not require Boost to be built or installed.</p> <p>The --with-boost-path value must be a directory containing a sub-directory called boost that contains the boost .hpp files.</p> <p>For example, if downloading the boost 1.55.0 source tarball to the adaptive user's home directory:</p> <pre>[adaptive]\$ cd ~ [adaptive]\$ wget http://sourceforge.net/projects/boost/files/boost/1.55.0/boost_1_55_0.tar.gz/download [adaptive]\$ tar xzf boost_1_55_0.tar.gz [adaptive]\$ ls boost_1_55_0 boost boost-build.jam ...</pre> <p>In this case use --with-boost-path=/home/adaptive/boost_1_55_0 during configure.</p> <p>Another example would be to use an installed version of Boost. If the installed Boost header files exist in /usr/include/boost/*.hpp, use --with-boost-path=/usr/include.</p>
--with-cpa-include=DIR	Include path for cpalib.h.
--with-cpa-lib=DIR	Lib path for libcpalib.
--with-debug=no	Do not compile with debugging symbols.
--with-default-server-r=HOSTNAME	Set the name of the computer that clients will access when no machine name is specified as part of the queue name. It defaults to the hostname of the machine on which PBS is being compiled.
--with-environ=PATH	Set the path containing the environment variables for the daemons. For SP2 and AIX systems, suggested setting is to /etc/environment. Defaults to the file "pbs_environment" in the server-home. Relative paths are interpreted within the context of the server-home.
--with-gnu-ld	Assume the C compiler uses GNU ld [default=no].
--with-mail-domain=MAILDOMAIN	Override the default domain for outgoing mail messages, i.e. "user@maildomain". The default maildomain is the hostname where the job was submitted from.

Option	Description
--with-modulefiles[=DIR]	Use module files in specified directory [/etc/modulefiles].
--with-momlogdir	Use this directory for MOM logs.
--with-momlogsuffix	Use this suffix for MOM logs.
--without-PACKAGE	Do not use PACKAGE (same as --with-PACKAGE=no).
--without-readline	Do not include readline support (default: included if found).
--with-PACKAGE[=ARG]	Use PACKAGE [ARG=yes].
--with-pam=DIR	Directory that holds the system PAM modules. Defaults to /lib(64)/security on Linux.
--with-pic	Try to use only PIC/non-PIC objects [default=use both].
--with-qstatrc-file=FILE	Set the name of the file that qstat will use if there is no ".qstatrc" file in the directory where it is being invoked. Relative path names will be evaluated relative to the server home directory (see above). If this option is not specified, the default name for this file will be set to "qstatrc" (no dot) in the server home directory.
--with-rcp	One of "scp", "rcp", "mom_rcp", or the full path of a remote file copy program. scp is the default if found, otherwise mom_rcp is used. Some rcp programs don't always exit with valid error codes in case of failure. mom_rcp is a copy of BSD rcp included with this source that has correct error codes, but it is also old, unmaintained, and doesn't have large file support.
--with-sched=TYPE	Sets the scheduler type. If TYPE is "c", the scheduler will be written in C. If TYPE is "tcl" the server will use a Tcl based scheduler. If TYPE is "basl", TORQUE will use the rule based scheduler. If TYPE is "no", then no scheduling is done. "c" is the default.
--with-sched-code=PATH	Sets the name of the scheduler to use. This only applies to BASL schedulers and those written in the C language. For C schedulers this should be a directory name and for BASL schedulers a filename ending in ".basl". It will be interpreted relative to srctree/src/schedulers.SCHD_TYPE/samples. As an example, an appropriate BASL scheduler relative path would be "nas.basl". The default scheduler code for "C" schedulers is "fifo".

Option	Description
--with-scp	In TORQUE 2.1 and later, SCP is the default remote copy protocol. See --with-rcp if a different protocol is desired.
--with-sendmail[=FILE]	Sendmail executable to use.
--with-server-home=DIR	Set the server home/spool directory for PBS use. Defaults to /var/spool/torque.
--with-server-name-file=FILE	Set the file that will contain the name of the default server for clients to use. If this is not an absolute pathname, it will be evaluated relative to the server home directory that either defaults to /usr/spool/PBS or is set using the --with-server-home option to configure. If this option is not specified, the default name for this file will be set to "server_name".
--with-tcl	Directory containing tcl configuration (tclConfig.sh).
--with-tclatrsep=CHAR	Set the Tcl attribute separator character this will default to "." if unspecified.
--with-tclinclude	Directory containing the public Tcl header files.
--with-tclx	Directory containing tclx configuration (tclxConfig.sh).
--with-tk	Directory containing tk configuration (tkConfig.sh).
--with-tkinclude	Directory containing the public Tk header files.
--with-tkx	Directory containing tkx configuration (tkxConfig.sh).
--with-tmpdir=DIR	Set the tmp directory that pbs_mom will use. Defaults to "/tmp". This is a Cray-specific feature.
--with-xauth=PATH	Specify path to xauth program.

HAVE_WORDEXP

`Wordxp()` performs a shell-like expansion, including environment variables. By default, `HAVE_WORDEXP` is set to **1** in `src/pbs_config.h`. If set to 1, will limit the characters that can be used in a job name to those allowed for a file in the current environment, such as BASH. If set to 0, any valid character for the file system can be used.

If a user would like to disable this feature by setting `HAVE_WORDEXP` to 0 in `src/include/pbs_config.h`, it is important to note that the error and the

output file names will not expand environment variables, including `$PBS_JOBID`. The other important consideration is that characters that BASH dislikes, such as `()`, will not be allowed in the output and error file names for jobs by default.

- [MOM Hierarchy on page 3311](#) (optional)

Server Configuration Overview

There are several steps to ensure that the server and the nodes are completely aware of each other and able to communicate directly. Some of this configuration takes place within TORQUE directly using the `qmgr` command. Other configuration settings are managed using the `pbs_server nodes` file, DNS files such as `/etc/hosts` and the `/etc/hosts.equiv` file.

Name Service Configuration

Each node, as well as the server, must be able to resolve the name of every node with which it will interact. This can be accomplished using `/etc/hosts`, DNS, NIS, or other mechanisms. In the case of `/etc/hosts`, the file can be shared across systems in most cases.

A simple method of checking proper name service configuration is to verify that the server and the nodes can "ping" each other.

Configuring Job Submission Hosts

Using RCmd authentication

When jobs can be submitted from several different hosts, these hosts should be trusted via the R* commands (such as rsh and rcp). This can be enabled by adding the hosts to the `/etc/hosts.equiv` file of the machine executing the `pbs_server` daemon or using other R* command authorization methods. The exact specification can vary from OS to OS (see the man page for **ruserok** to find out how your OS validates remote users). In most cases, configuring this file is as simple as adding a line to your `/etc/hosts.equiv` file, as in the following:

```
/etc/hosts.equiv:
```

```
#[+ | -] [hostname] [username]
mynode.myorganization.com
.....
```

Either of the hostname or username fields may be replaced with a wildcard symbol (+). The (+) may be used as a stand-alone wildcard but not connected to a username or hostname, e.g., `+node01` or `+user01`. However, a (-) may be used in that manner to specifically exclude a user.

Following the Linux man page instructions for `hosts.equiv` may result in a failure. You cannot precede the user or hostname with a (+). To clarify, `node1 +user1` will not work and **user1** will not be able to submit jobs.

For example, the following lines will not work or will not have the desired effect:

```
+node02 user1
node02 +user1
```

These lines will work:

```
node03 +
+ jsmith
node04 -tjones
```

The most restrictive rules must precede more permissive rules. For example, to restrict user tsmith but allow all others, follow this format:

```
node01 -tsmith
node01 +
```

Please note that when a hostname is specified, it must be the fully qualified domain name (FQDN) of the host. Job submission can be further secured using the server or queue **acl_hosts** and **acl_host_enabled** parameters (for details, see [Queue Attributes on page 3372](#)).

Using the "submit_hosts" service parameter

Trusted submit host access may be directly specified without using RCmd authentication by setting the server `submit_hosts` parameter via **qmgr** as in

the following example:

```
> qmgr -c 'set server submit_hosts = host1'
> qmgr -c 'set server submit_hosts += host2'
> qmgr -c 'set server submit_hosts += host3'
```

i Use of **submit_hosts** is potentially subject to DNS spoofing and should not be used outside of controlled and trusted environments.

Allowing job submission from compute hosts

If preferred, all compute nodes can be enabled as job submit hosts without setting `.rhosts` or `hosts.equiv` by setting the [allow_node_submit](#) parameter to **true**.

Configuring TORQUE on a Multi-Homed Server

If the `pbs_server` daemon is to be run on a multi-homed host (a host possessing multiple network interfaces), the interface to be used can be explicitly set using the [SERVERHOST](#) parameter.

Architecture Specific Notes

With some versions of Mac OS/X, it is required to add the line `$restricted *.<DOMAIN>` to the `pbs_mom` configuration file. This is required to work around some socket bind bugs in the OS.

Specifying Non-Root Administrators

By default, only root is allowed to start, configure and manage the `pbs_server` daemon. Additional trusted users can be authorized using the parameters **managers** and **operators**. To configure these parameters use the [qmgr](#) command, as in the following example:

```
> qmgr
Qmgr: set server managers += josh@*.fsc.com
Qmgr: set server operators += josh@*.fsc.com
```

All manager and operator specifications must include a user name and either a fully qualified domain name or a host expression.

i To enable all users to be trusted as both operators and administrators, place the **+** (plus) character on its own line in the `server_priv/acl_svr/operators` and `server_priv/acl_svr/managers` files.

Setting Up Email

Moab relies on emails from TORQUE about job events. To set up email, do the following:

To set up email

1. Use the `--with-sendmail` configure option at configure time. TORQUE needs to know where the email application is. If this option is not used, TORQUE tries to find the sendmail executable. If it isn't found, TORQUE cannot send emails.

```
> ./configure --with-sendmail=<path_to_executable>
```

2. Set `mail_domain` in your server settings. If your domain is `clusterresources.com`, execute:

```
> qmgr -c 'set server mail_domain=clusterresources.com'
```

3. (Optional) You can override the default [mail_body_fmt](#) and [mail_subject_fmt](#) values via **qmgr**:

```
> qmgr -c 'set server mail_body_fmt=Job: %i \n Name: %j \n On host: %h \n \n %m \n \n %d'
> qmgr -c 'set server mail_subject_fmt=Job %i - %r'
```

By default, users receive e-mails on job aborts. Each user can select which kind of e-mails to receive by using the [qsub -m](#) option when submitting the job. If you want to dictate when each user should receive e-mails, use a submit filter (for details, see [Appendix J: Job Submission Filter \("qsub Wrapper"\) on page 3585](#)).

Using MUNGE Authentication

MUNGE is an authentication service that creates and validates user credentials. It was developed by Lawrence Livermore National Laboratory (LLNL) to be highly scalable so it can be used in large environments such as HPC clusters. To learn more about MUNGE and how to install it, see <http://code.google.com/p/munge/>.

Configuring TORQUE to use MUNGE is a compile time operation. When you are building TORQUE, use `-enable-munge-auth` as a command line option with `./configure`.

```
> ./configure -enable-munge-auth
```

You can use only one authorization method at a time. If `-enable-munge-auth` is configured, the privileged port ruserok method is disabled.

TORQUE does not link any part of the MUNGE library into its executables. It calls the MUNGE and UNMUNGE utilities which are part of the MUNGE daemon. The MUNGE daemon must be running on the server and all submission hosts. The TORQUE client utilities call MUNGE and then deliver the encrypted credential to `pbs_server` where the credential is then unmunged and the server verifies the user and host against the authorized users configured in `serverdb`.

Authorized users are added to `serverdb` using **qmgr** and the **authorized_users** parameter. The syntax for **authorized_users** is `authorized_`

`users=<user>@<host>`. To add an authorized user to the server you can use the following `qmgr` command:

```
> qmgr -c 'set server authorized_users=user1@hosta
> qmgr -c 'set server authorized_users+=user2@hosta
```

The previous example adds `user1` and `user2` from `hosta` to the list of authorized users on the server. Users can be removed from the list of authorized users by using the `-=` syntax as follows:

```
> qmgr -c 'set server authorized_users-=user1@hosta
```

Users must be added with the `<user>@<host>` syntax. The user and the host portion can use the `'*'` wildcard to allow multiple names to be accepted with a single entry. A range of user or host names can be specified using a `[a-b]` syntax where *a* is the beginning of the range and *b* is the end.

```
> qmgr -c 'set server authorized_users=user[1-10]@hosta
```

This allows `user1` through `user10` on `hosta` to run client commands on the server.

[Advanced Configuration on page 3299](#)

MOM Hierarchy

i Mom hierarchy is designed for large systems to configure how information is passed directly to the `pbs_server`.

The MOM hierarchy allows you to override the compute nodes' default behavior of reporting status updates directly to the `pbs_server`. Instead, you configure compute nodes so that each node sends its status update information to another compute node. The compute nodes pass the information up a tree or hierarchy until eventually the information reaches a node that will pass the information directly to `pbs_server`. This can significantly reduce network traffic and ease the load on the `pbs_server` in a large system.

MOM Hierarchy Example

The following example illustrates how information is passed to the `pbs_server` without and with `mom_hierarchy`.

Without mom_hierarchy

With mom_hierarchy

i The dotted lines indicates an alternate path if the hierarchy-designated node goes down.

The following is the mom_hierarchy_file for the with mom_hierarchy example:

```

<path>
  <level>hostA,hostB</level>
  <level>hostB,hostC,hostD</level>
</path>
<path>
  <level>hostE,hostF</level>
  <level>hostE,hostF,hostG</level>
</path>
  
```

Setting Up the MOM Hierarchy

The name of the file that contains the configuration information is named `mom_hierarchy`. By default, it is located in the `/var/spool/torque/server_priv`

directory. The file uses syntax similar to XML:

```
<path>
  <level>comma-separated node list</level>
  <level>comma-separated node list</level>
  ...
</path>
...
```

The `<path></path>` tag pair identifies a group of compute nodes. The `<level></level>` tag pair contains a comma-separated list of compute node names listed by their hostnames. Multiple paths can be defined with multiple levels within each path.

Within a `<path></path>` tag pair the levels define the hierarchy. All nodes in the top level communicate directly with the server. All nodes in lower levels communicate to the first available node in the level directly above it. If the first node in the upper level goes down, the nodes in the subordinate level will then communicate to the next node in the upper level. If no nodes are available in an upper level then the node will communicate directly to the server.

If an upper level node has gone down and then becomes available, the lower level nodes will eventually find that the node is available and start sending their updates to that node.

i If you want to specify MOMs on a different port than the default, you must list the node in the form: `hostname:mom_manager_port`.

For example:

```
<path>
  <level>hostname:mom_manager_port,... </level>
  ...
</path>
...
```

Putting the MOM Hierarchy on the MOMs

You can put the MOM hierarchy file directly on the MOMs. The default location is `/var/spool/torque/mom_priv/mom_hierarchy`. This way, the `pbs_server` doesn't have to send the hierarchy to all the MOMs during each `pbs_server` startup. The hierarchy file still has to exist on the `pbs_server` and if the file versions conflict, the `pbs_server` version overwrites the local MOM file. When using a global file system accessible from both the MOMs and the `pbs_server`, it is recommended that the hierarchy file be symbolically linked to the MOMs.

Once the hierarchy file exists on the MOMs, start `pbs_server` with the `-n` option which tells `pbs_server` to not send the hierarchy file on startup. Instead, `pbs_server` waits until a MOM requests it.

Manual Setup of Initial Server Configuration

On a new installation of TORQUE, the server database must be initialized using the command `pbs_server -t create`. This command creates a file in `$TORQUEHOME/server_priv` named `serverdb` which contains the server configuration information.

The following output from `qmgr` shows the base configuration created by the command `pbs_server -t create`:

```
qmgr -c 'p s'
#
Set server attributes.
#
set server acl_hosts = kmn
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6
```

This is a bare minimum configuration and it is not very useful. By using `qmgr`, the server configuration can be modified to set up TORQUE to do useful work. The following `qmgr` commands will create a queue and enable the server to accept and run jobs. These commands must be executed by root.

```
pbs_server -t create
qmgr -c "set server scheduling=true"
qmgr -c "create queue batch queue_type=execution"
qmgr -c "set queue batch started=true"
qmgr -c "set queue batch enabled=true"
qmgr -c "set queue batch resources_default.nodes=1"
qmgr -c "set queue batch resources_default.walltime=3600"
qmgr -c "set server default_queue=batch"
```

i When TORQUE reports a new queue to Moab a class of the same name is automatically applied to all nodes.

In this example, the configuration database is initialized and the scheduling interface is activated using ('`scheduling=true`'). This option allows the scheduler to receive job and node events which allow it to be more responsive (See [scheduling on page 3538](#) for more information). The next command creates a queue and specifies the queue type. Within PBS, the queue must be declared an '`execution`' queue in order for it to run jobs. Additional configuration (i.e., setting the queue to `started` and `enabled`) allows the queue to *accept* job submissions, and *launch* queued jobs.

The next two lines are optional, setting default `node` and `walltime` attributes for a submitted job. These defaults will be picked up by a job if values are not explicitly set by the submitting user. The final line, `default_queue=batch`, is also a convenience line and indicates that a job should be placed in the `batch` queue unless explicitly assigned to another queue.

Additional information on configuration can be found in the admin manual and in the [qmgr](#) main page.

[Appendix B: Server Parameters on page 3520](#)

[Node Features/Node Properties on page 693](#)

Basic Node Specification

For the `pbs_server` to communicate with each of the MOMs, it needs to know which machines to contact. Each node that is to be a part of the batch system must be specified on a line in the `server nodes` file. This file is located at `TORQUE_HOME/server_priv/nodes`. In most cases, it is sufficient to specify just the node name on a line as in the following example:

```
server_priv/nodes:
```

```
node001
node002
node003
node004
```

i The `server nodes` file also displays the parameters applied to the node. See [Adding nodes](#) for more information on the parameters.

Related Topics

[Server Node File Configuration on page 3315](#)

Specifying Virtual Processor Count for a Node

By default each node has one virtual processor. Increase the number using the **np** attribute in the nodes file. The value of `np` can be equal to the number of physical cores on the node or it can be set to a value which represents available

"execution slots" for the node. The value used is determined by the administrator based on hardware, system, and site criteria.

The following example shows how to set the `np` value in the nodes file. In this example, we are assuming that node001 and node002 have four physical cores. The administrator wants the value of `np` for node001 to reflect that it has four cores. However, node002 will be set up to handle multiple virtual processors without regard to the number of physical cores on the system.

server_priv/nodes:

```
node001 np=4
node002 np=12
...
```

Related Topics

[Server Node File Configuration on page 3315](#)

Specifying GPU Count for a Node

Administrators can manually set the number of GPUs on a node or if they are using NVIDIA GPUs and drivers, they can have them detected automatically. For more information about how to set up TORQUE with GPUS, see [Accelerators on page 948](#).

To manually set the number of GPUs on a node, use the `gpus` attribute in the nodes file. The value of GPUs is determined by the administrator based on hardware, system, and site criteria.

The following example shows how to set the GPU value in the nodes file. In the example, we assume node001 and node002 each have two physical GPUs. The administrator wants the value of node001 to reflect the physical GPUs available on that system and adds `gpus=2` to the nodes file entry for node001. However, node002 will be set up to handle multiple virtual GPUs without regard to the number of physical GPUs on the system.

server_priv/nodes:

```
node001 gpus=1
node002 gpus=4
...
```

Related Topics

[Server Node File Configuration on page 3315](#)

Specifying Node Features (Node Properties)

Node features can be specified by placing one or more white space-delimited strings on the line for the associated host as in the following example:

server_priv/nodes:

```
node001 np=2 fast ia64
node002 np=4 bigmem fast ia64 smp
...
```

These features can be used by users to request specific nodes when submitting jobs. For example:

```
qsub -l nodes=1:bigmem+1:fast job.sh
```

This job submission will look for a node with the bigmem feature (node002) and a node with the fast feature (either node001 or node002).

[Server Node File Configuration on page 3315](#)

Testing Server Configuration

If you have initialized TORQUE using the `torque.setup` script or started TORQUE using `pbs_server -t create` and `pbs_server` is still running, terminate the server by calling `qterm`. Next, start `pbs_server` again without the `-t create` arguments. Follow the script below to verify your server configuration. The output for the examples below is based on the nodes file example in [Specifying node features](#) and [Server configuration](#).

```
# verify all queues are properly configured
> qstat -q

server:kmn

Queue      Memory      CPU Time      Walltime      Node      Run      Que      Lm      State
-----
batch      --           --           --           --           0       0       --      ER
                                     0       0

# view additional server configuration
> qmgr -c 'p s'
#
# Create queues and set their attributes
#
# Create and define queue batch
#
create queue batch
set queue batch queue_type = Execution
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server acl_hosts = kmn
set server managers = user1@kmn
set server operators = user1@kmn
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 300
set server job_stat_rate = 45
set server poll_jobs = True
set server mom_job_sync = True
set server keep_completed = 300
set server next_job_number = 0

# verify all nodes are correctly reporting
> pbsnodes -a
node001
  state=free
  np=2
  properties=bigmem,fast,ia64,smp
  ntype=cluster
  status=rectime=1328810402,varattr=,jobs=,state=free,netload=6814326158,gres=,loadave
=0.21,ncpus=6,physmem=8193724kb,
availmem=13922548kb,totmem=16581304kb,idletime=3,nusers=3,nsessions=18,sessions=1876
1120 1912 1926 1937 1951 2019 2057 28399 2126 2140 2323 5419 17948 19356 27726 22254
29569,uname=Linux kmn 2.6.38-11-generic #48-Ubuntu SMP Fri Jul 29 19:02:55 UTC 2011
x86_64,opsys=linux
  mom_service_port = 15002
  mom_manager_port = 15003
  gpus = 0
# submit a basic job - DO NOT RUN AS ROOT
> su - testuser
> echo "sleep 30" | qsub

# verify jobs display
> qstat

Job id      Name      User      Time Use      S      Queue
-----
```

```
0.kmn      STDIN   knielson      0  Q  batch
```

At this point, the job should be in the **Q** state and will not run because a scheduler is not running yet. TORQUE can use its native scheduler by running `pbs_sched` or an advanced scheduler (such as [Moab Workload Manager](#)). See [Integrating schedulers](#) for details on setting up an advanced scheduler.

Related Topics

[TORQUE Installation Overview on page 3283](#)

TORQUE on NUMA Systems

Starting in TORQUE version 3.0, TORQUE can be configured to take full advantage of Non-Uniform Memory Architecture (NUMA) systems. The following instructions are a result of development on SGI Altix and UV hardware.

For details, see these topics:

- [TORQUE NUMA Configuration on page 3319](#)
- [Building TORQUE with NUMA Support on page 3319](#)

TORQUE NUMA Configuration

There are three steps to configure TORQUE to take advantage of NUMA architectures:

1. Configure TORQUE with `--enable-numa-support`.
2. Create the `mom_priv/mom.layout` file.
3. Configure `server_priv/nodes`.

Related Topics

[TORQUE on NUMA Systems on page 3319](#)

Building TORQUE with NUMA Support

To turn on NUMA support for TORQUE the `--enable-numa-support` option must be used during the configure portion of the installation. In addition to any other configuration options, add the `--enable-numa-support` option as indicated in the following example:

```
$ ./configure --enable-numa-support
```

i Don't use MOM hierarchy with NUMA.

When TORQUE is enabled to run with NUMA support, there is only a single instance of `pbs_mom` (MOM) that is run on the system. However, TORQUE will report that there are multiple nodes running in the cluster. While `pbs_mom` and `pbs_server` both know there is only one instance of `pbs_mom`, they manage the cluster as if there were multiple separate MOM nodes.

The `mom.layout` file is a virtual mapping between the system hardware configuration and how the administrator wants TORQUE to view the system. Each line in `mom.layout` equates to a node in the cluster and is referred to as a NUMA node.

Automatically Creating `mom.layout` (Recommended)

A perl script named `mom_gencfg` is provided in the `contrib/` directory that generates the `mom.layout` file for you. The script can be customized by setting a few variables in it. To automatically create the `mom.layout` file, follow these instructions (these instructions are also included in the script):

1. Verify `hwloc` version 1.1 or higher is installed - see `contrib/hwloc_install.sh`.
2. Install `Sys::Hwloc` from CPAN.
3. Verify `$PBS_HOME` is set to the proper value.
4. Update the variables in the 'Config Definitions' section of the script. Especially update `firstNodeId` and `nodesPerBoard` if desired. The `firstNodeId` variable should be set above 0 if you have a root `cpuset` that you wish to exclude and the `nodesPerBoard` variable is the number of NUMA nodes per board. Each node is defined in `/sys/devices/system/node`, in a subdirectory `node<node index>`
5. Back up your current file in case a variable is set incorrectly or neglected.
6. Run the script.
7.

```
$ ./mom_gencfg
```

Manually Creating `mom.layout`

To properly set up the `mom.layout` file, it is important to know how the hardware is configured. Use the `topology` command line utility and inspect the contents of `/sys/devices/system/node`. The `hwloc` library can also be used to create a custom discovery tool.

Typing `topology` on the command line of a NUMA system produces something similar to the following:

```
Partition number: 0
6 Blades
72 CPUs
378.43 Gb Memory Total
```

Blade	ID	asic	NASID	Memory
0	r001i01b00	UVHub 1.0	0	67089152 kB

From this partial output, note that this system has 72 CPUs on 6 blades. Each blade has 12 CPUs grouped into clusters of 6 CPUs. If the entire content of this command were printed you would see each Blade ID and the CPU ID assigned to each blade.

The topology command shows how the CPUs are distributed, but you likely also need to know where memory is located relative to CPUs, so go to `/sys/devices/system/node`. If you list the node directory you will see something similar to the following:

```
# ls -al
total 0
drwxr-xr-x 14 root root 0 Dec 3 12:14 .
drwxr-xr-x 14 root root 0 Dec 3 12:13 ..

```

The directory entries `node0`, `node1`, ..., `node11` represent groups of memory and CPUs local to each other. These groups are a node board, a grouping of resources that are close together. In most cases, a node board is made up of memory and processor cores. Each bank of memory is called a memory node by the operating system, and there are certain CPUs that can access that memory very rapidly. Note under the directory for node board `node0` that there is an entry called `cpulist`. This contains the CPU IDs of all CPUs local to the memory in node board 0.

Now create the `mom.layout` file. The content of `cpulist` 0-5 are local to the memory of node board 0, and the memory and cpus for that node are specified in the layout file by saying `nodes=0`. The `cpulist` for node board 1 shows 6-11 and memory node index 1. To specify this, simply write `nodes=1`. Repeat this for all twelve node boards and create the following `mom.layout` file for the 72 CPU system.

```
nodes=0
nodes=1
nodes=2
nodes=3
nodes=4
nodes=5
nodes=6
nodes=7
nodes=8
nodes=9
nodes=10
nodes=11
```

Each line in the `mom.layout` file is reported as a node to `pbs_server` by the `pbs_mom` daemon.

The `mom.layout` file does not need to match the hardware layout exactly. It is possible to combine node boards and create larger NUMA nodes. The following example shows how to do this:

```
nodes=0-1
```

The memory nodes can be combined the same as CPUs. The memory nodes combined must be contiguous. You cannot combine mem 0 and 2.

Configuring `server_priv/nodes`

The `pbs_server` requires awareness of how the MOM is reporting nodes since there is only one MOM daemon and multiple MOM nodes. So, configure the `server_priv/nodes` file with the **`num_node_boards`** and **`numa_board_str`** attributes. The attribute `num_node_boards` tells `pbs_server` how many numa nodes are reported by the MOM. Following is an example of how to configure the nodes file with `num_node_boards`:

```
numa-10 np=72 num_node_boards=12
```

This line in the nodes file tells `pbs_server` there is a host named `numa-10` and that it has 72 processors and 12 nodes. The `pbs_server` divides the value of `np`

(72) by the value for `num_node_boards` (12) and determines there are 6 CPUs per NUMA node.

In this example, the NUMA system is uniform in its configuration of CPUs per node board, but a system does not need to be configured with the same number of CPUs per node board. For systems with non-uniform CPU distributions, use the attribute **`numa_board_str`** to let `pbs_server` know where CPUs are located in the cluster.

The following is an example of how to configure the `server_priv/nodes` file for non-uniformly distributed CPUs:

```
Numa-11 numa_board_str=6,8,12
```

In this configuration, `pbs_server` knows it has three MOM nodes and the nodes have 6, 8, and 12 CPUs respectively. Note that the attribute `np` is not used. The `np` attribute is ignored because the number of CPUs per node is expressly given.

Enforcement of memory resource limits

TORQUE can better enforce memory limits with the use of the utility **`memacctd`**. The `memacctd` utility is provided by SGI on SuSe Linux Enterprise Edition (SLES). It is a daemon that caches memory footprints when it is queried. When configured to use the memory monitor, TORQUE queries `memacctd`. It is up to the user to make sure `memacctd` is installed. See the [SGI memacctd man page](#) for more information.

To configure TORQUE to use memacctd for memory enforcement

1. Start **`memacctd`** as instructed by SGI.
2. Reconfigure TORQUE with `--enable-memacct`. This will link in the necessary library when TORQUE is recompiled.
3. Recompile and reinstall TORQUE.
4. Restart all MOM nodes.
5. (Optional) Alter the **`qsub`** filter to include a default memory limit for all jobs that are not submitted with memory limit.

TORQUE Multi-MOM

Starting in TORQUE version 3.0 users can run multiple MOMs on a single node. The initial reason to develop a multiple MOM capability was for testing

purposes. A small cluster can be made to look larger since each MOM instance is treated as a separate node.

When running multiple MOMs on a node each MOM must have its own service and manager ports assigned. The default ports used by the MOM are 15002 and 15003. With the multi-mom alternate ports can be used without the need to change the default ports for `pbs_server` even when running a single instance of the MOM.

For details, see these topics:

- [Multi-MOM Configuration on page 3324](#)
- [Stopping pbs_mom in Multi-MOM Mode on page 3325](#)

Multi-MOM Configuration

There are three steps to setting up multi-MOM capability:

1. [Configure server_priv/nodes on page 3324](#)
2. [/etc/hosts file on page 3324](#)
3. [Starting pbs_mom with Multi-MOM Options on page 3325](#)

Configure server_priv/nodes

The attributes **`mom_service_port`** and **`mom_manager_port`** were added to the nodes file syntax to accommodate multiple MOMs on a single node. By default `pbs_mom` opens ports 15002 and 15003 for the service and management ports respectively. For multiple MOMs to run on the same IP address they need to have their own port values so they can be distinguished from each other. `pbs_server` learns about the port addresses of the different MOMs from entries in the `server_priv/nodes` file. The following is an example of a nodes file configured for multiple MOMs:

```
hosta      np=2
hosta-1    np=2 mom_service_port=30001 mom_manager_port=30002
hosta-2    np=2 mom_service_port=31001 mom_manager_port=31002
hosta-3    np=2 mom_service_port=32001 mom_manager_port=32002
```

Note that all entries have a unique host name and that all port values are also unique. The entry `hosta` does not have a `mom_service_port` or `mom_manager_port` given. If unspecified, then the MOM defaults to ports 15002 and 15003.

/etc/hosts file

Host names in the `server_priv/nodes` file must be resolvable. Creating an alias for each host enables the server to find the IP address for each MOM; the server uses the port values from the `server_priv/nodes` file to contact the correct MOM. An example `/etc/hosts` entry for the previous `server_priv/nodes` example might look like the following:

```
192.65.73.10 hosta hosta-1 hosta-2 hosta-3
```

Even though the host name and all the aliases resolve to the same IP address, each MOM instance can still be distinguished from the others because of the unique port value assigned in the `server_priv/nodes` file.

Starting `pbs_mom` with Multi-MOM Options

To start multiple instances of `pbs_mom` on the same node, use the following syntax (see [pbs_mom on page 3443](#) for details):

```
pbs_mom -m -M <port value of MOM_service_port> -R <port value of MOM_manager_port> -A  
<name of MOM alias>
```

Continuing based on the earlier example, if you want to create four MOMs on `hosta`, type the following at the command line:

```
# pbs_mom -m -M 30001 -R 30002 -A hosta-1  
# pbs_mom -m -M 31001 -R 31002 -A hosta-2  
# pbs_mom -m -M 32001 -R 32002 -A hosta-3  
# pbs_mom
```

Notice that the last call to `pbs_mom` uses no arguments. By default `pbs_mom` opens on ports 15002 and 15003. No arguments are necessary because there are no conflicts.

[TORQUE Multi-MOM on page 3323](#)

[Stopping `pbs_mom` in Multi-MOM Mode on page 3325](#)

Stopping `pbs_mom` in Multi-MOM Mode

Terminate `pbs_mom` by using the `momctl -s` command (for details, see [momctl](#)). For any MOM using the default manager port 15003, the `momctl -s` command stops the MOM. However, to terminate MOMs with a manager port value not equal to 15003, you must use the following syntax:

```
momctl -s -p <port value of MOM_manager_port>
```

The **-p** option sends the terminating signal to the MOM manager port and the MOM is terminated.

Submitting and Managing Jobs

This section contains information about how you can submit and manage jobs with TORQUE. See the following topics for details:

- [Job Submission](#) on page 3326
- [Monitoring Jobs](#) on page 3343
- [Canceling Jobs](#) on page 3343
- [Job Preemption](#) on page 3344
- [Keeping Completed Jobs](#) on page 3344
- [Job Checkpoint and Restart](#) on page 3345
- [Job Exit Status](#) on page 3355
- [Service Jobs](#) on page 3359

Job Submission

Job submission is accomplished using the **qsub** command, which takes a number of command line arguments and integrates such into the specified PBS command file. The PBS command file may be specified as a filename on the **qsub** command line or may be entered via STDIN.

- The PBS command file does not need to be executable.
- The PBS command file may be *piped* into **qsub** (i.e., `cat pbs.cmd | qsub`).
- In the case of parallel jobs, the PBS command file is staged to, and executed on, the first allocated compute node only. (Use **pbsdsh** to run actions on multiple nodes.)
- The command script is executed from the user's home directory in all cases. (The script may determine the submission directory by using the `$PBS_O_WORKDIR` environment variable)
- The command script will be executed using the default set of user environment variables unless the **-V** or **-v** flags are specified to include aspects of the job submission environment.
- PBS directives should be declared first in the job script.

```
#PBS -S /bin/bash
#PBS -m abe
#PBS -M <yourEmail@company.com>
echo sleep 300
```

This is an example of properly declared PBS directives.

```
#PBS -S /bin/bash
SOMEVARIABLE=42
#PBS -m abe
#PBS -M <yourEmail@company.com>
echo sleep 300
```

This is an example of improperly declared PBS directives. PBS directives below "SOMEVARIABLE=42" are ignored.

i By default, job submission is allowed only on the TORQUE server host (host on which **pbs_server** is running). Enablement of job submission from other hosts is documented in [Server Configuration](#) on page 3307.

i Versions of TORQUE earlier than 2.4.5 attempted to apply queue and server defaults to a job that didn't have defaults specified. If a setting still did not have a value after that, TORQUE applied the queue and server maximum values to a job (meaning, the maximum values for an applicable setting were applied to jobs that had no specified or default value).

In TORQUE 2.4.5 and later, the queue and server maximum values are no longer used as a value for missing settings.

[Appendix J: Job Submission Filter \("qsub Wrapper"\)](#) on page 3585 – Allow local checking and modification of submitted job

Multiple Job Submission

Sometimes users will want to submit large numbers of jobs based on the same job script. Rather than using a script to repeatedly call `qsub`, a feature known as

job arrays now exists to allow the creation of multiple jobs with one `qsub` command. Additionally, this feature includes a new job naming convention that allows users to reference the entire set of jobs as a unit, or to reference one particular job from the set.

Job arrays are submitted through the `-t` option to `qsub`, or by using `#PBS -t` in your batch script. This option takes a comma-separated list consisting of either a single job ID number, or a pair of numbers separated by a dash. Each of these jobs created will use the same script and will be running in a nearly identical environment.

```
> qsub -t 0-4 job_script
1098[0].hostname

> qstat -t
1098[0].hostname ...
1098[1].hostname ...
1098[2].hostname ...
1098[3].hostname ...
1098[4].hostname ...
```

i Versions of TORQUE earlier than 2.3 had different semantics for the `-t` argument. In these versions, `-t` took a single integer number—a count of the number of jobs to be created.

Each `1098[x]` job has an environment variable called `PBS_ARRAYID`, which is set to the value of the array index of the job, so `1098[0].hostname` would have `PBS_ARRAYID` set to 0. This allows you to create job arrays where each job in the array performs slightly different actions based on the value of this variable, such as performing the same tasks on different input files. One other difference in the environment between jobs in the same array is the value of the `PBS_JOBNAME` variable.

```
# These two examples are equivalent in TORQUE 2.2
> qsub -t 0-99
> qsub -t 100

# You can also pass comma delimited lists of ids and ranges:
> qsub -t 0,10,20,30,40
> qsub -t 0-50,60,70,80
```

Running `qstat` displays a job summary, which provides an overview of the array's state. To see each job in the array, run `qstat -t`.

The `qalter`, `qdel`, `qhold`, and `qrls` commands can operate on arrays—either the entire array or a range of that array. Additionally, any job in the array may be accessed normally by using that job's ID, just as you would with any other job. For example, running the following command would run only the specified job:

```
qrun 1098[0].hostname
```

Slot Limit

The slot limit is a way for administrators to limit the number of jobs from a job array that can be eligible for scheduling at the same time. When a slot limit is used, TORQUE puts a hold on all jobs in the array that exceed the slot limit. When an eligible job in the array completes, TORQUE removes the hold flag from the next job in the array. Slot limits can be declared globally with the [max_slot_limit](#) parameter, or on a per-job basis with [qsub -t](#).

Managing Multi-Node Jobs

By default, when a multi-node job runs, the Mother Superior manages the job across all the sister nodes by communicating with each of them and updating `pbs_server`. Each of the sister nodes sends its updates and stdout and stderr directly to the Mother Superior. When you run an extremely large job using hundreds or thousands of nodes, you may want to reduce the amount of network traffic sent from the sisters to the Mother Superior by specifying a job radix. Job radix sets a maximum number of nodes with which the Mother Superior and resulting intermediate MOMs communicate and is specified using the [-W on page 3509](#) option for `qsub`.

For example, if you submit a smaller, 12-node job and specify `job_radix=3`, Mother Superior and each resulting intermediate MOM is only allowed to receive communication from 3 subordinate nodes.

Image 26-1: Job radix example

The Mother Superior picks three sister nodes with which to communicate the job information. Each of those nodes (intermediate MOMs) receives a list of all sister nodes that will be subordinate to it. They each contact up to three nodes and pass the job information on to those nodes. This pattern continues until the bottom level is reached. All communication is now passed across this new hierarchy. The stdout and stderr data is aggregated and sent up the tree until it reaches the Mother Superior, where it is saved and copied to the `.o` and `.e` files.

i Job radix is meant for extremely large jobs only. It is a tunable parameter and should be adjusted according to local conditions in order to produce the best results.

Requesting Resources

Various resources can be requested at the time of job submission. A job can request a particular node, a particular node attribute, or even a number of nodes with particular attributes. Either native TORQUE resources or external scheduler resource extensions may be specified. The native TORQUE resources are listed in the following table:

Resource	Format	Description
arch	string	Specifies the administrator defined system architecture required. This defaults to whatever the PBS_MACH string is set to in "local.mk".
cput	seconds, or [[HH:]MM:]SS	Maximum amount of CPU time used by all processes in the job.

Resource	Format	Description
cpuclock	string	<p>Specify the CPU clock frequency for each node requested for this job. A cpuclock request applies to every processor on every node in the request. Specifying varying CPU frequencies for different nodes or different processors on nodes in a single job request is not supported.</p> <p>Not all processors support all possible frequencies or ACPI states. If the requested frequency is not supported by the CPU, the nearest frequency is used.</p> <p>ALPS 1.4 or later is required when using cpuclock on Cray.</p> <p>The clock frequency can be specified via:</p> <ul style="list-style-type: none"> a number that indicates the clock frequency (with or without the SI unit suffix). <div data-bbox="706 709 1432 873" data-label="Text"> <pre>qsub -l cpuclock=1800,nodes=2 script.sh qsub -l cpuclock=1800mhz,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to 1800 MHz.</i></p> </div> a Linux power governor policy name. The governor names are: <ul style="list-style-type: none"> performance: This governor instructs Linux to operate each logical processor at its maximum clock frequency. This setting consumes the most power and workload executes at the fastest possible speed. powersave: This governor instructs Linux to operate each logical processor at its minimum clock frequency. This setting executes workload at the slowest possible speed. This setting does not necessarily consume the least amount of power since applications execute slower, and may actually consume more energy because of the additional time needed to complete the workload's execution. ondemand: This governor dynamically switches the logical processor's clock frequency to the maximum value when system load is high and to the minimum value when the system load is low. This setting causes workload to execute at the fastest possible speed or the slowest possible speed, depending on OS load. The system switches between consuming the most power and the least power.

Resource	Format	Description
		<div>  <p>The power saving benefits of <i>ondemand</i> might be non-existent due to frequency switching latency if the system load causes clock frequency changes too often. This has been true for older processors since changing the clock frequency required putting the processor into the C3 "sleep" state, changing its clock frequency, and then waking it up, all of which required a significant amount of time.</p> <p>Newer processors, such as the Intel Xeon E5-2600 Sandy Bridge processors, can change clock frequency dynamically and much faster.</p> </div> <ul style="list-style-type: none"> <i>conservative</i>: This governor operates like the <i>ondemand</i> governor but is more conservative in switching between frequencies. It switches more gradually and uses all possible clock frequencies. <p>This governor can switch to an intermediate clock frequency if it seems appropriate to the system load and usage, which the <i>ondemand</i> governor does not do.</p> <div> <pre>qsub -l cpuclock=performance,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to the performance power governor policy.</i></p> </div> <ul style="list-style-type: none"> an ACPI performance state (or P-state) with or without the P prefix. P-states are a special range of values (0-15) that map to specific frequencies. Not all processors support all 16 states, however, they all start at P0. P0 sets the CPU clock frequency to the highest performance state which runs at the maximum frequency. P15 sets the CPU clock frequency to the lowest performance state which runs at the lowest frequency. <div> <pre>qsub -l cpuclock=3,nodes=2 script.sh</pre> <pre>qsub -l cpuclock=p3,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to a performance state of 3.</i></p> </div> <p>When reviewing job or node properties when cpuclock was used, be mindful of unit conversion. The OS reports frequency in Hz, not MHz or GHz.</p>

Resource	Format	Description
epilogue	string	<p>Specifies a user owned epilogue script which will be run before the system epilogue and epilogue.user scripts at the completion of a job. The syntax is <code>epilogue=<file></code>. The file can be designated with an absolute or relative path.</p> <p>For more information, see Appendix G: Prologue and Epilogue Scripts on page 3575.</p>
feature	string	<p>Specifies a property or feature for the job. Feature corresponds to TORQUE node properties and Moab features.</p> <pre>qsub script.sh -l procs=10,feature=bigmem</pre>
file	size	The amount of total disk requested for the job. (Ignored on Unicos.)
host	string	Name of the host on which the job should be run. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent.
mem	size	<p>Maximum amount of physical memory used by the job. Ignored on Darwin, Digital Unix, Free BSD, HPUX 11, IRIX, NetBSD, and SunOS. Not implemented on AIX and HPUX 10.</p> <p>The <code>mem</code> resource will only work for single-node jobs. If your job requires multiple nodes, use <code>pmem</code> instead.</p>
ncpus	integer	<p>The number of processors in one task where a task cannot span nodes.</p> <div>  You cannot request both <code>ncpus</code> and <code>nodes</code> in the same job. </div>
nice	integer	Number between -20 (highest priority) and 19 (lowest priority). Adjust the process execution priority.

Resource	Format	Description
nodes	{<node_count> <hostname> [:ppn=<ppn>] [:gpus=<gpu>] [:<property> [:<property>]...] [+ ...]	<p>Number and/or type of nodes to be reserved for exclusive use by the job. The value is one or more node_specs joined with the + (plus) character: node_spec [+node_spec...]. Each node_spec is a number of nodes required of the type declared in the node_spec and a name of one or more properties desired for the nodes. The number, the name, and each property in the node_spec are separated by a : (colon). If no number is specified, one (1) is assumed. The name of a node is its hostname. The properties of nodes are:</p> <ul style="list-style-type: none"> • ppn=# - Specify the number of virtual processors per node requested for this job. The number of virtual processors available on a node by default is 1, but it can be configured in the \$TORQUE_HOME/server_priv/nodes file using the np attribute (see Server Node File Configuration on page 3315). The virtual processor can relate to a physical core on the node or it can be interpreted as an "execution slot" such as on sites that set the node np value greater than the number of physical cores (or hyper-thread contexts). The ppn value is a characteristic of the hardware, system, and site, and its value is to be determined by the administrator. • gpus=# - Specify the number of GPUs per node requested for this job. The number of GPUs available on a node can be configured in the \$TORQUE_HOME/server_priv/nodes file using the gpu attribute (see Server Node File Configuration on page 3315). The GPU value is a characteristic of the hardware, system, and site, and its value is to be determined by the administrator. • property - A string assigned by the system administrator specifying a node's features. Check with your administrator as to the node names and properties available to you. <div style="border: 1px solid black; padding: 10px; margin-top: 10px;"> <p>i TORQUE does not have a TPN (tasks per node) property. You can specify TPN in Moab Workload Manager with TORQUE as your resource manager, but TORQUE does not recognize the property when it is submitted directly to it via <code>qsub</code>.</p> </div> <p>See qsub -l nodes on page 3336 for examples.</p> <div style="border: 1px solid black; padding: 10px; margin-top: 10px;"> <p>i By default, the node resource is mapped to a virtual node (that is, directly to a processor, not a full physical compute node). This behavior can be changed within Maui or Moab by setting the <code>JOBNODEMATCHPOLICY</code> parameter. See Appendix A: Moab Parameters on page 1069 for more information.</p> </div>
opsys	string	Specifies the administrator defined operating system as defined in the MOM configuration file.

Resource	Format	Description
other	string	<p>Allows a user to specify site specific information. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent.</p> <div>  This does not work for <code>msub</code> using Moab and Maui. </div>
pccput	seconds, or [[HH:]MM:]SS	Maximum amount of CPU time used by any single process in the job.
pmem	size	Maximum amount of physical memory used by any single process of the job. (Ignored on Fujitsu. Not implemented on Digital Unix and HP-UX.)
procs	procs=<integer>	<p><i>(Applicable in version 2.5.0 and later.)</i> The number of processors to be allocated to a job. The processors can come from one or more qualified node(s). Only one procs declaration may be used per submitted qsub command.</p> <pre>> qsub -l nodes=3 -l procs=2</pre>
procs_bitmap	string	<p>A string made up of 1's and 0's in reverse order of the processor cores requested. A procs_bitmap=1110 means the job requests a node that has four available cores, but the job runs exclusively on cores two, three, and four. With this bitmap, core one is not used.</p> <p>For more information, see Scheduling Cores on page 3370.</p>
prologue	string	<p>Specifies a user owned prologue script which will be run after the system prologue and prologue.user scripts at the beginning of a job. The syntax is <code>prologue=<file></code>. The file can be designated with an absolute or relative path.</p> <p>For more information, see Appendix G: Prologue and Epilogue Scripts on page 3575.</p>
pvmem	size	Maximum amount of virtual memory used by any single process in the job. (Ignored on Unicos.)
size	integer	For TORQUE, this resource has no meaning. It is passed on to the scheduler for interpretation. In the Moab scheduler, the size resource is intended for use in Cray installations only.
software	string	<p>Allows a user to specify software required by the job. This is useful if certain software packages are only available on certain systems in the site. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent. (See License Management on page 794 for more information.)</p>

Resource	Format	Description
vmem	size	Maximum amount of virtual memory used by all concurrent processes in the job. (Ignored on Unicos.)
walltime	seconds, or [[HH:]MM:]SS	Maximum amount of real time during which the job can be in the running state.

size

The size format specifies the maximum amount in terms of bytes or words. It is expressed in the form *integer[*suffix*]*. The suffix is a multiplier defined in the following table ("b" means bytes [the default] and "w" means words). The size of a word is calculated on the execution server as its word size.

Suffix		Multiplier
b	w	1
kb	kw	1024
mb	mw	1,048,576
gb	gw	1,073,741,824
tb	tw	1,099,511,627,776

Example 26-1: `qsub -l nodes`

Usage	Description
<code>> qsub -l nodes=12</code>	Request 12 nodes of any type
<code>> qsub -l nodes=2:server+14</code>	Request 2 "server" nodes and 14 other nodes (a total of 16) - this specifies two node_specs, "2:server" and "14"
<code>> qsub -l nodes=s=server:hippi+10:noserver+3:bigmem:hippi</code>	Request (a) 1 node that is a "server" and has a "hippi" interface, (b) 10 nodes that are not servers, and (c) 3 nodes that have a large amount of memory and have hipp
<code>> qsub -l nodes=b2005+b1803+b1813</code>	Request 3 specific nodes by hostname

Usage	Description
<code>> qsub -l nodes=4:ppn=2</code>	Request 2 processors on each of four nodes
<code>> qsub -l nodes=1:ppn=4</code>	Request 4 processors on one node
<code>> qsub -l nodes=2:blue:ppn=2+red:ppn=3+b1014</code>	Request 2 processors on each of two blue nodes, three processors on one red node, and the compute node "b1014"

Example 26-2:

This job requests a node with 200MB of available memory:

```
> qsub -l mem=200mb /home/user/script.sh
```

Example 26-3:

This job will wait until node01 is free with 200MB of available memory:

```
> qsub -l nodes=node01,mem=200mb /home/user/script.sh
```

Requesting Generic Resources

When **generic** resources have been assigned to nodes using the server's nodes file, these resources can be requested at the time of job submission using the *other* field. (See [Managing Consumable Generic Resources on page 701](#) for details on configuration within Moab).

Example 26-4: Generic

This job will run on any node that has the generic resource **matlab**.

```
> qsub -l other=matlab /home/user/script.sh
```

i This can also be requested at the time of job submission using the `-W x=GRES:matlab` flag.

Related Topics

[Requesting Resources on page 3330](#)

[Job Submission on page 3326](#)

Requesting Floating Resources

When **floating** resources have been set up inside Moab, they can be requested in the same way as **generic** resources. Moab will automatically understand that these resources are floating and will schedule the job accordingly. (See [Managing Shared Cluster Resources \(Floating Resources\)](#) on page 696 for details on configuration within Moab.)

Example 26-5: Floating

This job will run on any node when there are enough floating resources available.

```
> qsub -l other=matlab /home/user/script.sh
```

i This can also be requested at the time of job submission using the `-W x=GRES:matlab` flag.

Exported Batch Environment Variables

When a batch job is started, a number of variables are introduced into the job's environment that can be used by the batch script in making decisions, creating output files, and so forth. These variables are listed in the following table:

Variable	Description
PBS_JOBNAME	User specified jobname
PBS_ARRAYID	Zero-based value of job array index for this job (in version 2.2.0 and later)

Variable	Description
PBS_GPUFILE	Line-delimited list of GPUs allocated to the job located in \$TORQUE_HOME/aux/jobidgpu. Each line follows the following format: <i><host>-gpu<number></i> For example, myhost-gpu1.
PBS_O_WORKDIR	Job's submission directory
PBS_ENVIRONMENT	N/A
PBS_TASKNUM	Number of tasks requested
PBS_O_HOME	Home directory of submitting user
PBS_MOMPORT	Active port for MOM daemon
PBS_O_LOGNAME	Name of submitting user
PBS_O_LANG	Language variable for job
PBS_JOBCOOKIE	Job cookie
PBS_JOBID	Unique pbs job id
PBS_NODENUM	Node offset number
PBS_NUM_NODES	Number of nodes allocated to the job
PBS_NUM_PPN	Number of procs per node allocated to the job
PBS_O_SHELL	Script shell
PBS_O_HOST	Host on which job script is currently running
PBS_QUEUE	Job queue

Variable	Description
PBS_NODEFILE	File containing line delimited list of nodes allocated to the job
PBS_NP	Number of execution slots (cores) for the job
PBS_O_PATH	Path variable used to locate executables within job script

Enabling Trusted Submit Hosts

By default, only the node running the `pbs_server` daemon is allowed to submit jobs. Additional nodes can be trusted as submit hosts by taking any of the following steps:

- Set the **`allow_node_submit`** server parameter (see [Allowing job submission from compute hosts on page 3309](#)).
Allows any host trusted as a compute host to also be trusted as a submit host.
- Set the **`submit_hosts`** server parameter (see [Using the "submit_hosts" service parameter on page 3308](#)).
Allows specified hosts to be trusted as a submit host.
- Use **`.rhosts`** to enable `ruserok()` based authentication (see [Using RCmd authentication on page 3308](#)).

See [Configuring Job Submission Hosts on page 3308](#) for more information.

i When you enable **`allow_node_submit`** on page 3522, you must also enable the **`allow_proxy_user`** on page 3523 parameter to allow user proxying when submitting and running jobs.

Job Files

TORQUE 4.5.0 was updated to accept XML-based job files in addition to the binary job files. The change allows job files to be more human-readable and easier to parse. Below is a sample job file in the new XML format:

```

<?xml version="1.0"?>
<job>
  <version>131842</version>
  <state>1</state>
  <substate>10</substate>
  <server_flags>33</server_flags>
  <start_time>0</start_time>
  <jobid>340</jobid>
  <fileprefix>340</fileprefix>
  <queue>batch</queue>
  <destination_queue></destination_queue>
  <record_type>1</record_type>
  <mom_address>0</mom_address>
  <mom_port>11</mom_port>
  <mom_rmpport>0</mom_rmpport>
  <attributes>
    <Job_Name flags="1">job2.sh</Job_Name>
    <Job_Owner flags="1">echan@moabServer.cn</Job_Owner>
    <job_state flags="1">Q</job_state>
    <queue flags="3">batch</queue>
    <server flags="1">company.com</server>
    <Checkpoint flags="1">u</Checkpoint>
    <ctime flags="1">1384292754</ctime>
    <Error_Path flags="1">moabServer.cn:/home/echan/work/job2.sh.e340</Error_Path>
    <Hold_Types flags="1">n</Hold_Types>
    <Join_Path flags="1">n</Join_Path>
    <Keep_Files flags="1">n</Keep_Files>
    <Mail_Points flags="1">a</Mail_Points>
    <mtime flags="1">1384292754</mtime>
    <Output_Path flags="1">moabServer.cn:/home/echan/work/job2.sh.o340</Output_Path>
    <Priority flags="1">0</Priority>
    <qtime flags="1">1384292754</qtime>
    <Rerunnable flags="1">True</Rerunnable>
    <Resource_List>
      <epilogue flags="1">/tmp/epilogue.sh</epilogue>
      <neednodes flags="1">moabServer:ppn=1</neednodes>
      <nodect flags="1">1</nodect>
      <nodes flags="1">moabServer:ppn=1</nodes>
    </Resource_List>
    <substate flags="1">10</substate>
    <Variable_List flags="1">PBS_O_QUEUE=batch
PBS_O_HOME=/home/echan
PBS_O_LOGNAME=echan
PBS_O_
PATH=/home/echan/eclipse:/usr/lib/lightdm/lightdm:/usr/local/sbin:/usr/local/bin:/usr/
sbin:/usr/bin:/sbin:/bin:/usr/games:/opt/moab/bin:/opt/moab/sbin
PBS_O_SHELL=/bin/bash
PBS_O_LANG=en_US
PBS_O_WORKDIR=/home/echan/work
PBS_O_HOST=moabServer.cn
PBS_O_SERVER=moabServer
</Variable_List>
    <euser flags="1">echan</euser>
    <egroup flags="5">company</egroup>
    <hop_count flags="1">1</hop_count>
    <queue_rank flags="1">2</queue_rank>
    <queue_type flags="1">E</queue_type>
    <etime flags="1">1384292754</etime>
    <submit_args flags="1">-l nodes=lei:ppn=1 -l epilogue=/tmp/epilogue.sh
./job2.sh</submit_args>

    <job_radix flags="1">0</job_radix>
  </attributes>
</job>

```

```
<submit_host flags="1">lei.ac</submit_host>
</attributes>
</job>
```

The above job was submitted with this submit command:

```
qsub -l nodes=moabServer:ppn=1 -l epilogue=/tmp/epilogue.sh ./job2.sh
```

Related Topics

[Job Submission on page 3326](#)

Monitoring Jobs

TORQUE allows users and administrators to monitor submitted jobs with the **qstat** command. If the command is run by a non-administrative user, it will output just that user's jobs. For example:

```
> qstat
Job id          Name          User          Time Use S Queue
-----
4807            scatter      user01        12:56:34 R batch
...
```

Related Topics

[Submitting and Managing Jobs on page 3326](#)

Canceling Jobs

TORQUE allows users and administrators to cancel submitted jobs with the **qdel** command. The job will be sent TERM and KILL signals killing the running processes. When the top-level job script exits, the job will exit. The only parameter is the ID of the job to be canceled.

If a job is canceled by an operator or manager, an email notification will be sent to the user. Operators and managers may add a comment to this email with the **-m** option.

```
$ qstat
Job id          Name          User          Time Use S Queue
-----
4807            scatter      user01        12:56:34 R batch
...
$ qdel -m "hey! Stop abusing the NFS servers" 4807
$
```

[Submitting and Managing Jobs on page 3326](#)

Job Preemption

TORQUE supports job preemption by allowing authorized users to suspend and resume jobs. This is supported using one of two methods. If the node supports OS-level preemption, TORQUE will recognize that during the configure process and enable it. Otherwise, the MOM may be configured to launch a custom *checkpoint script* in order to support preempting a job. Using a custom checkpoint script requires that the job understand how to resume itself from a checkpoint after the preemption occurs.

Configuring a Checkpoint Script on a MOM

To configure the MOM to support a checkpoint script, the `$checkpoint_script` parameter must be set in the MOM's configuration file found in `TORQUE_HOME/mom_priv/config`. The checkpoint script should have execute permissions set. A typical configuration file might look as follows:

`mom_priv/config:`

```
$pbsserver      node06
$logevent       255
$restricted     *.mycluster.org
$checkpoint_script /opt/moab/tools/mom-checkpoint.sh
```

The second thing that must be done to enable the checkpoint script is to change the value of `MOM_CHECKPOINT` to **1** in `/src/include/pbs_config.h`. (In some instances, `MOM_CHECKPOINT` may already be defined as `1`.) The new line should be as follows:

`/src/include/pbs_config.h:`

```
#define MOM_CHECKPOINT 1
```

Related Topics

[Submitting and Managing Jobs on page 3326](#)

Keeping Completed Jobs

TORQUE provides the ability to report on the status of completed jobs for a configurable duration after the job has completed. This can be enabled by setting the [keep_completed on page 3377](#) attribute on the job execution queue or the [keep_completed on page 3529](#) parameter on the server. This should be set to the number of seconds that jobs should be held in the queue. If you set `keep_completed` on the job execution queue, completed jobs will be reported in the **C** state and the exit status is seen in the `exit_status` job attribute.

- i** If the Mother Superior and TORQUE server are on the same server, expect the following behavior:
- When `keep_completed` is set, the job spool files will be deleted when the specified time arrives and TORQUE purges the job from memory.
 - When `keep_completed` is not set, TORQUE deletes the job spool files upon job completion.
 - If you manually purge a job (`qdel -p`) before the job completes or time runs out, TORQUE will never delete the spool files.

By maintaining status information about completed (or canceled, failed, etc.) jobs, administrators can better track failures and improve system performance. This allows TORQUE to better communicate with Moab Workload Manager and track the status of jobs. This gives Moab the ability to track specific failures and to schedule the workload around possible hazards. (See `NOFAILURERESERVETIME` in [Appendix A: Moab Parameters](#) on page 1069 for more information.)

Job Checkpoint and Restart

While TORQUE has had a job checkpoint and restart capability for many years, this was tied to machine specific features. Now TORQUE supports BLCR—an architecture independent package that provides for process checkpoint and restart.

- i** The support for BLCR is only for serial jobs, not for any MPI type jobs.

This section contains these topics:

- [Introduction to BLCR](#) on page 3346
- [Configuration Files and Scripts](#) on page 3346

Introduction to BLCR

BLCR is a kernel level package. It must be downloaded and installed from [BLCR](#).

After building and making the package, it must be installed into the kernel with commands as follows. These can be installed into the file `/etc/modules` but all of the testing was done with explicit invocations of **modprobe**.

Installing BLCR into the kernel:

```
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr_imports.ko
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr_vmadump.ko
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr.ko
```

The BLCR system provides four command line utilities:

- `cr_checkpoint`
- `cr_info`
- `cr_restart`
- `cr_run`

For more information about BLCR, see the [BLCR Administrator's Guide](#).

Related Topics

[Job Checkpoint and Restart on page 3345](#)

Configuration Files and Scripts

Configuring and Building TORQUE for BLCR:

```
> ./configure --enable-unixsockets=no --enable-blcr
> make
> sudo make install
```

Depending on where BLCR is installed you may also need to use the following configure options to specify BLCR paths:

Option	Description
<code>--with-blcr-include=DIR</code>	include path for <code>libcr.h</code>
<code>--with-blcr-lib=DIR</code>	lib path for <code>libcr</code>
<code>--with-blcr-bin=DIR</code>	bin path for BLCR utilities

The `pbs_mom` configuration file located in `/var/spool/torque/mom_priv` must be modified to identify the script names associated with invoking the

BLCR commands. The following variables should be used in the configuration file when using BLCR checkpointing.

Variable	Description
<code>\$checkpoint_interval</code>	How often periodic job checkpoints will be taken (minutes)
<code>\$checkpoint_script</code>	The name of the script file to execute to perform a job checkpoint
<code>\$restart_script</code>	The name of the script file to execute to perform a job restart
<code>\$checkpoint_run_exe</code>	The name of an executable program to be run when starting a checkpointable job (for BLCR, <code>cr_run</code>)

The following example shows the contents of the configuration file used for testing the BLCR feature in TORQUE.

i The script files below must be executable by the user. Be sure to use `chmod` to set the permissions to 754.

Example 26-6: Script file permissions

```
# chmod 754 blcr*
# ls -l
total 20
-rwxr-xr-- 1 root root 2112 2008-03-11 13:14 blcr_checkpoint_script
-rwxr-xr-- 1 root root 1987 2008-03-11 13:14 blcr_restart_script
-rw-r--r-- 1 root root 215 2008-03-11 13:13 config
drwxr-x--x 2 root root 4096 2008-03-11 13:21 jobs
-rw-r--r-- 1 root root 7 2008-03-11 13:15 mom.lock
```

Example 26-7: mom_priv/config

```
$checkpoint_script /var/spool/torque/mom_priv/blcr_checkpoint_script
$restart_script /var/spool/torque/mom_priv/blcr_restart_script
$checkpoint_run_exe /usr/local/bin/cr_run
$pbsserver makua.cridomain
$loglevel 7
```

Example 26-8: mom_priv/blcr_checkpoint_script

```

#!/usr/bin/perl
#####
#
# Usage: checkpoint_script
#
# This script is invoked by pbs_mom to checkpoint a job.
#
#####
use strict;

[Job Checkpoint and Restart on page 3345](#)

Starting a Checkpointable Job

Not every job is checkpointable. A job for which checkpointing is desirable must be started with the `-c` command line option. This option takes a comma-separated list of arguments that are used to control checkpointing behavior. The list of valid options available in the 2.4 version of TORQUE is show below.

Option	Description
none	No checkpointing (not highly useful, but included for completeness).
enabled	Specify that checkpointing is allowed, but must be explicitly invoked by either the <code>qhold</code> or <code>qchkpt</code> commands.
shutdown	Specify that checkpointing is to be done on a job at <code>pbs_mom</code> shutdown.
periodic	Specify that periodic checkpointing is enabled. The default interval is 10 minutes and can be changed by the <code>\$checkpoint_interval</code> option in the MOM configuration file, or by specifying an interval when the job is submitted.
interval=minutes	Specify the checkpoint interval in minutes.
depth=number	Specify a number (depth) of checkpoint images to be kept in the checkpoint directory.
dir=path	Specify a checkpoint directory (default is <code>/var/spool/torque/checkpoint</code>).

Example 26-10: Sample test program

```
#include "stdio.h"
int main( int argc, char *argv[] )
{
    int i;
    for (i=0; i<100; i++)
    {
        printf("i = %d\n", i);
        fflush(stdout);
        sleep(1);
    }
}
```

Example 26-11: Instructions for building test program

```
> gcc -o test test.c
```

Example 26-12: Sample test script

```
#!/bin/bash ./test
```

Example 26-13: Starting the test job

```
> qstat
> qsub -c enabled,periodic,shutdown,interval=1 test.sh
77.jakaa.cridomain
> qstat
```

Job id	Name	User	Time Use	S	Queue
77.jakaa	test.sh	jsmith	0	Q	batch

```
>
```

If you have no scheduler running, you might need to start the job with [grun](#).

As this program runs, it writes its output to a file in `/var/spool/torque/spool`. This file can be observed with the command `tail -f`.

Related Topics

[Job Checkpoint and Restart on page 3345](#)

Checkpointing a Job

Jobs are checkpointed by issuing a [ghold](#) command. This causes an image file representing the state of the process to be written to disk. The directory by default is `/var/spool/torque/checkpoint`.

This default can be altered at the queue level with the `qmgr` command. For example, the command `qmgr -c set queue batch checkpoint_dir=/tmp` would change the checkpoint directory to `/tmp` for the queue 'batch'.

The default directory can also be altered at job submission time with the `-c dir=/tmp` command line option.

The name of the checkpoint directory and the name of the checkpoint image file become attributes of the job and can be observed with the command `qstat -f`. Notice in the output the names **checkpoint_dir** and **checkpoint_name**. The variable `checkpoint_name` is set when the image file is created and will not exist if no checkpoint has been taken.

A job can also be checkpointed without stopping or holding the job with the command [gchkpt](#).

Restarting a Job

Restarting a Job in the Held State

The **grls** command is used to restart the hibernated job. If you were using the `tail -f` command to watch the output file, you will see the test program start counting again.

It is possible to use the **galter** command to change the name of the checkpoint file associated with a job. This could be useful if there were several job checkpoints and it restarting the job from an older image was specified.

Restarting a Job in the Completed State

In this case, the job must be moved to the Queued state with the **grerun** command. Then the job must go to the Run state either by action of the scheduler or if there is no scheduler, through using the **grun** command.

Job Exit Status

Once a job under TORQUE has completed, the `exit_status` attribute will contain the result code returned by the job script. This attribute can be seen by submitting a `qstat -f` command to show the entire set of information associated with a job. The `exit_status` field is found near the bottom of the set of output lines.

Example 26-14: qstat -f (job failure)

```

Job Id: 179.host
Job_Name = STDIN
Job_Owner = user@host
job_state = C
queue = batchq server = host
Checkpoint = u ctime = Fri Aug 29 14:55:55 2008
Error_Path = host:/opt/moab/STDIN.e179
exec_host = node1/0
Hold_Types = n
Join_Path = n
Keep_Files = n
Mail_Points = a
mtime = Fri Aug 29 14:55:55 2008
Output_Path = host:/opt/moab/STDIN.o179
Priority = 0
qtime = Fri Aug 29 14:55:55 2008
Rerunable = True Resource_List.ncpus = 2
Resource_List.nodect = 1
Resource_List.nodes = node1
Variable_List = PBS_O_HOME=/home/user,PBS_O_LOGNAME=user,
PBS_O_PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:,PBS_O_
SHELL=/bin/bash,PBS_O_HOST=host,
PBS_O_WORKDIR=/opt/moab,PBS_O_QUEUE=batchq
sched_hint = Post job file processing error; job 179.host on host node1/0Bad
UID for job execution REJHOST=pala.cridomain MSG=cannot find user 'user' in
password file
etime = Fri Aug 29 14:55:55 2008
exit_status = -1

```

i The value of `Resource_List.*` is the amount of resources requested.

This code can be useful in diagnosing problems with jobs that may have unexpectedly terminated.

If TORQUE was unable to start the job, this field will contain a negative number produced by the `pbs_mom`. Otherwise, if the job script was successfully started, the value in this field will be the return value of the script.

Example 26-15: TORQUE supplied exit codes

Name	Value	Description
JOB_EXEC_OK	0	Job execution successful
JOB_EXEC_FAIL1	-1	Job execution failed, before files, no retry
JOB_EXEC_FAIL2	-2	Job execution failed, after files, no retry
JOB_EXEC_RETRY	-3	Job execution failed, do retry
JOB_EXEC_INITABT	-4	Job aborted on MOM initialization

Name	Value	Description
JOB_EXEC_INITRST	-5	Job aborted on MOM init, chkpt, no migrate
JOB_EXEC_INITRMG	-6	Job aborted on MOM init, chkpt, ok migrate
JOB_EXEC_BADRESRT	-7	Job restart failed
JOB_EXEC_CMDFAIL	-8	Exec() of user command failed
JOB_EXEC_STDOUTFAIL	-9	Could not create/open stdout stderr files
JOB_EXEC_OVERLIMIT_MEM	-10	Job exceeded a memory limit
JOB_EXEC_OVERLIMIT_WT	-11	Job exceeded a walltime limit
JOB_EXEC_OVERLIMIT_CPUT	-12	Job exceeded a CPU time limit

Example 26-16: Exit code from C program

```

$ cat error.c

#include
#include

int
main(int argc, char *argv)
{
    exit(256+11);
}

$ gcc -o error error.c

$ echo ./error | qsub
180.xxx.yyy

$ qstat -f
Job Id: 180.xxx.yyy
  Job_Name = STDIN
  Job_Owner = test.xxx.yyy
  resources_used.cput = 00:00:00
  resources_used.mem = 0kb
  resources_used.vmem = 0kb
  resources_used.walltime = 00:00:00
  job_state = C
  queue = batch
  server = xxx.yyy
  Checkpoint = u
  ctime = Wed Apr 30 11:29:37 2008
  Error_Path = xxx.yyy:/home/test/STDIN.e180
  exec_host = node01/0
  Hold_Types = n
  Join_Path = n
  Keep_Files = n
  Mail_Points = a
  mtime = Wed Apr 30 11:29:37 2008
  Output_Path = xxx.yyy:/home/test/STDIN.o180
  Priority = 0
  qtime = Wed Apr 30 11:29:37 2008
  Rerunnable = True
  Resource_List.needsnodes = 1
  Resource_List.nodect = 1
  Resource_List.nodes = 1
  Resource_List.walltime = 01:00:00
  session_id = 14107
  substate = 59
  Variable_List = PBS_O_HOME=/home/test,PBS_O_LANG=en_US.UTF-8,
    PBS_O_LOGNAME=test,
    PBS_O_PATH=/usr/local/perltests/bin:/home/test/bin:/usr/local/s
    bin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/games,
    PBS_O_SHELL=/bin/bash,PBS_SERVER=xxx.yyy,
    PBS_O_HOST=xxx.yyy,PBS_O_WORKDIR=/home/test,
    PBS_O_QUEUE=batch
  euser = test
  egroup = test
  hashname = 180.xxx.yyy
  queue_rank = 8
  queue_type = E
  comment = Job started on Wed Apr 30 at 11:29
  etime = Wed Apr 30 11:29:37 2008
  exit_status = 11
  start_time = Wed Apr 30 11:29:37 2008
  start_count = 1

```

Notice that the C routine **exit** passes only the low order byte of its argument. In this case, 256+11 is really 267 but the resulting exit code is only 11 as seen in the output.

[Submitting and Managing Jobs on page 3326](#)

Service Jobs

TORQUE service jobs are a special kind of job that is treated differently by TORQUE than normal batch jobs. TORQUE service jobs are *not* related to Moab's dynamic service jobs. A TORQUE service job cannot dynamically grow and shrink in size over time.

Jobs are marked as service jobs at the time they are submitted to Moab or TORQUE. Just like a normal job, a script file is specified with the job. In a batch job, the contents of the script file are taken by TORQUE and executed on the compute nodes. For a service job, however, the script file is assumed to respond to certain command-line arguments. Instead of just executing the script, TORQUE will use these command-line arguments to start, stop, and check on the status of the job. Listed below are the three command-line arguments that must be supported by any script submitted as part of a TORQUE service job:

- **start**: The script should take this argument and launch its service/workload. The script should remain executing/running until the service stops.
- **stop**: The script should take this argument and stop the service/workload that was earlier started.
- **status**: The script should take this argument and return, via standard out, either "running" if the service/workload is running as expected or "stopped" if the service is not running.

This feature was created with long-running services in mind. The command-line arguments should be familiar to users who interact with Unix services, as each of the service scripts found in `/etc/init.d/` also accept and respond to the arguments as explained above.

For example, if a user wants to start the Apache 2 server on a compute node, they can use a TORQUE service job and specify a script which will start, stop, and check on the status of the "httpd" daemon--possibly by using the already present `/etc/init.d/httpd` script.

If you wish to submit service jobs only through TORQUE, no special version of Moab is required. If you wish to submit service jobs using Moab's msub, then Moab 5.4 is required.

For details, see these topics:

- [Submitting Service Jobs](#) on page 3360
- [Submitting Service Jobs in MCM](#) on page 3360
- [Managing Service Jobs](#) on page 3360

Submitting Service Jobs

There is a new option to **qsub**, "-s" which can take either a 'y' or 'n' (yes or no, respectively). When "-s y" is present, then the job is marked as a service job.

```
qsub -l walltime=100:00:00,nodes=1 -s y service_job.py
```

The example above submits a job to TORQUE with a walltime of 100 hours, one node, and it is marked as a service job. The script "service_job.py" will be used to start, stop, and check the status of the service/workload started on the compute nodes.

Moab, as of version 5.4, is able to accept the "-s y" option when **msub** is used for submission. Moab will then pass this information to TORQUE when the job is migrated.

Related Topics

[Service Jobs](#) on page 3359

Submitting Service Jobs in MCM

Submitting a service job in MCM requires the latest Adaptive Computing Suite snapshot of MCM. It also requires MCM to be started with the "--future=2" option.

Once MCM is started, open the **Create Workload** window and verify **Show Advanced Options** is checked. Notice that there is a **Service** checkbox that can be selected in the **Flags/Options** area. Use this to specify the job is a service job.

Related Topics

[Service Jobs](#) on page 3359

Managing Service Jobs

Managing a service job is done much like any other job; only a few differences exist.

Examining the job with **qstat -f** will reveal that the job has the `service = True` attribute. Non-service jobs will not make any mention of the "service" attribute.

Canceling a service job is done with [qdel](#), `mjobctl -c`, or through any of the GUI's as with any other job. TORQUE, however, cancels the job by calling the service script with the "stop" argument instead of killing it directly. This behavior also occurs if the job runs over its wallclock and TORQUE/Moab is configured to cancel the job.

If a service job completes when the script exits after calling it with "start," or if TORQUE invokes the script with "status" and does not get back "running," it will *not* be terminated by using the "stop" argument.

[Service Jobs on page 3359](#)

Managing Nodes

This section contains information about adding and configuring compute nodes. It explains how to work with host security for systems that require dedicated access to compute nodes. It also contains information about scheduling specific cores on a node at job submission.

For details, see these topics:

- [Adding Nodes on page 3361](#)
- [Node Properties on page 3363](#)
- [Changing Node State on page 3363](#)
- [Host Security on page 3366](#)
- [Linux Cpuset Support on page 3368](#)
- [Scheduling Cores on page 3370](#)

Adding Nodes

TORQUE can add and remove nodes either dynamically with [qmgr](#) or by manually editing the `TORQUE_HOME/server_priv/nodes` file. See [Initializing/Configuring TORQUE on the Server \(pbs_server\) on page 3291](#).

i Nodes cannot be added or deleted dynamically if there is a `mom_hierarchy` file in the `server_priv` directory.

i When you make changes to nodes by directly editing the `nodes` file, you must restart `pbs_server` for those changes to take effect. Changes made using `qmgr` do not require a restart.

i Before a newly added node is set to a free state, the cluster must be informed that the new node is valid and they can trust it for running jobs. Once this is done, the node will automatically transition to free.

Run-time Node Changes

TORQUE can dynamically add nodes with the `qmgr` command. For example, the following command will add node **node003**:

```
> qmgr -c 'create node node003[,node004,node005...] [np=n,][TTL=yyyy-mm-ddThh:mm:ssZ,][acl="user==user1:user2:user3",][requestid=n]'
```

The optional parameters are used as follows:

- `np` – Number of virtual processors.
- `TTL` – (Time to Live) Specifies the time in UTC format that the node is supposed to be retired by Moab. Moab will not schedule any jobs on a node after its time to live has passed.
- `acl` – (Access control list) Can be used to control which users have access to the node in Moab.
- `requestid` – An ID that can be used to track the request that created the node.

You can alter the parameters of a node using a set command as follows:

```
qmgr -c 'set node node003 np=y'
qmgr -c 'set node node003 TTL=yyyy-mm-ddThh:mm:ssZ'
qmgr -c 'set node node003 requestid=23234'
qmgr -c 'set node node003 acl="user10,user11,user12"'
qmgr -c 'set node node003 acl+="user5,user6"'
qmgr -c 'set node node003 acl-=user1'
```

i TORQUE does not use the `TTL`, `acl`, and `requestid` parameters. Information for those parameters are simply passed to Moab.

The above command appends the `$TORQUE_HOME/server_priv/nodes` file with:

```
node003 np=3 TTL=2014-08-06T14:30:00Z acl=user1,user2,user3 requestid=3210
node004 ...
```

Nodes can also be removed with a similar command:

```
> qmgr -c 'delete node node003[,node004,node005...]'
```

Related Topics

[Changing Node State on page 3363](#)

[Managing Nodes on page 3361](#)

Node Properties

TORQUE can associate properties with nodes to aid in identifying groups of nodes. It's typical for a site to conglomerate a heterogeneous set of resources. To identify the different sets, properties can be given to each node in a set. For example, a group of nodes that has a higher speed network connection could have the property "ib". TORQUE can set, update, or remove properties either dynamically with [qmgr](#) or by manually editing the `nodes` file.

Run-time Node Changes

TORQUE can dynamically change the properties of a node with the `qmgr` command. For example, note the following to give **node001** the properties of "bigmem" and "dualcore":

```
> qmgr -c "set node node001 properties = bigmem"
> qmgr -c "set node node001 properties += dualcore"
```

To relinquish a stated property, use the `"-="` operator.

Manual Node Changes

The properties of each node are enumerated in `TORQUE_HOME/server_priv/nodes`. The feature(s) must be in a space delimited list after the node name. For example, to give **node001** the properties of "bigmem" and "dualcore" and **node002** the properties of "bigmem" and "matlab," edit the nodes file to contain the following:

`server_priv/nodes:`

```
node001 bigmem dualcore
node002 np=4 bigmem matlab
```

i For changes to the nodes file to be activated, `pbs_server` must be restarted.

i For a full description of this file, please see the *PBS Administrator Guide*.

Related Topics

[Job Submission](#) on page 3326

[Managing Nodes](#) on page 3361

Changing Node State

A common task is to prevent jobs from running on a particular node by marking it *offline* with `pbsnodes -o nodename`. Once a node has been marked offline,

the scheduler will no longer consider it available for new jobs. Simply use `pbsnodes -c nodename` when the node is returned to service.

Also useful is `pbsnodes -l`, which lists all nodes with an interesting state, such as down, unknown, or offline. This provides a quick glance at nodes that might be having a problem. (See [pbsnodes](#) for details.)

Related Topics

[Managing Nodes on page 3361](#)

Changing Node Power States

In TORQUE 8.1.0 and later, the `pbsnodes -m` command can modify the power state of nodes. Node cannot go from one low-power state to another low-power state. They must be brought up to the Running state and then moved to the new low-power state. The supported power states are:

State	Description
Running	<ul style="list-style-type: none">Physical machine is actively workingPower conservation is on a per-device basisProcessor power consumption controlled by P-states
Standby	<ul style="list-style-type: none">System appears offProcessor halted (OS executes a "halt" instruction)Processor maintains CPU and system cache stateRAM refreshed to maintain memory stateMachine in low-power modeRequires interrupt to exit stateLowest-latency sleep state - has no effect on software
Suspend	<ul style="list-style-type: none">System appears offProcessor and support chipset have no powerOS maintains CPU, system cache, and support chipset state in memoryRAM in slow refreshMachine in lowest-power stateUsually requires specific interrupt (keyboard, mouse) to exit stateThird lowest-latency sleep state - system must restore power to processor and support chipset

State	Description
Hibernate	<ul style="list-style-type: none"> • System is off • Physical machine state and memory saved to disk • Requires restoration of power and machine state to exit state • Second highest-latency sleep state - system performs faster boot using saved machine state and copy of memory
Shutdown	<ul style="list-style-type: none"> • Equivalent to <code>shutdown now</code> command as root

In order to wake nodes and bring them up to a running state:

- the nodes must support, and be configured to use, Wake-on-LAN (WOL).
- the `pbsnodes` command must report the node's MAC address correctly.

To configure nodes to use Wake-on-LAN

1. Enable WOL in the BIOS for each node. If needed, contact your hardware manufacturer for details.
2. Use the `ethtool` command to determine what types of WOL packets your hardware supports. TORQUE uses the `g` packet. If the `g` packet is not listed, you cannot use WOL with TORQUE.

```
[root]# ethtool eth0
Settings for eth0:
    Supported ports: [ TP ]
    Supported link modes:   10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Supported pause frame use: No
    Supports auto-negotiation: Yes
    Advertised link modes:  10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Advertised pause frame use: No
    Advertised auto-negotiation: Yes
    Speed: 100Mb/s
    Duplex: Full
    Port: Twisted Pair
    PHYAD: 2
    Transceiver: internal
    Auto-negotiation: on
    MDI-X: off
    Supports Wake-on: pumbg
    Wake-on: p
        Current message level: 0x00000007 (7)
                               drv probe link
    Link detected: yes
```

This Ethernet interface supports the `g` WOL packet, but is currently set to use the `p` packet.

3. If your Ethernet interface supports the `g` packet, but is configured for a

different packet, use `ethtool -s <interface> wol g` to configure it to use `g`.

```
[root]# ethtool -s eth0 wol g
[root]# ethtool eth0
Settings for eth0:
    Supported ports: [ TP ]
    Supported link modes:   10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Supported pause frame use: No
    Supports auto-negotiation: Yes
    Advertised link modes:  10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full
    Advertised pause frame use: No
    Advertised auto-negotiation: Yes
    Speed: 100Mb/s
    Duplex: Full
    Port: Twisted Pair
    PHYAD: 2
    Transceiver: internal
    Auto-negotiation: on
    MDI-X: off
    Supports Wake-on: pumbg
    Wake-on: g
    Current message level: 0x00000007 (7)
                           drv probe link
    Link detected: yes
```

Now the power state of your nodes can be modified and they can be woken up from power-saving states.

Host Security

Enabling PAM with TORQUE

TORQUE is able to take advantage of the authentication services provided through Pluggable Authentication Modules (PAM) to help administrators manage access to compute nodes by users. The PAM module available in TORQUE is located in the PAM security directory. This module, when used in conjunction with other PAM modules, restricts access to the compute node unless the user has a job currently running on the node. The following configurations are examples only. For more information about PAM, see the [PAM \(Pluggable Authentication Modules\) documentation](#) from LinuxDocs.

To enable TORQUE PAM configure TORQUE using the `--with-pam` option. Using `--with-pam` is sufficient but if your PAM security modules are not in the default `/lib/security` or `/lib64/security` directory, you can specify the location using `--with-pam=<DIR>` where `<DIR>` is the directory where you want the modules to be installed. When TORQUE is installed the files `pam_`

`pbssimpleauth.la` and `pam_pbssimpleauth.so` appear in `/lib/security`, `/lib64/security`, or the directory designated on the configuration line.

PAM is very flexible and policies vary greatly from one site to another. The following example restricts users trying to access a node using SSH. Administrators need to assess their own installations and decide how to apply the TORQUE PAM restrictions.

In this example, after installing TORQUE with PAM enabled, you would add the following two lines to `/etc/pam.d/sshd`:

```
account required pam_pbssimpleauth.so
account required pam_access.so
```

In `/etc/security/access.conf` make sure all users who access the compute node are added to the configuration. This is an example which allows the users `root`, `george`, `allen`, and `michael` access.

```
 -:ALL EXCEPT root george allen michael torque:ALL
```

With this configuration, if user `george` has a job currently running on the compute node, `george` can use `ssh` to login to the node. If there are currently no jobs running, `george` is disconnected when attempting to login.

TORQUE PAM is good at keeping users out who do not have jobs running on a compute node. However, it does not have the ability to force a user to log out once they are in. To accomplish this use epilogue or prologue scripts to force users off the system.

Legacy TORQUE PAM Configuration

There is an alternative PAM configuration for TORQUE that has been available since 2006. It can be found in the `contrib/pam_authuser` directory of the source tree. Adaptive Computing does not currently support this method but the instructions are given here for those who are currently using it and for those who wish to use it.

For systems requiring dedicated access to compute nodes (for example, users with sensitive data), TORQUE prologue and epilogue scripts provide a vehicle to leverage the authentication provided by linux-PAM modules. (See [Appendix G: Prologue and Epilogue Scripts on page 3575](#) for more information.)

To allow only users with running jobs (and root) to access compute nodes

1. Untar `contrib/pam_authuser.tar.gz` (found in the src tar ball).
2. Compile `pam_authuser.c` with `make` and `make install` on every compute node.
3. Edit `/etc/system-auth` as described in `README.pam_authuser`, again on every compute node.

4. Either make a tarball of the `epilogue*` and `prologue*` scripts (to preserve the symbolic link) and untar it in the `mom_priv` directory, or just copy `epilogue*` and `prologue*` to `mom_priv/`.

The `prologue*` scripts are Perl scripts that add the user of the job to `/etc/authuser`. The `epilogue*` scripts then remove the first occurrence of the user from `/etc/authuser`. File locking is employed in all scripts to eliminate the chance of race conditions. There is also some commented code in the `epilogue*` scripts, which, if uncommented, kills all processes owned by the user (using `pkill`), provided that the user doesn't have another valid job on the same node.

prologue and **epilogue** scripts were added to the `pam_authuser` tarball in version 2.1 of TORQUE.

- [Configuring Cpuset on page 3369](#)
- [Cpuset Advantages/Disadvantages on page 3369](#)

Cpuset Overview

Linux kernel 2.6 Cpusets are logical, hierarchical groupings of CPUs and units of memory. Once created, individual processes can be placed within a cpuset. The processes will only be allowed to run/access the specified CPUs and memory. Cpusets are managed in a virtual file system mounted at `/dev/cpuset`. New cpusets are created by simply making new directories. Cpusets gain CPUs and memory units by simply writing the unit number to files within the cpuset.

Cpuset Support

i All nodes using cpusets must have the `hwloc` library version 1.2 or higher installed.

When started, `pbs_mom` will create an initial top-level cpuset at `/dev/cpuset/torque`. This cpuset contains all CPUs and memory of the host machine. If this "torqueset" already exists, it will be left unchanged to allow the administrator to override the default behavior. All subsequent cpusets are created within the torqueset.

When a job is started, the jobset is created at `/dev/cpuset/torque/$jobid` and populated with the CPUs listed in the `exec_host job` attribute. Also created are individual tasksets for each CPU within the jobset. This happens before prologue, which allows it to be easily modified, and it happens on all nodes.

The top-level batch script process is executed in the jobset. Tasks launched through the TM interface (`pbsdsh` and `PW's mpiexec`) will be executed within the appropriate taskset.

On job exit, all tasksets and the jobset are deleted.

Configuring Cpuset

To configure cpuset

1. As root, mount the virtual filesystem for cpusets:

```
mkdir /dev/cpuset
mount -t cpuset none /dev/cpuset
```

 Do this for each MOM that is to use cpusets.

2. Because `cpuset` usage is a build-time option in TORQUE, you must add `--enable-cpuset` to your configure options:

```
./configure --enable-cpuset
```

3. Use this configuration for the MOMs across your system.

Cpuset Advantages/Disadvantages

Presently, any job can request a single CPU and proceed to use everything available in the machine. This is occasionally done to circumvent policy, but most often is simply an error on the part of the user. Cpuset support will easily constrain the processes to not interfere with other jobs.

Jobs on larger NUMA systems may see a performance boost if jobs can be intelligently assigned to specific CPUs. Jobs may perform better if striped across physical processors, or contained within the fewest number of memory controllers.

TM tasks are constrained to a single core, thus a multi-threaded process could seriously suffer.

[Geometry Request Configuration on page 3370](#)

Scheduling Cores

In TORQUE 2.4 and later, you can request specific cores on a node at job submission by using geometry requests. To use this feature, specify the **procs_bitmap** resource request of `qsub-l` (see [qsub](#)) at job submission.

See these topics for details:

- [Geometry Request Configuration](#) on page 3370
- [Geometry Request Usage](#) on page 3370
- [Geometry Request Considerations](#) on page 3371

Geometry Request Configuration

A Linux kernel of 2.6 or later is required to use geometry requests, because this feature uses Linux cpusets in its implementation. In order to use this feature, the cpuset directory has to be mounted. For more information on how to mount the cpuset directory, see [Linux Cpuset Support](#) on page 3368. If the operating environment is suitable for geometry requests, configure TORQUE with the `--enable-geometry-requests` option.

```
> ./configure --prefix=/home/john/torque --enable-geometry-requests
```

TORQUE is configured to install to `/home/john/torque` and to enable the geometry requests feature.

i The geometry request feature uses a subset of the cpusets feature. When you configure TORQUE using `--enable-cpuset` and `--enable-geometry-requests` at the same time, and use `-l procs_bitmap=X`, the job will get the requested cpuset. Otherwise, the job is treated as if only `--enable-cpuset` was configured.

Related Topics

[Scheduling Cores](#) on page 3370

Geometry Request Usage

Once enabled, users can submit jobs with a geometry request by using the `procs_bitmap=<string>` resource request. **procs_bitmap** requires a numerical string made up of 1's and 0's. A 0 in the bitmap means the job cannot run on the core that matches the 0's index in the bitmap. The index is in reverse order of the number of cores available. If a job is submitted with `procs_bitmap=1011`, then the job requests a node with four free cores, and uses only cores one, two, and four.

i The geometry request feature requires a node that has all cores free. A job with a geometry request cannot run on a node that has cores that are busy, even if the node has more than enough cores available to run the job.

```
qsub -l procs_bitmap=0011 ossl.sh
```

The job **ossl.sh** is submitted with a geometry request of **0011**.

In the above example, the submitted job can run only on a node that has four cores. When a suitable node is found, the job runs exclusively on cores one and two.

Related Topics

[Scheduling Cores on page 3370](#)

Geometry Request Considerations

As previously stated, jobs with geometry requests require a node with all of its cores available. After the job starts running on the requested cores, the node cannot run other jobs, even if the node has enough free cores to meet the requirements of the other jobs. Once the geometry requesting job is done, the node is available to other jobs again.

Scheduling Accelerator Hardware

TORQUE works with accelerators (such as NVIDIA GPUs and Intel MICs) and can collect and report metrics from them or submit workload to them. This feature requires the use of the Moab scheduler. See [Accelerators on page 948](#) for information on configuring accelerators in TORQUE.

Setting Server Policies

This section explains how to set up and configure your queue. It lists the queue attributes and describes how to set up a routing queue. This section also explains how to set up TORQUE to run in high availability mode. For details, see these topics:

- [Queue Configuration on page 3372](#)
- [Server High Availability on page 3386](#)

Queue Configuration

Under TORQUE, queue configuration is accomplished using the **Server High Availability** command. With this tool, the first step is to create the queue. This is accomplished using the `create` subcommand of `qmgr` as in the following example:

```
> qmgr -c "create queue batch queue_type=execution"
```

Once created, the queue must be configured to be operational. At a minimum, this includes setting the options **started** and **enabled**. Further configuration is possible using any combination of the attributes listed in what follows.

For Boolean attributes, *T*, *t*, *1*, *Y*, and *y* are all synonymous with "TRUE," and *F*, *f*, *0*, *N*, and *n* all mean "FALSE."

For **queue_type**, *E* and *R* are synonymous with "Execution" and "Routing" (respectively).

See these topics for more details:

This section also lists some queue resource limits (see [Assigning Queue Resource Limits](#) on page 3382).

i For Boolean attributes, *T*, *t*, *1*, *Y*, and *y* are all synonymous with "TRUE," and *F*, *f*, *0*, *N*, and *n* all mean "FALSE."

acl_groups	
Format	<GROUP>[@<HOST>][+<USER>[@<HOST>]]...
Default	---
Description	<p>Specifies the list of groups which may submit jobs to the queue. If <code>acl_group_enable</code> is set to true, only users with a primary group listed in <code>acl_groups</code> may utilize the queue.</p> <p>i If the <code>PBSACLUSEGROUPLIST</code> variable is set in the <code>pbs_server</code> environment, <code>acl_groups</code> checks against all groups of which the job user is a member.</p>

acl_groups**Example**

```
> qmgr -c "set queue batch acl_groups=staff"
> qmgr -c "set queue batch acl_groups+=ops@h1"
> qmgr -c "set queue batch acl_groups+=staff@h1"
```

Used in conjunction with [acl_group_enable](#).

acl_group_enable**Format**

<BOOLEAN>

Default

FALSE

Description

If **TRUE**, constrains TORQUE to only allow jobs submitted from groups specified by the [acl_groups](#) parameter.

Example

```
qmgr -c "set queue batch acl_group_enable=true"
```

acl_group_sloppy**Format**

<BOOLEAN>

Default

FALSE

Description

If **TRUE**, [acl_groups](#) will be checked against all groups of which the job users is a member.

Example

acl_hosts**Format**

<HOST>[+<HOST>]...

Default

Description

Specifies the list of hosts that may submit jobs to the queue.

Example

```
qmgr -c "set queue batch acl_hosts=h1+h1+h1"
```

Used in conjunction with [acl_host_enable](#).

acl_host_enable	
Format	<BOOLEAN>
Default	FALSE
Description	If TRUE , constrains TORQUE to only allow jobs submitted from hosts specified by the acl_hosts parameter.
Example	<pre>qmgr -c "set queue batch acl_host_enable=true"</pre>

acl_logic_or	
Format	<BOOLEAN>
Default	FALSE
Description	If TRUE , user and group acls are logically OR'd together, meaning that either acl may be met to allow access. If FALSE or unset, then both acls are AND'd, meaning that both acls must be satisfied.
Example	<pre>qmgr -c "set queue batch acl_logic_or=true"</pre>

acl_users	
Format	<USER>[@<HOST>][+<USER>[@<HOST>]]...
Default	---
Description	Specifies the list of users who may submit jobs to the queue. If acl_user_enable is set to TRUE , only users listed in acl_users may use the queue.
Example	<pre>> qmgr -c "set queue batch acl_users=john" > qmgr -c "set queue batch acl_users+=steve@h1" > qmgr -c "set queue batch acl_users+=stevek@h1"</pre> <div>  Used in conjunction with acl_user_enable. </div>

acl_user_enable

Format	<BOOLEAN>
Default	FALSE
Description	If TRUE , constrains TORQUE to only allow jobs submitted from users specified by the acl_users parameter.
Example	<pre>qmgr -c "set queue batch acl_user_enable=true"</pre>

disallowed_types

Format	<type>[+<type>]...
Default	---
Description	Specifies classes of jobs that are not allowed to be submitted to this queue. Valid types are interactive, batch, rerunable, nonrerunable, fault_tolerant (as of version 2.4.0 and later), fault_intolerant (as of version 2.4.0 and later), and job_array (as of version 2.4.1 and later).
Example	<pre>qmgr -c "set queue batch disallowed_types = interactive" qmgr -c "set queue batch disallowed_types += job_array"</pre>

enabled

Format	<BOOLEAN>
Default	FALSE
Description	Specifies whether the queue accepts new job submissions.
Example	<pre>qmgr -c "set queue batch enabled=true"</pre>

features_required

Format	feature1[feature2[,feature3...]]
---------------	----------------------------------

features_required

Default	---
Description	Specifies that all jobs in this queue will require these features in addition to any they may have requested. A feature is a synonym for a property.
Example	<pre>qmgr -c 's q batch features_required=fast'</pre>

keep_completed

Format	<INTEGER>
Default	0
Description	Specifies the number of seconds jobs should be held in the Completed state after exiting. For more information, see Keeping Completed Jobs on page 3344 .
Example	<pre>qmgr -c "set queue batch keep_completed=120"</pre>

kill_delay

Format	<INTEGER>
Default	2
Description	<p>Specifies the number of seconds between sending a SIGTERM and a SIGKILL to a job in a specific queue that you want to cancel. It is possible that the job script, and any child processes it spawns, can receive several SIGTERM signals before the SIGKILL signal is received.</p> <div>  All MOMs must be configured with <code>\$exec with exec true</code> in order for kill_delay to work, even when relying on default kill_delay settings. </div>
Example	<pre>qmgr -c "set queue batch kill_delay=30"</pre>

max_queuable

Format	<INTEGER>
---------------	-----------

max_queuable

Default	unlimited
Description	Specifies the maximum number of jobs allowed in the queue at any given time (includes idle, running, and blocked jobs).
Example	<pre>qmgr -c "set queue batch max_queuable=20"</pre>

max_running

Format	<INTEGER>
Default	unlimited
Description	Specifies the maximum number of jobs in the queue allowed to run at any given time.
Example	<pre>qmgr -c "set queue batch max_running=20"</pre>

max_user_queuable

Format	<INTEGER>
Default	unlimited
Description	Specifies the maximum number of jobs, per user, allowed in the queue at any given time (includes idle, running, and blocked jobs). Version 2.1.3 and greater.
Example	<pre>qmgr -c "set queue batch max_user_queuable=20"</pre>

max_user_run

Format	<INTEGER>
Default	unlimited
Description	Specifies the maximum number of jobs, per user, in the queue allowed to run at any given time.

max_user_run**Example**

```
qmgr -c "set queue batch max_user_run=10"
```

priority**Format**

<INTEGER>

Default

0

Description

Specifies the priority value associated with the queue.

Example

```
qmgr -c "set queue batch priority=20"
```

queue_type**Format**One of *e*, *execution*, *r*, or *route* (see [Creating a Routing Queue on page 3384](#))**Default**

Description

Specifies the queue type.

This value must be explicitly set for all queues.

Example

```
qmgr -c "set queue batch queue_type=execution"
```

required_login_property**Format**

<STRING>

Default

Description

Adds the specified login property as a requirement for all jobs in this queue.

Example

```
qmgr -c 's q <queuename> required_login_property=INDUSTRIAL'
```

resources_available	
Format	<STRING>
Default	---
Description	Specifies to cumulative resources available to all jobs running in the queue. See qsub will not allow the submission of jobs requesting many processors on page 3425 for more information.
Example	<pre>qmgr -c "set queue batch resources_available.nodect=20"</pre> <div>  You must restart pbs_server for changes to take effect. Also, resources_available is constrained by the smallest of queue.resources_available and server.resources_available. </div>

resources_default	
Format	<STRING>
Default	---
Description	Specifies default resource requirements for jobs submitted to the queue.
Example	<pre>qmgr -c "set queue batch resources_default.walltime=3600"</pre>

resources_max	
Format	<STRING>
Default	---
Description	Specifies the maximum resource limits for jobs submitted to the queue.
Example	<pre>qmgr -c "set queue batch resources_max.nodect=16"</pre>

resources_min	
Format	<STRING>
Default	---
Description	Specifies the minimum resource limits for jobs submitted to the queue.
Example	<pre>qmgr -c "set queue batch resources_min.nodect=2"</pre>

route_destinations	
Format	<queue>[@<host>]
Default	---
Description	Specifies the potential destination queues for jobs submitted to the associated routing queue. <div> This attribute is only valid for routing queues (see Creating a Routing Queue on page 3384).</div>
Example	<pre>> qmgr -c "set queue route route_destinations=fast" > qmgr -c "set queue route route_destinations+=slow" > qmgr -c "set queue route route_destinations+=medium@hostname"</pre> <p>To set multiple queue specifications, use multiple commands:</p> <pre>> qmgr -c 's s route_destinations=batch' > qmgr -c 's s route_destinations+=long' > qmgr -c 's s route_destinations+=short'</pre>

started	
Format	<BOOLEAN>
Default	FALSE
Description	Specifies whether jobs in the queue are allowed to execute.
Example	<pre>qmgr -c "set queue batch started=true"</pre>

Assigning Queue Resource Limits

Administrators can use resources limits to help direct what kind of jobs go to different queues. There are four queue attributes where resource limits can be set: **resources_available**, **resources_default**, **resources_max**, and **resources_min**. The list of supported resources that can be limited with these attributes are *arch*, *mem*, *nodect*, *nodes*, *procct*, *pvmem*, *vmem*, and *walltime*.

Resource	Format	Description
arch	string	Specifies the administrator defined system architecture required.
mem	size	Amount of physical memory used by the job. (Ignored on Darwin, Digital Unix, Free BSD, HPUX 11, IRIX, NetBSD, and SunOS. Also ignored on Linux if number of nodes is not 1. Not implemented on AIX and HPUX 10.)
ncpus	integer	Sets the number of processors in one task where a task cannot span nodes. <div> You cannot request both ncpus and nodes in the same queue.</div>
nodect	integer	Sets the number of nodes available. By default, TORQUE will set the number of nodes available to the number of nodes listed in the <code>\$TORQUE_HOME/server_priv/nodes</code> file. <i>nodect</i> can be set to be greater than or less than that number. Generally, it is used to set the node count higher than the number of physical nodes in the cluster.
nodes	integer	Specifies the number of nodes.
procct	integer	Sets limits on the total number of execution slots (procs) allocated to a job. The number of procs is calculated by summing the products of all node and ppn entries for a job. For example <code>qsub -l nodes=2:ppn=2+3:ppn=4 job.sh</code> would yield a <i>procct</i> of 16. $2*2$ ($2:ppn=2$) + $3*4$ ($3:ppn=4$).
pvmem	size	Amount of virtual memory used by any single process in a job.
vmem	size	Amount of virtual memory used by all concurrent processes in the job.
walltime	seconds, or [[HH:] MM:]SS	Amount of real time during which a job can be in a running state.

size

The size format specifies the maximum amount in terms of bytes or words. It is expressed in the form *integer[*suffix*]*. The suffix is a multiplier defined in the following table ("b" means bytes [the default] and "w" means words). The size of a word is calculated on the execution server as its word size.

Suffix		Multiplier
b	w	1
kb	kw	1024
mb	mw	1,048,576
gb	gw	1,073,741,824
tb	tw	1,099,511,627,776

Related Topics

[Queue Configuration on page 3372](#)

[Example Queue Configuration on page 3383](#)

Example Queue Configuration

The following series of **qmgr** commands will create and configure a queue named batch:

```
qmgr -c "create queue batch queue_type=execution"
qmgr -c "set queue batch started=true"
qmgr -c "set queue batch enabled=true"
qmgr -c "set queue batch resources_default.nodes=1"
qmgr -c "set queue batch resources_default.walltime=3600"
```

This queue will accept new jobs and, if not explicitly specified in the job, will assign a nodecount of 1 and a walltime of 1 hour to each job.

Related Topics

[Queue Configuration on page 3372](#)

Setting a Default Queue

By default, a job must explicitly specify which queue it is to run in. To change this behavior, the server parameter **default_queue** may be specified as in the following example:

```
qmgr -c "set server default_queue=batch"
```

Related Topics

[Queue Configuration on page 3372](#)

Mapping a Queue to Subset of Resources

TORQUE does not currently provide a simple mechanism for mapping queues to nodes. However, schedulers such as Moab and Maui can provide this functionality.

The simplest method is using `default_resources.neednodes` on an execution queue, setting it to a particular node attribute. Maui/Moab will use this information to ensure that jobs in that queue will be assigned nodes with that attribute. For example, suppose we have some nodes bought with money from the chemistry department, and some nodes paid by the biology department.

```
$TORQUE_HOME/server_priv/nodes:
node01 np=2 chem
node02 np=2 chem
node03 np=2 bio
node04 np=2 bio
qmgr:
set queue chem resources_default.neednodes=chem
set queue bio resources_default.neednodes=bio
```

i This example does not preclude other queues from accessing those nodes. One solution is to use some other generic attribute with all other nodes and queues.

More advanced configurations can be made with standing reservations and QoSs.

Related Topics

[Queue Configuration on page 3372](#)

Creating a Routing Queue

A routing queue will steer a job to a destination queue based on job attributes and queue constraints. It is set up by creating a queue of **queue_type** "Route" with a **route_destinations** attribute set, as in the following example.

```

qmgr

# routing queue
create queue route
set queue route queue_type = Route
set queue route route_destinations = reg_64
set queue route route_destinations += reg_32
set queue route route_destinations += reg
set queue route enabled = True
set queue route started = True

# queue for jobs using 1-15 nodes
create queue reg
set queue reg queue_type = Execution
set queue reg resources_min.ncpus = 1
set queue reg resources_min.nodect = 1
set queue reg resources_default.ncpus = 1
set queue reg resources_default.nodes = 1
set queue reg enabled = True
set queue reg started = True

# queue for jobs using 16-31 nodes
create queue reg_32
set queue reg_32 queue_type = Execution
set queue reg_32 resources_min.ncpus = 31
set queue reg_32 resources_min.nodes = 16
set queue reg_32 resources_default.walltime = 12:00:00
set queue reg_32 enabled = True
set queue reg_32 started = True

# queue for jobs using 32+ nodes
create queue reg_64
set queue reg_64 queue_type = Execution
set queue reg_64 resources_min.ncpus = 63
set queue reg_64 resources_min.nodes = 32
set queue reg_64 resources_default.walltime = 06:00:00
set queue reg_64 enabled = True
set queue reg_64 started = True

# have all jobs go through the routing queue
set server default_queue = batch
set server resources_default.ncpus = 1
set server resources_default.walltime = 24:00:00
...

```

In this example, the compute nodes are dual processors and default walltimes are set according to the number of processors/nodes of a job. Jobs with 32 nodes (63 processors) or more will be given a default walltime of 6 hours. Also, jobs with 16-31 nodes (31-62 processors) will be given a default walltime of 12 hours. All other jobs will have the server default walltime of 24 hours.

The ordering of the `route_destinations` is important. In a routing queue, a job is assigned to the first possible destination queue based on the **`resources_max`**, **`resources_min`**, **`acl_users`**, and **`acl_groups`** attributes. In the preceding example, the attributes of a single processor job would first be checked against the `reg_64` queue, then the `reg_32` queue, and finally the `reg` queue.

Adding the following settings to the earlier configuration elucidates the queue resource requirements:

```
qmgr
set queue reg resources_max.ncpus = 30
set queue reg resources_max.nodect = 15
set queue reg_16 resources_max.ncpus = 62
set queue reg_16 resources_max.nodect = 31
```

The time of enforcement of server and queue defaults is important in this example. TORQUE applies server and queue defaults differently in job centric and queue centric modes. For job centric mode, TORQUE waits to apply the server and queue defaults until the job is assigned to its final execution queue. For queue centric mode, it enforces server defaults before it is placed in the routing queue. In either mode, queue defaults override the server defaults. TORQUE defaults to job centric mode. To set queue centric mode, set `queue_centric_limits`, as in what follows:

```
qmgr
set server queue_centric_limits = true
```

An artifact of job centric mode is that if a job does not have an attribute set, the server and routing queue defaults are not applied when queue resource limits are checked. Consequently, a job that requests 32 nodes (not `ncpus=32`) will not be checked against a `min_resource.ncpus` limit. Also, for the preceding example, a job without any attributes set will be placed in the `reg_64` queue, since the server `ncpus` default will be applied after the job is assigned to an execution queue.

i Routine queue defaults are not applied to job attributes in versions 2.1.0 and before.

i If the error message "qsub: Job rejected by all possible destinations" is reported when submitting a job, it may be necessary to add queue location information, (i.e., in the routing queue's **route_destinations** attribute, change "batch" to "batch@localhost").

Server High Availability

You can now run TORQUE in a redundant or high availability mode. This means that there can be multiple instances of the server running and waiting to take over processing in the event that the currently running server fails.

i The high availability feature is available in the 2.3 and later versions of TORQUE. TORQUE 2.4 includes several enhancements to high availability (see [Server High Availability](#) on page 3386).

i Contact Adaptive Computing before attempting to implement any type of high availability.

i The "native" high availability implementation, as described here, is only suitable for Moab Basic Edition. Contact Adaptive Computing for information on high availability for Enterprise Edition.

For more details, see these sections:

- [Redundant server host machines](#) on page 3387
- [Server High Availability](#) on page 3386
- [Enhanced High Availability with Moab](#) on page 3389
- [How Commands Select the Correct Server Host](#) on page 3389
- [Job Names](#) on page 3390
- [Persistence of the pbs_server Process](#) on page 3390
- [High Availability of the NFS Server](#) on page 3390
- [Installing TORQUE in High Availability Mode](#) on page 3390
- [Installing TORQUE in High Availability Mode on Headless Nodes](#) on page 3395
- [Example Setup of High Availability](#) on page 3399

Redundant server host machines

High availability enables Moab HPC Suite to continue running even if pbs_server is brought down. This is done by running multiple copies of pbs_server which have their `torque/server_priv` directory mounted on a shared file system.

i Do not use symlinks when sharing the TORQUE home directory or server_priv directories. A workaround for this is to use `mount --rbind /path/to/share /var/spool/torque`. Also, it is highly recommended that you only share the server_priv and not the entire `$TORQUEHOMEDIR`.

The `torque/server_name` must include the host names of all nodes that run pbs_server. All MOM_nodes also must include the host names of all nodes running pbs_server in their `torque/server_name` file. The syntax of the `torque/server_name` is a comma delimited list of host names.

For example:

```
host1,host2,host3
```

i When configuring high availability, do not use `$pbsserver` to specify the host names. You must use the `$TORQUEHOMEDIR/server_name` file.

All instances of `pbs_server` need to be started with the `--ha` command line option that allows the servers to run at the same time. Only the first server to start will complete the full startup. The second server to start will block very early in the startup when it tries to lock the file `torque/server_priv/server.lock`. When the second server cannot obtain the lock, it will spin in a loop and wait for the lock to clear. The sleep time between checks of the lock file is one second.

Notice that not only can the servers run on independent server hardware, there can also be multiple instances of the `pbs_server` running on the same machine. This was not possible before as the second one to start would always write an error and quit when it could not obtain the lock.

Enabling High Availability

To use high availability, you must start each instance of `pbs_server` with the `--ha` option.

Prior to version 4.0, TORQUE with HA was configured with an `--enable-high-availability` option. That option is no longer required.

Three server options help manage high availability. The server parameters are [lock_file](#), [lock_file_update_time](#), and [lock_file_check_time](#).

The `lock_file` option allows the administrator to change the location of the lock file. The default location is `torque/server_priv`. If the `lock_file` option is used, the new location must be on the shared partition so all servers have access.

The `lock_file_update_time` and `lock_file_check_time` parameters are used by the servers to determine if the primary server is active. The primary `pbs_server` will update the lock file based on the `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs, the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
> qmgr -c "set server lock_file_check_time=5"
```

In the above example, after the primary `pbs_server` goes down, the backup `pbs_server` takes up to 5 seconds to take over. It takes additional time for all MOMs to switch over to the new `pbs_server`.

i The clock on the primary and redundant servers must be synchronized in order for high availability to work. Use a utility such as NTP to ensure your servers have a synchronized time.

i Do not use anything but a plain simple NFS fileshare that is not used by anybody or anything else (i.e., only Moab can use the fileshare).

i Do not use any general-purpose NAS, do not use any parallel file system, and do not use company-wide shared infrastructure to set up Moab high availability using "native" high availability.

Enhanced High Availability with Moab

When TORQUE is run with an external scheduler such as Moab, and the `pbs_server` is not running on the same host as Moab, `pbs_server` needs to know where to find the scheduler. To do this, use the `-l` option as demonstrated in the example below (the port is required and the default is 15004).

```
> pbs_server -l <moabhost:port>
```

If Moab is running in HA mode, add a `-l` option for each redundant server.

```
> pbs_server -l <moabhost1:port> -l <moabhost2:port>
```

If `pbs_server` and Moab run on the same host, use the `--ha` option as demonstrated in the example below.

```
> pbs_server --ha
```

The root user of each Moab host must be added to the **operators** and **managers** lists of the server. This enables Moab to execute root level operations in TORQUE.

How Commands Select the Correct Server Host

The various commands that send messages to `pbs_server` usually have an option of specifying the server name on the command line, or if none is specified will use the default server name. The default server name comes either from the environment variable `PBS_DEFAULT` or from the file `torque/server_name`.

When a command is executed and no explicit server is mentioned, an attempt is made to connect to the first server name in the list of hosts from `PBS_DEFAULT` or `torque/server_name`. If this fails, the next server name is tried. If all servers in the list are unreachable, an error is returned and the command fails.

Note that there is a period of time after the failure of the current server during which the new server is starting up where it is unable to process commands. The new server must read the existing configuration and job information from the disk, so the length of time that commands cannot be received varies. Commands issued during this period of time might fail due to timeouts expiring.

Job Names

Job names normally contain the name of the host machine where `pbs_server` is running. When job names are constructed, only the server name in `$PBS_DEFAULT` or the first name from the server specification list, `$TORQUE_HOME/server_name`, is used in building the job name.

Persistence of the `pbs_server` Process

The system administrator must ensure that `pbs_server` continues to run on the server nodes. This could be as simple as a *cron* job that counts the number of `pbs_server`'s in the process table and starts some more if needed.

High Availability of the NFS Server

 Before installing a specific NFS HA solution please contact Adaptive Computing Support for a detailed discussion on NFS HA type and implementation path.

One consideration of this implementation is that it depends on NFS file system also being redundant. NFS can be set up as a redundant service. See the following.

- [Setting Up A Highly Available NFS Server](#)
- [Making NFS Work On Your Network](#)
- [Sourceforge Linux NFS FAQ](#)
- [NFS v4 main site](#)

There are also other ways to set up a shared file system. See the following:

- [Red Hat Global File System](#)
- [Data sharing with a GFS storage cluster](#)

Installing TORQUE in High Availability Mode

The following procedure demonstrates a TORQUE installation in high availability (HA) mode.

Requirements

- gcc (GCC) 4.1.2
- BASH shell
- Servers configured the following way:
 - 2 main servers with identical architecture:
 - `server1` — Primary server running TORQUE with a shared file system (this example uses NFS)
 - `server2` — Secondary server running with TORQUE with a shared file system (this example uses NFS)
 - `fileServer` — Shared file system (this example uses NFS)
 - Compute nodes

To install TORQUE in HA mode

1. Stop all firewalls or update your firewall to allow traffic from TORQUE services.

```
> service iptables stop
> chkconfig iptables off
```

If you are unable to stop the firewall due to infrastructure restriction, open the following ports:

- 15001[tcp,udp]
- 15002[tcp,udp]
- 15003[tcp,udp]

2. Disable SELinux

```
> vi /etc/sysconfig/selinux

SELINUX=disabled
```

3. Update your main `~/.bashrc` profile to ensure you are always referencing the applications to be installed on all servers.

```
# TORQUE
export TORQUEHOME=/var/spool/torque

# Library Path
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:${TORQUEHOME}/lib

# Update system paths
export PATH=${TORQUEHOME}/bin:${TORQUEHOME}/sbin:${PATH}
```

4. Verify `server1` and `server2` are resolvable via either DNS or looking for an entry in the `/etc/hosts` file.
5. Configure the NFS Mounts by following these steps:

- a. Create mount point folders on fileServer.

```
fileServer# mkdir -m 0755 /var/spool/torque
fileServer# mkdir -m 0750 /var/spool/torque/server_priv
```

- b. Update /etc/exports on fileServer. The IP addresses should be that of server2.

```
/var/spool/torque/server_priv 192.168.0.0/255.255.255.0(rw, sync, no_root_squash)
```

- c. Update the list of NFS exported file systems.

```
fileServer# exportfs -r
```

6. If the NFS daemons are not already running on fileServer, start them.

```
> systemctl restart rpcbind.service
> systemctl start nfs-server.service
> systemctl start nfs-lock.service
> systemctl start nfs-idmap.service
```

7. Mount the exported file systems on server1 by following these steps:

- a. Create the directory reference and mount them.

```
server1# mkdir /var/spool/torque/server_priv
```

Repeat this process for server2.

- b. Update /etc/fstab on server1 to ensure that NFS mount is performed on startup.

```
fileServer:/var/spool/torque/server_priv /var/spool/torque/server_priv nfs
rsiz= 8192,wsiz=8192,timeo=14,intr
```

Repeat this step for server2.

8. Install TORQUE by following these steps:

- a. Download and extract TORQUE 5.1.0 on server1.

```
server1# wget http://github.com/adaptivecomputing/torque/
branches/<version>/torque-<version>.tar.gz
server1# tar -xvzf torque-<version>.tar.gz
```

- b. Navigate to the TORQUE directory and compile TORQUE on server1.

```
server1# configure
server1# make
server1# make install
server1# make packages
```

- c. If the installation directory is shared on both head nodes, then run make install on server1.

```
server1# make install
```

If the installation directory is not shared, repeat step 8a-b (downloading and installing TORQUE) on `server2`.

9. Start `trqauthd`.

```
server1# /etc/init.d/trqauthd start
```

10. Configure TORQUE for HA.

- a. List the host names of all nodes that run `pbs_server` in the `torque/server_name` file. You must also include the host names of all nodes running `pbs_server` in the `torque/server_name` file of each MOM node. The syntax of `torque/server_name` is a comma-delimited list of host names.

```
server1
server2
```

- b. Create a simple queue configuration for TORQUE job queues on `server1`.

```
server1# pbs_server -t create
server1# qmgr -c "set server scheduling=true"
server1# qmgr -c "create queue batch queue_type=execution"
server1# qmgr -c "set queue batch started=true"
server1# qmgr -c "set queue batch enabled=true"
server1# qmgr -c "set queue batch resources_default.nodes=1"
server1# qmgr -c "set queue batch resources_default.walltime=3600"
server1# qmgr -c "set server default_queue=batch"
```

i Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- c. Add the root users of TORQUE to the TORQUE configuration as an operator and manager.

```
server1# qmgr -c "set server managers += root@server1"
server1# qmgr -c "set server managers += root@server2"
server1# qmgr -c "set server operators += root@server1"
server1# qmgr -c "set server operators += root@server2"
```

i Because `server_priv/*` is a shared drive, you do not need to repeat this step on Server 2.

- d. You must update the lock file mechanism for TORQUE in order to determine which server is the primary. To do so, use the `lock_file_update_time` and `lock_file_check_time` parameters. The primary `pbs_server` will update the lock file based on the specified `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs,

the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
server1# qmgr -c "set server lock_file_check_time=5"
server1# qmgr -c "set server lock_file_update_time=3"
```

i Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- e. List the servers running `pbs_server` in the TORQUE `acl_hosts` file.

```
server1# qmgr -c "set server acl_hosts += server1"
server1# qmgr -c "set server acl_hosts += server2"
```

i Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- f. Restart the running `pbs_server` in HA mode.

```
server1# qterm
```

- g. Start the `pbs_server` on the secondary server.

```
server1# pbs_server --ha -l server2:port
server2# pbs_server --ha -l server1:port
```

11. Check the status of TORQUE in HA mode.

```
server1# qmgr -c "p s"
server2# qmgr -c "p s"
```

The commands above returns all settings from the active TORQUE server from either node.

Drop one of the `pbs_servers` to verify that the secondary server picks up the request.

```
server1# qterm
server2# qmgr -c "p s"
```

Stop the `pbs_server` on `server2` and restart `pbs_server` on `server1` to verify that both nodes can handle a request from the other.

12. Install a `pbs_mom` on the compute nodes.

- a. Copy the install scripts to the compute nodes and install.
- b. Navigate to the shared source directory of TORQUE and run the following:

```
node1# torque-package-mom-linux-x86_64.sh --install
node2# torque-package-clients-linux-x86_64.sh --install
```

Repeat this for each compute node. Verify that the `/var/spool/torque/server-name` file shows all your compute nodes.

- c. On `server1` or `server2`, configure the nodes file to identify all available MOMs. To do so, edit the `/var/spool/torque/server_priv/nodes` file.

```
node1 np=2
node2 np=2
```

i Change the `np` flag to reflect number of available processors on that node.

- d. Recycle the `pbs_servers` to verify that they pick up the MOM configuration.

```
server1# qterm; pbs_server --ha -l server2:port
server2# qterm; pbs_server --ha -l server1:port
```

- e. Start the `pbs_mom` on each execution node.

```
node5# pbs_mom
node6# pbs_mom
```

Installing TORQUE in High Availability Mode on Headless Nodes

The following procedure demonstrates a TORQUE installation in high availability (HA) mode on nodes with no local hard drive.

Requirements

- gcc (GCC) 4.1.2
- BASH shell
- Servers (these cannot be two VMs on the same hypervisor) configured the following way:
 - 2 main servers with identical architecture
 - `server1` — Primary server running TORQUE with a file system share (this example uses NFS)
 - `server2` — Secondary server running with TORQUE with a file system share (this example uses NFS)
 - Compute nodes
 - `fileServer` — A shared file system server (this example uses NFS)

To install TORQUE in HA mode on a node with no local hard drive

1. Stop all firewalls or update your firewall to allow traffic from TORQUE services.

```
> service iptables stop
> chkconfig iptables off
```

If you are unable to stop the firewall due to infrastructure restriction, open the following ports:

- 15001[tcp,udp]
- 15002[tcp,udp]
- 15003[tcp,udp]

2. Disable SELinux

```
> vi /etc/sysconfig/selinux
SELINUX=disabled
```

3. Update your main ~/.bashrc profile to ensure you are always referencing the applications to be installed on all servers.

```
# TORQUE
export TORQUEHOME=/var/spool/torque

# Library Path
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:${TORQUEHOME}/lib

# Update system paths
export PATH=${TORQUEHOME}/bin:${TORQUEHOME}/sbin:$ {PATH}
```

4. Verify server1 and server2 are resolvable via either DNS or looking for an entry in the /etc/hosts file.

5. Configure the NFS Mounts by following these steps:

a. Create mount point folders on fileServer.

```
fileServer# mkdir -m 0755 /var/spool/torque
```

b. Update /etc/exports on fileServer. The IP addresses should be that of server2.

```
/var/spool/torque/ 192.168.0.0/255.255.255.0(rw,sync,no_root_squash)
```

c. Update the list of NFS exported file systems.

```
fileServer# exportfs -r
```

6. If the NFS daemons are not already running on fileServer, start them.

```
> systemctl restart rpcbind.service
> systemctl start nfs-server.service
> systemctl start nfs-lock.service
> systemctl start nfs-idmap.service
```

7. Mount the exported file systems on server1 by following these steps:

a. Create the directory reference and mount them.

```
server1# mkdir /var/spool/torque
```

Repeat this process for `server2`.

- b. Update `/etc/fstab` on `server1` to ensure that NFS mount is performed on startup.

```
fileServer:/var/spool/torque/server_priv /var/spool/torque/server_priv nfs
rsiz= 8192,wsiz=8192,timeo=14,intr
```

Repeat this step for `server2`.

8. Install TORQUE by following these steps:

- a. Download and extract TORQUE 5.1.0 on `server1`.

```
server1# wget http://github.com/adaptivecomputing/torque/
branches/<version>/torque-<version>.tar.gz
server1# tar -xvzf torque-<version>.tar.gz
```

- b. Navigate to the TORQUE directory and compile TORQUE with the HA flag on `server1`.

```
server1# configure --prefix=/var/spool/torque
server1# make
server1# make install
server1# make packages
```

- c. If the installation directory is shared on both head nodes, then run `make install` on `server1`.

```
server1# make install
```

If the installation directory is not shared, repeat step 8a-b (downloading and installing TORQUE) on `server2`.

9. Start `trqauthd`.

```
server1# /etc/init.d/trqauthd start
```

10. Configure TORQUE for HA.

- a. List the host names of all nodes that run `pbs_server` in the `torque/server_name` file. You must also include the host names of all nodes running `pbs_server` in the `torque/server_name` file of each MOM node. The syntax of `torque/server_name` is a comma-delimited list of host names.

```
server1,server2
```

- b. Create a simple queue configuration for TORQUE job queues on `server1`.

```
server1# pbs_server -t create
server1# qmgr -c "set server scheduling=true"
server1# qmgr -c "create queue batch queue_type=execution"
server1# qmgr -c "set queue batch started=true"
server1# qmgr -c "set queue batch enabled=true"
server1# qmgr -c "set queue batch resources_default.nodes=1"
server1# qmgr -c "set queue batch resources_default.walltime=3600"
server1# qmgr -c "set server default_queue=batch"
```

i Because TORQUEHOME is a shared drive, you do not need to repeat this step on server2.

- c. Add the root users of TORQUE to the TORQUE configuration as an operator and manager.

```
server1# qmgr -c "set server managers += root@server1"
server1# qmgr -c "set server managers += root@server2"
server1# qmgr -c "set server operators += root@server1"
server1# qmgr -c "set server operators += root@server2"
```

i Because TORQUEHOME is a shared drive, you do not need to repeat this step on server2.

- d. You must update the lock file mechanism for TORQUE in order to determine which server is the primary. To do so, use the `lock_file_update_time` and `lock_file_check_time` parameters. The primary `pbs_server` will update the lock file based on the specified `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs, the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
server1# qmgr -c "set server lock_file_check_time=5"
server1# qmgr -c "set server lock_file_update_time=3"
```

i Because TORQUEHOME is a shared drive, you do not need to repeat this step on server2.

- e. List the servers running `pbs_server` in the TORQUE `acl_hosts` file.

```
server1# qmgr -c "set server acl_hosts += server1"
server1# qmgr -c "set server acl_hosts += server2"
```

i Because TORQUEHOME is a shared drive, you do not need to repeat this step on server2.

- f. Restart the running `pbs_server` in HA mode.

```
server1# qterm
```

- g. Start the `pbs_server` on the secondary server.

```
server1# pbs_server --ha -l server2:port
server2# pbs_server --ha -l server1:port
```

11. Check the status of TORQUE in HA mode.

```
server1# qmgr -c "p s"
server2# qmgr -c "p s"
```

The commands above returns all settings from the active TORQUE server from either node.

Drop one of the `pbs_servers` to verify that the secondary server picks up the request.

```
server1# qterm
server2# qmgr -c "p s"
```

Stop the `pbs_server` on `server2` and restart `pbs_server` on `server1` to verify that both nodes can handle a request from the other.

12. Install a `pbs_mom` on the compute nodes.

- a. On `server1` or `server2`, configure the `nodes` file to identify all available MOMs. To do so, edit the `/var/spool/torque/server_priv/nodes` file.

```
node1 np=2
node2 np=2
```

i Change the `np` flag to reflect number of available processors on that node.

- b. Recycle the `pbs_servers` to verify that they pick up the MOM configuration.

```
server1# qterm; pbs_server --ha -l server2:port
server2# qterm; pbs_server --ha -l server1:port
```

- c. Start the `pbs_mom` on each execution node.

```
server1# pbs_mom -d <mom-server1>
server2# pbs_mom -d <mom-server2>
```

Example Setup of High Availability

1. The machines running `pbs_server` must have access to a shared `server_priv/` directory (usually an NFS share on a MoM).
2. All MoMs must have the same content in their `server_name` file. This can be done manually or via an NFS share. The `server_name` file contains a comma-delimited list of the hosts that run `pbs_server`.

```
# List of all servers running pbs_server
server1,server2
```

3. The machines running pbs_server must be listed in [acl_hosts](#).

```
> qmgr -c "set server acl_hosts += server1"
> qmgr -c "set server acl_hosts += server2"
```

4. Start pbs_server with the --ha option.

```
[root@server1]$ pbs_server --ha
[root@server2]$ pbs_server --ha
```

[Setting Server Policies on page 3371](#)

[Queue Configuration on page 3372](#)

Setting min_threads and max_threads

There are two threadpools in TORQUE, one for background tasks and one for incoming requests from the MOMs and through the API (client commands, Moab, and so forth). The [min_threads on page 3534](#) and [max_threads on page 3533](#) parameters control the number of total threads used for both, not for each individually. The incoming requests' threadpool has three-quarters of **min_threads** for its minimum, and three-quarters of **max_threads** for its maximum, with the background pool receiving the other one-quarter.

Additionally, pbs_server no longer allows incoming requests to pile up indefinitely. When the threadpool is too busy for incoming requests, it indicates such, returning PBSE_SERVER_BUSY with the accompanying message that "Pbs Server is currently too busy to service this request. Please retry this request." The threshold for this message, if the request is from a manager, is that at least two threads be available in the threadpool. If the request comes from a non-manager, 5% of the threadpool must be available for the request to be serviced. Note that availability is calculated based on the maximum threads and not based on the current number of threads allocated.

If an undesirably large number of requests are given a busy response, one option is to increase the number of maximum threads for the threadpool. If the load on the server is already very high, then this is probably not going to help, but if the CPU load is lower, then it may help. Remember that by default the threadpool shrinks down once the extra threads are no longer needed. This is controlled via the [thread_idle_seconds on page 3539](#) server parameter.

i Any change in the **min_threads**, **max_threads**, or **thread_idle_seconds** parameters requires a restart of pbs_server to take effect.

Integrating Schedulers for TORQUE

Selecting the cluster scheduler is an important decision and significantly affects cluster utilization, responsiveness, availability, and intelligence. The default TORQUE scheduler, `pbs_sched`, is very basic and will provide poor utilization of your cluster's resources. Other options, such as Maui Scheduler or Moab Workload Manager, are highly recommended. If you are using Maui or Moab, see [Moab-TORQUE Integration Guide on page 1377](#). If using `pbs_sched`, simply start the `pbs_sched` daemon.

i If you are installing Moab Cluster Manager, TORQUE and Moab were configured at installation for interoperability and no further action is required.

Configuring Data Management

This section contains information about SCP-based data management with TORQUE. It describes how to use TORQUE with NFS and other networked filesystems. It also outlines file staging requirements. For details, see these topics:

- [SCP Setup on page 3401](#)
- [NFS and Other Networked Filesystems on page 3404](#)
- [File stage-in/stage-out on page 3405](#)

SCP Setup

To use SCP-based data management, TORQUE must be authorized to migrate data to any of the compute nodes. If this is not already enabled within the cluster, this can be achieved with the process described below. This process enables uni-directional access for a particular user from a *source* host to a *destination* host.

i These directions were written using [OpenSSH version 3.6](#) and may not transfer correctly to older versions.

To set up TORQUE for SCP, follow the directions in each of these topics:

- [Generating SSH Key on Source Host on page 3402](#)
- [Copying Public SSH Key to Each Destination Host on page 3402](#)

- [Configuring the SSH Daemon on Each Destination Host on page 3403](#)
- [Validating Correct SSH Configuration on page 3403](#)
- [Enabling Bi-Directional SCP Access on page 3403](#)
- [Compiling TORQUE to Support SCP on page 3404](#)
- [Troubleshooting on page 3404](#)

Related Topics

[Configuring Data Management on page 3401](#)

Generating SSH Key on Source Host

On the source host as the transfer user, execute the following:

```
> ssh-keygen -t rsa
```

This will prompt for a passphrase (optional) and create two files (`id_rsa` and `id_rsa.pub`) inside `~/.ssh/`.

Related Topics

[SCP Setup on page 3401](#)

[Copying Public SSH Key to Each Destination Host on page 3402](#)

Copying Public SSH Key to Each Destination Host

Transfer public key to each destination host as the transfer user:

Easy key copy:

```
ssh-copy-id [-i [identity_file]] [user@]machine
```

Manual steps to copy keys:

```
> scp ~/.ssh/id_rsa.pub destHost:~ (enter password)
```

Create an `authorized_keys` file on each destination host:

```
> ssh destHost (enter password)
> cat id_rsa.pub >> .ssh/authorized_keys
```

If the `.ssh` directory does not exist, create it with 700 privileges (`mkdir .ssh;`
`chmod 700 .ssh`):

```
> chmod 700 .ssh/authorized_keys
```

Related Topics

[Generating SSH Key on Source Host on page 3402](#)

[SCP Setup on page 3401](#)

Configuring the SSH Daemon on Each Destination Host

Some configuration of the SSH daemon may be required on the destination host. (Because this is not always the case, see [Validating Correct SSH Configuration on page 3403](#) and test the changes made to this point. If the tests fail, proceed with this step and then try testing again.) Typically, this is done by editing the `/etc/ssh/sshd_config` file (root access needed). To verify correct configuration, see that the following attributes are set (not commented):

```

RSAAuthentication yes
PubkeyAuthentication yes

```

If configuration changes were required, the SSH daemon will need to be restarted (root access needed):

```
> /etc/init.d/sshd restart
```

Related Topics

[SCP Setup on page 3401](#)

Validating Correct SSH Configuration

If all is properly configured, the following command issued on the *source* host should succeed and not prompt for a password:

```
> scp destHost:/etc/motd /tmp
```

i If this is your first time accessing *destination* from *source*, it may ask you if you want to add the fingerprint to a file of known hosts. If you specify yes, this message should no longer appear and should not interfere with scp copying via TORQUE. Also, it is important that the full hostname appear in the `known_hosts` file. To do this, use the full hostname for *destHost*, as in `machine.domain.org` instead of just `machine`.

Related Topics

[SCP Setup on page 3401](#)

Enabling Bi-Directional SCP Access

The preceding steps allow *source* access to destination without prompting for a password. The reverse, however, is not true. Repeat the steps, but this time using the *destination* as the *source*, etc. to enable bi-directional SCP access (i.e. *source* can send to *destination* and *destination* can send to *source* without password prompts.)

Compiling TORQUE to Support SCP

i In TORQUE 2.1 and later, SCP is the default remote copy protocol. These instructions are only necessary for earlier versions.

TORQUE must be re-configured (and then rebuilt) to use SCP by passing in the `--with-scp` flag to the configure script:

```
> ./configure --prefix=xxx --with-scp
> make
```

i If special SCP flags are required in your local setup, these can be specified using the `$rcpcmd` parameter.

Related Topics

[SCP Setup on page 3401](#)

Troubleshooting

If, after following all of the instructions in this section (see [SCP Setup on page 3401](#)), TORQUE is still having problems transferring data with SCP, set the `PBSDEBUG` environment variable and restart the `pbs_mom` for details about copying. Also check the MOM log files for more details.

Related Topics

[SCP Setup on page 3401](#)

NFS and Other Networked Filesystems

When a batch job starts, its `stdin` file (if specified) is copied from the submission directory on the remote submission host. This file is placed in the `$PBSMOMHOME` directory on the mother superior node (i.e., `/usr/spool/PBS/spool`). As the job runs, `stdout` and `stderr` files are generated and placed in this directory using the naming convention `$JOBID.OU` and `$JOBID.ER`.

When the job completes, the MOM copies the files into the directory from which the job was submitted. By default, this file copying will be accomplished using a remote copy facility such as `rcp` or `scp`.

If a shared file system such as NFS, DFS, or AFS is available, a site can specify that the MOM should take advantage of this by specifying the `$usecp` directive inside the MOM configuration file (located in the `$PBSMOMHOME/mom_priv` directory) using the following format:

```
$usecp <HOST>:<SRCDIR> <DSTDIR>
```

<HOST> can be specified with a leading wildcard ('*') character. The following example demonstrates this directive:

```
mom_priv/config
# /home is NFS mounted on all hosts
$usecp */home /home
# submission hosts in domain fte.com should map '/data' directory on submit host to
# '/usr/local/data' on compute host
$usecp *.fte.com:/data /usr/local/data
```

If for any reason the MOM daemon is unable to copy the output or error files to the submission directory, these files are instead copied to the `undelivered` directory also located in `$PBSMOMHOME`.

Related Topics

[Configuring Data Management on page 3401](#)

File stage-in/stage-out

File staging requirements are specified using the `stagein` and `stageout` directives of the `qsub` command. Stagein requests occur before the job starts execution, while stageout requests happen after a job completes.

On completion of the job, all staged-in and staged-out files are removed from the execution system. The `file_list` is in the form `local_file@hostname:remote_file[,...]` regardless of the direction of the copy. The name `local_file` is the name of the file on the system where the job executed. It may be an absolute path or relative to the home directory of the user. The name `remote_file` is the destination name on the host specified by `hostname`. The name may be absolute or relative to the user's home directory on the destination host. The use of wildcards in the file name is not recommended.

The file names map to a remote copy program (`rcp/scp/cp`, depending on configuration) called on the execution system in the following manner:

For stagein: `rcp/scp hostname:remote_file local_file`

For stageout: `rcp/scp local_file hostname:remote_file`

Examples

```
# stage /home/john/input_source.txt from node13.fsc to /home/john/input_
destination.txt on master compute node
> qsub -l nodes=1,walltime=100 -W stagein=input_
source.txt@node13.fsc:/home/john/input_destination.txt

# stage /home/bill/output_source.txt on master compute node to /tmp/output_
destination.txt on node15.fsc
> qsub -l nodes=1,walltime=100 -W stageout=/tmp/output_
source.txt@node15.fsc:/home/bill/output_destination.txt
```

```
$ fortune >xxx;echo cat xxx|qsub -W stagein=xxx@`hostname`:xxx
199.myhost.mydomain
$ cat STDIN*199
Anyone who has had a bull by the tail knows five or six more things
than someone who hasn't.

MPI (Message Passing Interface) Support

A message passing library is used by parallel jobs to augment communication between the tasks distributed across the cluster. TORQUE can run with any message passing library and provides limited integration with some [MPI](#) libraries.

For more information, see these topics:

- [MPICH on page 3406](#)
- [Open MPI on page 3408](#)

MPICH

One of the most popular MPI libraries is [MPICH](#) available from [Argonne National Lab](#). If using this release, you may want to consider also using the [mpiexec](#) tool for launching MPI applications. Support for mpiexec has been integrated into TORQUE.

MPIExec Overview

mpiexec is a replacement program for the script *mpirun*, which is part of the *mpich* package. It is used to initialize a parallel job from within a PBS batch or interactive environment. mpiexec uses the task manager library of PBS to spawn copies of the executable on the nodes in a PBS allocation.

Reasons to use mpiexec rather than a script (mpirun) or an external daemon (mpd):

- Starting tasks with the task manager (TM) interface is much faster than invoking a separate rsh * once for each process.
- Resources used by the spawned processes are accounted correctly with mpiexec, and reported in the PBS logs, because all the processes of a parallel job remain under the control of PBS, unlike when using mpirun-like scripts.

- Tasks that exceed their assigned limits of CPU time, wallclock time, memory usage, or disk space are killed cleanly by PBS. It is quite hard for processes to escape control of the resource manager when using `mpiexec`.
- You can use `mpiexec` to enforce a security policy. If all jobs are forced to spawn using `mpiexec` and the PBS execution environment, it is not necessary to enable `rsh` or `ssh` access to the compute nodes in the cluster.

For more information, see the [mpiexec](#) homepage.

MPIExec Troubleshooting

Although problems with `mpiexec` are rare, if issues do occur, the following steps may be useful:

- Determine current version using `mpiexec --version` and review the [change log](#) available on the [MPI homepage](#) to determine if the reported issue has already been corrected.
- Send email to the `mpiexec` mailing list at mpiexec@osc.edu.
- Browse the `mpiexec` user list [archives](#) for similar problems and resolutions.
- Read the FAQ contained in the `README` file and the `mpiexec` man pages contained within the `mpiexec` distribution.
- Increase the logging of `mpiexec` operation with `mpiexec --verbose` (reports messages to `stderr`).
- Increase logging of the master and slave resource manager execution daemons associated with the job (with TORQUE, use `$loglevel` to 5 or higher in `$TORQUE_ROOT/mom_priv/config` and look for '`tm`' messages after associated `join job` messages).
- Use `tracejob` (included with TORQUE) or `qtracejob` (included with OSC's `pbstools` package) to isolate failures within the cluster.
- If the message `'exec: Error: get_hosts: pbs_connect: Access from host not allowed, or unknown host'` appears, this indicates that `mpiexec` cannot communicate with the `pbs_server` daemon. In most cases, this indicates that the `$TORQUE_ROOT/server_name` file points to the wrong server or the node cannot resolve the server's name. The [qstat](#) command can be run on the node to test this.

General MPI Troubleshooting

When using MPICH, some sites have issues with orphaned MPI child processes remaining on the system after the master MPI process has been terminated. To address this, TORQUE epilogue scripts can be created that properly clean up the orphaned processes (see [Appendix G: Prologue and Epilogue Scripts on page 3575](#)).

[MPI \(Message Passing Interface\) Support on page 3406](#)

Open MPI

[Open MPI](#) is a new MPI implementation that combines technologies from multiple projects to create the best possible library. It supports the TM interface for integration with TORQUE. More information is available in the [FAQ](#).

Related Topics

[MPI \(Message Passing Interface\) Support on page 3406](#)

Resources

A primary task of any resource manager is to monitor the state, health, configuration, and utilization of managed resources. TORQUE is specifically designed to monitor compute hosts for use in a batch environment. TORQUE is not designed to monitor non-compute host resources such as software licenses, networks, file systems, and so forth, although these resources can be integrated into the cluster using some scheduling systems.

With regard to monitoring compute nodes, TORQUE reports about a number of attributes broken into three major categories:

- [Configuration on page 3408](#)
- [Utilization on page 3409](#)
- [Node States on page 3410](#)

Configuration

Configuration includes both detected hardware configuration and specified batch attributes.

Attribute	Description	Details
Architecture (arch)	operating system of the node	The value reported is a derivative of the operating system installed.

Attribute	Description	Details
Node Features (properties)	arbitrary string attributes associated with the node	No node features are specified by default. If required, they are set using the <code>nodes</code> file located in the <code>TORQUE_HOME/server_priv</code> directory. They may specify any string and are most commonly used to allow users to request certain subsets of nodes when submitting jobs.
Local Disk (size)	configured local disk	By default, local disk space is not monitored. If the MOM configuration size [fs=<FS>] parameter is set, TORQUE will report, in kilobytes, configured disk space within the specified directory.
Memory (physmem)	local memory/RAM	Local memory/RAM is monitored and reported in kilobytes.
Processors (ncpus/np)	real/virtual processors	The number of processors detected by TORQUE is reported via the <code>ncpus</code> attribute. However, for scheduling purposes, other factors are taken into account. In its default configuration, TORQUE operates in "dedicated" mode with each node possessing a single virtual processor. In dedicated mode, each job task will consume one virtual processor and TORQUE will accept workload on each node until all virtual processors on that node are in use. While the number of virtual processors per node defaults to 1, this may be configured using the <code>nodes</code> file located in the <code>TORQUE_HOME/server_priv</code> directory. An alternative to dedicated mode is "timeshared" mode. If TORQUE's time-shared mode is enabled, TORQUE will accept additional workload on each node until the node's <i>maxload</i> limit is reached.
Swap (totmem)	virtual memory/Swap	Virtual memory/Swap is monitored and reported in kilobytes.

Utilization

Utilization includes information regarding the amount of node resources currently in use as well as information about who or what is consuming it.

Attribute	Description	Details
Disk (size)	local disk availability	By default, local disk space is not monitored. If the MOM configuration size [fs=<FS>] parameter is set, TORQUE will report configured and currently available disk space within the specified directory in kilobytes.
Memory (availmem)	real memory/RAM	Available real memory/RAM is monitored and reported in kilobytes.

Attribute	Description	Details
Network (netload)	local network adapter usage	Reports total number of bytes transferred in or out by the network adapter.
Processor Utilization (loadave)	node's cpu load average	Reports the node's 1 minute bsd load average.

Node States

State information includes administrative status, general node health information, and general usage status.

Attribute	Description	Details
Idle Time (idletime)	time since local keyboard/mouse activity has been detected	Time in seconds since local keyboard/mouse activity has been detected.
State (state)	monitored/admin node state	<p>A node can be in one or more of the following states:</p> <ul style="list-style-type: none"> • <i>busy</i> - node is full and will not accept additional work • <i>down</i> - node is failing to report, is detecting local failures with node • <i>free</i> - node is ready to accept additional work • <i>job-exclusive</i> - all available virtual processors are assigned to jobs • <i>job-sharing</i> - node has been allocated to run multiple shared jobs and will remain in this state until jobs are complete • <i>offline</i> - node has been instructed by an admin to no longer accept work • <i>reserve</i> - node has been reserved by the server • <i>time-shared</i> - node always allows multiple jobs to run concurrently • <i>unknown</i> - node has not been detected

Accounting Records

TORQUE maintains accounting records for batch jobs in the following directory:

```
$TORQUEROOT/server_priv/accounting/<TIMESTAMP>
```

`$TORQUEROOT` defaults to `/usr/spool/PBS` and `<TIMESTAMP>` is in the format: `YYYYMMDD`.

These records include events, time stamps, and information on resources requested and used.

Records for four different event types are produced and are described in the following table:

Record marker	Record type	Description
A	abort	Job has been aborted by the server
C	checkpoint	Job has been checkpointed and held
D	delete	Job has been deleted
E	exit	Job has exited (either successfully or unsuccessfully)
Q	queue	Job has been submitted/queued
R	rerun	Attempt to rerun the job has been made
S	start	Attempt to start the job has been made (if the job fails to properly start, it may have multiple job start records)
T	restart	Attempt to restart the job (from checkpoint) has been made (if the job fails to properly start, it may have multiple job start records)

Accounting Variables

The following table offers accounting variable descriptions. Descriptions for accounting variables not indicated in the table, particularly those prefixed with **Resources_List**, are available at [Job Submission on page 3326](#).

Variable	Description
ctime	Time job was created
etime	Time job became eligible to run
qtime	Time job was queued
start	Time job started to run

A sample record in this file can look like the following:

```
08/26/2014 17:07:44;Q;11923.napali;queue=batch
08/26/2014 17:07:50;S;11923.napali;user=dbeer group=company jobname=STDIN queue=batch
ctime=1409094464 qtime=1409094464 etime=1409094464 start=1409094470 owner=dbeer@napali
exec_host=napali/0+napali/1+napali/2+napali/3+napali/4+napali/5+torque-devtest-
03/0+torque-devtest-03/1+torque-devtest-03/2+torque-devtest-03/3+torque-devtest-
03/4+torque-devtest-03/5 Resource_List.nodes=2:ppn=6 Resource_List.nodect=2
Resource_List.nodes=2:ppn=6
08/26/2014 17:08:04;E;11923.napali;user=dbeer group=company jobname=STDIN queue=batch
ctime=1409094464 qtime=1409094464 etime=1409094464 start=1409094470 owner=dbeer@napali
exec_host=napali/0+napali/1+napali/2+napali/3+napali/4+napali/5+torque-devtest-
03/0+torque-devtest-03/1+torque-devtest-03/2+torque-devtest-03/3+torque-devtest-
03/4+torque-devtest-03/5 Resource_List.nodes=2:ppn=6 Resource_List.nodect=2
Resource_List.nodes=2:ppn=6 session=11352 total_execution_slots=12 unique_node_count=2
end=1409094484 Exit_status=265 resources_used.cput=00:00:00 resources_used.mem=82700kb
resources_used.vmem=208960kb resources_used.walltime=00:00:14 Error_Path=/dev/pts/11
Output_Path=/dev/pts/11
```

i The value of `Resource_List.*` is the amount of resources requested, and the value of `resources_used.*` is the amount of resources actually used.

i `total_execution_slots` and `unique_node_count` display additional information regarding the job resource usage.

Job Logging

New in TORQUE 2.5.3 is the ability to log job information for completed jobs. The information stored in the log file is the same information produced with the command `qstat -f`. The log file data is stored using an XML format. Data can be extracted from the log using the utility `showjobs` found in the `contrib/` directory of the TORQUE source tree. Custom scripts that can parse the XML data can also be used.

For details about job logging, see these topics:

- [Job Log Location and Name on page 3412](#)
- [Enabling Job Logs on page 3413](#)

Job Log Location and Name

When job logging is enabled (See [Enabling Job Logs on page 3413](#).), the job log is kept at `$TORQUE_HOME/job_logs`. The naming convention for the job log is the same as for the server log or MOM log. The log name is created from the current year/month/day.

For example, if today's date is 26 October, 2010 the log file is named 20101026.

A new log file is created each new day that data is written to the log.

Related Topics

[Enabling Job Logs on page 3413](#)

[Job Logging on page 3412](#)

Enabling Job Logs

There are five new server parameters used to enable job logging. These parameters control what information is stored in the log and manage the log files.

Parameter	Description
record_job_info	This must be set to true in order for job logging to be enabled. If not set to true, the remaining server parameters are ignored.
record_job_script	If set to true, this adds the contents of the script executed by a job to the log.
job_log_file_max_size	This specifies a soft limit (in kilobytes) for the job log's maximum size. The file size is checked every five minutes and if the <i>current day</i> file size is greater than or equal to this value, it is rolled from <i><filename></i> to <i><filename.1></i> and a new empty log is opened. If the current day file size exceeds the maximum size a second time, the <i><filename.1></i> log file is rolled to <i><filename.2></i> , the current log is rolled to <i><filename.1></i> , and a new empty log is opened. Each new log causes all other logs to roll to an extension that is one greater than its current number. Any value less than 0 is ignored by pbs_server (meaning the log will not be rolled).
job_log_file_roll_depth	This sets the maximum number of new log files that are kept in a day if the job_log_file_max_size parameter is set. For example, if the roll depth is set to 3, no file can roll higher than <i><filename.3></i> . If a file is already at the specified depth, such as <i><filename.3></i> , the file is deleted so it can be replaced by the incoming file roll, <i><filename.2></i> .
job_log_keep_days	This maintains logs for the number of days designated. If set to 4, any log file older than 4 days old is deleted.

[Job Logging on page 3412](#)

Troubleshooting

There are a few general strategies that can be followed to determine the cause of unexpected behavior. These are a few of the tools available to help determine where problems occur. See these topics for details:

- [Host Resolution on page 3414](#)
- [Firewall Configuration on page 3414](#)
- [TORQUE Log Files on page 3415](#)
- [Using "tracejob" to Locate Job Failures on page 3416](#)
- [Using GDB to Locate Job Failures on page 3419](#)
- [Other Diagnostic Options on page 3420](#)
- [Stuck Jobs on page 3420](#)
- [Frequently Asked Questions \(FAQ\) on page 3421](#)
- [Compute Node Health Check on page 3427](#)
- [Debugging on page 3430](#)

Host Resolution

The TORQUE server host must be able to perform both forward and reverse name lookup on itself and on all compute nodes. Likewise, each compute node must be able to perform forward and reverse name lookup on itself, the TORQUE server host, and all other compute nodes. In many cases, name resolution is handled by configuring the node's `/etc/hosts` file although *DNS* and *NIS* services may also be used. Commands such as `nslookup` or `dig` can be used to verify proper host resolution.

i Invalid host resolution may exhibit itself with compute nodes reporting as down within the output of `pbsnodes`-a and with failure of the `momctl`-d3 command.

Related Topics

[Troubleshooting on page 3414](#)

Firewall Configuration

Be sure that, if you have firewalls running on the server or node machines, you allow connections on the appropriate ports for each machine. TORQUE `pbs_mom` daemons use UDP ports 1023 and below if privileged ports are configured

(privileged ports is the default). The `pbs_server` and `pbs_mom` daemons use TCP and UDP ports 15001-15004 by default.

Firewall based issues are often associated with server to MOM communication failures and messages such as 'premature end of message' in the log files.

Also, the `tcpdump` program can be used to verify the correct network packets are being sent.

Related Topics

[Troubleshooting on page 3414](#)

TORQUE Log Files

`pbs_server` and `pbs_mom` Log Files

The `pbs_server` keeps a daily log of all activity in the `TORQUE_HOME/server_logs` directory. The `pbs_mom` also keeps a daily log of all activity in the `TORQUE_HOME/mom_logs/` directory. These logs contain information on communication between server and MOM as well as information on jobs as they enter the queue and as they are dispatched, run, and terminated. These logs can be very helpful in determining general job failures. For MOM logs, the verbosity of the logging can be adjusted by setting the `$loglevel` parameter in the `mom_priv/config` file. For server logs, the verbosity of the logging can be adjusted by setting the server `log_level` attribute in `qmgr`.

For both `pbs_mom` and `pbs_server` daemons, the log verbosity level can also be adjusted by setting the environment variable **PBSLOGLEVEL** to a value between 0 and 7. Further, to dynamically change the log level of a running daemon, use the `SIGUSR1` and `SIGUSR2` signals to increase and decrease the active loglevel by one. Signals are sent to a process using the `kill` command.

For example, `kill -USR1 `pgrep pbs_mom`` would raise the log level up by one.

The current loglevel for `pbs_mom` can be displayed with the command `momctl -d3`.

`trqauthd` Log Files

As of TORQUE 4.1.3, `trqauthd` logs its events in the `$TORQUE_HOME/client_logs` directory. It names the log files in the format `<YYYYMMDD>`, creating a new log daily as events occur.

i You might see some peculiar behavior if you mount the `client_logs` directory for shared access via network-attached storage.

When `trqauthd` first gets access on a particular day, it writes an "open" message to the day's log file. It also writes a "close" message to the last log file it accessed prior to that, which is usually the previous day's log file, but not always. For example, if it is Monday and no client commands were executed over the weekend, `trqauthd` writes the "close" message to Friday's file.

Since the various `trqauthd` binaries on the submit hosts (and potentially, the compute nodes) each write an "open" and "close" message on the first access of a new day, you'll see multiple (seemingly random) accesses when you have a shared log.

The `trqauthd` records the following events along with the date and time of the occurrence:

- When `trqauthd` successfully starts. It logs the event with the IP address and port.
- When a user successfully authenticates with `trqauthd`.
- When a user fails to authenticate with `trqauthd`.
- When `trqauthd` encounters any unexpected errors.

Example 26-17: trqauthd logging sample

```
2012-10-05 15:05:51.8404 Log opened
2012-10-05 15:05:51.8405 TORQUE authd daemon started and listening on IP:port
101.0.1.0:12345
2012-10-10 14:48:05.5688 User hfrye at IP:port abc:12345 logged in
```

[Troubleshooting on page 3414](#)

Using "tracejob" to Locate Job Failures

Overview

The *tracejob* utility extracts job status and job events from accounting records, MOM log files, server log files, and scheduler log files. Using it can help identify where, how, a why a job failed. This tool takes a job id as a parameter as well as arguments to specify which logs to search, how far into the past to search, and other conditions.

Syntax

```
tracejob [-a|s|l|m|q|v|z] [-c count] [-w size] [-p path] [ -n
<DAYS>] [-f filter_type] <JOBID>
```

```
-p : path to PBS_SERVER_HOME
-w : number of columns of your terminal
-n : number of days in the past to look for job(s) [default
1]
-f : filter out types of log entries, multiple -f's can be
specified
      error, system, admin, job, job_usage, security, sched,
debug,
      debug2, or absolute numeric hex equivalent
-z : toggle filtering excessive messages
-c : what message count is considered excessive
-a : don't use accounting log files
-s : don't use server log files
-l : don't use scheduler log files
-m : don't use MOM log files
-q : quiet mode - hide all error messages
-v : verbose mode - show more error messages
```

Example

```
> tracejob -n 10 1131
Job: 1131.icluster.org
03/02/2005 17:58:28 S enqueueing into batch, state 1 hop 1

```

i The `tracejob` command operates by searching the `pbs_server` accounting records and the `pbs_server`, MOM, and scheduler logs. To function properly, it must be run on a node and as a user which can access these files. By default, these files are all accessible by the user root and only available on the cluster management node. In particular, the files required by `tracejob` are located in the following directories:

```
TORQUE_HOME/server_priv/accounting
TORQUE_HOME/server_logs
TORQUE_HOME/mom_logs
TORQUE_HOME/sched_logs
```

i `tracejob` may only be used on systems where these files are made available. Non-root users may be able to use this command if the permissions on these directories or files are changed appropriately.

i The value of `Resource_List.*` is the amount of resources requested, and the value of `resources_used.*` is the amount of resources actually used.

Using GDB to Locate Job Failures

If either the `pbs_mom` or `pbs_server` fail unexpectedly (and the log files contain no information on the failure) `gdb` can be used to determine whether or not the program is crashing. To start `pbs_mom` or `pbs_server` under [GDB](#) export the environment variable `PBSDEBUG=yes` and start the program (i.e., `gdb pbs_mom` and then issue the `run` subcommand at the `gdb` prompt).

`GDB` may run for some time until a failure occurs and at which point, a message will be printed to the screen and a `gdb` prompt again made available. If this occurs, use the `gdb where` subcommand to determine the exact location in the code. The information provided may be adequate to allow local diagnosis and correction. If not, this output may be sent to the mailing list or to [help](#) for further assistance.

i See the `PBSCOREDUMP` parameter for enabling creation of core files (see [Debugging on page 3430](#)).

[Troubleshooting on page 3414](#)

Other Diagnostic Options

When *PBSDEBUG* is set, some client commands will print additional diagnostic information.

```
$ export PBSDEBUG=yes
$ cmd
```

To debug different kinds of problems, it can be useful to see where in the code time is being spent. This is called profiling and there is a Linux utility "gprof" that will output a listing of routines and the amount of time spent in these routines. This does require that the code be compiled with special options to instrument the code and to produce a file, gmon.out, that will be written at the end of program execution.

The following listing shows how to build TORQUE with profiling enabled. Notice that the output file for pbs_mom will end up in the *mom_priv* directory because its startup code changes the default directory to this location.

```
# ./configure "CFLAGS=-pg -lgcov -fPIC"
# make -j5
# make install
# pbs_mom ... do some stuff for a while ...
# momctl -s
# cd /var/spool/torque/mom_priv
# gprof -b `which pbs_mom` gmon.out |less
#
```

Another way to see areas where a program is spending most of its time is with the valgrind program. The advantage of using valgrind is that the programs do not have to be specially compiled.

```
# valgrind --tool=callgrind pbs_mom
```

Stuck Jobs

If a job gets stuck in TORQUE, try these suggestions to resolve the issue:

- Use the [qdel](#) command to cancel the job.
- Force the MOM to send an obituary of the job ID to the server.

```
> qsig -s 0 <JOBID>
```

- You can try clearing the stale jobs by using the [momctl](#) command on the compute nodes where the jobs are still listed.

```
> momctl -c 58925 -h compute-5-20
```

- Setting the **qmgr** server setting `mom_job_sync` to *True* might help prevent jobs from hanging.

```
> qmgr -c "set server mom_job_sync = True"
```

To check and see if this is already set, use:

```
> qmgr -c "p s"
```

- If the suggestions above cannot remove the stuck job, you can try **qdel** -p. However, since the -p option purges all information generated by the job, this is not a recommended option unless the above suggestions fail to remove the stuck job.

```
> qdel -p <JOBID>
```

- The last suggestion for removing stuck jobs from compute nodes is to restart the `pbs_mom`.

For additional troubleshooting, run a tracejob on one of the stuck jobs. You can then create an [online support ticket](#) with the full server log for the time period displayed in the trace job.

Cannot connect to server: error=15034

This error occurs in TORQUE clients (or their APIs) because TORQUE cannot find the `server_name` file and/or the `PBS_DEFAULT` environment variable is not set. The `server_name` file or `PBS_DEFAULT` variable indicate the `pbs_server`'s hostname that the client tools should communicate with. The `server_name` file is usually located in TORQUE's local state directory. Make sure the file exists, has proper permissions, and that the version of TORQUE you are running was built with the proper directory settings. Alternatively you can set the `PBS_DEFAULT` environment variable. Restart TORQUE daemons if you make changes to these settings.

Deleting 'stuck' jobs

To manually delete a "stale" job which has no process, and for which the mother superior is still alive, sending a sig 0 with `qsig` will often cause MOM to realize the job is stale and issue the proper JobObit notice. Failing that, use **`momctl -c`** to forcefully cause MOM to purge the job. The following process should never be necessary:

- Shut down the MOM on the mother superior node.
- Delete all files and directories related to the job from `TORQUE_HOME/mom_priv/jobs`.
- Restart the MOM on the mother superior node.

If the mother superior MOM has been lost and cannot be recovered (i.e. hardware or disk failure), a job running on that node can be purged from the output of **`qstat`** using the [`qdel` on page 3472](#) `-p` command or can be removed manually using the following steps:

To remove job X

1. Shut down `pbs_server`.

```
> qterm
```

2. Remove job pool files.

```
> rm TORQUE_HOME/server_priv/jobs/X.SC TORQUE_HOME/server_priv/jobs/X.JB
```

3. Restart pbs_server

```
> pbs_server
```

Which user must run TORQUE?

TORQUE (pbs_server & pbs_mom) must be started by a user with root privileges.

Scheduler cannot run jobs - rc: 15003

For a scheduler, such as Moab or Maui, to control jobs with TORQUE, the scheduler needs to be run by a user in the server operators / managers list (see [gmgr](#)). The default for the server operators / managers list is root@localhost. For TORQUE to be used in a grid setting with Silver, the scheduler needs to be run as root.

PBS_Server: pbsd_init, Unable to read server database

If this message is displayed upon starting pbs_server it means that the local database cannot be read. This can be for several reasons. The most likely is a version mismatch. Most versions of TORQUE can read each other's databases. However, there are a few incompatibilities between OpenPBS and TORQUE. Because of enhancements to TORQUE, it cannot read the job database of an OpenPBS server (job structure sizes have been altered to increase functionality). Also, a compiled in 32-bit mode cannot read a database generated by a 64-bit pbs_server and vice versa.

To reconstruct a database (excluding the job database)

1. First, print out the old data with this command:

```
%> qmgr -c "p s"
#
# Create queues and set their attributes.
#
#
# Create and define queue batch
# create queue batch
set queue batch queue_type = Execution
set queue batch acl_host_enable = False
set queue batch resources_max.nodect = 6
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch resources_available.nodect = 18
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server managers = griduser@oahu.icluster.org
set server managers += scott@*.icluster.org
set server managers += wightman@*.icluster.org
set server operators = griduser@oahu.icluster.org
set server operators += scott@*.icluster.org
set server operators += wightman@*.icluster.org
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server resources_available.nodect = 80
set server node_ping_rate = 300
set server node_check_rate = 600
set server tcp_timeout = 6
```

2. Copy this information somewhere.
3. Restart pbs_server with the following command:

```
> pbs_server -t create
```

4. When you are prompted to overwrite the previous database, enter y, then enter the data exported by the qmgr command as in this example:

```
> cat data | qmgr
```

5. Restart pbs_server without the flags:

```
> qterm
> pbs_server
```

This will reinitialize the database to the current version.

i Reinitializing the server database will reset the next jobid to 1

qsub will not allow the submission of jobs requesting many processors

TORQUE's definition of a node is context sensitive and can appear inconsistent. The `qsub -l nodes=<X>` expression can at times indicate a request for X processors and other time be interpreted as a request for X nodes. While `qsub` allows multiple interpretations of the keyword nodes, aspects of the TORQUE server's logic are not so flexible. Consequently, if a job is using `-l nodes` to specify processor count and the requested number of processors exceeds the available number of physical nodes, the server daemon will reject the job.

To get around this issue, the server can be told it has an inflated number of nodes using the `resources_available` attribute. To take effect, this attribute should be set on both the server and the associated queue as in the example below. (See [resources_available](#) for more information.)

```
> qmgr
Qmgr: set server resources_available.nodect=2048
Qmgr: set queue batch resources_available.nodect=2048
```

i The `pbs_server` daemon will need to be restarted before these changes will take effect.

qsub reports 'Bad UID for job execution'

```
[guest@login2]$ qsub test.job
qsub: Bad UID for job execution
```

Job submission hosts must be explicitly specified within TORQUE or enabled via RCmd security mechanisms in order to be trusted. In the example above, the host 'login2' is not configured to be trusted. This process is documented in [Configuring Job Submission Hosts on page 3308](#).

Why does my job keep bouncing from running to queued?

There are several reasons why a job will fail to start. Do you see any errors in the MOM logs? Be sure to increase the loglevel on MOM if you don't see anything. Also be sure TORQUE is configured with `--enable-syslog` and look in `/var/log/messages` (or wherever your syslog writes).

Also verify the following on all machines:

- DNS resolution works correctly with matching forward and reverse
- Time is synchronized across the head and compute nodes
- User accounts exist on all compute nodes
- User home directories can be mounted on all compute nodes
- Prologue scripts (if specified) exit with 0

If using a scheduler such as Moab or Maui, use a scheduler tool such as `checkjob` to identify job start issues.

How do I use PVM with TORQUE?

- Start the master pvmd on a compute node and then add the slaves
- `mpiexec` can be used to launch slaves using `rsh` or `ssh` (use `export PVM_RSH=/usr/bin/ssh` to use `ssh`)

i Access can be managed by `rsh/ssh` without passwords between the batch nodes, but denying it from anywhere else, including the interactive nodes. This can be done with `xinetd` and `sshd` configuration (root is allowed to `ssh` everywhere). This way, the `pvm` daemons can be started and killed from the job script.

The problem is that this setup allows the users to bypass the batch system by writing a job script that uses `rsh/ssh` to launch processes on the batch nodes. If there are relatively few users and they can more or less be trusted, this setup can work.

My build fails attempting to use the TCL library

TORQUE builds can fail on TCL dependencies even if a version of TCL is available on the system. TCL is only utilized to support the `xpbsmon` client. If your site does not use this tool (most sites do not use `xpbsmon`), you can work around this failure by rerunning `configure` with the `--disable-gui` argument.

My job will not start, failing with the message 'cannot send job to mom, state=PRERUN'

If a node crashes or other major system failures occur, it is possible that a job may be stuck in a corrupt state on a compute node. TORQUE 2.2.0 and higher automatically handle this when the `mom_job_sync` parameter is set via [qmgr](#) (the default). For earlier versions of TORQUE, set this parameter and restart the `pbs_mom` daemon.

This error can also occur if not enough free space is available on the partition that holds TORQUE.

How do I determine what version of TORQUE I am using?

There are times when you want to find out what version of TORQUE you are using. An easy way to do this is to run the following command:

```
qmgr
> qmgr -c "p s" | grep pbs_ver
```

How do I resolve autogen.sh errors that contain "error: possibly undefined macro: AC_MSG_ERROR"?

Verify the `pkg-config` package is installed.

How do I resolve compile errors with libssl or libcrypto for TORQUE 4.0 on Ubuntu 10.04?

When compiling TORQUE 4.0 on Ubuntu 10.04 the following errors might occur:

```
libtool: link: gcc -Wall -pthread -g -D_LARGEFILE64_SOURCE -o .libs/trqauthd trq_auth_
daemon.o trq_main.o -ldl -lssl -lcrypto -L/home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs /home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs/libtorque.so -lpthread -lrt -pthread
/usr/bin/ld: cannot find -lssl
collect2: ld returned 1 exit status
make[3]: *** [trqauthd] Error 1

libtool: link: gcc -Wall -pthread -g -D_LARGEFILE64_SOURCE -o .libs/trqauthd trq_auth_
daemon.o trq_main.o -ldl -lssl -lcrypto -L/home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs /home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs/libtorque.so -lpthread -lrt -pthread
/usr/bin/ld: cannot find -lcrypto
collect2: ld returned 1 exit status
make[3]: *** [trqauthd] Error 1
```

To resolve the compile issue, use these commands:

```
> cd /usr/lib
> ln -s /lib/libcrypto.so.0.9. libcrypto.so
> ln -s /lib/libssl.so.0.9.8 libssl.so
```

Why are there so many error messages in the client logs (trqauthd logs) when I don't notice client commands failing?

If a client makes a connection to the server and the trqauthd connection for that client command is authorized *before* the client's connection, the trqauthd connection is rejected. The connection is retried, but if all retry attempts are rejected, trqauthd logs a message indicating a failure. Some client commands then open a new connection to the server and try again. The client command fails only if all its retries fail.

Compute Node Health Check

TORQUE provides the ability to perform health checks on each compute node. If these checks fail, a failure message can be associated with the node and routed to the scheduler. Schedulers (such as Moab) can forward this

information to administrators by way of scheduler triggers, make it available through scheduler diagnostic commands, and automatically mark the node down until the issue is resolved. (See the `RMMMSGIGNORE` parameter in [Appendix A: Moab Parameters on page 1069](#) for more information.)

Additionally, Michael Jennings at LBNL has authored an open-source bash node health check script project. It offers an easy way to perform some of the most common node health checking tasks, such as verifying network and filesystem functionality. More information is available on the [project's page](#).

For more information about node health checks, see these topics:

- [Configuring MOMs to Launch a Health Check on page 3428](#)
- [Creating the Health Check Script on page 3428](#)
- [Adjusting Node State Based on the Health Check Output on page 3429](#)
- [Example Health Check Script on page 3429](#)

Related Topics

[Troubleshooting on page 3414](#)

Configuring MOMs to Launch a Health Check

The health check feature is configured via the `mom_priv/config` file using the parameters described below:

Parameter	Format	Default	Description
<code>\$node_check_script</code>	<STRING>	N/A	(Required) Specifies the fully qualified pathname of the health check script to run
<code>\$node_check_interval</code>	<INTEGER>	1	(Optional) Specifies the number of MOM intervals between health checks (by default, each MOM interval is 45 seconds long - this is controlled via the \$status_update_time on page 3555 node parameter. The integer may be followed by a list of event names (currently supported are <code>jobstart</code> and <code>jobend</code>). (See pbs_mom for more information.)

Related Topics

[Compute Node Health Check on page 3427](#)

Creating the Health Check Script

The health check script is executed directly by the `pbs_mom` daemon under the root user id. It must be accessible from the compute node and may be a script

or compile executable program. It may make any needed system calls and execute any combination of system utilities but should not execute resource manager client commands. Also, as of TORQUE 1.0.1, the pbs_mom daemon blocks until the health check is completed and does not possess a built-in timeout. Consequently, it is advisable to keep the launch script execution time short and verify that the script will not block even under failure conditions.

If the script detects a failure, it should return the keyword **ERROR** to stdout followed by an error message. When a failure is detected, the ERROR keyword should be printed to stdout before any other data. The message (up to 1024 characters) immediately following the ERROR keyword must all be contained on the same line. The message is assigned to the node attribute 'message' of the associated node.

Related Topics

[Compute Node Health Check on page 3427](#)

Adjusting Node State Based on the Health Check Output

If the health check reports an error, the node attribute "message" is set to the error string returned. Cluster schedulers can be configured to adjust a given node's state based on this information. For example, by default, Moab sets a node's state to down if a node error message is detected. The node health script continues to run at the configured interval (see [Configuring MOMs to Launch a Health Check on page 3428](#) for more information), and if it does not generate the error message again during one of its later executions, Moab picks that up at the beginning of its next iteration and restores the node to an online state.

Related Topics

[Compute Node Health Check on page 3427](#)

Example Health Check Script

As mentioned, the health check can be a shell script, PERL, Python, C-executable, or anything which can be executed from the command line capable of setting STDOUT. The example below demonstrates a very simple health check:

```
#!/bin/sh
/bin/mount | grep global
if [ $? != "0" ]
then
    echo "ERROR cannot locate filesystem global"
fi
```

Related Topics

[Compute Node Health Check on page 3427](#)

Debugging

TORQUE supports a number of diagnostic and debug options including the following:

PBSDEBUG environment variable - If set to 'yes', this variable will prevent `pbs_server`, `pbs_mom`, and/or `pbs_sched` from backgrounding themselves allowing direct launch under a debugger. Also, some client commands will provide additional diagnostic information when this value is set.

PBSLOGLEVEL environment variable - Can be set to any value between 0 and 7 and specifies the logging verbosity level (default = 0)

PBSCOREDUMP environment variable - If set, it will cause the offending resource manager daemon to create a core file if a `SIGSEGV`, `SIGILL`, `SIGFPE`, `SIGSYS`, or `SIGTRAP` signal is received. The core dump will be placed in the daemon's home directory (`$PBSHOME/mom_priv` for `pbs_mom` and `$PBSHOME/server_priv` for `pbs_server`).

i To enable core dumping in a Red Hat system, you must add the following line to the `/etc/init.d/pbs_mom` and `/etc/init.d/pbs_server` scripts:

```
export DAEMON_COREFILE_LIMIT=unlimited
```

NDEBUG #define - if set at build time, will cause additional low-level logging information to be output to stdout for `pbs_server` and `pbs_mom` daemons.

tracejob reporting tool - can be used to collect and report logging and accounting information for specific jobs (See [Using "tracejob" to Locate Job Failures on page 3416](#)) for more information.

i **PBSLOGLEVEL** and **PBSCOREDUMP** must be added to the `$PBSHOME/pbs_environment` file, not just the current environment. To set these variables, add a line to the `pbs_environment` file as either "variable=value" or just "variable". In the case of "variable=value", the environment variable is set up as the value specified. In the case of "variable", the environment variable is set based upon its value in the current environment.

TORQUE Error Codes

Error code name	Number	Description
PBSE_FLOOR	15000	No error
PBSE_UNKJOBID	15001	Unknown job identifier

Error code name	Number	Description
PBSE_NOATTR	15002	Undefined attribute
PBSE_ATTRRO	15003	Attempt to set READ ONLY attribute
PBSE_IVALREQ	15004	Invalid request
PBSE_UNKREQ	15005	Unknown batch request
PBSE_TOOMANY	15006	Too many submit retries
PBSE_PERM	15007	No permission
PBSE_IFF_NOT_FOUND	15008	"pbs_iff" not found; unable to authenticate

Appendix A: Commands Overview

Client Commands

Command	Description
<code>momctl</code>	Manage/diagnose MOM (node execution) daemon
<code>pbsdsh</code>	Launch tasks within a parallel job
<code>pbsnodes</code>	View/modify batch status of compute nodes

Command	Description
<u>qalter</u>	Modify queued batch jobs
<u>qchkpt</u>	Checkpoint batch jobs
<u>qdel</u>	Delete/cancel batch jobs
<u>qgpumode</u>	Specifies new mode for GPU
<u>qgpureset</u>	Reset the GPU
<u>qhold</u>	Hold batch jobs
<u>qmgr</u>	Manage policies and other batch configuration
<u>qmove on page 3481</u>	Move batch jobs
<u>qorder on page 3483</u>	Exchange order of two batch jobs in any queue
<u>qrerun</u>	Rerun a batch job
<u>qrls</u>	Release batch job holds
<u>qrun</u>	Start a batch job
<u>qsig</u>	Send a signal to a batch job
<u>qstat</u>	View queues and jobs
<u>qsub</u>	Submit jobs
<u>qterm</u>	Shutdown pbs server daemon
tracejob	Trace job actions and states recorded in TORQUE logs (see <u>Using "tracejob" to Locate Job Failures on page 3416</u>)

Binary Executables

Command	Description
<code>pbs_iff</code>	Interprocess authentication service
<code>pbs_mom</code>	Start MOM (node execution) daemon
<code>pbs_server</code>	Start server daemon
<code>pbs_track</code>	Tell pbs_mom to track a new process

momctl

(PBS MOM Control)

Synopsis

```
momctl -c { <JOBID> | all }
momctl -C
momctl -d { <INTEGER> | <JOBID> }
momctl -f <FILE>
momctl -h <HOST>[,<HOST>]...
momctl -p <PORT_NUMBER>
momctl -q <ATTRIBUTE>
momctl -r { <FILE> | LOCAL:<FILE> }
momctl -s
```

Overview

The `momctl` command allows remote shutdown, reconfiguration, diagnostics, and querying of the `pbs_mom` daemon.

Format

-c — Clear	
Format	{ <JOBID> all }

-c — Clear

Default	---
Description	Makes the MOM unaware of the job's existence. It does not clean up any processes associated with the job.
Example	<pre>momctl - node1 -c 15406</pre>

-C — Cycle

Format	---
Default	---
Description	Cycle pbs_mom(s)
Example	<pre>momctl - node1 -C</pre> Cycle pbs_mom on node1.

-d — Diagnose

Format	{ <INTEGER> <JOBID> }
Default	0
Description	Diagnose MOM(s) (For more details, see Diagnose detail on page 3442 below.)
Example	<pre>momctl - node1 -d 2</pre> Print level 2 and lower diagnose information for the MOM on node1.

-f — Host File

Format	<FILE>
Default	---

-f — Host File

Description	A file containing only comma or whitespace (space, tab, or new line) delimited hostnames
Example	<pre>momctl -f hosts.txt -d</pre> <p>Print diagnose information for the MOMs running on the hosts specified in <code>hosts.txt</code>.</p>

-h — Host List

Format	<HOST>[,<HOST>]...
Default	localhost
Description	A comma separated list of hosts
Example	<pre>momctl -h node1,node2,node3 -d</pre> <p>Print diagnose information for the MOMs running on node1, node2, and node3.</p>

-p — Port

Format	<PORT_NUMBER>
Default	TORQUE's default port number
Description	The port number for the specified MOM(s)
Example	<pre>momctl -p 5455 -h node1 -d</pre> <p>Request diagnose information over port 5455 on node1.</p>

-q — Query

Format	<ATTRIBUTE>
Default	---
Description	Query <ATTRIBUTE> on specified MOM, where <ATTRIBUTE> is a property listed by pbsnodes -a (see Query attributes on page 3441 for a list of attributes)

-q — Query**Example**

```
momctl -q physmem
```

Print the amount of physmem on localhost.

-r — Reconfigure**Format**

```
{ <FILE> | LOCAL:<FILE> }
```

Default

```
---
```

Description

Reconfigure MOM(s) with remote or local config file, <FILE>. This does not work if \$remote_reconf is not set to true when the MOM is started.

Example

```
momctl -r /home/user1/new.config -h node1
```

Reconfigure MOM on node1 with /home/user1/new.config on node1.

-s — Shutdown**Format****Default**

```
---
```

Description

Shutdown pbs_mom

Example

```
momctl -s
```

Terminates pbs_mom process on localhost.

Query attributes

Attribute	Description
arch	node hardware architecture
availmem	available RAM
loadave	1 minute load average

Attribute	Description
ncpus	number of CPUs available on the system
netload	total number of bytes transferred over all network interfaces
nsessions	number of sessions active
nusers	number of users active
physmem	configured RAM
sessions	list of active sessions
totmem	configured RAM plus configured swap

Diagnose detail

Level	Description
0	<p>Display the following information:</p> <ul style="list-style-type: none"> • Local hostname • Expected server hostname • Execution version • MOM home directory • MOM config file version (if specified) • Duration MOM has been executing • Duration since last request from pbs_server daemon • Duration since last request to pbs_server daemon • RM failure messages (if any) • Log verbosity level • Local job list

Level	Description
1	<p>All information for level 0 plus the following:</p> <ul style="list-style-type: none"> Interval between updates sent to server Number of initialization messages sent to pbs_server daemon Number of initialization messages received from pbs_server daemon Prolog/epilog alarm time List of trusted clients
2	<p>All information from level 1 plus the following:</p> <ul style="list-style-type: none"> PID Event alarm status
3	<p>All information from level 2 plus the following:</p> <ul style="list-style-type: none"> syslog enabled

Example 26-18: MOM diagnostics

```

momctl -d 1

Host: nsrc/nsrc.fllcl.com      Server: 10.10.10.113      Version: torque_1.1.0p4
HomeDirectory:                /usr/spool/PBS/mom_priv
ConfigVersion:                147
MOM active:                   7390 seconds
Last Msg From Server:         7389 seconds (CLUSTER_ADDRS)
Server Update Interval:       20 seconds
Server Update Interval:       20 seconds
Init Msgs Received:           0 hellos/1 cluster-addr
Init Msgs Sent:               1 hellos
LOGLEVEL:                     0 (use SIGUSR1/SIGUSR2 to adjust)
Prolog Alarm Time:            300 seconds
Trusted Client List:          12.14.213.113,127.0.0.1
JobList:                      NONE

diagnostics complete

```

Example 26-19: System shutdown

```

> momctl -s -f /opt/clusterhostfile

shutdown request successful on node001
shutdown request successful on node002
shutdown request successful on node003
shutdown request successful on node004
shutdown request successful on node005
shutdown request successful on node006

```

pbs_mom

Start a pbs batch execution mini-server.

Synopsis

```
pbs_mom [-a alarm] [-A alias] [-C chkdiritory] [-c config] [-d directory] [-h help] [-H hostname] [-L logfile] [-M MOMport] [-R RPPport] [-p|-r] [-P purge] [-w] [-x]
```

Description

The `pbs_mom` command is located within the `TORQUE_HOME` directory and starts the operation of a batch Machine Oriented Mini-server (MOM) on the execution host. To ensure that the `pbs_mom` command is not runnable by the general user community, the server will only execute if its real and effective uid is zero.

The first function of `pbs_mom` is to place jobs into execution as directed by the server, establish resource usage limits, monitor the job's usage, and notify the server when the job completes. If they exist, `pbs_mom` will execute a prologue script before executing a job and an epilogue script after executing the job.

The second function of `pbs_mom` is to respond to resource monitor requests. This was done by a separate process in previous versions of PBS but has now been combined into one process. It provides information about the status of running jobs, memory available, etc.

The last function of `pbs_mom` is to respond to task manager requests. This involves communicating with running tasks over a TCP socket as well as communicating with other MOMs within a job (a.k.a. a "sisterhood").

`pbs_mom` will record a diagnostic message in a log file for any error occurrence. The log files are maintained in the `mom_logs` directory below the home directory of the server. If the log file cannot be opened, the diagnostic message is written to the system console.

Options

Flag	Name	Description
-a	alarm	Specifies the alarm timeout in seconds for computing a resource. Every time a resource request is processed, an alarm is set for the given amount of time. If the request has not completed before the given time, an alarm signal is generated. The default is 5 seconds.
-A	alias	Specifies this multimom's alias name. The alias name needs to be the same name used in the <code>mom.hierarchy</code> file. It is only needed when running multiple MOMs on the same machine. For more information, see TORQUE Multi-MOM on page 3323 .

Flag	Name	Description
-C	chkdirectory	Specifies the path of the directory used to hold checkpoint files. (Currently this is only valid on Cray systems.) The default directory is <code>TORQUE_HOME/spool/checkpoint</code> (see the -d option). The directory specified with the -C option must be owned by root and accessible (rwx) only by root to protect the security of the checkpoint files.
-c	config	Specifies an alternative configuration file, see description below. If this is a relative file name it will be relative to <code>TORQUE_HOME/mom_priv</code> , (see the -d option). If the specified file cannot be opened, <code>pbs_mom</code> will abort. If the -C option is not supplied, <code>pbs_mom</code> will attempt to open the default configuration file "config" in <code>TORQUE_HOME/mom_priv</code> . If this file is not present, <code>pbs_mom</code> will log the fact and continue.
-d	directory	Specifies the path of the directory which is the home of the server's working files, <code>TORQUE_HOME</code> . This option is typically used along with -M when debugging MOM. The default directory is given by <code>\$PBS_SERVER_HOME</code> which is typically <code>/usr/spool/PBS</code> .
-h	help	Displays the help/usage message.
-H	hostname	Sets the MOM's hostname. This can be useful on multi-homed networks.
-L	logfile	Specifies an absolute path name for use as the log file. If not specified, MOM will open a file named for the current date in the <code>TORQUE_HOME/mom_logs</code> directory (see the -d option).
-M	port	Specifies the port number on which the mini-server (MOM) will listen for batch requests.
-p	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. On any restart of MOM, the new mini-server will not be the parent of any running jobs, MOM has lost control of her offspring (not a new situation for a mother). With the -p option, MOM will allow the jobs to continue to run and monitor them indirectly via polling. This flag is redundant in that this is the default behavior when starting the server. The -p option is mutually exclusive with the -R and -q options.
-P	purge	Specifies the impact on jobs which were in execution when the mini-server shut down. With the -P option, it is assumed that either the entire system has been restarted or the MOM has been down so long that it can no longer guarantee that the pid of any running process is the same as the recorded job process pid of a recovering job. Unlike the -p option, no attempt is made to try and preserve or recover running jobs. All jobs are terminated and removed from the queue.

Flag	Name	Description
-q	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. With the -q option, MOM will allow the processes belonging to jobs to continue to run, but will not attempt to monitor them. The -q option is mutually exclusive with the -p and -R options.
-R	port	Specifies the port number on which the mini-server (MOM) will listen for resource monitor requests, task manager requests and inter-MOM messages. Both a UDP and a TCP port of this number will be used.
-r	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. With the -r option, MOM will kill any processes belonging to jobs, mark the jobs as terminated, and notify the batch server which owns the job. The -r option is mutually exclusive with the -p and -q options. Normally the mini-server is started from the system boot file without the -p or the -r option. The mini-server will make no attempt to signal the former session of any job which may have been running when the mini-server terminated. It is assumed that on reboot, all processes have been killed. If the -r option is used following a reboot, process IDs (pids) may be reused and MOM may kill a process that is not a batch session.
-w	wait_for_server	When started with -w, pbs_moms wait until they get their MOM hierarchy file from pbs_server to send their first update, or until 10 minutes pass. This reduces network traffic on startup and can bring up clusters faster.
-x	n/a	Disables the check for privileged port resource monitor connections. This is used mainly for testing since the privileged port is the only mechanism used to prevent any ordinary user from connecting.

Configuration file

The configuration file, located at `mom_priv/config` by default, can be specified on the command line at program start with the [-C](#) flag. The use of this file is to provide several types of run time information to `pbs_mom`: static resource names and values, external resources provided by a program to be run on request via a shell escape, and values to pass to internal set up functions at initialization (and re-initialization).

See the [Parameters on page 3540](#) page for a full list of `pbs_mom` parameters.

Each item type is on a single line with the component parts separated by white space. If the line starts with a hash mark (pound sign, #), the line is considered to be a comment and is skipped.

Static Resources

For static resource names and values, the configuration file contains a list of resource names/values pairs, one pair per line and separated by white space.

An example of static resource names and values could be the number of tape drives of different types and could be specified by:

- tape3480 4
- tape3420 2
- tapedat 1
- tape8mm 1

Shell Commands

If the first character of the value is an exclamation mark (!), the entire rest of the line is saved to be executed through the services of the system(3) standard library routine.

The shell escape provides a means for the resource monitor to yield arbitrary information to the scheduler. Parameter substitution is done such that the value of any qualifier sent with the query, as explained below, replaces a token with a percent sign (%) followed by the name of the qualifier. For example, here is a configuration file line which gives a resource name of "escape":

```
escape !echo %xxx %yyy
```

If a query for "escape" is sent with no qualifiers, the command executed would be `echo %xxx %yyy`.

If one qualifier is sent, `escape[xxx=hi there]`, the command executed would be `echo hi there %yyy`.

If two qualifiers are sent, `escape[xxx=hi][yyy=there]`, the command executed would be `echo hi there`.

If a qualifier is sent with no matching token in the command line, `escape[zzz=snafu]`, an error is reported.

Resources

Resource Manager queries can be made with [momctl](#) -q options to retrieve and set `pbs_mom` options. Any configured static resource may be retrieved with a request of the same name. These are resource requests not otherwise documented in the PBS ERS.

Request	Description
cycle	Forces an immediate MOM cycle.
status_update_time	Retrieve or set the \$status_update_time parameter.
check_poll_time	Retrieve or set the \$check_poll_time parameter.

Request	Description
configversion	Retrieve the config version.
jobstartblocktime	Retrieve or set the \$jobstartblocktime parameter.
enablemomrestart	Retrieve or set the \$enablemomrestart parameter.
loglevel	Retrieve or set the \$loglevel parameter.
down_on_error	Retrieve or set the EXPERIMENTAL \$down_on_error parameter.
diag0 - diag4	Retrieves varied diagnostic information.
rcpcmd	Retrieve or set the \$rcpcmd parameter.
version	Retrieves the pbs_mom version.

Health check

The health check script is executed directly by the pbs_mom daemon under the root user id. It must be accessible from the compute node and may be a script or compiled executable program. It may make any needed system calls and execute any combination of system utilities but should not execute resource manager client commands. Also, the pbs_mom daemon blocks until the health check is completed and does not possess a built-in timeout. Consequently, it is advisable to keep the launch script execution time short and verify that the script will not block even under failure conditions.

If the script detects a failure, it should return the keyword "Error" to `stdout` followed by an error message. The message (up to 256 characters) immediately following the Error string will be assigned to the node attribute message of the associated node.

If the script detects a failure when run from "jobstart", then the job will be rejected. You can use this behavior with an advanced scheduler, such as Moab Workload Manager, to cause the job to be routed to another node. TORQUE currently ignores Error messages by default, but you can configure an advanced scheduler to react appropriately.

If the experimental `$down_on_error` MOM setting is enabled, the MOM will set itself to state down and report to pbs_server. Additionally, the experimental `$down_on_error server` attribute can be enabled which has the same effect but moves the decision to pbs_server. It is redundant to have MOM's `$down_on_error` and pbs_servers `down_on_error` features enabled. See "down_on_error" in pbs_server_attributes(7B).

Files

File	Description
\$PBS_SERVER_HOME/server_name	Contains the hostname running pbs_server
\$PBS_SERVER_HOME/mom_priv	The default directory for configuration files, typically (/usr/spool/pbs)/mom_priv
\$PBS_SERVER_HOME/mom_logs	Directory for log files recorded by the server
\$PBS_SERVER_HOME/mom_priv/-prologue	The administrative script to be run before job execution
\$PBS_SERVER_HOME/mom_priv/e-epilogue	The administrative script to be run after job execution

Signal handling

pbs_mom handles the following signals:

Signal	Description
SIGHUP	Causes pbs_mom to re-read its configuration file, close and reopen the log file, and re-initialize resource structures.
SIGALRM	Results in a log file entry. The signal is used to limit the time taken by certain children processes, such as the prologue and epilogue.
SIGINT and SIGTERM	Results in pbs_mom exiting without terminating any running jobs. This is the action for the following signals as well: SIGXCPU, SIGXFSZ, SIGCPULIM, and SIGSHUTDN.
SIGUSR1, SIGUSR2	Causes the MOM to increase and decrease logging levels, respectively.
SIGPIPE, SIGINFO	Are ignored.
SIGBUS, SIGFPE, SIGILL, SIGTRAP, and SIGSYS	Cause a core dump if the PBSCOREDUMP environmental variable is defined.

All other signals have their default behavior installed.

Exit status

If the `pbs_mom` command fails to begin operation, the server exits with a value greater than zero.

pbs_server

(PBS Server) pbs batch system manager

Synopsis

```
pbs_server [-a active] [-c] [-d config_path] [-f force
overwrite] [-p port] [-A acctfile]
[-l location] [-L logfile] [-S scheduler_port]
[-H hostname] [-t type] [--ha]
[-n don't send hierarchy] [--about] [-v] [--version]
```

Description

The `pbs_server` command starts the operation of a batch server on the local host. Typically, this command will be in a local boot file such as `/etc/rc.local`. If the batch server is already in execution, `pbs_server` will exit with an error. To ensure that the `pbs_server` command is not runnable by the general user community, the server will only execute if its real and effective uid is zero.

The server will record a diagnostic message in a log file for any error occurrence. The log files are maintained in the `server_logs` directory below the home directory of the server. If the log file cannot be opened, the diagnostic message is written to the system console.

As of TORQUE 4.0, the `pbs_server` is multi-threaded which leads to quicker response to client commands, is more robust, and allows for higher job throughput.

Options

Option	Name	Description
-A	acctfile	Specifies an absolute path name of the file to use as the accounting file. If not specified, the file name will be the current date in the <code>PBS_HOME/server_priv/accounting</code> directory.
-a	active	Specifies if scheduling is active or not. This sets the server attribute scheduling. If the option argument is "true" ("True", "t", "T", or "1"), the server is active and the PBS job scheduler will be called. If the argument is "false" ("False", "f", "F", or "0"), the server is idle, and the scheduler will not be called and no jobs will be run. If this option is not specified, the server will retain the prior value of the scheduling attribute.
-c	wait_for_moms	This directs <code>pbs_server</code> to send the MOM hierarchy only to MOMs that request it for the first 10 minutes. After 10 minutes, it attempts to send the MOM hierarchy to MOMs that haven't requested it already. This greatly reduces traffic on start up.
-d	config_directory	Specifies the path of the directory which is home to the server's configuration files, <code>PBS_HOME</code> . A host may have multiple servers. Each server must have a different configuration directory. The default configuration directory is given by the symbol <code>\$PBS_SERVER_HOME</code> which is typically <code>var/spool/torque</code> .
-f	force overwrite	Forces an overwrite of the server database. This can be useful to bypass the <code>yes/no</code> prompt when running something like <code>pbs_server -t create</code> and can ease installation and configuration of TORQUE via scripts.
-H	hostname	Causes the server to start under a different hostname as obtained from <code>gethostname(2)</code> . Useful for servers with multiple network interfaces to support connections from clients over an interface that has a hostname assigned that differs from the one that is returned by <code>gethostname(2)</code> .
--ha	high_availability	Starts server in high availability mode (for details, see Server High Availability on page 3386).
-L	logfile	Specifies an absolute path name of the file to use as the log file. If not specified, the file will be the current date in the <code>PBS_HOME/server_logs</code> directory (see the -d option).
-l	location	Specifies where to find Moab when it does not reside on the same host as TORQUE.
-n	no send	This directs <code>pbs_server</code> to not send the hierarchy to all the MOMs on startup. Instead, the hierarchy is only sent if a MOM requests it. This flag works only in conjunction with the local MOM hierarchy feature.

Option	Name	Description
-p	port	Specifies the port number on which the server will listen for batch requests. If multiple servers are running on a single host, each must have its own unique port number. This option is for use in testing with multiple batch systems on a single host.
-S	scheduler_ port	Specifies the port number to which the server should connect when contacting the scheduler. The argument scheduler_conn is of the same syntax as under the -M option.
-t	type	<p>If the job is rerunnable or restartable, and -t create is specified, the server will discard any existing configuration files, queues, and jobs, and initialize configuration files to the default values. The server is idled.</p> <div>  If -t is not specified, the job states will remain the same. </div>

Files

File	Description
TORQUE_HOME/server_priv	Default directory for configuration files, typically <code>/usr/spool/pbs/server_priv</code>
TORQUE_HOME/server_logs	Directory for log files recorded by the server

Signal handling

On receipt of the following signals, the server performs the defined action:

Action	Description
SIGHUP	The current server log and accounting log are closed and reopened. This allows for the prior log to be renamed and a new log started from the time of the signal.
SIGINT	Causes an orderly shutdown of pbs_server.
SIGUSR1, SIGUSR2	Causes server to increase and decrease logging levels, respectively.
SIGTERM	Causes an orderly shutdown of pbs_server.

Action	Description
SIGSHUTDN	On systems (Unicos) where SIGSHUTDN is defined, it also causes an orderly shutdown of the server.
SIGPIPE	This signal is ignored.

All other signals have their default behavior installed.

Exit status

If the server command fails to begin batch operation, the server exits with a value greater than zero.

`pbs_track`

Starts a new process and informs `pbs_mom` to start tracking it.

Synopsis

```
pbs_track -j <JOBID> [-b] <executable> [args]
```

Description

The `pbs_track` command tells a `pbs_mom` daemon to monitor the lifecycle and resource usage of the process that it launches using `exec()`. The `pbs_mom` is told about this new process via the Task Manager API, using `tm_adopt()`. The process must also be associated with a job that already exists on the `pbs_mom`.

By default, `pbs_track` will send its PID to TORQUE via `tm_adopt()`. It will then perform an `exec()`, causing `<executable>` to run with the supplied arguments. `pbs_track` will not return until the launched process has completed because it becomes the launched process.

This command can be considered related to the `pbsdsh` command which uses the `tm_spawn()` API call. The `pbsdsh` command asks a `pbs_mom` to launch and track a new process on behalf of a job. When it is not desirable or possible for the `pbs_mom` to spawn processes for a job, `pbs_track` can be used to allow an external entity to launch a process and include it as part of a job.

This command improves integration with TORQUE and SGI's MPT MPI implementation.

Options

Option	Description
<code>-j</code> <code><JOBID></code>	Job ID the new process should be associated with.
<code>-b</code>	Instead of having <code>pbs_track</code> send its PID to TORQUE, it will <code>fork()</code> first, send the child PID to TORQUE, and then execute from the forked child. This essentially "backgrounds" <code>pbs_track</code> so that it will return after the new process is launched.

Operands

The `pbs_track` command accepts a path to a program/executable (`<executable>`) and, optionally, one or more arguments to pass to that program.

Exit status

Because the `pbs_track` command becomes a new process (if used without `-b`), its exit status will match that of the new process. If the `-b` option is used, the exit status will be zero if no errors occurred before launching the new process.

If `pbs_track` fails, whether due to a bad argument or other error, the exit status will be set to a non-zero value.

pbsdsh

The `pbsdsh` command distributes tasks to nodes under `pbs`.

i Some limitations exist in the way that `pbsdsh` can be used. Please note the following situations are not currently supported:

- Running multiple instances of `pbsdsh` concurrently within a single job.
- Using the `-o` and `-s` options concurrently; although requesting these options together is permitted, only the output from the first node is displayed rather than output from every node in the chain.

Synopsis

```
pbsdsh [-c copies] [-o] [-s] [-u] [-v] program [args]
pbsdsh [-n node] [-o] [-s] [-u] [-v] program [args]
pbsdsh [-h nodename] [-o] [-v] program [args]
```

Description

Executes (spawns) a normal Unix program on one or more nodes under control of the Portable Batch System, PBS. `Pbsdsh` uses the Task Manager API (see `tm_spawn(3)`) to distribute the program on the allocated nodes.

When run without the `-c` or the `-n` option, `pbsdsh` will spawn the program on all nodes allocated to the PBS job. The spawns take place concurrently – all execute at (about) the same time.

Users will find the `PBS_TASKNUM`, `PBS_NODENUM`, and the `PBS_VNODENUM` environmental variables useful. They contain the TM task id, the node identifier, and the cpu (virtual node) identifier.

i Note that under particularly high workloads, the `pbsdsh` command may not function properly.

Options

Option	Name	Description
-c	copies	The program is spawned on the first Copies nodes allocated. This option is mutually exclusive with -n .
-h	hostname	The program is spawned on the node specified.
-n	node	The program is spawned on one node which is the n-th node allocated. This option is mutually exclusive with -c .
-o	---	Capture stdout of the spawned program. Normally stdout goes to the job's output.
-s	---	If this option is given, the program is run in turn on each node, one after the other.
-u	---	The program is run once on each node (unique). This ignores the number of allocated processors on a given node.
-v	---	Verbose output about error conditions and task exit status is produced.

Operands

The first operand, program, is the program to execute.

Additional operands are passed as arguments to the program.

Standard error

The `pbsdsh` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the command, the exit status will be a value of zero.

If the `pbsdsh` command fails to process any operand, or fails to contact the MOM daemon on the localhost the command exits with a value greater than zero.

pbsnodes

PBS node manipulation.

Synopsis

```
pbsnodes [-{a|x}] [-q] [-s server] [node[:property]
pbsnodes -l [-q] [-s server] [state] [nodename[:property ...]
pbsnodes -m <running|standby|suspend|hibernate|shutdown> <host
list>
pbsnodes [-{c|d|o|r}] [-q] [-s server] [-n -l] [-N "note"]
[node[:property]
```

Description

The `pbsnodes` command is used to mark nodes down, free or offline. It can also be used to list nodes and their state. Node information is obtained by sending a request to the PBS job server. Sets of nodes can be operated on at once by specifying a node property prefixed by a colon. (For more information, see Node states.)

Nodes do not exist in a single state, but actually have a set of states. For example, a node can be simultaneously "busy" and "offline". The "free" state is the absence of all other states and so is never combined with other states.

In order to execute `pbsnodes` with other than the `-a` or `-l` options, the user must have PBS Manager or Operator privilege.

Options

	Description
-	All attributes of a node or all nodes are listed. This is the default if no flag is given.
-x	Same as <code>-a</code> , but the output has an XML-like format.
-c	Clear OFFLINE from listed nodes.

C F t i c r	Description
- C	Print MOM diagnosis on the listed nodes. Not yet implemented. Use momctl instead.

Description

- Set the hosts in the specified host list to the requested power state. If a compute node does not support the energy-saving power state you request, the command returns an error and leaves the state unchanged. In order for the command to wake a node from a low-power state, Wake-on-LAN (WOL) must be enabled for the node.

i In order for the command to wake a node from a low-power state, Wake-on-LAN must be enabled for the node and it must support the `g` WOL packet. For more information, see [Changing Node Power States](#) on page 3364.

The allowable power states are:

- **Running:** The node is up and running.
- **Standby:** CPU is halted but still powered. Moderate power savings but low latency entering and leaving this state.
- **Suspend:** Also known as Suspend-to-RAM. Machine state is saved to RAM. RAM is put into self-refresh mode. Much more significant power savings with longer latency entering and leaving state.
- **Hibernate:** Also known as Suspend-to-disk. Machine state is saved to disk and then powered down. Significant power savings but very long latency entering and leaving state.
- **Shutdown:** Equivalent to `shutdown now` command as root.

The host list is a space-delimited list of node host names.

Description

```
pbsnodes -m shutdown node01 node02 node03 node04
```

With this command, pbs_server tells the pbs_mom associated with nodes01-04 to shut down the node.

The `pbsnodes` output shows the current power state of nodes. In this example, note that `pbsnodes` returns the MAC addresses of the nodes.

```

- Add the OFFLINE state. This is different from being marked DOWN. OFFLINE prevents new jobs from running on the specified nodes. This gives the administrator a tool to hold a node out of service without changing anything else. The OFFLINE state will never be set or cleared automatically by `pbs_server`; it is purely for the manager or operator.
- Purge the node record from `pbs_server`. Not yet implemented.
- Reset the listed nodes by clearing OFFLINE and adding DOWN state. `pbs_server` will ping the node and, if they communicate correctly, free the node.

	Description
-l	<ul style="list-style-type: none"> List node names and their state. If no state is specified, only nodes in the DOWN, OFFLINE, or UNKNOWN states are listed. Specifying a state string acts as an output filter. Valid state strings are "active", "all", "busy", "down", "free", "job-exclusive", "job-sharing", "offline", "reserve", "state-unknown", "time-shared", and "up". <ul style="list-style-type: none"> Using <i>all</i> displays all nodes and their attributes. Using <i>active</i> displays all nodes which are job-exclusive, job-sharing, or busy. Using <i>up</i> displays all nodes in an "up state". Up states include job-exclusive, job-sharing, reserve, free, busy and time-shared. All other strings display the nodes which are currently in the state indicated by the string.
-N	<ul style="list-style-type: none"> Specify a "note" attribute. This allows an administrator to add an arbitrary annotation to the listed nodes. To clear a note, use <code>-N ""</code> or <code>-N n</code>.
-l	<ul style="list-style-type: none"> Show the "note" attribute for nodes that are DOWN, OFFLINE, or UNKNOWN. This option requires -l.
-C	<ul style="list-style-type: none"> Suppress all error messages.
-s	<ul style="list-style-type: none"> Specify the PBS server's hostname or IP address.

qalter

Alter batch job.

Synopsis

```
qalter [-a date_time] [-A account_string] [-c interval] [-e path_
name]
[-h hold_list] [-j join_list] [-k keep_list] [-l resource_list]
[-m mail_options] [-M mail_list] [-n] [-N name] [-o path_name]
[-p priority] [-r y|n] [-S path_name_list] [-u user_list]
[-v variable_list] [-W additional_attributes]
[-t array_range]
job_identifier ...
```

Description

The `qalter` command modifies the attributes of the job or jobs specified by `job_identifier` on the command line. Only those attributes listed as options on the command will be modified. If any of the specified attributes cannot be modified for a job for any reason, none of that job's attributes will be modified.

The `qalter` command accomplishes the modifications by sending a Modify Job batch request to the batch server which owns each job.

Options

Option	Name	Description
-a	date_time	<p>Replaces the time at which the job becomes eligible for execution. The date_time argument syntax is:</p> <pre>[[[[CC] YY] MM] DD] hhmm [. SS]</pre> <p>If the month, MM, is not specified, it will default to the current month if the specified day DD, is in the future. Otherwise, the month will be set to next month. Likewise, if the day, DD, is not specified, it will default to today if the time hhmm is in the future. Otherwise, the day will be set to tomorrow.</p> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
-A	account_string	<p>Replaces the account string associated with the job. This attribute cannot be altered once the job has begun execution.</p>

Option	Name	Description
-c	checkpoint_interval	<p>Replaces the interval at which the job will be checkpointed. If the job executes upon a host which does not support checkpointing, this option will be ignored.</p> <p>The interval argument is specified as:</p> <ul style="list-style-type: none"> • <i>n</i> – No checkpointing is to be performed. • <i>s</i> – Checkpointing is to be performed only when the server executing the job is shutdown. • <i>c</i> – Checkpointing is to be performed at the default minimum cpu time for the queue from which the job is executing. • <i>c=minutes</i> – Checkpointing is performed at intervals of the specified amount of time in minutes. Minutes are the number of minutes of CPU time used, not necessarily clock time. <div style="border: 1px solid #005596; border-radius: 5px; padding: 10px; margin-top: 10px;">  This value must be greater than zero. If the number is less than the default checkpoint time, the default time will be used. </div> <p>This attribute can be altered once the job has begun execution, but the new value does not take effect unless the job is rerun.</p>
-e	path_name	<p>Replaces the path to be used for the standard error stream of the batch job. The path argument is of the form:</p> <p>[hostname:]path_name</p> <p>where <i>hostname</i> is the name of a host to which the file will be returned and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX 1003.1. The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> • <i>path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <i>qalter</i> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component. • <i>hostname:path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <i>qalter</i> command will not expand the path name. The execution server will expand it relative to the home directory of the user on the system specified by hostname. <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>

Option	Name	Description
-h	hold_list	<p>Updates the types of holds on the job. The hold_list argument is a string of one or more of the following characters:</p> <ul style="list-style-type: none"> • <i>u</i> – Add the USER type hold. • <i>s</i> – Add the SYSTEM type hold if the user has the appropriate level of privilege. (Typically reserved to the batch administrator.) • <i>o</i> – Add the OTHER (or OPERATOR) type hold if the user has the appropriate level of privilege. (Typically reserved to the batch administrator and batch operator.) • <i>n</i> – Set to none and clear the hold types which could be applied with the user's level of privilege. Repetition of characters is permitted, but "n" may not appear in the same option argument with the other three characters. <p>This attribute can be altered once the job has begun execution, but the hold will not take effect unless the job is rerun.</p>
-j	join	<p>Declares which standard streams of the job will be merged together. The join argument value may be the characters "oe" and "eo", or the single character "n".</p> <p>An argument value of oe directs that the standard output and standard error streams of the job will be merged, intermixed, and returned as the standard output. An argument value of eo directs that the standard output and standard error streams of the job will be merged, intermixed, and returned as the standard error.</p> <p>A value of n directs that the two streams will be two separate files. This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p> <div>  If using either the <code>-e</code> or the <code>-o</code> option and the <code>-j eo oe</code> option, the <code>-j</code> option takes precedence and all standard error and output messages go to the chosen output file. </div>

Option	Name	Description
-k	keep	<p>Defines which if either of standard output or standard error of the job will be retained on the execution host. If set for a stream, this option overrides the path name for that stream.</p> <p>The argument is either the single letter "e", "o", or "n", or one or more of the letters "e" and "o" combined in either order.</p> <ul style="list-style-type: none"> <i>n</i> – No streams are to be retained. <i>e</i> – The standard error stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.e.sequence</code> where <code>job_name</code> is the name specified for the job, and <code>sequence</code> is the sequence number component of the job identifier. <i>o</i> – The standard output stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.o.sequence</code> where <code>job_name</code> is the name specified for the job, and <code>sequence</code> is the sequence number component of the job identifier. <i>eo</i> – Both the standard output and standard error streams will be retained. <i>oe</i> – Both the standard output and standard error streams will be retained. <p>This attribute cannot be altered once the job has begun execution.</p>
-l	resource_list	<p>Modifies the list of resources that are required by the job. The <code>resource_list</code> argument is in the following syntax:</p> <pre>resource_name[=[value]] [, resource_name[=[value]] , ...]</pre> <p>For the complete list of resources that can be modified, see Requesting Resources on page 3330.</p> <p>If a requested modification to a resource would exceed the resource limits for jobs in the current queue, the server will reject the request.</p> <p>If the job is running, only certain resources can be altered. Which resources can be altered in the run state is system dependent. A user may only lower the limit for those resources.</p>
-m	mail_options	<p>Replaces the set of conditions under which the execution server will send a mail message about the job. The <code>mail_options</code> argument is a string which consists of the single character "n", or one or more of the characters "a", "b", and "e".</p> <p>If the character "n" is specified, no mail will be sent.</p> <p>For the letters "a", "b", and "e":</p> <ul style="list-style-type: none"> <i>a</i> – Mail is sent when the job is aborted by the batch system. <i>b</i> – Mail is sent when the job begins execution. <i>e</i> – Mail is sent when the job ends.

Option	Name	Description
-M	user_list	<p>Replaces the list of users to whom mail is sent by the execution server when it sends mail about the job.</p> <p>The user_list argument is of the form:</p> <pre>user[@host] [,user[@host],...]</pre>
-n	node-exclusive	<p>Sets or unsets exclusive node allocation on a job. Use the y and n options to enable or disable the feature. This affects only cpusets and compatible schedulers.</p> <pre>> qalter ... -n y #enables exclusive node allocation on a job > qalter ... -n n #disables exclusive node allocation on a job</pre>
-N	name	<p>Renames the job. The name specified may be up to and including 15 characters in length. It must consist of printable, nonwhite space characters with the first character alphabetic.</p>
-o	path	<p>Replaces the path to be used for the standard output stream of the batch job. The path argument is of the form:</p> <pre>[hostname:]path_name</pre> <p>where <i>hostname</i> is the name of a host to which the file will be returned and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX. The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> <i>path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component. <i>hostname:path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will not expand the path name. The execution server will expand it relative to the home directory of the user on the system specified by hostname. <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
-p	priority	<p>Replaces the priority of the job. The priority argument must be an integer between -1024 and +1023 inclusive.</p> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
-r	[y/n]	<p>Declares whether the job is rerunnable (see the qrerun command). The option argument c is a single character. PBS recognizes the following characters: y and n. If the argument is "y", the job is marked rerunnable.</p> <p>If the argument is "n", the job is marked as not rerunnable.</p>

Option	Name	Description
-S	path	<p>Declares the shell that interprets the job script.</p> <p>The option argument <code>path_list</code> is in the form:</p> <pre>path[@host] [,path[@host], ...]</pre> <p>Only one path may be specified for any host named. Only one path may be specified without the corresponding host name. The path selected will be the one with the host name that matched the name of the execution host. If no matching host is found, then the path specified (without a host) will be selected.</p> <p>If the <code>-S</code> option is not specified, the option argument is the null string, or no entry from the <code>path_list</code> is selected, the execution will use the login shell of the user on the execution host.</p> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
-t	array_range	<p>The <code>array_range</code> argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code></p> <p>If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.</p> <p>An optional "slot limit" can be specified to limit the amount of jobs that can run concurrently in the job array. The default value is unlimited. The slot limit must be the last thing specified in the <code>array_request</code> and is delimited from the array by a percent sign (%).</p> <pre>qalter weatherSimulationArray[] -t %20</pre> <p>Here, the array <code>weatherSimulationArray[]</code> is configured to allow a maximum of 20 concurrently running jobs.</p> <p>Slot limits can be applied at job submit time with qsub, or can be set in a global server parameter policy with max_slot_limit.</p>
-u	user_list	<p>Replaces the user name under which the job is to run on the execution system.</p> <p>The <code>user_list</code> argument is of the form:</p> <pre>user[@host] [,user[@host], ...]</pre> <p>Only one user name may be given for per specified host. Only one of the user specifications may be supplied without the corresponding host specification. That user name will be used for execution on any host not named in the argument list.</p> <p>This attribute cannot be altered once the job has begun execution.</p>
-W	additional_attributes	<p>The <code>-w</code> option allows for the modification of additional job attributes.</p> <p>Note if white space occurs anywhere within the option argument string or the equal sign, "=", occurs within an <code>attribute_value</code> string, then the string must be enclosed with either single or double quote marks.</p> <p>To see the attributes PBS currently supports within the <code>-w</code> option, see Table 26-26: -W additional_attributes on page 3468.</p>

Table 26-26: -W additional_attributes

Attribute	Description
depend=dependency_list	<p>Redefines the dependencies between this and other jobs. The dependency_list is in the form:</p> <pre>type[:argument[:argument...]][,type:argument...]</pre> <p>The argument is either a numeric count or a PBS job id according to type. If argument is a count, it must be greater than 0. If it is a job id and is not fully specified in the form: <code>seq_number.server.name</code>, it will be expanded according to the default server rules. If argument is null (the preceding colon need not be specified), the dependency of the corresponding type is cleared (unset).</p> <ul style="list-style-type: none"> • <i>synccount:count</i> – This job is the first in a set of jobs to be executed at the same time. Count is the number of additional jobs in the set. • <i>syncwith:jobid</i> – This job is an additional member of a set of jobs to be executed at the same time. In the above and following dependency types, jobid is the job identifier of the first job in the set. • <i>after:jobid [:jobid...]</i> – This job may be scheduled for execution at any point after jobs jobid have started execution. • <i>afterok:jobid [:jobid...]</i> – This job may be scheduled for execution only after jobs jobid have terminated with no errors. See the csh warning under "Extended Description". • <i>afternotok:jobid [:jobid...]</i> – This job may be scheduled for execution only after jobs jobid have terminated with errors. See the csh warning under "Extended Description". • <i>afterany:jobid [:jobid...]</i> – This job may be scheduled for execution after jobs jobid have terminated, with or without errors. • <i>on:count</i> – This job may be scheduled for execution after count dependencies on other jobs have been satisfied. This dependency is used in conjunction with any of the 'before' dependencies shown below. If job A has on:2, it will wait for two jobs with 'before' dependencies on job A to be fulfilled before running. • <i>before:jobid [:jobid...]</i> – When this job has begun execution, then jobs jobid... may begin. • <i>beforeok:jobid [:jobid...]</i> – If this job terminates execution without errors, then jobs jobid... may begin. See the csh warning under "Extended Description". • <i>beforenotok:jobid [:jobid...]</i> – If this job terminates execution with errors, then jobs jobid... may begin. See the csh warning under "Extended Description". • <i>beforeany:jobid [:jobid...]</i> – When this job terminates execution, jobs jobid... may begin. <p>If any of the before forms are used, the job referenced by jobid must have been submitted with a dependency type of on.</p> <p>If any of the before forms are used, the jobs referenced by jobid must have the same owner as the job being altered. Otherwise, the dependency will not take effect.</p> <p>Error processing of the existence, state, or condition of the job specified to qalter is a deferred service, i.e. the check is performed after the job is queued. If an error is detected, the job will be deleted by the server. Mail will be sent to the job submitter stating the error.</p>

Attribute	Description
group_list=g_list	<p>Alters the group name under which the job is to run on the execution system.</p> <p>The <code>g_list</code> argument is of the form:</p> <pre>group[@host] [,group[@host], ...]</pre> <p>Only one group name may be given per specified host. Only one of the group specifications may be supplied without the corresponding host specification. That group name will be used for execution on any host not named in the argument list.</p>
stagein=file_list stageout=file_list	<p>Alters which files are staged (copied) in before job start or staged out after the job completes execution. The <code>file_list</code> is in the form:</p> <pre>local_file@hostname:remote_file[,...]</pre> <p>The name <code>local_file</code> is the name on the system where the job executes. It may be an absolute path or a path relative to the home directory of the user. The name <code>remote_file</code> is the destination name on the host specified by <code>hostname</code>. The name may be absolute or relative to the user's home directory on the destination host.</p>

Operands

The `qalter` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name][@server]
```

Standard error

Any error condition, either in processing the options or the operands, or any error received in reply to the batch requests will result in an error message being written to standard error.

Exit status

Upon successful processing of all the operands presented to the `qalter` command, the exit status will be a value of zero.

If the `qalter` command fails to process any operand, the command exits with a value greater than zero.

qchkpt

Checkpoint pbs batch jobs.

Synopsis

```
qchkpt <JOBID>[ <JOBID>] ...
```

Description

The `qchkpt` command requests that the PBS MOM generate a checkpoint file for a running job.

This is an extension to POSIX.2d.

The `qchkpt` command sends a Chkpt Job batch request to the server as described in the general section.

Options

None.

Operands

The `qchkpt` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

Examples

```
> qchkpt 3233 request a checkpoint for job 3233
```

Standard error

The `qchkpt` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qchkpt` command, the exit status will be a value of zero.

If the `qchkpt` command fails to process any operand, the command exits with a value greater than zero.

<JOBID>[ <JOBID>]... | 'all' | 'ALL'
```

Description

The `qdel` command deletes jobs in the order in which their job identifiers are presented to the command. A job is deleted by sending a Delete Job batch request to the batch server that owns the job. A job that has been deleted is no longer subject to management by batch services.

A batch job may be deleted by its owner, the batch operator, or the batch administrator.

A batch job being deleted by a server will be sent a SIGTERM signal following by a SIGKILL signal. The time delay between the two signals is an attribute of the execution queue from which the job was run (set table by the administrator). This delay may be overridden by the **-W** option.

See the PBS ERS section 3.1.3.3, "Delete Job Request", for more information.

Options

Option	Name	Description
-a	asynchronous delete	Performs an asynchronous delete. The server responds to the user before contacting the MOM. The option <code>qdel -a all</code> performs <code>qdel all</code> due to restrictions from being single-threaded.
-b	seconds	Defines the maximum number of seconds <code>qdel</code> will block attempting to contact <code>pbs_server</code> . If <code>pbs_server</code> is down, or for a variety of communication failures, <code>qdel</code> will continually retry connecting to <code>pbs_server</code> for job submission. This value overrides the <code>CLIENTRETRY</code> parameter in <code>torque.cfg</code> . This is a non-portable TORQUE extension. Portability-minded users can use the <code>PBS_CLIENTRETRY</code> environmental variable. A negative value is interpreted as infinity. The default is 0.
-p	purge	Forcibly purges the job from the server. This should only be used if a running job will not exit because its allocated nodes are unreachable. The admin should make every attempt at resolving the problem on the nodes. If a job's mother superior recovers after purging the job, any epilogue scripts may still run. This option is only available to a batch operator or the batch administrator.
-t	array_range	The <code>array_range</code> argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list (examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code>). If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.
-m	message	Specify a comment to be included in the email. The argument <code>message</code> specifies the comment to send. This option is only available to a batch operator or the batch administrator.
-W	delay	Specifies the wait delay between the sending of the SIGTERM and SIGKILL signals. The argument is the length of time in seconds of the delay.

Operands

The `qdel` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name][@server]
```

or

all

Examples

```
# delete the job array
qdel <arrayid>
#example
qdel 1234[]

# delete one job from the array
qdel 1234[1]

# to delete all jobs, including job arrays
qdel all
```

i There is not an option that allows you to delete all job arrays without deleting jobs.

Standard error

The `qdel` command will write a diagnostic messages to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qdel` command, the exit status will be a value of zero.

If the `qdel` command fails to process any operand, the command exits with a value greater than zero.

qgpumode

(GPU mode)

Synopsis

qgpumode [-H](#) host [-q](#) gpuid [-m](#) mode

Description

The `qgpumode` command specifies the mode for the GPU. This command triggers an immediate update of the `pbs_server`.

i For additional information about options for configuring GPUs, see in the Moab Workload Manager Administrator Guide.

Options

Option	Description
-H	Specifies the host where the GPU is located.
-g	Specifies the ID of the GPU. This varies depending on the version of the Nvidia driver used. For driver 260.x, it is 0, 1, and so on. For driver 270.x, it is the PCI bus address, i.e., 0:5:0.
-m	<p>Specifies the new mode for the GPU:</p> <ul style="list-style-type: none"> 0 (Default/Shared): Default/shared compute mode. Multiple threads can use <code>cudaSetDevice()</code> with this device. 1 (Exclusive Thread): Compute-exclusive-thread mode. Only one thread in one process is able to use <code>cudaSetDevice()</code> with this device. 2 (Prohibited): Compute-prohibited mode. No threads can use <code>cudaSetDevice()</code> with this device. 3 (Exclusive Process): Compute-exclusive-process mode. Many threads in one process are able to use <code>cudaSetDevice()</code> with this device. <div style="border: 1px dashed #ccc; padding: 5px; margin: 10px 0;"> <pre>qgpumode -H node01 -g 0 -m 1</pre> <p><i>This puts the first GPU on node01 into mode 1 (exclusive)</i></p> </div> <div style="border: 1px dashed #ccc; padding: 5px; margin: 10px 0;"> <pre>qgpumode -H node01 -g 0 -m 0</pre> <p><i>This puts the first GPU on node01 into mode 0 (shared)</i></p> </div>

Related Topics

[qgpureset on page 3475](#)

qgpureset (reset GPU)

Synopsis

```
qgpureset -H host -g gpuid -p -v
```

Description

The `qgpureset` command resets the GPU.

Options

Option	Description
-H	Specifies the host where the GPU is located.
-g	Specifies the ID of the GPU. This varies depending on the version of the Nvidia driver used. For driver 260.x, it is 0, 1, and so on. For driver 270.x, it is the PCI bus address, i.e., 0:5:0.
-p	Specifies to reset the GPU's permanent ECC error count.
-v	Specifies to reset the GPU's volatile ECC error count.

Related Topics

[qgpumode on page 3474](#)

qhold

(*hold job*)

Synopsis

```
qhold [{-h <HOLD LIST>|-t <array_range>}] <JOBID>[ <JOBID>]
...
```

Description

The `qhold` command requests that the server place one or more holds on a job. A job that has a hold is not eligible for execution. There are three supported holds: USER, OTHER (also known as operator), and SYSTEM.

A user may place a USER hold upon any job the user owns. An "operator", who is a user with "operator privilege," may place either an USER or an OTHER hold on any job. The batch administrator may place any hold on any job.

If no -h option is given, the USER hold will be applied to the jobs described by the `job_identifier` operand list.

If the job identified by `job_identifier` is in the queued, held, or waiting states, then the hold type is added to the job. The job is then placed into held state if it resides in an execution queue.

If the job is in running state, then the following additional action is taken to interrupt the execution of the job. If checkpoint/restart is supported by the host system, requesting a hold on a running job will (1) cause the job to be checkpointed, (2) the resources assigned to the job will be released, and (3) the job is placed in the held state in the execution queue.

If checkpoint/restart is not supported, `qhold` will only set the requested hold attribute. This will have no effect unless the job is rerun with the [`qrerun`](#) command.

Options

Option	Name	Description
-h	hold_list	The hold_list argument is a string consisting of one or more of the letters "u", "o", or "s" in any combination. The hold type associated with each letter is: <ul style="list-style-type: none"> <i>u</i> – USER <i>o</i> – OTHER <i>s</i> – SYSTEM
-t	array_range	The array_range argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list (examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code>) . If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.

Operands

The `qhold` command accepts one or more job_identifier operands of the form:
sequence_number[.server_name][@server]

Example

```
> qhold -h u 3233 place user hold on job 3233
```

Standard error

The `qhold` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qhold` command, the exit status will be a value of zero.

If the `qhold` command fails to process any operand, the command exits with a value greater than zero.

qmgr

(*PBS Queue Manager*) PBS batch system manager.

Synopsis

```
qmgr [-a] [-c command] [-e] [-n] [-z] [server...]
```

Description

The `qmgr` command provides an administrator interface to query and configure batch system parameters (see [Appendix B: Server Parameters on page 3520](#)).

The command reads directives from standard input. The syntax of each directive is checked and the appropriate request is sent to the batch server or servers.

The list or print subcommands of `qmgr` can be executed by general users. Creating or deleting a queue requires PBS Manager privilege. Setting or unsetting server or queue attributes requires PBS Operator or Manager privilege.

i By default, the user `root` is the only PBS Operator and Manager. To allow other users to be privileged, the server attributes `operators` and `managers` will need to be set (i.e., as `root`, issue `'qmgr -c 'set server managers += <USER1>@<HOST>'`). See [TORQUE/PBS Integration Guide - RM Access Control on page 1381](#).

If `qmgr` is invoked without the `-c` option and standard output is connected to a terminal, `qmgr` will write a prompt to standard output and read a directive from standard input.

Commands can be abbreviated to their minimum unambiguous form. A command is terminated by a new line character or a semicolon, ";", character. Multiple commands may be entered on a single line. A command may extend across lines by escaping the new line character with a back-slash "\".

Comments begin with the "#" character and continue to end of the line. Comments and blank lines are ignored by `qmgr`.

Options

Option	Name	Description
-a	---	Abort <code>qmgr</code> on any syntax errors or any requests rejected by a server.
-c	command	Execute a single command and exit <code>qmgr</code> .
-e	---	Echo all commands to standard output.
-n	---	No commands are executed, syntax checking only is performed.
-z	---	No errors are written to standard error.

Operands

The *server* operands identify the name of the batch server to which the administrator requests are sent. Each *server* conforms to the following syntax:

```
host_name[:port]
```

where *host_name* is the network name of the host on which the server is running and *port* is the port number to which to connect. If *port* is not specified, the default port number is used.

If *server* is not specified, the administrator requests are sent to the local server.

Standard input

The `qmgr` command reads standard input for directives until end of file is reached, or the exit or quit directive is read.

Standard output

If Standard Output is connected to a terminal, a command prompt will be written to standard output when `qmgr` is ready to read a directive.

If the **-e** option is specified, `qmgr` will echo the directives read from standard input to standard output.

Standard error

If the **-z** option is not specified, the `qmgr` command will write a diagnostic message to standard error for each error occurrence.

Directive syntax

A `qmgr` directive is one of the following forms:

```
command server [names] [attr OP value[,attr OP value,...]]
command queue [names] [attr OP value[,attr OP value,...]]
command node [names] [attr OP value[,attr OP value,...]]
```

where *command* is the command to perform on an object.

Commands are:

Command	Description
active	Sets the active objects. If the active objects are specified, and the name is not given in a <code>qmgr</code> cmd the active object names will be used.
create	Is to create a new object, applies to queues and nodes.
delete	Is to destroy an existing object, applies to queues and nodes.
set	Is to define or alter attribute values of the object.
unset	Is to clear the value of attributes of the object. <div>  This form does not accept an OP and value, only the attribute name. </div>
list	Is to list the current attributes and associated values of the object.
print	Is to print all the queue and server attributes in a format that will be usable as input to the <code>qmgr</code> command.
names	Is a list of one or more names of specific objects The name list is in the form: <code>[name] [@server] [,queue_name[@server] ...]</code> with no intervening white space. The name of an object is declared when the object is first created. If the name is <code>@server</code> , then all the objects of specified type at the server will be affected.

Command	Description
attr	Specifies the name of an attribute of the object which is to be set or modified. If the attribute is one which consist of a set of resources, then the attribute is specified in the form: <code>attribute_name.resource_name</code>
OP	Operation to be performed with the attribute and its value: <ul style="list-style-type: none"> • "-" – set the value of the attribute. If the attribute has an existing value, the current value is replaced with the new value. • "+=" – increase the current value of the attribute by the amount in the new value. • "-=" – decrease the current value of the attribute by the amount in the new value.
value	The value to assign to an attribute. If the value includes white space, commas or other special characters, such as the "#" character, the value string must be enclosed in quote marks ("").

The following are examples of `qmgr` directives:

```
create queue fast priority=10,queue_type=e,enabled = true,max_running=0
set queue fast max_running +=2
create queue little
set queue little resources_max.mem=8mw,resources_max.cput=10
unset queue fast max_running
set node state = "down,offline"
active server s1,s2,s3
list queue @server1
set queue max_running = 10          - uses active queues
```

Exit status

Upon successful processing of all the operands presented to the `qmgr` command, the exit status will be a value of zero.

If the `qmgr` command fails to process any operand, the command exits with a value greater than zero.

qmove

Move PBS batch jobs.

Synopsis

```
qmove destination jobId [jobId ...]
```

Description

To move a job is to remove the job from the queue in which it resides and instantiate the job in another queue. The `qmove` command issues a Move Job batch request to the batch server that currently owns each job specified by *jobId*.

A job in the **Running**, **Transiting**, or **Exiting** state cannot be moved.

Operands

The first operand, the new *destination*, is one of the following:

```
queue
```

```
@server
```

```
queue@server
```

If the *destination* operand describes only a queue, then `qmove` will move jobs into the queue of the specified name at the job's current server. If the *destination* operand describes only a batch server, then `qmove` will move jobs into the default queue at that batch server. If the *destination* operand describes both a queue and a batch server, then `qmove` will move the jobs into the specified queue at the specified server.

All following operands are *jobIds* which specify the jobs to be moved to the new *destination*. The `qmove` command accepts one or more *jobId* operands of the form: `sequenceNumber [.serverName] [@server]`

Standard error

The `qmove` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qmove` command, the exit status will be a value of zero.

If the `qmove` command fails to process any operand, the command exits with a value greater than zero.

qorder

Exchange order of two PBS batch jobs in any queue.

Synopsis

```
qorder job1_identifier job2_identifier
```

Description

To order two jobs is to exchange the jobs' positions in the queue(s) in which the jobs reside. The two jobs must be located on the same server. No attribute of the job, such as priority, is changed. The impact of changing the order in the queue(s) is dependent on local job schedule policy. For information about your local job schedule policy, contact your systems administrator.

 A job in the **running** state cannot be reordered.

Operands

Both operands are `job_identifiers` that specify the jobs to be exchanged. The `qorder` command accepts two `job_identifier` operands of the following form:

```
sequence_number[.server_name][@server]
```

The two jobs must be in the same location, so the server specification for the two jobs must agree.

Standard error

The `qorder` command will write diagnostic messages to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qorder` command, the exit status will be a value of zero.

If the `qorder` command fails to process any operand, the command exits with a value greater than zero.

qrerun*(Rerun a batch job)***Synopsis**

```
qrerun [{-f}] <JOBID>[ <JOBID>] ...
```

Description

The **qrerun** command directs that the specified jobs are to be rerun if possible. To rerun a job is to terminate the session leader of the job and return the job to the queued state in the execution queue in which the job currently resides.

If a job is marked as not rerunable then the rerun request will fail for that job. If the mini-server running the job is down, or it rejects the request, the Rerun Job batch request will return a failure unless **-f** is used.

Using **-f** violates IEEE Batch Processing Services Standard and should be handled with great care. It should only be used under exceptional circumstances. The best practice is to fix the problem mini-server host and let **qrerun** run normally. The nodes may need manual cleaning (see the **-r** option on the [qsub](#) and [qalter](#) commands).

Options

Option	Description
-f	Force a rerun on a job

```
qrerun -f 15406
```

i The **qrerun all** command is meant to be run if all of the compute nodes go down. If the machines have actually crashed, then we know that all of the jobs need to be restarted. The behavior if you don't run this would depend on how you bring up the **pbs_mom** daemons, but by default would be to cancel all of the jobs.

Running the command makes it so that all jobs are requeued without attempting to contact the moms on which they should be running.

Operands

The `qrerun` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name][@server]
```

Standard error

The `qrerun` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qrerun` command, the exit status will be a value of zero.

If the `qrerun` command fails to process any operand, the command exits with a value greater than zero.

Examples

```
> qrerun 3233
```

(Job 3233 will be re-run.)

qrls

(Release hold on PBS batch jobs)

Synopsis

```
qrls [{-h <HOLD LIST>|-t <array_range>}] <JOBID>[ <JOBID>] ...
```

Description

The `qrls` command removes or releases holds which exist on batch jobs.

A job may have one or more types of holds which make the job ineligible for execution. The types of holds are USER, OTHER, and SYSTEM. The different types of holds may require that the user issuing the `qrls` command have special

privileges. A user may always remove a USER hold on their own jobs, but only privileged users can remove OTHER or SYSTEM holds. An attempt to release a hold for which the user does not have the correct privilege is an error and no holds will be released for that job.

If no **-h** option is specified, the USER hold will be released.

If the job has no execution_time pending, the job will change to the queued state. If an execution_time is still pending, the job will change to the waiting state.

Options

Command	Name	Description
-h	hold_list	Defines the types of hold to be released from the jobs. The hold_list option argument is a string consisting of one or more of the letters "u", "o", and "s" in any combination. The hold type associated with each letter is: <ul style="list-style-type: none"> • <i>u</i> – USER • <i>o</i> – OTHER • <i>s</i> – SYSTEM
-t	array_range	The array_range argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: -t 1-100 or -t 1,10,50-100 If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.

Operands

The **qrsls** command accepts one or more job_identifier operands of the form:

```
sequence_number[.server_name][@server]
```

Examples

```
> qrsls -h u 3233 release user hold on job 3233
```

Standard error

The **qrsls** command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qrls` command, the exit status will be a value of zero.

If the `qrls` command fails to process any operand, the command exits with a value greater than zero.

qrun

(Run a batch job)

Synopsis

```
qrun [ { -H <HOST> | -a } ] <JOBID> [ <JOBID> ] ...
```

Overview

The `qrun` command runs a job.

Format

-H	
Format	<STRING> Host Identifier
Default	---
Description	Specifies the host within the cluster on which the job(s) are to be run. The host argument is the name of a host that is a member of the cluster of hosts managed by the server. If the option is not specified, the server will select the "worst possible" host on which to execute the job.
Example	<pre>qrun -H hostname 15406</pre>

-a	
Format	---
Default	---
Description	Run the job(s) asynchronously.
Example	<code>qrun -a 15406</code>

Command details

The `qrun` command is used to force a batch server to initiate the execution of a batch job. The job is run regardless of scheduling position or resource requirements.

In order to execute `qrun`, the user must have PBS Operation or Manager privileges.

Examples

```
> qrun 3233
```

(Run job 3233.)

`qsig`

(Signal a job)

Synopsis

```
qsig [{-s <SIGNAL>}] <JOBID>[ <JOBID>] ...
[-a]
```

Description

The `qsig` command requests that a signal be sent to executing batch jobs. The signal is sent to the session leader of the job. If the `-s` option is not specified, SIGTERM is sent. The request to signal a batch job will be rejected if:

- The user is not authorized to signal the job.
- The job is not in the running state.
- The requested signal is not supported by the system upon which the job is executing.

The `qsig` command sends a Signal Job batch request to the server which owns the job.

Options

Option	Name	Description
-s	signal	<p>Declares which signal is sent to the job.</p> <p>The signal argument is either a signal name, e.g. SIGKILL, the signal name without the SIG prefix, e.g. KILL, or an unsigned signal number, e.g. 9. The signal name SIGNULL is allowed; the server will send the signal 0 to the job which will have no effect on the job, but will cause an obituary to be sent if the job is no longer executing. Not all signal names will be recognized by <code>qsig</code>. If it doesn't recognize the signal name, try issuing the signal number instead.</p> <p>Two special signal names, "suspend" and "resume", are used to suspend and resume jobs. Cray systems use the Cray-specific <code>suspend()</code>/<code>resume()</code> calls.</p> <p>On non-Cray system, suspend causes a SIGTSTP to be sent to all processes in the job's top task, wait 5 seconds, and then send a SIGSTOP to all processes in all tasks on all nodes in the job. This differs from TORQUE 2.0.0 which did not have the ability to propagate signals to sister nodes. Resume sends a SIGCONT to all processes in all tasks on all nodes.</p> <p>When suspended, a job continues to occupy system resources but is not executing and is not charged for walltime. The job will be listed in the "S" state. Manager or operator privilege is required to suspend or resume a job.</p> <div>  Interactive jobs may not resume properly because the top-level shell will background the suspended child process. </div>
-a	asynchronously	Makes the command run asynchronously.

Operands

The `qsig` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

Examples

```
> qsig -s SIGKILL 3233      send a SIGKILL to job 3233
> qsig -s KILL 3233         send a SIGKILL to job 3233
> qsig -s 9 3233           send a SIGKILL to job 3233
```

Standard error

The `qsig` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qsig` command, the exit status will be a value of zero.

If the `qsig` command fails to process any operand, the command exits with a value greater than zero.

qstat

Show status of PBS batch jobs.

Synopsis

```
qstat [-c] [-C] [-f [-1]] [-W site_specific] [job_identifier...
| destination...] [time]
qstat [-a|-i|-r|-e] [-c] [-n [-1]] [-s] [-G|-M] [-R] [-u user_
list]
[job_identifier... | destination...]
qstat -Q [-f [-1]] [-c] [-W site_specific] [destination...]
qstat -q [-c] [-G|-M] [destination...]
qstat -B [-c] [-f [-1]] [-W site_specific] [server_name...]
qstat -t [-c] [-C]
```

Description

The `qstat` command is used to request the status of jobs, queues, or a batch server. The requested status is written to standard out.

When requesting job status, synopsis format 1 or 2, `qstat` will output information about each `job_identifier` or all jobs at each destination. Jobs for which the user does not have status privilege are not displayed.

When requesting queue or server status, synopsis format 3 through 5, `qstat` will output information about each destination.

 You can configure TORQUE with `CFLAGS='DTXT'` to change the alignment of text in `qstat` output. This noticeably improves `qstat -r` output.

Options

Option	Description
-c	Completed jobs are not displayed in the output. If desired, you can set the <code>PBS_QSTAT_NO_COMPLETE</code> environment variable to cause all <code>qstat</code> requests to not show completed jobs by default.
-C	Specifies that TORQUE will provide only a condensed output (job name, resources used, queue, state, and job owner) for jobs that have not changed recently (as per the <code>job_full_report_time</code> parameter). Jobs that have recently changed will continue to send a full output.
-f	Specifies that a full status display be written to standard out. The [time] value is the amount of walltime, in seconds, remaining for the job. [time] does not account for wall-time multipliers.
-a	All jobs are displayed in the alternative format (see Standard output on page 3493). If the operand is a destination id, all jobs at that destination are displayed. If the operand is a job id, information about that job is displayed.
-e	If the operand is a job id or not specified, only jobs in executable queues are displayed. Setting the <code>PBS_QSTAT_EXEONLY</code> environment variable will also enable this option.
-i	Job status is displayed in the alternative format. For a destination id operand, statuses for jobs at that destination which are not running are displayed. This includes jobs which are queued, held or waiting. If an operand is a job id, status for that job is displayed regardless of its state.
-r	If an operand is a job id, status for that job is displayed. For a destination id operand, statuses for jobs at that destination which are running are displayed; this includes jobs which are suspended. Note that if there is no walltime given for a job, then elapsed time does not display.
-n	In addition to the basic information, nodes allocated to a job are listed.
-1	In combination with -n , the <code>-1</code> option puts all of the nodes on the same line as the job ID. In combination with -f , attributes are not folded to fit in a terminal window. This is intended to ease the parsing of the <code>qstat</code> output.
-s	In addition to the basic information, any comment provided by the batch administrator or scheduler is shown.
-G	Show size information in giga-bytes.

Option	Description
-M	Show size information, disk or memory in mega-words. A word is considered to be 8 bytes.
-R	In addition to other information, disk reservation information is shown. Not applicable to all systems.
-t	<p>Normal <code>qstat</code> output displays a summary of the array instead of the entire array, job for job. <code>qstat -t</code> expands the output to display the entire array. Note that arrays are now named with brackets following the array name; for example:</p> <pre>dbeer@napali:~/dev/torque/array_changes\$ echo sleep 20 qsub -t 0-299 189[] .napali</pre> <p>Individual jobs in the array are now also noted using square brackets instead of dashes; for example, here is part of the output of <code>qstat -t</code> for the preceding array:</p> <pre>189[299].napali STDIN[299] dbeer 0 Q batch</pre>
-u	<p>Job status is displayed in the alternative format. If an operand is a job id, status for that job is displayed. For a destination id operand, statuses for jobs at that destination which are owned by the user(s) listed in <code>user_list</code> are displayed. The syntax of the <code>user_list</code> is:</p> <pre>user_name[@host] [,user_name[@host], ...]</pre> <p>Host names may be wild carded on the left end, e.g. <code>*.nasa.gov</code>. User_name without a <code>@host</code> is equivalent to <code>user_name@*</code>, that is at any host.</p>
-Q	Specifies that the request is for queue status and that the operands are destination identifiers.
-q	Specifies that the request is for queue status which should be shown in the alternative format.
-B	Specifies that the request is for batch server status and that the operands are the names of servers.

Operands

If neither the **-Q** nor the **-B** option is given, the operands on the `qstat` command must be either job identifiers or destinations identifiers.

If the operand is a job identifier, it must be in the following form:

```
sequence_number[.server_name] [@server]
```

where *sequence_number*.*server_name* is the job identifier assigned at submittal time (see [qsub](#)). If the *.server_name* is omitted, the name of the default server will be used. If *@server* is supplied, the request will be for the job identifier currently at that Server.

If the operand is a destination identifier, it is one of the following three forms:

- queue
- @server
- queue@server

If queue is specified, the request is for status of all jobs in that queue at the default server. If the @server form is given, the request is for status of all jobs at that server. If a full destination identifier, queue@server, is given, the request is for status of all jobs in the named queue at the named server.

If the **-Q** option is given, the operands are destination identifiers as specified above. If queue is specified, the status of that queue at the default server will be given. If queue@server is specified, the status of the named queue at the named server will be given. If @server is specified, the status of all queues at the named server will be given. If no destination is specified, the status of all queues at the default server will be given.

If the **-B** option is given, the operand is the name of a server.

Standard output

Displaying job status

If job status is being displayed in the default format and the **-f** option is not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the job identifier assigned by PBS.
- the job name given by the submitter.
- the job owner.
- the CPU time used.
- the job state:

Item	Description
C	Job is completed after having run.
E	Job is exiting after having run.
H	Job is held.
Q	Job is queued, eligible to run or routed.

Item	Description
R	Job is running.
T	Job is being moved to new location.
W	Job is waiting for its execution time (-a option) to be reached.
S	(Unicos only) Job is suspended.

- the queue in which the job resides.

If job status is being displayed and the [-f](#) option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See [Configuration on page 3497](#) for details. If Tcl is not being used, full display for each job consists of the header line:

```
Job Id: job identifier
```

Followed by one line per job attribute of the form:

```
attribute_name = value
```

If any of the options [-a](#), [-i](#), [-r](#), [-u](#), [-n](#), [-s](#), [-G](#), or [-M](#) are provided, the alternative display format for jobs is used. The following items are displayed on a single line, in the specified order, separated by white space:

- the job identifier assigned by PBS
- the job owner
- the queue in which the job currently resides
- the job name given by the submitter
- the session id (if the job is running)
- the number of nodes requested by the job
- the number of cpus or tasks requested by the job
- the amount of memory requested by the job
- either the cpu time, if specified, or wall time requested by the job, (hh:mm)
- the jobs current state
- the amount of cpu time or wall time used by the job (hh:mm)

If the [-r](#) option is provided, the line contains:

- the job identifier assigned by PBS
- the job owner

- the queue in which the job currently resides
- the number of nodes requested by the job
- the number of cpus or tasks requested by the job
- the amount of memory requested by the job
- either the cpu time or wall time requested by the job
- the jobs current state
- the amount of cpu time or wall time used by the job
- the amount of SRFS space requested on the big file system
- the amount of SRFS space requested on the fast file system
- the amount of space requested on the parallel I/O file system

The last three fields may not contain useful information at all sites or on all systems

Displaying queue status

If queue status is being displayed and the **-f** option was not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the queue name
- the maximum number of jobs that may be run in the queue concurrently
- the total number of jobs in the queue
- the enable or disabled status of the queue
- the started or stopped status of the queue
- for each job state, the name of the state and the number of jobs in the queue in that state
- the type of queue, execution or routing

If queue status is being displayed and the **-f** option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See the configuration section for details. If Tcl is not being used, the full display for each queue consists of the header line:

```
Queue: queue_name
```

Followed by one line per queue attribute of the form:

```
attribute_name = value
```

If the **-Q** option is specified, queue information is displayed in the alternative format: The following information is displayed on a single line:

- the queue name
- the maximum amount of memory a job in the queue may request
- the maximum amount of cpu time a job in the queue may request
- the maximum amount of wall time a job in the queue may request
- the maximum amount of nodes a job in the queue may request
- the number of jobs in the queue in the running state
- the number of jobs in the queue in the queued state
- the maximum number (limit) of jobs that may be run in the queue concurrently
- the state of the queue given by a pair of letters:
 - either the letter *E* if the queue is Enabled or *D* if Disabled
 - and
 - either the letter *R* if the queue is Running (started) or *S* if Stopped.

Displaying server status

If batch server status is being displayed and the **-f** option is not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the server name
- the maximum number of jobs that the server may run concurrently
- the total number of jobs currently managed by the server
- the status of the server
- for each job state, the name of the state and the number of jobs in the server in that state

If server status is being displayed and the **-f** option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See the configuration section for details. If Tcl is not being used, the full display for the server consists of the header line:

```
Server: server name
```

Followed by one line per server attribute of the form:

```
attribute_name = value
```

Standard error

The `qstat` command will write a diagnostic message to standard error for each error occurrence.

Configuration

If `qstat` is compiled with an option to include a Tcl interpreter, using the `-f` flag to get a full display causes a check to be made for a script file to use to output the requested information. The first location checked is `$HOME/.qstatrc`. If this does not exist, the next location checked is administrator configured. If one of these is found, a Tcl interpreter is started and the script file is passed to it along with three global variables. The command line arguments are split into two variable named `flags` and `operands`. The status information is passed in a variable named `objects`. All of these variables are Tcl lists. The `flags` list contains the name of the command (usually "`qstat`") as its first element. Any other elements are command line option flags with any options they use, presented in the order given on the command line. They are broken up individually so that if two flags are given together on the command line, they are separated in the list. For example, if the user typed:

```
qstat -QfWbigdisplay
```

the `flags` list would contain

```
qstat -Q -f -W bigdisplay
```

The `operands` list contains all other command line arguments following the flags. There will always be at least one element in `operands` because if no operands are typed by the user, the default destination or server name is used. The `objects` list contains all the information retrieved from the server(s) so the Tcl interpreter can run once to format the entire output. This list has the same number of elements as the `operands` list. Each element is another list with two elements.

The first element is a string giving the type of objects to be found in the second. The string can take the values "server", "queue", "job" or "error".

The second element will be a list in which each element is a single batch status object of the type given by the string discussed above. In the case of "error", the list will be empty. Each object is again a list. The first element is the name of the object. The second is a list of attributes.

The third element will be the object text.

All three of these object elements correspond with fields in the structure `batch_status` which is described in detail for each type of object by the man pages for `pbs_statjob(3)`, `pbs_statqueue(3)`, and `pbs_statserver(3)`. Each attribute in the second element list whose elements correspond with the `attrl` structure. Each will be a list with two elements. The first will be the attribute name and the second will be the attribute value.

Exit status

Upon successful processing of all the operands presented to the `qstat` command, the exit status will be a value of zero.

If the `qstat` command fails to process any operand, the command exits with a value greater than zero.

qsub

Submit PBS job.

Synopsis

```
qsub [-a date_time] [-A account_string] [-b secs] [-c
checkpoint_options]
[-C directive_prefix] [-d path] [-D path] [-e path] [-f] [-F]
[-h]
[-I ] [-j join ] [-k keep ] [-l resource_list ]
[-m mail_options] [-M user_list] [-n] [-N name] [-o path]
[-p priority] [-P user[:group]] [-q destination] [-r c] [-S
path_to_shell(s)]
[-t array_request] [-u user_list]
[-v variable_list] [-V] [-W additional_attributes] [-x] [-X]
[-z] [script]
```

Description

To create a job is to submit an executable script to a batch server. The batch server will be the default server unless the `-q` option is specified. The command parses a script prior to the actual script execution; it does not execute a script itself. All script-writing rules remain in effect, including the `"#!/"` at the head of the file (see discussion of `PBS_DEFAULT` under [Environment variables on](#)

[page 3514](#)). Typically, the script is a shell script which will be executed by a command shell such as sh or csh.

Options on the `qsub` command allow the specification of attributes which affect the behavior of the job.

The `qsub` command will pass certain environment variables in the `Variable_List` attribute of the job. These variables will be available to the job. The value for the following variables will be taken from the environment of the `qsub` command: `HOME`, `LANG`, `LOGNAME`, `PATH`, `MAIL`, `SHELL`, and `TZ`. These values will be assigned to a new name which is the current name prefixed with the string `"PBS_O_"`. For example, the job will have access to an environment variable named `PBS_O_HOME` which have the value of the variable `HOME` in the `qsub` command environment.

In addition to the above, the following environment variables will be available to the batch job:

Variable	Description
PBS_O_HOST	The name of the host upon which the <code>qsub</code> command is running.
PBS_SERVER	The hostname of the <code>pbs_server</code> which <code>qsub</code> submits the job to.
PBS_O_QUEUE	The name of the original queue to which the job was submitted.
PBS_O_WORKDIR	The absolute path of the current working directory of the <code>qsub</code> command.
PBS_ARRAYID	Each member of a job array is assigned a unique identifier (see <code>-t</code> option).
PBS_ENVIRONMENT	Set to <code>PBS_BATCH</code> to indicate the job is a batch job, or to <code>PBS_INTERACTIVE</code> to indicate the job is a PBS interactive job (see <code>-I</code> option).
PBS_GPUFILE	The name of the file containing the list of assigned GPUs. For more information about how to set up TORQUE with GPUS, see Accelerators on page 948 .
PBS_JOBID	The job identifier assigned to the job by the batch system. It can be used in the stdout and stderr paths. TORQUE replaces <code>\$PBS_JOBID</code> with the job's jobid (for example, <code>#PBS -o /tmp/\$PBS_JOBID.output</code>).
PBS_JOBNAME	The job name supplied by the user.
PBS_NODEFILE	The name of the file contains the list of nodes assigned to the job (for parallel and cluster systems).
PBS_QUEUE	The name of the queue from which the job is executed.

Options

Option	Name	Description
-a	date_time	<p>Declares the time after which the job is eligible for execution.</p> <p>The <code>date_time</code> argument is in the form:</p> <pre>[[[CC] YY] MM] DD] hhmm [.SS]</pre> <p>where <i>CC</i> is the first two digits of the year (the century), <i>YY</i> is the second two digits of the year, <i>MM</i> is the two digits for the month, <i>DD</i> is the day of the month, <i>hh</i> is the hour, <i>mm</i> is the minute, and the optional <i>SS</i> is the seconds.</p> <p>If the month (<i>MM</i>) is not specified, it will default to the current month if the specified day (<i>DD</i>) is in the future. Otherwise, the month will be set to next month. Likewise, if the day (<i>DD</i>) is not specified, it will default to today if the time (<i>hhmm</i>) is in the future. Otherwise, the day will be set to tomorrow.</p> <p>For example, if you submit a job at 11:15 am with a time of <code>-a 1110</code>, the job will be eligible to run at 11:10 am tomorrow.</p>
-A	account_string	<p>Defines the account string associated with the job. The <code>account_string</code> is an undefined string of characters and is interpreted by the server which executes the job. See section 2.7.1 of the PBS ERS.</p>
-b	seconds	<p>Defines the maximum number of seconds <code>qsub</code> will block attempting to contact <code>pbs_server</code>. If <code>pbs_server</code> is down, or for a variety of communication failures, <code>qsub</code> will continually retry connecting to <code>pbs_server</code> for job submission.</p> <p>This value overrides the <code>CLIENTRETRY</code> parameter in <code>torque.cfg</code>. This is a non-portable TORQUE extension. Portability-minded users can use the <code>PBS_CLIENTRETRY</code> environmental variable. A negative value is interpreted as infinity. The default is 0.</p>

Option	Name	Description
-c	checkpoint_options	<p>Defines the options that will apply to the job. If the job executes upon a host which does not support checkpoint, these options will be ignored.</p> <p>Valid checkpoint options are:</p> <ul style="list-style-type: none"> • <i>none</i> – No checkpointing is to be performed. • <i>enabled</i> – Specify that checkpointing is allowed but must be explicitly invoked by either the ghold or gchkpt commands. • <i>shutdown</i> – Specify that checkpointing is to be done on a job at pbs_mom shutdown. • <i>periodic</i> – Specify that periodic checkpointing is enabled. The default interval is 10 minutes and can be changed by the \$checkpoint_interval option in the MOM config file or by specifying an interval when the job is submitted • <i>interval=minutes</i> – Checkpointing is to be performed at an interval of minutes, which is the integer number of minutes of wall time used by the job. This value must be greater than zero. • <i>depth=number</i> – Specify a number (depth) of checkpoint images to be kept in the checkpoint directory. • <i>dir=path</i> – Specify a checkpoint directory (default is /var/spool/torque/checkpoint).
-C	directive_prefix	<p>Defines the prefix that declares a directive to the <code>qsub</code> command within the script file. (See the paragraph on script directives under Extended description on page 3515.)</p> <p>If the <code>-C</code> option is presented with a <code>directive_prefix</code> argument that is the null string, <code>qsub</code> will not scan the script file for directives.</p>
-d	path	<p>Defines the working directory path to be used for the job. If the <code>-d</code> option is not specified, the default working directory is the home directory. This option sets the environment variable <code>PBS_O_INITDIR</code>.</p>
-D	path	<p>Defines the root directory to be used for the job. This option sets the environment variable <code>PBS_O_ROOTDIR</code>.</p>

Option	Name	Description
-e	path	<p>Defines the path to be used for the standard error stream of the batch job. The path argument is of the form:</p> <pre>[hostname:]path_name</pre> <p>where <i>hostname</i> is the name of a host to which the file will be returned, and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX.</p> <div>  When specifying a directory for the location you need to include a trailing slash. </div> <p>The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> • <i>path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component. • <i>hostname:path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will not expand the path name relative to the current working directory of the command. On delivery of the standard error, the path name will be expanded relative to the user's home directory on the hostname system. • <i>path_name</i> – where <i>path_name</i> specifies an absolute path name, then the <code>qsub</code> will supply the name of the host on which it is executing for the hostname. • <i>hostname:path_name</i> – where <i>path_name</i> specifies an absolute path name, the path will be used as specified. <p>If the <code>-e</code> option is not specified, the default file name for the standard error stream will be used. The default name has the following form:</p> <ul style="list-style-type: none"> • <i>job_name.esequence_number</i> – where <i>job_name</i> is the name of the job (see the <code>-n</code> name option) and <i>sequence_number</i> is the job number assigned when the job is submitted.
-f	---	<p>Job is made fault tolerant. Jobs running on multiple nodes are periodically polled by mother superior. If one of the nodes fails to report, the job is canceled by mother superior and a failure is reported. If a job is fault tolerant, it will not be canceled based on failed polling (no matter how many nodes fail to report). This may be desirable if transient network failures are causing large jobs not to complete, where ignoring one failed polling attempt can be corrected at the next polling attempt.</p> <div>  If TORQUE is compiled with <code>PBS_NO_POSIX_VIOLATION</code> (there is no config option for this), you have to use <code>-W fault_tolerant=true</code> to mark the job as fault tolerant. </div>

Option	Name	Description
-F	---	<p>Specifies the arguments that will be passed to the job script when the script is launched. The accepted syntax is:</p> <pre>qsub -F "myarg1 myarg2 myarg3=myarg3value" myscript2.sh</pre> <div>  Quotation marks are required. <code>qsub</code> will fail with an error message if the argument following <code>-F</code> is not a quoted value. The <code>pbs_mom</code> server will pass the quoted value as arguments to the job script when it launches the script. </div>
-h	---	Specifies that a user hold be applied to the job at submission time.
-l	---	<p>Declares that the job is to be run "interactively". The job will be queued and scheduled as any PBS batch job, but when executed, the standard input, output, and error streams of the job are connected through <code>qsub</code> to the terminal session in which <code>qsub</code> is running. Interactive jobs are forced to not rerunable. See Extended description on page 3515 for additional information of interactive jobs.</p>
-j	join	<p>Declares if the standard error stream of the job will be merged with the standard output stream of the job.</p> <p>An option argument value of <code>oe</code> directs that the two streams will be merged, intermixed, as standard output. An option argument value of <code>eo</code> directs that the two streams will be merged, intermixed, as standard error.</p> <p>If the join argument is <code>n</code> or the option is not specified, the two streams will be two separate files.</p> <div>  If using either the <code>-e</code> or the <code>-o</code> option and the <code>-j eo oe</code> option, the <code>-j</code> option takes precedence and all standard error and output messages go to the chosen output file. </div>

Option	Name	Description
-k	keep	<p>Defines which (if either) of standard output or standard error will be retained on the execution host. If set for a stream, this option overrides the path name for that stream. If not set, neither stream is retained on the execution host.</p> <p>The argument is either the single letter "e" or "o", or the letters "e" and "o" combined in either order. Or the argument is the letter "n".</p> <ul style="list-style-type: none"> • <i>e</i> – The standard error stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.esquence</code> where <i>job_name</i> is the name specified for the job, and <i>sequence</i> is the sequence number component of the job identifier. • <i>o</i> – The standard output stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.osequence</code> where <i>job_name</i> is the name specified for the job, and <i>sequence</i> is the sequence number component of the job identifier. • <i>eo</i> – Both the standard output and standard error streams will be retained. • <i>oe</i> – Both the standard output and standard error streams will be retained. • <i>n</i> – Neither stream is retained.
-l	resource_list	<p>Defines the resources that are required by the job and establishes a limit to the amount of resource that can be consumed. If not set for a generally available resource, such as CPU time, the limit is infinite. The resource_list argument is of the form: <code>resource_name[=[value]][, resource_name[=[value]], ...]</code></p> <div style="border: 1px solid #0070c0; border-radius: 10px; padding: 10px; margin: 10px 0;"> <p> In this situation, you should request the more inclusive resource first. For example, a request for procs should come before a gres request.</p> </div> <p>In TORQUE 3.0.2 or later, <code>qsub</code> supports the mapping of <code>-l gpus=X</code> to <code>-l gres=gpus:X</code>. This allows users who are using NUMA systems to make requests such as <code>-l ncpus=20:gpus=5</code> indicating they are not concerned with the GPUs in relation to the NUMA nodes they request, they only want a total of 20 cores and 5 GPUs.</p> <p>For more information, see Requesting Resources on page 3330.</p> <p>For information on specifying multiple types of resources for allocation, see Multi-Req Support on page 659.</p>

Option	Name	Description
-m	mail_options	<p>Defines the set of conditions under which the execution server will send a mail message about the job. The mail_options argument is a string which consists of either the single character "n", or one or more of the characters "a", "b", and "e".</p> <p>If the character "n" is specified, no normal mail is sent. Mail for job cancels and other events outside of normal job processing are still sent.</p> <p>For the letters "a", "b", and "e":</p> <ul style="list-style-type: none"> • <i>a</i> – Mail is sent when the job is aborted by the batch system. • <i>b</i> – Mail is sent when the job begins execution. • <i>e</i> – Mail is sent when the job terminates. <p>If the <code>-m</code> option is not specified, mail will be sent if the job is aborted.</p>
-M	user_list	<p>Declares the list of users to whom mail is sent by the execution server when it sends mail about the job.</p> <p>The user_list argument is of the form:</p> <pre>user[@host] [, user[@host] , ...]</pre> <p>If unset, the list defaults to the submitting user at the <code>qsub</code> host, i.e. the job owner.</p>
-n	node-exclusive	<p>Allows a user to specify an exclusive-node access/allocation request for the job. This affects only cpusets and compatible schedulers (see Linux Cpuset Support on page 3368).</p>
-N	name	<p>Declares a name for the job. The name specified may be an unlimited number of characters in length. It must consist of printable, nonwhite space characters with the first character alphabetic.</p> <p>If the <code>-N</code> option is not specified, the job name will be the base name of the job script file specified on the command line. If no script file name was specified and the script was read from the standard input, then the job name will be set to STDIN.</p>

Option	Name	Description
-o	path	<p>Defines the path to be used for the standard output stream of the batch job. The path argument is of the form:</p> <pre>[hostname:]path_name</pre> <p>where <i>hostname</i> is the name of a host to which the file will be returned, and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX.</p> <div>  When specifying a directory for the location you need to include a trailing slash. </div> <p>The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> <i>path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component. <i>hostname:path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will not expand the path name relative to the current working directory of the command. On delivery of the standard output, the path name will be expanded relative to the user's home directory on the hostname system. <i>path_name</i> – where <i>path_name</i> specifies an absolute path name, then the <code>qsub</code> will supply the name of the host on which it is executing for the hostname. <i>hostname:path_name</i> where <i>path_name</i> specifies an absolute path name, the path will be used as specified. <p>If the <code>-o</code> option is not specified, the default file name for the standard output stream will be used. The default name has the following form:</p> <ul style="list-style-type: none"> <i>job_name.osequence_number</i> – where <i>job_name</i> is the name of the job (see the -n name option) and <i>sequence_number</i> is the job number assigned when the job is submitted.
-p	priority	<p>Defines the priority of the job. The priority argument must be a integer between -1024 and +1023 inclusive. The default is no priority which is equivalent to a priority of zero.</p>
-P	user [:group]	<p>Allows a root user or manager to submit a job as another user. TORQUE treats proxy jobs as though the jobs were submitted by the supplied username. This feature is available in TORQUE 2.4.7 and later, however, TORQUE 2.4.7 does not have the ability to supply the <code>[:group]</code> option; it is available in TORQUE 2.4.8 and later.</p>

Option	Name	Description
-q	destination	<p>Defines the destination of the job. The destination names a queue, a server, or a queue at a server.</p> <p>The <code>qsub</code> command will submit the script to the server defined by the destination argument. If the destination is a routing queue, the job may be routed by the server to a new destination.</p> <p>If the <code>-q</code> option is not specified, the <code>qsub</code> command will submit the script to the default server. (See Environment variables on page 3514 and the PBS ERS section 2.7.4, "Default Server".)</p> <p>If the <code>-q</code> option is specified, it is in one of the following three forms:</p> <ul style="list-style-type: none"> • queue • @server • queue@server <p>If the destination argument names a queue and does not name a server, the job will be submitted to the named queue at the default server.</p> <p>If the destination argument names a server and does not name a queue, the job will be submitted to the default queue at the named server.</p> <p>If the destination argument names both a queue and a server, the job will be submitted to the named queue at the named server.</p>
-r	y/n	<p>Declares whether the job is rerunnable (see the grerun command). The option argument is a single character, either y or n.</p> <p>If the argument is "y", the job is rerunnable. If the argument is "n", the job is not rerunnable. The default value is y, rerunnable.</p>
-S	path_list	<p>Declares the path to the desired shell for this job.</p> <pre>qsub script.sh -S /bin/tcsh</pre> <p>If the shell path is different on different compute nodes, use the following syntax:</p> <pre>path[@host] [,path[@host], ...]</pre> <pre>qsub script.sh -S /bin/tcsh@node1,/usr/bin/tcsh@node2</pre> <p>Only one path may be specified for any host named. Only one path may be specified without the corresponding host name. The path selected will be the one with the host name that matched the name of the execution host. If no matching host is found, then the path specified without a host will be selected, if present.</p> <p>If the <code>-S</code> option is not specified, the option argument is the null string, or no entry from the <code>path_list</code> is selected, the execution will use the user's login shell on the execution host.</p>

Option	Name	Description
-t	array_request	<p>Specifies the task ids of a job array. Single task arrays are allowed.</p> <p>The array_request argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code></p> <p>An optional <i>slot limit</i> can be specified to limit the amount of jobs that can run concurrently in the job array. The default value is unlimited. The slot limit must be the last thing specified in the array_request and is delimited from the array by a percent sign (%).</p> <pre>qsub script.sh -t 0-299%5</pre> <p>This sets the slot limit to 5. Only 5 jobs from this array can run at the same time.</p> <p>You can use qalter to modify slot limits on an array. The server parameter max_slot_limit can be used to set a global slot limit policy.</p>
-u	user_list	<p>Defines the user name under which the job is to run on the execution system.</p> <p>The user_list argument is of the form:</p> <pre>user[@host] [,user[@host],...]</pre> <p>Only one user name may be given per specified host. Only one of the user specifications may be supplied without the corresponding host specification. That user name will be used for execution on any host not named in the argument list. If unset, the user list defaults to the user who is running <code>qsub</code>.</p>
-v	variable_list	<p>Expands the list of environment variables that are exported to the job.</p> <p>In addition to the variables described in the "Description" section above, variable_list names environment variables from the <code>qsub</code> command environment which are made available to the job when it executes. The variable_list is a comma separated list of strings of the form <code>variable</code> or <code>variable=value</code>. These variables and their values are passed to the job. Note that <code>-v</code> has a higher precedence than <code>-V</code>, so identically named variables specified via <code>-v</code> will provide the final value for an environment variable in the job.</p>
-V	---	<p>Declares that all environment variables in the <code>qsub</code> commands environment are to be exported to the batch job.</p>

Option	Name	Description
-W	additional_attributes	<p>The -W option allows for the specification of additional job attributes. The general syntax of -W is in the form:</p> <pre>-W attr_name=attr_value.</pre> <p>You can use multiple -W options with this syntax:</p> <pre>-W attr_name1=attr_value1 -W attr_name2=attr_value2.</pre> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p>i If white space occurs anywhere within the option argument string or the equal sign, "=", occurs within an attribute_value string, then the string must be enclosed with either single or double quote marks.</p> </div> <p>PBS currently supports the following attributes within the -W option:</p> <ul style="list-style-type: none"> • depend=dependency_list – Defines the dependency between this and other jobs. The dependency_list is in the form: <pre>type[:argument[:argument...]][,type:argument...]</pre> <p>The argument is either a numeric count or a PBS job id according to type. If argument is a count, it must be greater than 0. If it is a job id and not fully specified in the form <code>seq_number.server.name</code>, it will be expanded according to the default server rules which apply to job IDs on most commands. If argument is null (the preceding colon need not be specified), the dependency of the corresponding type is cleared (unset). For more information, see depend=dependency_list valid dependencies on page 3510.</p> • group_list=g_list – Defines the group name under which the job is to run on the execution system. The g_list argument is of the form: <pre>group[@host][,group[@host],...]</pre> <p>Only one group name may be given per specified host. Only one of the group specifications may be supplied without the corresponding host specification. That group name will be used for execution on any host not named in the argument list. If not set, the group_list defaults to the primary group of the user under which the job will be run.</p> • interactive=true – If the interactive attribute is specified, the job is an interactive job. The -I option is an alternative method of specifying this attribute. • job_radix=<int> – To be used with parallel jobs. It directs the Mother Superior of the job to create a distribution radix of size <i><int></i> between sisters. See Managing Multi-Node Jobs on page 3329. • stagein=file_list • stageout=file_list – Specifies which files are staged (copied) in before job start or staged out after the job completes execution. On completion of the job, all staged-in and staged-out files are removed from the execution system. The file_list is in the form: <pre>local_file@hostname:remote_file[,...]</pre> <p>regardless of the direction of the copy. The name local_file is the name of the file on the system where the job executed. It may be an absolute path or relative to the home directory of the user. The name remote_file is the destination name on the host specified by hostname. The name may be</p>

Option	Name	Description
		<p>absolute or relative to the user's home directory on the destination host. The use of wildcards in the file name is not recommended. The file names map to a remote copy program (rcp) call on the execution system in the follow manner:</p> <ul style="list-style-type: none"> ◦ For stagein: <code>rcp hostname:remote_file local_file</code> ◦ For stageout: <code>rcp local_file hostname:remote_file</code> <p>Data staging examples:</p> <pre>-W stagein=/tmp/input.txt@headnode:/home/user/input.txt -W stageout=/tmp/output.txt@headnode:/home/user/output.txt</pre> <p>If TORQUE has been compiled with wordexp support, then variables can be used in the specified paths. Currently only <code>\$PBS_JOBID</code>, <code>\$HOME</code>, and <code>\$TMPDIR</code> are supported for stagein.</p> <ul style="list-style-type: none"> • <code>umask=XXX</code> – Sets umask used to create stdout and stderr spool files in pbs_mom spool directory. Values starting with 0 are treated as octal values, otherwise the value is treated as a decimal umask value.
-x	---	<p>By default, if you submit an interactive job with a script, the script will be parsed for PBS directives but the rest of the script will be ignored since it's an interactive job. The <code>-x</code> option allows the script to be executed in the interactive job and then the job completes. For example:</p> <pre>script.sh #!/bin/bash ls ---end script--- qsub -I script.sh qsub: waiting for job 5.napali to start dbeer@napali:~# <displays the contents of the directory, because of the ls command> qsub: job 5.napali completed</pre>
-X	---	Enables X11 forwarding. The <code>DISPLAY</code> environment variable must be set.
-z	---	Directs that the <code>qsub</code> command is not to write the job identifier assigned to the job to the commands standard output.

depend=dependency_list valid dependencies

 For job dependencies to work correctly, you must set the **keep_completed** on page 3529 server parameter.

Dependency	Description
<code>synccount:count</code>	This job is the first in a set of jobs to be executed at the same time. Count is the number of additional jobs in the set.
<code>syncwith:jobid</code>	This job is an additional member of a set of jobs to be executed at the same time. In the above and following dependency types, jobid is the job identifier of the first job in the set.
<code>after:jobid[:jobid...]</code>	This job may be scheduled for execution at any point after jobs jobid have started execution.
<code>afterok:jobid[:jobid...]</code>	This job may be scheduled for execution only after jobs jobid have terminated with no errors. See the csh warning under Extended description on page 3515 .
<code>afternotok:jobid[:jobid...]</code>	This job may be scheduled for execution only after jobs jobid have terminated with errors. See the csh warning under Extended description on page 3515 .
<code>afterany:jobid[:jobid...]</code>	This job may be scheduled for execution after jobs jobid have terminated, with or without errors.
<code>on:count</code>	This job may be scheduled for execution after count dependencies on other jobs have been satisfied. This form is used in conjunction with one of the "before" forms (see below).
<code>before:jobid[:jobid...]</code>	When this job has begun execution, then jobs jobid... may begin.
<code>beforeok:jobid[:jobid...]</code>	If this job terminates execution without errors, then jobs jobid... may begin. See the csh warning under Extended description on page 3515 .
<code>beforenotok:jobid[:jobid...]</code>	If this job terminates execution with errors, then jobs jobid... may begin. See the csh warning under Extended description on page 3515 .

Dependency	Description
<code>beforeany:jobid[:jobid...]</code>	<p>When this job terminates execution, jobs <code>jobid...</code> may begin.</p> <p>If any of the before forms are used, the jobs referenced by <code>jobid</code> must have been submitted with a dependency type of <code>on</code>.</p> <p>If any of the before forms are used, the jobs referenced by <code>jobid</code> must have the same owner as the job being submitted. Otherwise, the dependency is ignored.</p>
<p>i Array dependencies make a job depend on an array or part of an array. If no count is given, then the entire array is assumed. For examples, see Dependency examples on page 3513.</p>	
<code>afterstartarray:arrayid[count]</code>	After this many jobs have started from <code>arrayid</code> , this job may start.
<code>afterokarray:arrayid[count]</code>	This job may be scheduled for execution only after jobs in <code>arrayid</code> have terminated with no errors.
<code>afternotokarray:arrayid[count]</code>	This job may be scheduled for execution only after jobs in <code>arrayid</code> have terminated with errors.
<code>afteranyarray:arrayid[count]</code>	This job may be scheduled for execution after jobs in <code>arrayid</code> have terminated, with or without errors.
<code>beforestartarray:arrayid[count]</code>	Before this many jobs have started from <code>arrayid</code> , this job may start.
<code>beforeokarray:arrayid[count]</code>	If this job terminates execution without errors, then jobs in <code>arrayid</code> may begin.
<code>beforenotokarray:arrayid[count]</code>	If this job terminates execution with errors, then jobs in <code>arrayid</code> may begin.
<code>beforeanyarray:arrayid[count]</code>	<p>When this job terminates execution, jobs in <code>arrayid</code> may begin.</p> <p>If any of the before forms are used, the jobs referenced by <code>arrayid</code> must have been submitted with a dependency type of <code>on</code>.</p> <p>If any of the before forms are used, the jobs referenced by <code>arrayid</code> must have the same owner as the job being submitted. Otherwise, the dependency is ignored.</p>

Dependency	Description
 Error processing of the existence, state, or condition of the job on which the newly submitted job is a deferred service, i.e. the check is performed after the job is queued. If an error is detected, the new job will be deleted by the server. Mail will be sent to the job submitter stating the error.	

Dependency examples

```
qsub -W depend=afterok:123.big.iron.com /tmp/script
```

```
qsub -W depend=before:234.hunk1.com:235.hunk1.com
```

```
/tmp/script
```

```
qsub script.sh -W depend=afterokarray:427[]
```

(This assumes every job in array 427 has to finish successfully for the dependency to be satisfied.)

```
qsub script.sh -W depend=afterokarray:427[][5]
```

(This means that 5 of the jobs in array 427 have to successfully finish in order for the dependency to be satisfied.)

Operands

The `qsub` command accepts a script operand that is the path to the script of the job. If the path is relative, it will be expanded relative to the working directory of the `qsub` command.

If the script operand is not provided or the operand is the single character "-", the `qsub` command reads the script from standard input. When the script is being read from Standard Input, `qsub` will copy the file to a temporary file. This temporary file is passed to the library interface routine `pbs_submit`. The temporary file is removed by `qsub` after `pbs_submit` returns or upon the receipt of a signal which would cause `qsub` to terminate.

Standard input

The `qsub` command reads the script for the job from standard input if the script operand is missing or is the single character "-".

Input files

The script file is read by the `qsub` command. `qsub` acts upon any directives found in the script.

When the job is created, a copy of the script file is made and that copy cannot be modified.

Standard output

Unless the **-z** option is set, the job identifier assigned to the job will be written to standard output if the job is successfully created.

Standard error

The **qsub** command will write a diagnostic message to standard error for each error occurrence.

Environment variables

The values of some or all of the variables in the **qsub** commands environment are exported with the job (see the **-v** and **-V** options).

The environment variable **PBS_DEFAULT** defines the name of the default server. Typically, it corresponds to the system name of the host on which the server is running. If **PBS_DEFAULT** is not set, the default is defined by an administrator established file.

The environment variable **PBS_DPREFIX** determines the prefix string which identifies directives in the script.

The environment variable **PBS_CLIENTRETRY** defines the maximum number of seconds **qsub** will block (see the **-b** option). Despite the name, currently **qsub** is the only client that supports this option.

torque.cfg

The **torque.cfg** file, located in **PBS_SERVER_HOME** (**/var/spool/torque** by default) controls the behavior of the **qsub** command. This file contains a list of parameters and values separated by whitespace.

- **QSUBSLEEP** – takes an integer operand which specifies time to sleep when running **qsub** command. Used to prevent users from overwhelming the scheduler.
- **SUBMITFILTER** – specifies the path to the submit filter used to pre-process job submission. The default path is **libexecdir/qsub_filter**, which falls back to **/usr/local/sbin/torque_submitfilter** for backwards compatibility. This **torque.cfg** parameter overrides this default.
- **SERVERHOST**
- **QSUBHOST**
- **QSUBSENDUID**
- **XAUTHPATH**
- **CLIENTRETRY**
- **VALIDATEGROUP**

- *DEFAULTCKPT*
- *VALIDATEPATH*
- *RERUNNABLEBYDEFAULT*

For example:

```
QSUBSLEEP 2
```

```
RERUNNABLEBYDEFAULT false
```

Extended description

Script Processing:

A job script may consist of PBS directives, comments and executable statements. A PBS directive provides a way of specifying job attributes in addition to the command line options. For example:

```
:
#PBS -N Job_name
#PBS -l walltime=10:30,mem=320kb
#PBS -m be
#
step1 arg1 arg2
step2 arg3 arg4
```

The `qsub` command scans the lines of the script file for directives. An initial line in the script that begins with the characters `"#!/"` or the character `":"` will be ignored and scanning will start with the next line. Scanning will continue until the first executable line, that is a line that is not blank, not a directive line, nor a line whose first nonwhite space character is `"#"`. If directives occur on subsequent lines, they will be ignored.

A line in the script file will be processed as a directive to `qsub` if and only if the string of characters starting with the first nonwhite space character on the line and of the same length as the directive prefix matches the directive prefix.

The remainder of the directive line consists of the options to `qsub` in the same syntax as they appear on the command line. The option character is to be preceded with the `"-"` character.

If an option is present in both a directive and on the command line, that option and its argument, if any, will be ignored in the directive. The command line takes precedence.

If an option is present in a directive and not on the command line, that option and its argument, if any, will be processed as if it had occurred on the command line.

The directive prefix string will be determined in order of preference from:

- The value of the **-c** option argument if the option is specified on the command line.
- The value of the environment variable PBS_DPREFIX if it is defined.
- The four character string #PBS.

If the **-c** option is found in a directive in the script file, it will be ignored.

User Authorization:

When the user submits a job from a system other than the one on which the PBS Server is running, the name under which the job is to be executed is selected according to the rules listed under the **-u** option. The user submitting the job must be authorized to run the job under the execution user name. This authorization is provided if:

- The host on which `qsub` is run is trusted by the execution host (see `/etc/hosts.equiv`).
- The execution user has an `.rhosts` file naming the submitting user on the submitting host.

C-Shell .logout File:

The following warning applies for users of the c-shell, `csh`. If the job is executed under the `csh` and a `.logout` file exists in the home directory in which the job executes, the exit status of the job is that of the `.logout` script, not the job script. This may impact any inter-job dependencies. To preserve the job exit status, either remove the `.logout` file or place the following line as the first line in the `.logout` file:

```
set EXITVAL = $status
```

and the following line as the last executable line in `.logout`:

```
exit $EXITVAL
```

Interactive Jobs:

If the **-I** option is specified on the command line or in a script directive, or if the "interactive" job attribute declared true via the **-W** option, `-W interactive=true`, either on the command line or in a script directive, the job is an interactive job. The script will be processed for directives, but will not be included with the job. When the job begins execution, all input to the job is from the terminal session in which `qsub` is running.

When an interactive job is submitted, the `qsub` command will not terminate when the job is submitted. `qsub` will remain running until the job terminates, is aborted, or the user interrupts `qsub` with an SIGINT (the control-C key). If `qsub` is interrupted prior to job start, it will query if the user wishes to exit. If the user response "yes", `qsub` exits and the job is aborted.

Once the interactive job has started execution, input to and output from the job pass through `qsub`. Keyboard generated interrupts are passed to the job. Lines entered that begin with the tilde (~) character and contain special sequences are escaped by `qsub`. The recognized escape sequences are:

Sequence	Description
<code>~.</code>	<code>qsub</code> terminates execution. The batch job is also terminated.
<code>~susp</code>	Suspend the <code>qsub</code> program if running under the C shell. "susp" is the suspend character (usually CNTL-Z).
<code>~asusp</code>	Suspend the input half of <code>qsub</code> (terminal to job), but allow output to continue to be displayed. Only works under the C shell. "asusp" is the auxiliary suspend character, usually CNTL-Y.

Exit status

Upon successful processing, the `qsub` exit status will be a value of zero.

If the `qsub` command fails, the command exits with a value greater than zero.

qterm

Terminate processing by a PBS batch server.

Synopsis

```
qterm [-t type] [server...]
```

Description

The `qterm` command terminates a batch server. When a server receives a terminate command, the server will go into the "Terminating" state. No new jobs will be allowed to be started into execution or enqueued into the server. The impact on jobs currently being run by the server depends

In order to execute `qterm`, the user must have PBS Operation or Manager privileges.

Options

Option	Name	Description
-t	type	<p>Specifies the type of shut down. The types are:</p> <ul style="list-style-type: none"> <i>immediate</i> – If checkpointing is supported, all running jobs are to immediately stop execution. If checkpointing is supported, running jobs that can be checkpointed are checkpointed, terminated, and requeued. If checkpoint is not supported or the job cannot be checkpointed, running jobs are requeued if the rerunable attribute is true. Otherwise, jobs are killed. <i>delay</i> – If checkpointing is supported, running jobs that can be checkpointed are checkpointed, terminated, and requeued. If a job cannot be checkpointed, but can be rerun, the job is terminated and requeued. Otherwise, running jobs are allowed to continue to run. <div style="border: 1px solid #005596; border-radius: 5px; padding: 10px; margin: 10px 0;"> <p> Note, the operator or administrator may use the qgrerun and qdel commands to remove running jobs.</p> </div> <ul style="list-style-type: none"> <i>quick</i> – This is the default action if the <code>-t</code> option is not specified. This option is used when you wish that running jobs be left running when the server shuts down. The server will cleanly shutdown and can be restarted when desired. Upon restart of the server, jobs that continue to run are shown as running; jobs that terminated during the server's absence will be placed into the exiting state.

Operands

The server operand specifies which servers are to shut down. If no servers are given, then the default server will be terminated.

Standard error

The `qterm` command will write a diagnostic message to standard error for each error occurrence.

Exit status

Upon successful processing of all the operands presented to the `qterm` command, the exit status will be a value of zero.

If the `qterm` command fails to process any operand, the command exits with a value greater than zero.

trqauthd

(TORQUE authorization daemon)

Synopsis

```
trqauthd -D
trqauthd -d
```

Description

The `trqauthd` daemon, introduced in TORQUE 4.0.0, replaced the `pbs_iff` authentication process. When users connect to `pbs_server` by calling one of the TORQUE utilities or by using the TORQUE APIs, the new user connection must be authorized by a trusted entity which runs as root. The advantage of `trqauthd`'s doing this rather than `pbs_iff` is that `trqauthd` is resident, meaning you do not need to be loaded every time a connection is made; multi-threaded; scalable; and more easily adapted to new functionality than `pbs_iff`.

Beginning in TORQUE 4.2.6, `trqauthd` can remember the currently active `pbs_server` host, enhancing high availability functionality. Previously, `trqauthd` tried to connect to each host in the `$TORQUE_HOME/<server_name>` file until it could successfully connect. Because it now remembers the active server, it tries to connect to that server first. If it fails to connect, it will go through the `<server_name>` file and try to connect to a host where an active `pbs_server` is running.

Options

-D — Debug	
Format	---
Default	---
Description	Run <code>trqauthd</code> in debug mode.
Example	<code>trqauthd -D</code>

-d — Terminate	
Format	---
Default	---
Description	Terminate <code>trqauthd</code> .
Example	<code>trqauthd -d</code>

Appendix B: Server Parameters

TORQUE server parameters are specified using the [qmgr](#) command. The `set` subcommand is used to modify the **server** object. For example:

```
> qmgr -c 'set server default_queue=batch'
```

acl_hosts

Format	<HOST>[,<HOST>]... or <HOST>[range] or <HOST*> where the asterisk (*) can appear anywhere in the host name
Default	Not set.

acl_hosts**Description**

Specifies a list of hosts which can have access to pbs_server when acl_host_enable is set to TRUE. This does not enable a node to submit jobs. To enable a node to submit jobs use submit_hosts.

Hosts which are in the \$TORQUE_HOME/server_priv/nodesfile do not need to be added to this list.

```
Qmgr: set queue batch acl_hosts="hostA,hostB"
Qmgr: set queue batch acl_hosts+=hostC
Qmgr: set server acl_hosts="hostA,hostB"
Qmgr: set server acl_hosts+=hostC
```

In version 2.5 and later, the wildcard (*) character can appear anywhere in the host name, and ranges are supported; these specifications also work for managers and operators.

```
Qmgr: set server acl_hosts = "galaxy*.tom.org"
Qmgr: set server acl_hosts += "galaxy[0-50].tom.org"
```

acl_host_enable**Format**

<BOOLEAN>

Default

FALSE

Description

When set to TRUE, hosts not in the pbs_server nodes file must be added to the **acl_hosts** list in order to get access to pbs_server.

acl_logic_or**Format**

<BOOLEAN>

Default

FALSE

Description

When set to TRUE, the user and group queue ACLs are logically OR'd. When set to FALSE, they are AND'd.

allow_node_submit**Format**

<BOOLEAN>

Default

FALSE

allow_node_submit

Description	When set to <code>TRUE</code> , allows all hosts that are in the <code>\$TORQUE_HOME/server_priv/nodes</code> file (MOM nodes) to submit jobs to <code>pbs_server</code> .
--------------------	--

allow_proxy_user

Format	<BOOLEAN>
Default	FALSE
Description	When set to <code>TRUE</code> , specifies that users can proxy from one user to another. Proxy requests will be either validated by <code>ruserok()</code> or by the scheduler (see Job Submission on page 3326).

auto_node_np

Format	<BOOLEAN>
Default	DISABLED
Description	When set to <code>TRUE</code> , automatically configures a node's <code>np</code> (number of processors) value based on the <code>ncpus</code> value from the status update. Requires full manager privilege to set or alter.

automatic_requeue_exit_code

Format	<LONG>
Default	---
Description	This is an exit code, defined by the admin, that tells <code>pbs_server</code> to requeue the job instead of considering it as completed. This allows the user to add some additional checks that the job can run meaningfully, and if not, then the job script exits with the specified code to be requeued.

checkpoint_defaults

Format	<STRING>
Default	---

checkpoint_defaults

Description Specifies for a queue the default checkpoint values for a job that does not have checkpointing specified. The checkpoint_defaults parameter only takes effect on execution queues.

```
set queue batch checkpoint_defaults="enabled, periodic, interval=5"
```

clone_batch_delay

Format <INTEGER>

Default 1

Description Specifies the delay (in seconds) between clone batches (see [clone_batch_size](#)).

clone_batch_size

Format <INTEGER>

Default 256

Description Job arrays are created in batches of size *X*. *X* jobs are created, and after the [clone_batch_delay](#), *X* more are created. This repeats until all are created.

copy_on_rerun

Format <BOOLEAN>

Default FALSE

Description When set to TRUE, Moab HPC Suite will copy the output and error files over to the user-specified directory when the `grerun` command is executed (i.e. a job preemption). Output and error files are only created when a job is in running state before the preemption occurs.

 `pbs_server` and `pbs_mom` need to be on the same version.

 When you change the value, you must perform a `pbs_server` restart for the change to effect.

cray_enabled	
Format	<BOOLEAN>
Default	FALSE
Description	When set to TRUE , specifies that this instance of pbs_server has Cray hardware that reports to it. See Installation Notes for Moab and TORQUE for Cray on page 1386 .

\$cuda_visible_devices	
Format	<BOOLEAN>
Default	TRUE
Description	When set to TRUE , the MOM will set the CUDA_VISIBLE_DEVICES environment variable for jobs using NVIDIA GPUs. If set to FALSE , the MOM will not set CUDA_VISIBLE_DEVICES for any jobs.
Example	<pre>\$cuda_visible_devices true</pre>

default_queue	
Format	<STRING>
Default	---
Description	Indicates the queue to assign to a job if no queue is explicitly specified by the submitter.

disable_server_id_check	
Format	<BOOLEAN>
Default	FALSE
Description	<p>When set to TRUE, makes it so the user for the job doesn't have to exist on the server. The user must still exist on all the compute nodes or the job will fail when it tries to execute.</p> <div>  <p>If you have disable_server_id_check set to TRUE, a user could request a group to which they do not belong. Setting VALIDATEGROUP to TRUE in the <code>torque.cfg</code> file prevents such a scenario (see Appendix K: "torque.cfg" Configuration File on page 3586).</p> </div>

display_job_server_suffix

Format	<BOOLEAN>
Default	TRUE
Description	<p>When set to <code>TRUE</code>, TORQUE will display both the job ID and the host name. When set to <code>FALSE</code>, only the job ID will be displayed.</p> <div>  If set to <code>FALSE</code>, the environment variable <code>NO_SERVER_SUFFIX</code> must be set to <code>TRUE</code> for <code>pbs_track</code> to work as expected. </div>

interactive_jobs_can_roam

Format	<BOOLEAN>
Default	FALSE
Description	<p>By default, interactive jobs run from the login node that they submitted from. When <code>TRUE</code>, interactive jobs may run on login nodes other than the one where the jobs were submitted to. See Installation Notes for Moab and TORQUE for Cray on page 1386.</p>

job_exclusive_on_use

Format	<BOOLEAN>
Default	FALSE
Description	<p>When <code>job_exclusive_on_use</code> is set to <code>TRUE</code>, pbsnodes will show job-exclusive on a node when there's at least one of its processors running a job. This differs with the default behavior which is to show job-exclusive on a node when all of its processors are running a job.</p>
Example	<pre>set server job_exclusive_on_use=TRUE</pre>

job_force_cancel_time

Format	<INTEGER>
Default	Disabled

job_force_cancel_time

Description	If a job has been deleted and is still in the system after <i>x</i> seconds, the job will be purged from the system. This is mostly useful when a job is running on a large number of nodes and one node goes down. The job cannot be deleted because the MOM cannot be contacted. The <code>qdel</code> fails and none of the other nodes can be reused. This parameter can be used to remedy such situations.
--------------------	---

job_log_file_max_size

Format	<INTEGER>
Default	---
Description	This specifies a soft limit (in kilobytes) for the job log's maximum size. The file size is checked every five minutes and if the <i>current day</i> file size is greater than or equal to this value, it is rolled from <filename> to <filename.1> and a new empty log is opened. If the current day file size exceeds the maximum size a second time, the <filename.1> log file is rolled to <filename.2>, the current log is rolled to <filename.1>, and a new empty log is opened. Each new log causes all other logs to roll to an extension that is one greater than its current number. Any value less than 0 is ignored by <code>pbs_server</code> (meaning the log will not be rolled).

job_log_file_roll_depth

Format	<INTEGER>
Default	---
Description	This sets the maximum number of new log files that are kept in a day if the job_log_file_max_size parameter is set. For example, if the roll depth is set to 3, no file can roll higher than <filename.3>. If a file is already at the specified depth, such as <filename.3>, the file is deleted so it can be replaced by the incoming file roll, <filename.2>.

job_log_keep_days

Format	<INTEGER>
Default	---
Description	This maintains logs for the number of days designated. If set to 4, any log file older than 4 days old is deleted.

job_nanny	
Format	<BOOLEAN>
Default	FALSE
Description	When set to TRUE , enables the experimental "job deletion nanny" feature. All job cancels will create a repeating task that will resend KILL signals if the initial job cancel failed. Further job cancels will be rejected with the message "job cancel in progress." This is useful for temporary failures with a job's execution node during a job delete request.

job_stat_rate	
Format	<INTEGER>
Default	300 (30 in TORQUE 1.2.0p5 and earlier)
Description	If the mother superior has not sent an update by the specified time, at the specified time pbs_server requests an update on job status from the mother superior.

job_start_timeout	
Format	<INTEGER>
Default	---
Description	Specifies the pbs_server to pbs_mom TCP socket timeout in seconds that is used when the pbs_server sends a job start to the pbs_mom. It is useful when the MOM has extra overhead involved in starting jobs. If not specified, then the tcp_timeout parameter is used.

job_sync_timeout	
Format	<INTEGER>
Default	60
Description	When a stray job is reported on multiple nodes, the server sends a kill signal to one node at a time. This timeout determines how long the server waits between kills if the job is still being reported on any nodes.

keep_completed	
Format	<INTEGER>
Default	---
	 If you ran <code>torque.setup</code> on TORQUE installation, the default is 300.
Description	<p>The amount of time a job will be kept in the queue after it has entered the completed state. <code>keep_completed</code> <i>must</i> be set for job dependencies to work.</p> <p>For more information, see Keeping Completed Jobs on page 3344.</p>

lock_file	
Format	<STRING>
Default	<code>torque/server_priv/server.lock</code>
Description	<p>Specifies the name and location of the lock file used to determine which high availability server should be active.</p> <p>If a full path is specified, it is used verbatim by TORQUE. If a relative path is specified, TORQUE will prefix it with <code>torque/server_priv</code>.</p>

lock_file_update_time	
Format	<INTEGER>
Default	3
Description	Specifies how often (in seconds) the thread will update the lock file.

lock_file_check_time	
Format	<INTEGER>
Default	9
Description	Specifies how often (in seconds) a high availability server will check to see if it should become active.

log_events	
Format	Bitmap
Default	---
Description	<p>By default, all events are logged. However, you can customize things so that only certain events show up in the log file. These are the bitmaps for the different kinds of logs:</p> <pre>#define PBSEVENT_ERROR 0x0001 /* internal errors */ #define PBSEVENT_SYSTEM 0x0002 /* system (server) events */ #define PBSEVENT_ADMIN 0x0004 /* admin events */ #define PBSEVENT_JOB 0x0008 /* job related events */ #define PBSEVENT_JOB_USAGE 0x0010 /* End of Job accounting */ #define PBSEVENT_SECURITY 0x0020 /* security violation events */ #define PBSEVENT_SCHED 0x0040 /* scheduler events */ #define PBSEVENT_DEBUG 0x0080 /* common debug messages */ #define PBSEVENT_DEBUG2 0x0100 /* less needed debug messages */ #define PBSEVENT_FORCE 0x8000 /* set to force a message */</pre> <p>If you want to log only error, system, and job information, use <code>qmgr</code> to set <code>log_events</code> to 11:</p> <pre>set server log_events = 11</pre>

log_file_max_size	
Format	<INTEGER>
Default	0
Description	<p>Specifies a soft limit, in kilobytes, for the server's log file. The file size is checked every 5 minutes, and if the <i>current day</i> file size is greater than or equal to this value then it will be rolled from <i>X</i> to <i>X.1</i> and a new empty log will be opened. Any value less than or equal to 0 will be ignored by <code>pbs_server</code> (the log will not be rolled).</p>

log_file_roll_depth	
Format	<INTEGER>
Default	1
Description	<p>Controls how deep the current day log files will be rolled, if <code>log_file_max_size</code> is set, before they are deleted.</p>

log_keep_days

Format	<INTEGER>
Default	0
Description	Specifies how long (in days) a server or MOM log should be kept.

log_level

Format	<INTEGER>
Default	0
Description	Specifies the <code>pbs_server</code> logging verbosity. Maximum value is 7.

mail_body_fmt

Format	A printf-like format string
Default	PBS Job Id: %i Job Name: %j Exec host: %h %m %d
Description	<p>Override the default format for the body of outgoing mail messages. A number of printf-like format specifiers and escape sequences can be used:</p> <ul style="list-style-type: none"> \n new line \t tab \\ backslash \' single quote \" double quote %d details concerning the message %h PBS host name %i PBS job identifier %j PBS job name %m long reason for message %r short reason for message %% a single %

mail_domain

Format	<STRING>
---------------	----------

mail_domain

Default	---
Description	Override the default domain for outgoing mail messages. If set, emails will be addressed to <user>@<hostdomain>. If unset, the job's Job_Owner attribute will be used. If set to <i>never</i> , TORQUE will never send emails.

mail_from

Format	<STRING>
Default	adm
Description	Specify the name of the sender when TORQUE sends emails.

mail_subject_fmt

Format	A printf-like format string
Default	PBS JOB %i
Description	<p>Override the default format for the subject of outgoing mail messages. A number of printf-like format specifiers and escape sequences can be used:</p> <ul style="list-style-type: none"> \n new line \t tab \\ backslash \' single quote \" double quote %d details concerning the message %h PBS host name %i PBS job identifier %j PBS job name %m long reason for message %r short reason for message %% a single %

managers

Format	<user>@<host.sub.domain>[, <user>@<host.sub.domain>...]
---------------	---

managers	
Default	root@localhost
Description	List of users granted batch administrator privileges. The host, sub-domain, or domain name may be wildcarded by the use of an asterisk character (*). Requires full manager privilege to set or alter.

max_job_array_size	
Format	<INTEGER>
Default	Unlimited
Description	Sets the maximum number of jobs that can be in a single job array.

max_slot_limit	
Format	<INTEGER>
Default	Unlimited
Description	<p>This is the maximum number of jobs that can run concurrently in any job array. Slot limits can be applied at submission time with qsub, or it can be modified with qalter.</p> <pre>qmgr -c 'set server max_slot_limit=10'</pre> <p>No array can request a slot limit greater than 10. Any array that does not request a slot limit receives a slot limit of 10. Using the example above, slot requests greater than 10 are rejected with the message: "Requested slot limit is too large, limit is 10."</p>

max_threads	
Format	<INTEGER>
Default	The value of min_threads $((2 * \text{the number of procs listed in } /proc/cpuinfo) + 1) * 20$
Description	This is the maximum number of threads that should exist in the thread pool at any time. See Setting min_threads and max_threads on page 3400 for more information.

max_user_queueable	
Format	<INTEGER>
Default	Unlimited
Description	<p>When set, max_user_queueable places a system-wide limit on the amount of jobs that an individual user can queue.</p> <pre>qmgr -c 'set server max_user_queueable=500'</pre>

min_threads	
Format	<INTEGER>
Default	(2 * the number of procs listed in /proc/cpuinfo) + 1. If TORQUE is unable to read /proc/cpuinfo, the default is 10.
Description	This is the minimum number of threads that should exist in the thread pool at any time. See Setting min_threads and max_threads on page 3400 for more information.

moab_array_compatible	
Format	<BOOLEAN>
Default	TRUE
Description	This parameter places a hold on jobs that exceed the slot limit in a job array. When one of the active jobs is completed or deleted, one of the held jobs goes to a queued state.

mom_job_sync	
Format	<BOOLEAN>
Default	TRUE
Description	<p>When set to TRUE, specifies that the pbs_server will synchronize its view of the job queue and resource allocation with compute nodes as they come online. If a job exists on a compute node, it will be automatically cleaned up and purged. (Enabled by default in TORQUE 2.2.0 and higher.)</p> <p>Jobs that are no longer reported by the mother superior are automatically purged by pbs_server. Jobs that pbs_server instructs the MOM to cancel have their processes killed in addition to being deleted (instead of leaving them running as in versions of TORQUE prior to 4.1.1).</p>

next_job_number	
Format	<INTEGER>
Default	---
Description	<p>Specifies the ID number of the next job. If you set your job number too low and TORQUE repeats a job number that it has already used, the job will fail. Before setting next_job_number to a number lower than any number that TORQUE has already used, you must clear out your .e and .o files.</p> <div>  If you use Moab Workload Manager and have configured it to synchronize job IDs with TORQUE, then Moab will generate the job ID and next_job_number will have no effect on the job ID. See Resource Manager Configuration on page 718 for more information. </div>

node_check_rate	
Format	<INTEGER>
Default	600
Description	Specifies the minimum duration (in seconds) that a node can fail to send a status update before being marked down by the pbs_server daemon.

node_pack	
Format	<BOOLEAN>
Default	---
Description	Controls how multiple processor nodes are allocated to jobs. If this attribute is set to TRUE, jobs will be assigned to the multiple processor nodes with the fewest free processors. This packs jobs into the fewest possible nodes leaving multiple processor nodes free for jobs which need many processors on a node. If set to false, jobs will be scattered across nodes reducing conflicts over memory between jobs. If unset, the jobs are packed on nodes in the order that the nodes are declared to the server (in the nodes file). Default value: unset - assigned to nodes as nodes in order that were declared.

node_ping_rate	
Format	<INTEGER>

node_ping_rate

Default	300
Description	Specifies the maximum interval (in seconds) between successive "pings" sent from the <code>pbs_server</code> daemon to the <code>pbs_mom</code> daemon to determine node/daemon health.

no_mail_force

Format	<BOOLEAN>
Default	FALSE
Description	When set to TRUE , eliminates all e-mails when <code>mail_options</code> (see qsub on page 3498) is set to "n". The job owner won't receive e-mails when a job is deleted by a different user or a job failure occurs. If <code>no_mail_force</code> is unset or is FALSE , then the job owner receives e-mails when a job is deleted by a different user or a job failure occurs.

np_default

Format	<INTEGER>
Default	---
Description	Allows the administrator to unify the number of processors (np) on all nodes. The value can be dynamically changed. A value of 0 tells <code>pbs_server</code> to use the value of np found in the nodes file. The maximum value is 32767.

operators

Format	<user>@<host.sub.domain>[,<user>@<host.sub.domain>...]
Default	root@localhost
Description	List of users granted batch operator privileges. Requires full manager privilege to set or alter.

pass_cpuclock

Format	<BOOLEAN>
---------------	-----------

pass_cpuclock	
Default	TRUE
Description	<p>If set to TRUE, the <code>pbs_server</code> daemon passes the option and its value to the <code>pbs_mom</code> daemons for direct implementation by the daemons, making the CPU frequency adjustable as part of a resource request by a job submission.</p> <p>If set to FALSE, the <code>pbs_server</code> daemon creates and passes a <code>PBS_CPUCLOCK</code> job environment variable to the <code>pbs_mom</code> daemons that contains the value of the cpuclock attribute used as part of a resource request by a job submission. The CPU frequencies on the MOMs are not adjusted. The environment variable is for use by prologue and epilogue scripts, enabling administrators to log and research when users are making cpuclock requests, as well as researchers and developers to perform CPU clock frequency changes using a method outside of that employed by the TORQUE <code>pbs_mom</code> daemons.</p>

poll_jobs	
Format	<BOOLEAN>
Default	TRUE (FALSE in TORQUE 1.2.0p5 and earlier)
Description	<p>If set to TRUE, <code>pbs_server</code> will poll job info from MOMs over time and will not block on handling requests which require this job information.</p> <p>If set to FALSE, no polling will occur and if requested job information is stale, <code>pbs_server</code> may block while it attempts to update this information. For large systems, this value should be set to TRUE.</p>

query_other_jobs	
Format	<BOOLEAN>
Default	FALSE
Description	When set to TRUE , specifies whether or not non-admin users may view jobs they do not own.

record_job_info	
Format	<BOOLEAN>
Default	FALSE
Description	This must be set to TRUE in order for job logging to be enabled.

record_job_script	
Format	<BOOLEAN>
Default	FALSE
Description	<p>If set to TRUE, this adds the contents of the script executed by a job to the log.</p> <div>  For record_job_script to take effect, record_job_info on page 3537 must be set to TRUE. </div>

resources_available	
Format	<STRING>
Default	---
Description	<p>Allows overriding of detected resource quantity limits (see Assigning Queue Resource Limits on page 3382). <code>pbs_server</code> must be restarted for changes to take effect. Also, <code>resources_available</code> is constrained by the smallest of <code>queue.resources_available</code> and the <code>server.resources_available</code>.</p>

scheduling	
Format	<BOOLEAN>
Default	---
Description	<p>Allows <code>pbs_server</code> to be scheduled. When FALSE, <code>pbs_server</code> is a resource manager that works on its own. When TRUE, TORQUE allows a scheduler, such as Moab or Maui, to dictate what <code>pbs_server</code> should do.</p>

submit_hosts	
Format	"<HOSTNAME>[<HOSTNAME>]..."
Default	Not set.

submit_hosts**Description**

Hosts in this list are able to submit jobs. This applies to any node whether within the cluster or outside of the cluster.

If **acl_host_enable** is set to **TRUE** and the host is not in the `$TORQUE/server_priv/nodes` file, then the host must also be in the **acl_hosts** list..

tcp_timeout**Format**

<INTEGER>

Default

300

Description

Specifies the timeout for idle TCP connections. If no communication is received by the server on the connection after the timeout, the server closes the connection. There is an exception for connections made to the server on port 15001 (default); timeout events are ignored on the server for such connections established by a client utility or scheduler. Responsibility rests with the client to close the connection first (See [Appendix F: Large Cluster Considerations on page 3569](#) for additional information.).

If you use Moab Workload Manager, prevent communication errors by giving **tcp_timeout** at least twice the value of the Moab **RMPOLLINTERVAL**.

thread_idle_seconds**Format**

<INTEGER>

Default

300

Description

This is the number of seconds a thread can be idle in the thread pool before it is deleted. If threads should not be deleted, set to **-1**. TORQUE will always maintain at least [min_threads](#) number of threads, even if all are idle.

Appendix C: Node Manager (MOM) Configuration

Under TORQUE, MOM configuration is accomplished using the `mom_priv/config` file located in the PBS directory on each execution server. You must create this file and insert any desired lines in a text editor (blank lines are allowed). When you modify the `mom_priv/config` file, you must restart `pbs_mom`.

The following examples demonstrate two methods of modifying the `mom_priv/config` file:

```
> echo "$loglevel 3" > /var/spool/torque/mom_priv/config
```

```
> vim /var/spool/torque/mom_priv/config
...
$loglevel 3
```

For details, see these topics:

Parameters

These parameters go in the `mom_priv/config` file. They control various behaviors for the MOMs.

[arch](#) on page 3541[\\$attempt_to_make_dir](#) on page 3542[\\$clienthost](#) on page 3542[\\$check_poll_time](#) on page 3542[\\$configuration](#) on page 3542[\\$cputmult](#) on page 3543[\\$down_on_error](#) on page 3543[\\$enablemomrestart](#) on page 3543[\\$exec_with_exec](#) on page 3543[\\$ext_pwd_retry](#) on page 3544[\\$ideal_load](#) on page 3544[\\$igncput](#) on page 3544[\\$ignmem](#) on page 3544[\\$ignvmem](#) on page 3545[\\$ignwalltime](#) on page 3545[\\$jobdirectory_sticky](#) on page 3545[\\$job_exit_wait_time](#) on page 3545[\\$job_output_file_unmask](#) on page 3546[\\$job_starter](#) on page 3546[\\$log_directory](#) on page 3546[\\$log_file_suffix](#) on page 3546[\\$logevent](#) on page 3547[\\$loglevel](#) on page 3547[\\$log_file_max_size](#) on page 3547[\\$log_file_roll_depth](#) on page 3547[\\$log_keep_days](#) on page 3548[\\$max_conn_timeout_micro_sec](#) on page 3548[\\$max_join_job_wait_time](#) on page 3548[\\$max_load](#) on page 3548[\\$memory_pressure_duration](#) on page 3549[\\$memory_pressure_threshold](#) on page 3549[\\$mom_hierarchy_retry_time](#) on page 3549[\\$mom_host](#) on page 3550[\\$node_check_script](#) on page 3550[\\$node_check_interval](#) on page 3550[\\$nodefile_suffix](#) on page 3550[\\$nospool_dir_list](#) on page 3551[\\$opsys](#) on page 3551[\\$pbsclient](#) on page 3551[\\$pbsserver](#) on page 3551[\\$prologalarm](#) on page 3552[\\$rcpcmd](#) on page 3552[\\$remote_reconfig](#) on page 3552[\\$remote_checkpoint_dirs](#) on page 3553[\\$reduce_prolog_checks](#) on page 3553[\\$reject_job_submission](#) on page 3553[\\$resend_join_job_wait_time](#) on page 3553[\\$restricted](#) on page 3554[\\$rpp_throttle](#) on page 3554[size\[fs=<FS>\]](#) on page 3554[\\$source_login_batch](#) on page 3554[\\$source_login_interactive](#) on page 3555[\\$spool_as_final_name](#) on page 3555[\\$status_update_time](#) on page 3555[\\$thread_unlink_calls](#) on page 3556[\\$timeout](#) on page 3556[\\$tmpdir](#) on page 3556[\\$usecp](#) on page 3556[\\$use_smt](#) on page 3557[\\$varattr](#) on page 3557[\\$wallmult](#) on page 3557[\\$xauthpath](#) on page 3558

arch

Format <STRING>**Description** Specifies the architecture of the local machine. This information is used by the scheduler only.**Example** arch ia64

\$attempt_to_make_dir

Format	<BOOLEAN>
Description	<p>When set to <i>TRUE</i>, specifies that you want TORQUE to attempt to create the output directories for jobs if they do not already exist.</p> <p>Default is <i>FALSE</i>.</p> <div>  TORQUE uses this parameter to make the directory as the <i>user</i> and not as <i>root</i>. TORQUE will create the directory (or directories) ONLY if the user has permissions to do so. </div>
Example	<code>\$attempt_to_make_dir true</code>

\$clienthost

Format	<STRING>
Description	<p>Specifies the machine running pbs_server.</p> <div>  This parameter is deprecated. Use \$pbsserver. </div>
Example	<code>\$clienthost node01.teracluster.org</code>

\$check_poll_time

Format	<STRING>
Description	Amount of time between checking running jobs, polling jobs, and trying to resend obituaries for jobs that haven't sent successfully. Default is 45 seconds.
Example	<code>\$check_poll_time 90</code>

\$configversion

Format	<STRING>
Description	Specifies the version of the config file data.
Example	<code>\$configversion 113</code>

\$cputmult	
Format	<FLOAT>
Description	<p>CPU time multiplier.</p> <div>  If set to 0.0, MOM level cputime enforcement is disabled. </div>
Example	<code>\$cputmult 2.2</code>

\$down_on_error	
Format	<BOOLEAN>
Description	Causes the MOM to report itself as state "down" to <code>pbs_server</code> in the event of a failed health check. This feature is experimental. For more information, see Parameters on page 3540 .
Example	<code>\$down_on_error true</code>

\$enablemomrestart	
Format	<BOOLEAN>
Description	Enables automatic restarts of the MOM. If enabled, the MOM will check if its binary has been updated and restart itself at a safe point when no jobs are running; thus making upgrades easier. The check is made by comparing the mtime of the <code>pbs_mom</code> executable. Command-line args, the process name, and the PATH env variable are preserved across restarts. It is recommended that this not be enabled in the config file, but enabled when desired with <code>momctl</code> (see Parameters on page 3540 for more information.)
Example	<code>\$enablemomrestart true</code>

\$exec_with_exec	
Format	<BOOLEAN>
Description	<code>pbs_mom</code> uses the <code>exec</code> command to start the job script rather than the TORQUE default method, which is to pass the script's contents as the input to the shell. This means that if you trap signals in the job script, they will be trapped for the job. Using the default method, you would need to configure the shell to also trap the signals. Default is FALSE.

\$exec_with_exec

Example	\$exec_with_exec true
----------------	-----------------------

\$ext_pwd_retry

Format	<INTEGER>
Description	(Available in TORQUE 2.5.10, 3.0.4, and later.) Specifies the number of times to retry checking the password. Useful in cases where external password validation is used, such as with LDAP. The default value is 3 retries.
Example	\$ext_pwd_retry = 5

\$ideal_load

Format	<FLOAT>
Description	Ideal processor load.
Example	\$ideal_load 4.0

\$igncpu

Format	<BOOLEAN>
Description	Ignores limit violation pertaining to CPU time. Default is FALSE.
Example	\$igncpu true

\$ignmem

Format	<BOOLEAN>
Description	Ignores limit violations pertaining to physical memory. Default is FALSE.
Example	\$ignmem true

\$ignvmem

Format	<BOOLEAN>
Description	Ignores limit violations pertaining to virtual memory. Default is FALSE.
Example	\$ignvmem true

\$ignwalltime

Format	<BOOLEAN>
Description	Ignore walltime (do not enable MOM based walltime limit enforcement).
Example	\$ignwalltime true

\$jobdirectory_sticky

Format	<BOOLEAN>
Description	When this option is set (<code>true</code>), the job directory on the MOM can have a sticky bit set. The default is <code>false</code> .
Example	\$jobdirectory_sticky true

\$job_exit_wait_time

Format	<INTEGER>
Description	This is the timeout to clean up parallel jobs after one of the sister nodes for the parallel job goes down or is otherwise unresponsive. The MOM sends out all of its kill job requests to sisters and marks the time. Additionally, the job is placed in the substate <code>JOB_SUBSTATE_EXIT_WAIT</code> . The MOM then periodically checks jobs in this state and if they are in this state for more than the specified time, death is assumed and the job gets cleaned up. Default is 10 minutes.
Example	\$job_exit_wait_time 300

\$job_output_file_unmask

Format	<STRING>
Description	Uses the specified umask when creating job output and error files. Values can be specified in base 8, 10, or 16; leading 0 implies octal and leading 0x or 0X hexadecimal. A value of "userdefault" will use the user's default umask. This parameter is in version 2.3.0 and later.
Example	<code>\$job_output_file_umask 027</code>

\$job_starter

Format	<STRING>
Description	Specifies the fully qualified pathname of the job starter. If this parameter is specified, instead of executing the job command and job arguments directly, the MOM will execute the job starter, passing the job command and job arguments to it as its arguments. The job starter can be used to launch jobs within a desired environment.
Example	<pre> \$job_starter /var/torque/mom_priv/job_starter.sh > cat /var/torque/mom_priv/job_starter.sh #!/bin/bash export FOOHOME=/home/foo ulimit -n 314 \$*</pre>

\$log_directory

Format	<STRING>
Description	Changes the log directory. Default is <code>TORQUE_HOME/mom_logs/</code> . <code>TORQUE_HOME</code> default is <code>/var/spool/torque/</code> but can be changed in the <code>./configure</code> script. The value is a string and should be the full path to the desired MOM log directory.
Example	<code>\$log_directory /opt/torque/mom_logs/</code>

\$log_file_suffix

Format	<STRING>
---------------	----------

\$log_file_suffix

Description	Optional suffix to append to log file names. If %h is the suffix, pbs_mom appends the hostname for where the log files are stored if it knows it, otherwise it will append the hostname where the MOM is running.
--------------------	---

Example	<pre>\$log_file_suffix %h = 20100223.mybox \$log_file_suffix foo = 20100223.foo</pre>
----------------	---

\$logevent

Format	<STRING>
---------------	----------

Description	Specifies a bitmap for event types to log.
--------------------	--

Example	<code>\$logevent 255</code>
----------------	-----------------------------

\$loglevel

Format	<INTEGER>
---------------	-----------

Description	Specifies the verbosity of logging with higher numbers specifying more verbose logging. Values may range between 0 and 7.
--------------------	---

Example	<code>\$loglevel 4</code>
----------------	---------------------------

\$log_file_max_size

Format	<INTEGER>
---------------	-----------

Description	Soft limit for log file size in kilobytes. Checked every 5 minutes. If the log file is found to be greater than or equal to log_file_max_size the current log file will be moved from X to X.1 and a new empty file will be opened.
--------------------	---

Example	<code>\$log_file_max_size = 100</code>
----------------	--

\$log_file_roll_depth

Format	<INTEGER>
---------------	-----------

\$log_file_roll_depth

Description	Specifies how many times a log file will be rolled before it is deleted.
Example	<code>\$log_file_roll_depth = 7</code>

\$log_keep_days

Format	<INTEGER>
Description	Specifies how many days to keep log files. pbs_mom deletes log files older than the specified number of days. If not specified, pbs_mom won't delete log files based on their age.
Example	<code>\$log_keep_days 10</code>

\$max_conn_timeout_micro_sec

Format	<INTEGER>
Description	Specifies how long pbs_mom should wait for a connection to be made. Default value is 10000 (.1 sec).
Example	<code>\$max_conn_timeout_micro_sec 30000</code> This sets the connection timeout on the MOM to .3 seconds..

\$max_join_job_wait_time

Format	<INTEGER>
Description	The interval to wait for jobs stuck in a prerun state before deleting them from the MOMs and requeueing them on the server. Default is 10 minutes.
Example	<code>\$max_join_job_wait_time 300</code>

\$max_load

Format	<FLOAT>
Description	Maximum processor load.

\$max_load

Example	\$max_load 4.0
----------------	----------------

\$memory_pressure_duration

Format	<INTEGER>
---------------	-----------

Description	(Applicable in version 3.0 and later.) Memory pressure duration sets a limit to the number of times the value of memory_pressure_threshold can be exceeded before a process is terminated. This can only be used with \$memory_pressure_threshold .
--------------------	---

Example	\$memory_pressure_duration 5
----------------	------------------------------

\$memory_pressure_threshold

Format	<INTEGER>
---------------	-----------

Description	<p>(Applicable in version 3.0 and later.) The memory_pressure of a cpuset provides a simple per-cpuset running average of the rate that the processes in a cpuset are attempting to free up in-use memory on the nodes of the cpuset to satisfy additional memory requests. The memory_pressure_threshold is an integer number used to compare against the reclaim rate provided by the memory_pressure file. If the threshold is exceeded and memory_pressure_duration is set, then the process terminates after exceeding the threshold by the number of times set in memory_pressure_duration. If memory_pressure duration is not set, then a warning is logged and the process continues. Memory_pressure_threshold is only valid with memory_pressure enabled in the root cpuset.</p> <p>To enable, log in as the super user and execute the command <code>echo 1 >> /dev/cpuset/memory_pressure_enabled</code>. See the cpuset man page for more information concerning memory pressure.</p>
--------------------	--

Example	\$memory_pressure_threshold 1000
----------------	----------------------------------

\$mom_hierarchy_retry_time

Format	<SECONDS>
---------------	-----------

Description	Specifies the amount of time that a MOM waits to retry a node in the hierarchy path after a failed connection to that node. The default is 90 seconds.
--------------------	--

Example	\$mom_hierarchy_retry_time 30
----------------	-------------------------------

\$mom_host	
Format	<STRING>
Description	Sets the local hostname as used by pbs_mom.
Example	\$mom_host node42

\$node_check_script	
Format	<STRING>
Description	Specifies the fully qualified pathname of the health check script to run (see Compute Node Health Check on page 3427 for more information).
Example	\$node_check_script /opt/batch_tools/nodecheck.pl

\$node_check_interval	
Format	<STRING>
Description	<p>Specifies the number of MOM intervals between subsequent executions of the specified health check. This value default to 1 indicating the check is run every MOM interval (see Compute Node Health Check on page 3427 for more information).</p> <p>\$node_check_interval has two special strings that can be set:</p> <ul style="list-style-type: none"> • <i>jobstart</i> – makes the node health script run when a job is started. • <i>jobend</i> – makes the node health script run after each job has completed on a node.
Example	\$node_check_interval 5

\$nodefile_suffix	
Format	<STRING>
Description	Specifies the suffix to append to a host names to denote the data channel network adapter in a multi-homed compute node.
Example	<p>\$nodefile_suffix i</p> <p>with the suffix of "i" and the control channel adapter with the name <i>node01</i>, the data channel would have a hostname of <i>node01i</i>.</p>

\$nospool_dir_list

Format	<STRING>
Description	<p>If this is configured, the job's output is spooled in the working directory of the job or the specified output directory.</p> <p>Specify the list in full paths, delimited by commas. If the job's working directory (or specified output directory) is in one of the paths in the list (or a subdirectory of one of the paths in the list), the job is spooled directly to the output location. \$nospool_dir_list * is accepted.</p> <p>The user that submits the job must have write permission on the folder where the job is written, and read permission on the folder where the file is spooled.</p> <p>Alternatively, you can use the \$spool_as_final_name parameter to force the job to spool directly to the final output.</p> <div>  This should generally be used only when the job can run on the same machine as where the output file goes, or if there is a shared filesystem. If not, this parameter can slow down the system or fail to create the output file. </div>
Example	\$nospool_dir_list /home/mike/jobs/, /var/tmp/spool/

opsys

Format	<STRING>
Description	Specifies the operating system of the local machine. This information is used by the scheduler only.
Example	opsys RHEL3

\$pbsclient

Format	<STRING>
Description	Specifies machines which the MOM daemon will trust to run resource manager commands via momctl . This may include machines where monitors, schedulers, or admins require the use of this command.
Example	\$pbsclient node01.teracluster.org

\$pbserver

Format	<STRING>
---------------	----------

\$pbsserver**Description**

Specifies the machine running pbs_server.

This parameter replaces the deprecated parameter [\\$clienthost](#).

Example

```
$pbsserver node01.teracluster.org
```

\$prologalarm**Format**

<INTEGER>

Description

Specifies maximum duration (in seconds) which the MOM will wait for the job prologue or job epilogue to complete. The default value is 300 seconds (5 minutes). The maximum value is 300 and when set to anything higher than that, it is treated as 300.

Example

```
$prologalarm 60
```

\$rcpcmd**Format**

<STRING>

Description

Specifies the full path and optional additional command line args to use to perform remote copies.

Example

```
mom_priv/config:
$rcpcmd /usr/local/bin/scp -i /etc/sshauth.dat
```

\$remote_reconfig**Format**

<STRING>

Description

Enables the ability to remotely reconfigure pbs_mom with a new config file. Default is disabled. This parameter accepts various forms of true, yes, and 1. For more information on how to reconfigure MOMs, see [momctl-r](#).

Example

```
$remote_reconfig true
```

\$remote_checkpoint_dirs	
Format	<STRING>
Description	Specifies which server checkpoint directories are remotely mounted. It tells the MOM which directories are shared with the server. Using remote checkpoint directories eliminates the need to copy the checkpoint files back and forth between the MOM and the server. All entries must be on the same line, separated by a space.
Example	<pre>\$remote_checkpoint_dirs /checkpointFiles /bigStorage /fast</pre> <p><i>This informs the MOM that the /checkpointFiles, /bigStorage, and /fast directories are remotely mounted checkpoint directories.</i></p>

\$reduce_prolog_checks	
Format	<STRING>
Description	If enabled, TORQUE will only check if the file is a regular file and is executable, instead of the normal checks listed on the prologue and epilogue page. Default is FALSE.
Example	<code>\$reduce_prolog_checks true</code>

\$reject_job_submission	
Format	<BOOLEAN>
Description	If set to TRUE , jobs will be rejected and the user will receive the message, "Jobs cannot be run on mom %s." Default is FALSE.
Example	<code>\$reject_job_submission job01</code>

\$resend_join_job_wait_time	
Format	<INTEGER>
Description	This is the timeout for the Mother Superior to re-send the join job request if it didn't get a reply from all the sister MOMs. The resend happens only once. Default is 5 minutes.
Example	<code>\$resend_join_job_wait_time 120</code>

\$restricted

Format	<STRING>
Description	Specifies hosts which can be trusted to access MOM services as non-root. By default, no hosts are trusted to access MOM services as non-root.
Example	<code>\$restricted *.teracluster.org</code>

\$rpp_throttle

Format	<INTEGER>
Description	This integer is in microseconds and causes a sleep after every RPP packet is sent. It is for systems that experience job failures because of incomplete data.
Example	<code>\$rpp_throttle 100</code> (will cause a 100 microsecond sleep)

size[fs=<FS>]

Format	N/A
Description	<p>Specifies that the available and configured disk space in the <FS> filesystem is to be reported to the pbs_server and scheduler.</p> <div>  To request disk space on a per job basis, specify the file resource as in <code>qsub -l nodes=1, file=1000kb</code>. </div> <div>  Unlike most MOM config options, the <i>size</i> parameter is not preceded by a "\$" character. </div>
Example	<code>size[fs=/localscratch]</code> The available and configured disk space in the /localscratch filesystem will be reported.

\$source_login_batch

Format	<STRING>
---------------	----------

\$source_login_batch

Description Specifies whether or not MOM will source the `/etc/profile`, etc. type files for *batch* jobs. Parameter accepts various forms of true, false, yes, no, 1 and 0. Default is TRUE. This parameter is in version 2.3.1 and later.

Example `$source_login_batch False`
MOM will bypass the sourcing of `/etc/profile`, etc. type files.

\$source_login_interactive

Format <STRING>

Description Specifies whether or not MOM will source the `/etc/profile`, etc. type files for *interactive* jobs. Parameter accepts various forms of true, false, yes, no, 1 and 0. Default is TRUE. This parameter is in version 2.3.1 and later.

Example `$source_login_interactive False`
MOM will bypass the sourcing of `/etc/profile`, etc. type files.

\$spool_as_final_name

Format <BOOLEAN>

Description This makes the job write directly to its output destination instead of a spool directory. This allows users easier access to the file if they want to watch the jobs output as it runs.

Example `$spool_as_final_name true`

\$status_update_time

Format <INTEGER>

Description Specifies the number of seconds between subsequent MOM-to-server update reports. Default is 45 seconds.

Example `status_update_time:`
`$status_update_time 120`
MOM will send server update reports every 120 seconds.

\$thread_unlink_calls

Format	<BOOLEAN>
Description	Threads calls to unlink when deleting a job. Default is false. If it is set to TRUE, pbs_mom will use a thread to delete the job's files.
Example	thread_unlink_calls: \$thread_unlink_calls true

\$timeout

Format	<INTEGER>
Description	Specifies the number of seconds before a TCP connection on the MOM will timeout. Default is 300 seconds. In version 3.x and earlier, this specifies the number of seconds before MOM-to-MOM messages will timeout if RPP is disabled. Default is 60 seconds.
Example	\$timeout 120 A TCP connection will wait up to 120 seconds before timing out. For 3.x and earlier, MOM-to-MOM communication will allow up to 120 seconds before timing out.

\$tmpdir

Format	<STRING>
Description	Specifies a directory to create job-specific scratch space (see Creating Per-Job Temporary Directories).
Example	\$tmpdir /localscratch

\$usecp

Format	<HOST>:<SRCDIR> <DSTDIR>
Description	Specifies which directories should be staged (see NFS and Other Networked Filesystems on page 3404)
Example	\$usecp *.fte.com:/data /usr/local/data

\$use_smt	
Format	<BOOLEAN>
Description	<p>Indicates that the user would like to use SMT. If set, each logical core inside of a physical core will be used as a normal core for cpusets. This parameter is on by default.</p> <div>  If SMT is used, you will need to set the <i>np</i> attribute so that each logical processor is counted. </div>
Example	<code>\$use_smt false</code>

\$varattr	
Format	<INTEGER> <STRING>
Description	<p>Provides a way to keep track of dynamic attributes on nodes.</p> <p><INTEGER> is how many seconds should go by between calls to the script to update the dynamic values. If set to -1, the script is read only one time.</p> <p><STRING> is the script path. This script should check for whatever dynamic attributes are desired, and then output lines in this format:</p> <pre>name=value</pre> <p>Include any arguments after the script's full path. These features are visible in the output of pbsnodes -a</p> <pre>varattr=Matlab=7.1;Octave=1.0.</pre> <p>For information about using \$varattr to request dynamic features in Moab, see Resource Manager Extensions on page 749.</p>
Example	<code>\$varattr 25 /usr/local/scripts/nodeProperties.pl arg1 arg2 arg3</code>

\$wallmult	
Format	<FLOAT>
Description	<p>Sets a factor to adjust walltime usage by multiplying a default job time to a common reference system. It modifies real walltime on a per-MOM basis (MOM configuration parameters). The factor is used for walltime calculations and limits in the same way that cputmult is used for cpu time.</p> <div>  If set to 0.0, MOM level walltime enforcement is disabled. </div>
Example	<code>\$wallmult 2.2</code>

\$xauthpath	
Format	<STRING>
Description	Specifies the path to the xauth binary to enable X11 forwarding.
Example	\$xauthpath /opt/bin/xauth/

[Appendix C: Node Manager \(MOM\) Configuration on page 3539](#)

Node Features and Generic Consumable Resource Specification

Node features (a.k.a. "node properties") are opaque labels which can be applied to a node. They are not consumable and cannot be associated with a value. (Use generic resources described below for these purposes). Node features are configured within the nodes file on the [pbs_server](#) head node. This file can be used to specify an arbitrary number of node features.

Additionally, per node consumable generic resources may be specified using the format "<ATTR> <VAL>" with no leading dollar ("\$") character. When specified, this information is routed to the scheduler and can be used in scheduling decisions. For example, to indicate that a given host has two tape drives and one node-locked matlab license available for batch jobs, the following could be specified:

mom_priv/config:

```
$clienthost 241.13.153.7
tape 2
matlab 1
```

Dynamic consumable resource information can be routed in by specifying a path preceded by an exclamation point. (!) as in the example below. If the resource value is configured in this manner, the specified file will be periodically executed to load the effective resource value.

mom_priv/config:

```
$clienthost 241.13.153.7
tape !/opt/rm/gettapecount.pl
matlab !/opt/tools/getlicensecount.pl
```

Command-line Arguments

Below is a table of `pbs_mom` command-line startup flags.

Flag	Description
a <integer>	Alarm time in seconds.
c <file>	Config file path.
C <dir-ectory>	Checkpoint path.
d <dir-ectory>	Home directory.
L <file>	Log file.
M <integer>	MOM port to listen on.
p	Perform 'poll' based job recovery on restart (jobs persist until associated processes terminate).
P	On restart, deletes all jobs that were running on MOM (Available in 2.4.X and later).
q	On restart, requeues all jobs that were running on MOM (Available in 2.4.X and later).
r	On restart, kills all processes associated with jobs that were running on MOM, and then requeues the jobs.
R <integer>	MOM 'RM' port to listen on.
S <integer>	pbs_server port to connect to.
v	Display version information and exit.
x	Disable use of privileged port.
?	Show usage information and exit.

For more details on these command-line options, see [pbs_mom on page 3443](#).

Appendix D: Diagnostics and Error Codes

TORQUE has a diagnostic script to assist you in giving TORQUE Support the files they need to support issues. It should be run by a user that has access to run all TORQUE commands and access to all TORQUE directories (this is usually root).

The script (`contrib/diag/tdiag.sh`) is available in TORQUE 2.3.8, TORQUE 2.4.3, and later. The script grabs the node file, server and MOM log files, and captures the output of `qmgr -c 'p s'`. These are put in a tar file.

The script also has the following options (this can be shown in the command line by entering `./tdiag.sh -h`):

USAGE: `./torque_diag [-d DATE] [-h] [-o OUTPUT_FILE] [-t TORQUE_HOME]`

- *DATE* should be in the format YYYYmmdd. For example, "20091130" would be the date for November 30th, 2009. If no date is specified, today's date is used.
- *OUTPUT_FILE* is the optional name of the output file. The default output file is `torque_diag<today's_date>.tar.gz`. *TORQUE_HOME* should be the path to your TORQUE directory. If no directory is specified, `/var/spool/torque` is the default.

Table 26-27: TORQUE error codes

Error code name	Number	Description
PBSE_FLOOR	15000	No error
PBSE_UNKJOBID	15001	Unknown job ID error
PBSE_NOATTR	15002	Undefined attribute
PBSE_ATTRRO	15003	Cannot set attribute, read only or insufficient permission
PBSE_IVALREQ	15004	Invalid request
PBSE_UNKREQ	15005	Unknown request
PBSE_TOOMANY	15006	Too many submit retries
PBSE_PERM	15007	Unauthorized Request
PBSE_IFF_NOT_FOUND	15008	trqauthd unable to authenticate

Error code name	Number	Description
PBSE_MUNGE_NOT_FOUND	15009	Munge executable not found, unable to authenticate
PBSE_BADHOST	15010	Access from host not allowed, or unknown host
PBSE_JOBEXIST	15011	Job with requested ID already exists
PBSE_SYSTEM	15012	System error
PBSE_INTERNAL	15013	PBS server internal error
PBSE_REGROUTE	15014	Dependent parent job currently in routing queue
PBSE_UNKSIG	15015	Unknown/illegal signal name
PBSE_BADATVAL	15016	Illegal attribute or resource value for
PBSE_MODATTRUN	15017	Cannot modify attribute while job running
PBSE_BADSTATE	15018	Request invalid for state of job
PBSE_UNKQUE	15020	Unknown queue
PBSE_BADCRED	15021	Invalid credential
PBSE_EXPIRED	15022	Expired credential
PBSE_QUNOENB	15023	Queue is not enabled
PBSE_QACCESS	15024	Access to queue is denied
PBSE_BADUSER	15025	Bad UID for job execution
PBSE_HOPCOUNT	15026	Job routing over too many hops
PBSE_QUEEXIST	15027	Queue already exists
PBSE_ATTRTYPE	15028	Incompatible type
PBSE_QUEBUSY	15029	Cannot delete busy queue

Error code name	Number	Description
PBSE_QUENBIG	15030	Queue name too long
PBSE_NOSUP	15031	No support for requested service
PBSE_QUENOEN	15032	Cannot enable queue, incomplete definition
PBSE_PROTOCOL	15033	Batch protocol error
PBSE_BADATLST	15034	Bad attribute list structure
PBSE_NOCONNECTS	15035	No free connections
PBSE_NOSERVER	15036	No server specified
PBSE_UNKRESC	15037	Unknown resource type
PBSE_EXCQRESC	15038	Job exceeds queue resource limits
PBSE_QUENODFLT	15039	No default queue specified
PBSE_NORERUN	15040	Job is not rerunnable
PBSE_ROUTErej	15041	Job rejected by all possible destinations (check syntax, queue resources, ...)
PBSE_ROUTEEXPD	15042	Time in Route Queue Expired
PBSE_MOMREJECT	15043	Execution server rejected request
PBSE_BADSCRIPT	15044	(qsub) cannot access script file
PBSE_STAGEIN	15045	Stage-in of files failed
PBSE_RESCUNAV	15046	Resource temporarily unavailable
PBSE_BADGRP	15047	Bad GID for job execution
PBSE_MAXQUED	15048	Maximum number of jobs already in queue

Error code name	Number	Description
PBSE_CKPSY	15049	Checkpoint busy, may retry
PBSE_EXLIMIT	15050	Resource limit exceeds allowable
PBSE_BADACCT	15051	Invalid Account
PBSE_ALRDYEXIT	15052	Job already in exit state
PBSE_NOCOPYFILE	15053	Job files not copied
PBSE_CLEANEOUT	15054	Unknown job id after clean init
PBSE_NOSYNCMSTR	15055	No master found for sync job set
PBSE_BADDEPEND	15056	Invalid Job Dependency
PBSE_DUPLIST	15057	Duplicate entry in list
PBSE_DISPROTO	15058	Bad DIS based Request Protocol
PBSE_EXECTHERE	15059	Cannot execute at specified host because of checkpoint or stagein files
PBSE_SISREJECT	15060	Sister rejected
PBSE_SISCOMM	15061	Sister could not communicate
PBSE_SVRDOWN	15062	Request not allowed: Server shutting down
PBSE_CKPSHORT	15063	Not all tasks could checkpoint
PBSE_UNKNODE	15064	Unknown node
PBSE_UNKNODEATR	15065	Unknown node-attribute
PBSE_NONODES	15066	Server has no node list
PBSE_NODENBIG	15067	Node name is too big

Error code name	Number	Description
PBSE_NODEEXIST	15068	Node name already exists
PBSE_BADNDATVAL	15069	Illegal value for
PBSE_MUTUALEX	15070	Mutually exclusive values for
PBSE_GMODERR	15071	Modification failed for
PBSE_NORELYMOM	15072	Server could not connect to MOM
PBSE_NOTSNODE	15073	No time-share node available
PBSE_JOBTYPE	15074	Wrong job type
PBSE_BADACLHOST	15075	Bad ACL entry in host list
PBSE_MAXUSERQUED	15076	Maximum number of jobs already in queue for user
PBSE_BADDISALLOWTYPE	15077	Bad type in disallowed_types list
PBSE_NOINTERACTIVE	15078	Queue does not allow interactive jobs
PBSE_NOBATCH	15079	Queue does not allow batch jobs
PBSE_NORERUNABLE	15080	Queue does not allow rerunable jobs
PBSE_NONONRERUNABLE	15081	Queue does not allow nonrerunable jobs
PBSE_UNKARRAYID	15082	Unknown Array ID
PBSE_BAD_ARRAY_REQ	15083	Bad Job Array Request
PBSE_BAD_ARRAY_DATA	15084	Bad data reading job array from file
PBSE_TIMEOUT	15085	Time out
PBSE_JOBNOTFOUND	15086	Job not found
PBSE_NOFAULTTOLERANT	15087	Queue does not allow fault tolerant jobs

Error code name	Number	Description
PBSE_NOFAULTINTOLERANT	15088	Queue does not allow fault intolerant jobs
PBSE_NOJOBARRAYS	15089	Queue does not allow job arrays
PBSE_RELAYED_TO_MOM	15090	Request was relayed to a MOM
PBSE_MEM_MALLOC	15091	Error allocating memory - out of memory
PBSE_MUTEX	15092	Error allocating controlling mutex (lock/unlock)
PBSE_THREADATTR	15093	Error setting thread attributes
PBSE_THREAD	15094	Error creating thread
PBSE_SELECT	15095	Error in socket select
PBSE_SOCKET_FAULT	15096	Unable to get connection to socket
PBSE_SOCKET_WRITE	15097	Error writing data to socket
PBSE_SOCKET_READ	15098	Error reading data from socket
PBSE_SOCKET_CLOSE	15099	Socket close detected
PBSE_SOCKET_LISTEN	15100	Error listening on socket
PBSE_AUTH_INVALID	15101	Invalid auth type in request
PBSE_NOT_IMPLEMENTED	15102	This functionality is not yet implemented
PBSE_QUENOTAVAILABLE	15103	Queue is currently not available
PBSE_TMPDIFFOWNER	15104	tmpdir owned by another user
PBSE_TMPNOTDIR	15105	tmpdir exists but is not a directory
PBSE_TMPNNAME	15106	tmpdir cannot be named for job
PBSE_CANTOPENSOCKET	15107	Cannot open demux sockets

Error code name	Number	Description
PBSE_CANTCONTACTSISTERS	15108	Cannot send join job to all sisters
PBSE_CANTCREATETMPDIR	15109	Cannot create tmpdir for job
PBSE_BADMOMSTATE	15110	Mom is down, cannot run job
PBSE_SOCKET_INFORMATION	15111	Socket information is not accessible
PBSE_SOCKET_DATA	15112	Data on socket does not process correctly
PBSE_CLIENT_INVALID	15113	Client is not allowed/trusted
PBSE_PREMATURE_EOF	15114	Premature End of File
PBSE_CAN_NOT_SAVE_FILE	15115	Error saving file
PBSE_CAN_NOT_OPEN_FILE	15116	Error opening file
PBSE_CAN_NOT_WRITE_FILE	15117	Error writing file
PBSE_JOB_FILE_CORRUPT	15118	Job file corrupt
PBSE_JOB_RERUN	15119	Job can not be rerun
PBSE_CONNECT	15120	Can not establish connection
PBSE_JOBWORKDELAY	15121	Job function must be temporarily delayed
PBSE_BAD_PARAMETER	15122	Parameter of function was invalid
PBSE_CONTINUE	15123	Continue processing on job. (Not an error)
PBSE_JOBSTATE	15124	Current sub state does not allow trasaction.
PBSE_CAN_NOT_MOVE_FILE	15125	Error moving file
PBSE_JOB_RECYCLED	15126	Job is being recycled
PBSE_JOB_ALREADY_IN_QUEUE	15127	Job is already in destination queue.

Error code name	Number	Description
PBSE_INVALID_MUTEX	15128	Mutex is NULL or otherwise invalid
PBSE_MUTEX_ALREADY_LOCKED	15129	The mutex is already locked by this object
PBSE_MUTEX_ALREADY_UNLOCKED	15130	The mutex has already been unlocked by this object
PBSE_INVALID_SYNTAX	15131	Command syntax invalid
PBSE_NODE_DOWN	15132	A node is down. Check the MOM and host
PBSE_SERVER_NOT_FOUND	15133	Could not connect to batch server
PBSE_SERVER_BUSY	15134	Server busy. Currently no available threads

Appendix E: Considerations Before Upgrading

TORQUE is flexible in regards to how it can be upgraded. In most cases, a TORQUE "shutdown" followed by a *configure, make, make install* procedure as documented in this guide is all that is required (see [Installing TORQUE on page 3283](#)). This process will preserve existing configuration and in most cases, existing workload.

A few considerations are included below:

- If upgrading from OpenPBS, PBSPro, or TORQUE 1.0.3 or earlier, queued jobs whether active or idle will be lost. In such situations, job queues should be completely drained of all jobs.
- If not using the `pbs_mom -r` or `-p` flag (see [Command-line Arguments on page 3559](#)), running jobs may be lost. In such cases, running jobs should be allowed to be completed or should be requeued before upgrading TORQUE.
- `pbs_mom` and `pbs_server` daemons of differing versions may be run together. However, not all combinations have been tested and unexpected failures may occur.
- When upgrading from early versions of TORQUE (pre-4.0) and Moab, you may encounter a problem where Moab core files are regularly created in `/opt/moab`. This can be caused by old TORQUE library files used by Moab that try to authorize with the old TORQUE `pbs_iff` authorization daemon.

You can resolve the problem by removing the old version library files from `/usr/local/lib`.

To upgrade

1. Build new release (do not install).
2. Stop all TORQUE daemons (see [qterm](#) and [momctl -s](#)).
3. Install new TORQUE (use *make install*).
4. Start all TORQUE daemons.

Rolling Upgrade

If you are upgrading to a new point release of your current version (for example, from 4.2.2 to 4.2.3) and not to a new major release from your current version (for example, from 4.1 to 4.2), you can use the following procedure to upgrade TORQUE without taking your nodes offline.

i Because TORQUE version 4.1.4 changed the way that `pbs_server` communicates with the MOMs, it is not recommended that you perform a rolling upgrade of TORQUE from version 4.1.3 to 4.1.4.

To perform a rolling upgrade in TORQUE

1. Enable the [pbs_mom on page 3443](#) flag on the MOMs you want to upgrade. The `enablemomrestart` option causes a MOM to check if its binary has been updated and restart itself at a safe point when no jobs are running. You can enable this in the MOM configuration file, but it is recommended that you use `momctl` instead.

```
> momctl -q enablemomrestart=1 -h :ALL
```

The `enablemomrestart` flag is enabled on all nodes.

2. Replace the `pbs_mom` binary, located in `/usr/local/bin` by default. `pbs_mom` will continue to run uninterrupted because the `pbs_mom` binary has already been loaded in RAM.

```
> torque-package-mom-linux-x86_64.sh --install
```

The next time `pbs_mom` is in an idle state, it will check for changes in the binary. If `pbs_mom` detects that the binary on disk has changed, it will restart automatically, causing the new `pbs_mom` version to load.

After the `pbs_mom` restarts on each node, the `enablemomrestart` parameter will be set back to false (0) for that node.

i If you have cluster with high utilization, you may find that the nodes never enter an idle state so pbs_mom never restarts. When this occurs, you must manually take the nodes offline and wait for the running jobs to complete before restarting pbs_mom. To set the node to an offline state, which will allow running jobs to complete but will not allow any new jobs to be scheduled on that node, use `pbsnodes -o <nodeName>`. After the new MOM has started, you must make the node active again by running `pbsnodes -c <nodeName>`.

Appendix F: Large Cluster Considerations

TORQUE has enhanced much of the communication found in the original OpenPBS project. This has resulted in a number of key advantages including support for:

- larger clusters.
- more jobs.
- larger jobs.
- larger messages.

In most cases, enhancements made apply to all systems and no tuning is required. However, some changes have been made configurable to allow site specific modification. The configurable communication parameters are: [node_check_rate](#), [node_ping_rate](#), and [tcp_timeout](#).

For details, see these topics:

- [Scalability Guidelines](#) on page 3569
- [End-User Command Caching](#) on page 3570
- [Moab and TORQUE Configuration for Large Clusters](#) on page 3572
- [Starting TORQUE in Large Environments](#) on page 3573
- [Other Considerations](#) on page 3574

Scalability Guidelines

In very large clusters (in excess of 1,000 nodes), it may be advisable to tune a number of communication layer timeouts. By default, PBS MOM daemons timeout on inter-MOM messages after 60 seconds. In TORQUE 1.1.0p5 and higher, this can be adjusted by setting the timeout parameter in the `mom_priv/config` file (see, [Appendix C: Node Manager \(MOM\) Configuration on page 3539](#)). If 15059 errors (cannot receive message from sisters) are seen in the MOM logs, it may be necessary to increase this value.

Client-to-server communication timeouts are specified via the [tcp_timeout](#) server option using the [qmgr](#) command.

i On some systems, *ulimit* values may prevent large jobs from running. In particular, the open file descriptor limit (i.e., `ulimit -n`) should be set to at least the maximum job size in procs + 20. Further, there may be value in setting the `fs.file-max` in `sysctl.conf` to a high value, such as:

```
/etc/sysctl.conf:  
fs.file-max = 65536
```

Related Topics

[Appendix F: Large Cluster Considerations](#) on page 3569

End-User Command Caching

qstat

In a large system, users may tend to place excessive load on the system by manual or automated use of resource manager end user client commands. A simple way of reducing this load is through the use of client command wrappers which cache data. The example script below will cache the output of the command '[qstat](#) -f' for 60 seconds and report this info to end users.

```

#!/bin/sh

# USAGE: qstat $@

CMDPATH=/usr/local/bin/qstat
CACHETIME=60
TMPFILE=/tmp/qstat.f.tmp

if [ "$1" != "-f" ] ; then
    #echo "direct check (arg1=$1) "
    $CMDPATH $1 $2 $3 $4
    exit $?
fi

if [ -n "$2" ] ; then
    #echo "direct check (arg2=$2)"
    $CMDPATH $1 $2 $3 $4
    exit $?
fi

if [ -f $TMPFILE ] ; then
    TMPFILEMTIME=`stat -c %Z $TMPFILE`
else
    TMPFILEMTIME=0
fi

NOW=`date +%s`

AGE=$(( $NOW - $TMPFILEMTIME ))

#echo AGE=$AGE

for i in 1 2 3;do
    if [ "$AGE" -gt $CACHETIME ] ; then
        #echo "cache is stale "

        if [ -f $TMPFILE.1 ] ; then
            #echo someone else is updating cache

            sleep 5

            NOW=`date +%s`

            TMPFILEMTIME=`stat -c %Z $TMPFILE`

            AGE=$(( $NOW - $TMPFILEMTIME ))
        else
            break;
        fi
    fi
done

if [ -f $TMPFILE.1 ] ; then
    #echo someone else is hung

    rm $TMPFILE.1
fi

if [ "$AGE" -gt $CACHETIME ] ; then
    #echo updating cache

    $CMDPATH -f > $TMPFILE.1

    mv $TMPFILE.1 $TMPFILE

fi

#echo "using cache"

```

```
cat $TMPFILE
exit 0
```

The above script can easily be modified to cache any command and any combination of arguments by changing one or more of the following attributes:

- script name
- value of \$CMDPATH
- value of \$CACHETIME
- value of \$TMPFILE

For example, to cache the command **[pbsnodes](#)** -a, make the following changes:

- Move original **[pbsnodes](#)** command to `pbsnodes.orig`.
- Save the script as 'pbsnodes'.
- Change \$CMDPATH to `pbsnodes.orig`.
- Change \$TMPFILE to `/tmp/pbsnodes.a.tmp`.

[Appendix F: Large Cluster Considerations on page 3569](#)

Moab and TORQUE Configuration for Large Clusters

There are a few basic configurations for Moab and TORQUE that can potentially improve performance on large clusters.

Moab configuration

In the `moab.cfg` file, add:

1. `RMPOLLINTERVAL 30,30` - This sets the minimum and maximum poll interval to 30 seconds.
2. `RMCFG[<name>] FLAGS=ASYNCSTART` - This tells Moab not to block until it receives a confirmation that the job starts.
3. `RMCFG[<name>] FLAGS=ASYNDELETE` - This tells Moab not to block until it receives a confirmation that the job was deleted.

TORQUE configuration

1. Follow the [Starting TORQUE in large environments](#) recommendations.
2. Increase `job_start_timeout` on `pbs_server`. The default is **300** (5 minutes), but for large clusters the value should be changed to something like **600** (10 minutes). Sites running very large parallel jobs might want to set this value even higher.

3. Use a node health check script on all MOM nodes. This helps prevent jobs from being scheduled on bad nodes and is especially helpful for large parallel jobs.
4. Make sure that `ulimit -n` (maximum file descriptors) is set to *unlimited*, or a very large number, and not the default.
5. For clusters with a high job throughput it is recommended that the server parameter `max_threads` be increased from the default. The default is $(2 * \text{number of cores} + 1) * 10$.

[Appendix F: Large Cluster Considerations on page 3569](#)

Starting TORQUE in Large Environments

If running TORQUE in a large environment, use these tips to help TORQUE start up faster.

Fastest possible start up

1. Create a [MOM hierarchy](#), even if your environment has a one-level MOM hierarchy (meaning all MOMs report directly to `pbs_server`), and copy the file to the `mom_priv` directory on the MOMs.
2. Start `pbs_server` with the [-n option](#). This specifies that `pbs_server` won't send the hierarchy to the MOMs unless a MOM requests it.
3. Start the MOMs normally.

If no daemons are running

1. Start `pbs_server` with the [-c option](#).
2. Start the MOMs without the `-w` option.

If MOMs are running and just restarting `pbs_server`

1. Start `pbs_server` without the `-c` option.

If restarting a MOM or all MOMs

1. Start `pbs_server` without the `-w` option. Starting it with `-w` causes the MOMs to appear to be down.

Related Topics

[Appendix F: Large Cluster Considerations on page 3569](#)

Other Considerations

job_stat_rate

In a large system, there may be many users, many jobs, and many requests for information. To speed up response time for users and for programs using the API the [job_stat_rate](#) can be used to tweak when the pbs_server daemon will query MOMs for job information. By increasing this number, a system will not be constantly querying job information and causing other commands to block.

poll_jobs

The [poll_jobs](#) parameter allows a site to configure how the pbs_server daemon will poll for job information. When set to TRUE, the pbs_server will poll job information in the background and not block on user requests. When set to FALSE, the pbs_server may block on user requests when it has stale job information data. Large clusters should set this parameter to TRUE.

Internal Settings

On large, slow, and/or heavily loaded systems, it may be desirable to increase the `pbs_tcp_timeout` setting used by the pbs_mom daemon in MOM-to-MOM communication. This setting defaults to 20 seconds and requires rebuilding code to adjust. For client-server based communication, this attribute can be set using the [qmgr](#) command. For MOM-to-MOM communication, a source code modification is required. To make this change, edit the `$TORQUEBUILDDIR/src/lib/Libifl/tcp_dis.c` file and set `pbs_tcp_timeout` to the desired maximum number of seconds allowed for a MOM-to-MOM request to be serviced.

i A system may be heavily loaded if it reports multiple 'End of File from addr' or 'Premature end of message' failures in the pbs_mom or pbs_server logs.

Scheduler Settings

If using Moab, there are a number of parameters which can be set on the scheduler which may improve TORQUE performance. In an environment containing a large number of short-running jobs, the `JOBAGGREGATIONTIME` parameter (see [Appendix A: Moab Parameters on page 1069](#)) can be set to reduce the number of workload and resource queries performed by the scheduler when an event based interface is enabled. If the pbs_server daemon is heavily loaded and PBS API timeout errors (i.e. "Premature end of message") are reported within the scheduler, the "TIMEOUT" attribute of the `RMCFG` parameter may be set with a value of between 30 and 90 seconds.

File System

TORQUE can be configured to disable file system blocking until data is physically written to the disk by using the `--disable-filesync` argument with `configure`. While having `filesync` enabled is more reliable, it may lead to server delays for sites with either a larger number of nodes, or a large number of jobs. `Filesync` is enabled by default.

Network ARP Cache

For networks with more than 512 nodes it is mandatory to increase the kernel's internal ARP cache size. For a network of ~1000 nodes, we use these values in `/etc/sysctl.conf` on all nodes and servers:

```
/etc/sysctl.conf

# Don't allow the arp table to become bigger than this
net.ipv4.neigh.default.gc_thresh3 = 4096
# Tell the gc when to become aggressive with arp table cleaning.
# Adjust this based on size of the LAN.
net.ipv4.neigh.default.gc_thresh2 = 2048
# Adjust where the gc will leave arp table alone
net.ipv4.neigh.default.gc_thresh1 = 1024
# Adjust to arp table gc to clean-up more often
net.ipv4.neigh.default.gc_interval = 3600
# ARP cache entry timeout
net.ipv4.neigh.default.gc_stale_time = 3600
```

Use `sysctl -p` to reload this file.

The ARP cache size on other Unixes can presumably be modified in a similar way.

An alternative approach is to have a static `/etc/ethers` file with all hostnames and MAC addresses and load this by `arp -f /etc/ethers`. However, maintaining this approach is quite cumbersome when nodes get new MAC addresses (due to repairs, for example).

[Appendix F: Large Cluster Considerations on page 3569](#)

Appendix G: Prologue and Epilogue Scripts

TORQUE provides administrators the ability to run scripts before and/or after each job executes. With such a script, a site can prepare systems, perform node health checks, prepend and append text to output and error log files, cleanup systems, and so forth.

The following table shows which MOM runs which script. All scripts must be in the `TORQUE_HOME/mom_priv/` directory and be available on every compute node. The "Mother Superior" is the `pbs_mom` on the first node allocated for a job. While it is technically a sister node, it is not a "Sister" for the purposes of the following table.

i The execution directory for each script is `TORQUE_HOME/mom_priv/`.

Script	Execution location	Execute as	File permissions
prologue	Mother Superior	root	Readable and executable by root and NOT writable by anyone but root (e.g., <code>-r-x-----</code>)
epilogue		root	
prologue.user		user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code>)
epilogue.user		user	
prologue.parallel	Sister	root	Readable and executable by root and NOT writable by anyone but root (e.g., <code>-r-x-----</code>)
epilogue.parallel		root	
prologue.user.parallel		user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code>)
epilogue.user.parallel		user	
epilogue.precancel	Mother Superior This script runs after a job cancel request is received from pbs_server and before a kill signal is sent to the job process.	user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code>)

i `epilogue.parallel` is available in version 2.1 and later.

This section contains these topics:

- [Script Order of Execution](#) on page 3576
- [Script Environment](#) on page 3577
- [Per Job Prologue and Epilogue Scripts](#) on page 3579
- [Prologue and Epilogue Scripts Time Out](#) on page 3579
- [Prologue Error Processing](#) on page 3580

Script Order of Execution

When jobs start, the order of script execution is `prologue` followed by `prologue.user`. On job exit, the order of execution is `epilogue.user` followed by `epilogue` unless a job is canceled. In that case,

`epilogue.precancel` is executed first. `epilogue.parallel` is executed only on the Sister nodes when the job is completed.

i The `epilogue` and `prologue` scripts are controlled by the system administrator. However, beginning in TORQUE version 2.4 a user `epilogue` and `prologue` script can be used on a per job basis. (See [Per Job Prologue and Epilogue Scripts](#) on page 3579 for more information.)

i Root squashing is now supported for `epilogue` and `prologue` scripts.

Related Topics

[Appendix G: Prologue and Epilogue Scripts](#) on page 3575

Script Environment

The `prologue` and `epilogue` scripts can be very simple. On most systems, the script must declare the execution shell using the `#!<SHELL>` syntax (for example, `#!/bin/sh`). In addition, the script may want to process context sensitive arguments passed by TORQUE to the script.

Prologue Environment

The following arguments are passed to the `prologue`, `prologue.user`, and `prologue.parallel` scripts:

Argument	Description
<code>argv[1]</code>	job id
<code>argv[2]</code>	job execution user name
<code>argv[3]</code>	job execution group name
<code>argv[4]</code>	job name (TORQUE 1.2.0p4 and higher only)
<code>argv[5]</code>	list of requested resource limits (TORQUE 1.2.0p4 and higher only)
<code>argv[6]</code>	job execution queue (TORQUE 1.2.0p4 and higher only)
<code>argv[7]</code>	job account (TORQUE 1.2.0p4 and higher only)

Epilogue Environment

TORQUE supplies the following arguments to the `epilogue`, `epilogue.user`, `epilogue.precancel`, and `epilogue.parallel` scripts:

Argument	Description
<code>argv[1]</code>	job id
<code>argv[2]</code>	job execution user name
<code>argv[3]</code>	job execution group name
<code>argv[4]</code>	job name
<code>argv[5]</code>	session id
<code>argv[6]</code>	list of requested resource limits
<code>argv[7]</code>	list of resources used by job
<code>argv[8]</code>	job execution queue
<code>argv[9]</code>	job account
<code>argv[10]</code>	job exit code

The `epilogue.precancel` script is run after a job cancel request is received by the MOM and before any signals are sent to job processes. If this script exists, it is run whether the canceled job was active or idle.

i The cancel job command (**`qdel`**) will take as long to return as the `epilogue.precancel` script takes to run. For example, if the script runs for 5 minutes, it takes 5 minutes for `qdel` to return.

For all scripts, the environment passed to the script is empty. However, if you submit the job using `msub` rather than `qsub`, some Moab environment variables are available in the TORQUE prologue and epilogue script environment: `MOAB_CLASS`, `MOAB_GROUP`, `MOAB_JOBARRAYINDEX`, `MOAB_JOBARRAYRANGE`, `MOAB_JOBID`, `MOAB_JOBNAME`, `MOAB_MACHINE`, `MOAB_NODECOUNT`, `MOAB_NODELIST`, `MOAB_PARTITION`, `MOAB_PROCCOUNT`, `MOAB_QOS`, `MOAB_TASKMAP`, and `MOAB_USER`. See [msub on page 364](#) for more information.

Also, standard input for both scripts is connected to a system dependent file. Currently, for all systems this is `/dev/null`. Except for epilogue scripts of an interactive job, `prologue.parallel`, `epilogue.precancel`, and `epilogue.parallel`, the standard output and error are connected to output and error files associated with the job. For an interactive job, since the pseudo terminal connection is released after the job completes, the standard input and error point to `/dev/null`. For `prologue.parallel` and `epilogue.parallel`, the user will need to redirect `stdout` and `stderr` manually.

Related Topics

[Appendix G: Prologue and Epilogue Scripts on page 3575](#)

Per Job Prologue and Epilogue Scripts

TORQUE supports per job prologue and epilogue scripts when using the `qsub -l` option. The syntax is:

```
qsub -l prologue=<prologue_script_path> epilogue=<epilogue_script_path> <script>.
```

The path can be either relative (from the directory where the job is submitted) or absolute. The files must be owned by the user with at least execute and read privileges, and the permissions must not be writeable by group or other.

```
/home/usertom/dev/
```

```
-r-x----- 1 usertom usertom 24 2009-11-09 16:11 prologue_script.sh
-r-x----- 1 usertom usertom 24 2009-11-09 16:11 epilogue_script.sh
```

Example 26-20:

```
$ qsub -l prologue=/home/usertom/dev/prologue_script.sh,
epilogue=/home/usertom/dev/epilogue_script.sh job14.pl
```

This job submission executes the `prologue` script first. When the `prologue` script is complete, `job14.pl` runs. When `job14.pl` completes, the `epilogue` script is executed.

Related Topics

[Appendix G: Prologue and Epilogue Scripts on page 3575](#)

Prologue and Epilogue Scripts Time Out

TORQUE takes preventative measures against prologue and epilogue scripts by placing an alarm around the scripts execution. By default, TORQUE sets the alarm to go off after 5 minutes of execution. If the script exceeds this time, it will be terminated and the node will be marked down. This timeout can be adjusted by setting the `$prologalarm` parameter in the `mom_priv/config` file.

i While TORQUE is executing the `epilogue`, `epilogue.user`, or `epilogue.precancel` scripts, the job will be in the *E* (exiting) state.

If an `epilogue.parallel` script cannot open the `.OU` or `.ER` files, an error is logged but the script is continued.

Related Topics

[Appendix G: Prologue and Epilogue Scripts](#) on page 3575

Prologue Error Processing

If the `prologue` script executes successfully, it should exit with a zero status. Otherwise, the script should return the appropriate error code as defined in the table below. The `pbs_mom` will report the script's exit status to `pbs_server` which will in turn take the associated action. The following table describes each exit code for the prologue scripts and the action taken.

Error	Description	Action
-4	The script timed out	Job will be requeued
-3	The <code>wait(2)</code> call returned an error	Job will be requeued
-2	Input file could not be opened	Job will be requeued
-1	Permission error (script is not owned by root, or is writable by others)	Job will be requeued
0	Successful completion	Job will run
1	Abort exit code	Job will be aborted
>1	other	Job will be requeued

Example 26-21:

Following are example prologue and epilogue scripts that write the arguments passed to them in the job's standard out file:

prologue	
Script	<pre>#!/bin/sh echo "Prologue Args:" echo "Job ID: \$1" echo "User ID: \$2" echo "Group ID: \$3" echo "" exit 0</pre>
stdout	<pre>Prologue Args: Job ID: 13724.node01 User ID: user1 Group ID: user1</pre>

epilogue	
Script	<pre>#!/bin/sh echo "Epilogue Args:" echo "Job ID: \$1" echo "User ID: \$2" echo "Group ID: \$3" echo "Job Name: \$4" echo "Session ID: \$5" echo "Resource List: \$6" echo "Resources Used: \$7" echo "Queue Name: \$8" echo "Account String: \$9" echo "" exit 0</pre>
stdout	<pre>Epilogue Args: Job ID: 13724.node01 User ID: user1 Group ID: user1 Job Name: script.sh Session ID: 28244 Resource List: neednodes=node01,nodes=1,walltime=00:01:00 Resources Used: cput=00:00:00,mem=0kb,vmem=0kb,walltime=00:00:07 Queue Name: batch Account String:</pre>

Example 26-22:

The Ohio Supercomputer Center contributed the following scripts:

"prologue creates a unique temporary directory on each node assigned to a job before the job begins to run, and epilogue deletes that directory after the job completes.

i Having a separate temporary directory on each node is probably not as good as having a good, high performance parallel filesystem.

```
prologue

#!/bin/sh
# Create TMPDIR on all the nodes
# Copyright 1999, 2000, 2001 Ohio Supercomputer Center
# prologue gets 3 arguments:
# 1 -- jobid
# 2 -- userid
# 3 -- grpid
#
jobid=$1
user=$2
group=$3
nodefile=/var/spool/pbs/aux/$jobid
if [ -r $nodefile ] ; then
    nodes=$(sort $nodefile | uniq)
else
    nodes=localhost
fi

Appendix H: Running Multiple TORQUE Servers and MOMs on the Same Node

TORQUE can be configured to allow multiple servers and MOMs to run on the same node. This example will show how to configure, compile and install two different TORQUE servers and MOMs on the same node. For details, see these topics:

- [Configuring the First TORQUE on page 3583](#)
- [Configuring the Second TORQUE on page 3583](#)
- [Bringing the First TORQUE Server online on page 3583](#)
- [Bringing the Second TORQUE Server Online on page 3584](#)

Configuring the First TORQUE

```
./configure --with-server-home=/usr/spool/PBS1 --bindir=/usr/spool/PBS1/bin --
sbindir=/usr/spool/PBS1/sbin
```

Then make and make install will place the first TORQUE into `/usr/spool/PBS1` with the executables in their corresponding directories.

Configuring the Second TORQUE

```
./configure --with-server-home=/usr/spool/PBS2 --bindir=/usr/spool/PBS2/bin --
sbindir=/usr/spool/PBS2/sbin
```

Then make and make install will place the second TORQUE into `/usr/spool/PBS2` with the executables in their corresponding directories.

Bringing the First TORQUE Server online

Each command, including `pbs_server` and `pbs_mom`, takes parameters indicating which servers and ports to connect to or listen on (when appropriate). Each of these is documented in their corresponding man pages (configure with `--enable-docs`).

In this example the first TORQUE server will accept batch requests on port 35000, communicate with the MOMs on port 35001, and communicate via RPP on port 35002. The first TORQUE MOM will try to connect to the server on port 35000, it will listen for requests from the server on port 35001 and will communicate via RPP on port 35002. (Each of these command arguments is discussed in further details on the corresponding man page. In particular, `-t create` is only used the first time a server is run.)

```
> pbs_server -p 35000 -M 35001 -R 35002 -t create
> pbs_mom -S 35000 -M 35001 -R 35002
```

Afterwards, when using a client command to make a batch request it is necessary to specify the server name and server port (35000):

```
> pbsnodes -a -s node01:35000
```

Submitting jobs can be accomplished using the `-q` option (`[queue][@host[:port]]`):

```
> qsub -q @node01:35000 /tmp/script.pbs
```

Bringing the Second TORQUE Server Online

In this example the second TORQUE server will accept batch requests on port 36000, communicate with the MOMS on port 36002, and communicate via RPP on port 36002. The second TORQUE MOM will try to connect to the server on port 36000, it will listen for requests from the server on port 36001 and will communicate via RPP on port 36002.

```
> pbs_server -p 36000 -M 36001 -R 36002 -t create
> pbs_mom -S 36000 -M 36001 -R 36002
```

Afterward, when using a client command to make a batch request it is necessary to specify the server name and server port (36002):

```
> pbsnodes -a -s node01:36000
> qsub -q @node01:36000 /tmp/script.pbs
```

Appendix I: Security Overview

The authorization model for TORQUE changed in version 4.0.0 from `pbs_iff` to a daemon called `trqauthd`. The job of the `trqauthd` daemon is the same as `pbs_iff`. The difference is that `trqauthd` is a resident daemon whereas `pbs_iff` is invoked by each client command. `pbs_iff` is not scalable and is prone to failure under even small loads. `trqauthd` is very scalable and creates the possibility for better security measures in the future.

trqauthd and pbs_iff Authorization Theory

The key to security of both `trqauthd` and `pbs_iff` is the assumption that any host which has been added to the TORQUE cluster has been secured by the administrator. Neither `trqauthd` nor `pbs_iff` do authentication. They only do authorization of users. Given that the host system is secure the following is the procedure by which `trqauthd` and `pbs_iff` authorize users to `pbs_server`.

1. Client utility makes a connection to `pbs_server` on a dynamic port.
2. Client utility sends a request to `trqauthd` with the user name and port.

3. `trqauthd` verifies the user ID and then sends a request to `pbs_server` on a privileged port with the user ID and dynamic port to authorize the connection.
4. `trqauthd` reports results of the server to client utility.

Both `trqauthd` and `pbs_iff` use Unix domain sockets for communication from the client utility. Unix domain sockets have the ability to verify that a user is who they say they are by using security features that are part of the file system.

Appendix J: Job Submission Filter ("qsub Wrapper")

When a "submit filter" exists, TORQUE will send the command file (or contents of STDIN if piped to `qsub`) to that script/executable and allow it to evaluate the submitted request based on specific site policies. The resulting file is then handed back to `qsub` and processing continues. Submit filters can check user jobs for correctness based on site policies. They can also modify user jobs as they are submitted. Some examples of what a submit filter might evaluate and check for are:

- Memory Request - Verify that the job requests memory and rejects if it does not.
- Job event notifications - Check if the job does one of the following and rejects it if it:
 - explicitly requests no notification.
 - requests notifications but does not provide an email address.
- Walltime specified - Verify that the walltime is specified.
- Global Walltime Limit - Verify that the walltime is below the global max walltime.
- Test Walltime Limit - If the job is a test job, this check rejects the job if it requests a walltime longer than the testing maximum.

The script below reads the original submission request from STDIN and shows how you could insert parameters into a job submit request:

```
#!/bin/sh
# add default memory constraints to all requests
# that did not specify it in user's script or on command line
echo "#PBS -l mem=16MB"
while read i
do
  echo $i
done
```

The same command line arguments passed to `qsub` will be passed to the submit filter and in the same order. Exit status of -1 will cause `qsub` to reject the submission with a message stating that it failed due to administrative policies.

The "submit filter" must be executable, must be available on each of the nodes where users may submit jobs, and by default must be located at `${libexecdir}/qsub_filter` (for version 2.1 and older: `/usr/local/sbin/torque_submitfilter`). At run time, if the file does not exist at this new preferred path then qsub will fall back to the old hard-coded path. The submit filter location can be customized by setting the `SUBMITFILTER` parameter inside the file (see [Appendix K: "torque.cfg" Configuration File on page 3586](#)), as in the following example:

torque.cfg:

```
SUBMITFILTER /opt/torque/submit.pl
...
```

 Initial development courtesy of Oak Ridge National Laboratories.

Appendix K: "torque.cfg" Configuration File

CLIENTRETRY	
Format	<INT>
Default	0
Description	Seconds between retry attempts to talk to pbs_server.
Example	<div><pre>CLIENTRETRY 10</pre><p><i>TORQUE waits 10 seconds after a failed attempt before it attempts to talk to pbs_server again.</i></p></div>

DEFAULTCKPT	
For mat	One of <i>None</i> , <i>Enabled</i> , <i>Shutdown</i> , <i>Periodic</i> , <i>Interval=minutes</i> , <i>depth=number</i> , or <i>dir=path</i>
Default	<i>None</i>
Description	Default value for job's checkpoint attribute. For a description of all possible values, see qsub on page 3498 <div> This default setting can be overridden at job submission with the <code>qsub -c</code> option.</div>

DEFAULTCKPT

Example

```
DEFAULTCKPT Shutdown
```

By default, TORQUE checkpoints at pbs_mom shutdown.

FAULT_TOLERANT_BY_DEFAULT

Format

<BOOLEAN>

Default

FALSE

Description

Sets all jobs to fault tolerant by default. (See `qsub -f` for more information on fault tolerance.)

Example

```
FAULT_TOLERANT_BY_DEFAULT TRUE
```

Jobs are fault tolerant by default. They will not be canceled based on failed polling, no matter how many nodes fail to report.

HOST_NAME_SUFFIX

Format

<STRING>

Default

Description

Specifies a hostname suffix. When `qsub` submits a job, it also submits the username of the submitter and the name of the host from which the user submitted the job. TORQUE appends the value of `HOST_NAME_SUFFIX` to the hostname. This is useful for multi-homed systems that may have more than one name for a host.

Example

```
HOST_NAME_SUFFIX -ib
```

When a job is submitted, the -ib suffix is appended to the host name.

QSUBHOST

Format

<HOSTNAME>

Default

QSUBHOST

Description	The hostname given as the argument of this option will be used as the PBS_O_HOST variable for job submissions. By default, PBS_O_HOST is the hostname of the submission host. This option allows administrators to override the default hostname and substitute a new name.
Example	<pre>QSUBHOST host1</pre> <p><i>The default hostname associated with a job is host1.</i></p>

QSUBSENDUID

Format	N/A
Default	---
Description	Integer for job's PBS_OUID variable. Specifying the parameter name anywhere in the config file enables the feature. Removing the parameter name disables the feature.
Example	<pre>QSUBSENDUID</pre> <p><i>TORQUE assigns a unique ID to a job when it is submitted by qsub.</i></p>

QSUBSLEEP

Format	<INT>
Default	0
Description	Specifies time, in seconds, to sleep between a user's submitting and TORQUE's starting a qsub command. Used to prevent users from overwhelming the scheduler.
Example	<pre>QSUBSLEEP 2</pre> <p><i>When a job is submitted with qsub, it will sleep for 2 seconds.</i></p>

RERUNNABLEBYDEFAULT

Format	<BOOLEAN>
---------------	-----------

RERUNNABLEBYDEFAULT

Default	TRUE
Description	Specifies if a job is re-runnable by default. Setting this to false causes the re-runnable attribute value to be false unless the users specifies otherwise with the qsub -r option. (New in TORQUE 2.4.)
Example	<pre>RERUNNABLEBYDEFAULT FALSE</pre> <p><i>By default, qsub jobs cannot be rerun.</i></p>

SERVERHOST

Format	<STRING>
Default	localhost
Description	If set, the qsub on page 3498 command will open a connection to the host specified by the SERVERHOST string.
Example	<pre>SERVERHOST orion15</pre> <p><i>The server will open socket connections and and communicate using serverhost orion15.</i></p>

SUBMITFILTER

Format	<STRING>
Default	\${libexecdir}/qsub_filter (for version 2.1 and older: /usr/local/sbin/torque_submitfilter)
Description	Specifies the location of the submit filter (see Appendix J: Job Submission Filter ("qsub Wrapper") on page 3585 used to pre-process job submission.
Example	<pre>SUBMITFILTER /usr/local/sbin/qsub_filter</pre> <p><i>The location of the submit filter is specified as /usr/local/sbin/qsub_filter.</i></p>

TRQ_IFNAME	
Format	<STRING>
Default	null
Description	Allows you to specify a specific network interface to use for outbound TORQUE requests. The string is the name of a network interface, such as <i>eth0</i> or <i>eth1</i> , depending on which interface you want to use.
Example	<pre>TRQ_IFNAME eth1</pre> <p><i>Outbound TORQUE requests are handled by eth1.</i></p>

VALIDATEGROUP	
Format	<BOOLEAN>
Default	FALSE
Description	Validate submit user's group on qsub commands. For TORQUE builds released after 2/8/2011, <i>VALIDATEGROUP</i> also checks any groups requested in <i>group_list</i> at the submit host. Set <i>VALIDATEGROUP</i> to "TRUE" if you set disable_server_id_check to TRUE.
Example	<pre>VALIDATEGROUP TRUE</pre> <p><i>qsub verifies the submitter's group ID.</i></p>

VALIDATEPATH	
Format	<BOOLEAN>
Default	TRUE
Description	Validate local existence of '-d' working directory.
Example	<pre>VALIDATEPATH FALSE</pre> <p><i>qsub does not validate the path.</i></p>

Appendix L: TORQUE Quick Start Guide

Initial Installation

TORQUE is now hosted at <https://github.com> under the adaptivecomputing organization. To download source, you will need to use the [git](#) utility. For example:

```
[root]# git clone https://github.com/adaptivecomputing.com/torque.git -b 5.1.0 5.1.0
```

To download a different version, replace each 5.1.0 with the desired version. After downloading a copy of the repository, you can list the current branches by typing `git branch -a` from within the directory of the branch you cloned.

i If you're checking source out from git, read the `README.building-40` file in the repository.

Extract and build the distribution on the machine that will act as the "TORQUE server" - the machine that will monitor and control all compute nodes by running the `pbs_server` daemon. See the example below:

```
> tar -xzf torque.tar.gz
> cd torque
> ./configure
> make
> make install
```

i OSX 10.4 users need to change the `#define __TDARWIN` in `src/include/pbs_config.h` to `#define __TDARWIN_8`.

i After installation, verify you have PATH environment variables configured for `/usr/local/bin/` and `/usr/local/sbin/`. Client commands are installed to `/usr/local/bin` and server binaries are installed to `/usr/local/sbin`.

i In this document, `TORQUE_HOME` corresponds to where TORQUE stores its configuration files. The default is `/var/spool/torque`.

Initialize/Configure TORQUE on the Server (`pbs_server`)

- Once installation on the TORQUE server is complete, configure the `pbs_server` daemon by executing the command `torque.setup <USER>` found packaged with the distribution source code, where `<USER>` is a username that will act as the TORQUE admin. This script will set up a basic batch queue to get you started. If you experience problems, make sure that the most recent TORQUE executables are being executed, or that the

executables are in your current PATH.

i If you are upgrading from TORQUE 2.5.9, run `pbs_server -u` before running `torque.setup`.

```
[root]# pbs_server -u
```

- If doing this step manually, be certain to run the command `pbs_server -t create` to create the new batch database. If this step is not taken, the `pbs_server` daemon will be unable to start.
- Proper server configuration can be verified by following the steps listed in Testing server configuration.

Install TORQUE on the Compute Nodes

To configure a compute node do the following on each machine (see page 19, Section 3.2.1 of *PBS Administrator's Manual* for full details):

- Create the self-extracting, distributable packages with `make packages` (See the `INSTALL` file for additional options and features of the distributable packages) and use the parallel shell command from your cluster management suite to copy and execute the package on all nodes (i.e. xCAT users might do `prcp torque-package-linux-i686.sh main:/tmp/; psh main /tmp/torque-package-linux-i686.sh --install`). Optionally, distribute and install the clients package.

Configure TORQUE on the Compute Nodes

- For each compute host, the MOM daemon must be configured to trust the `pbs_server` daemon. In TORQUE 2.0.0p4 and earlier, this is done by creating the `TORQUE_HOME/mom_priv/config` file and setting the `$pbsserver` parameter. In TORQUE 2.0.0p5 and later, this can also be done by creating the `TORQUE_HOME/server_name` file and placing the server hostname inside.
- Additional config parameters may be added to `TORQUE_HOME/mom_priv/config` (see [Appendix C: Node Manager \(MOM\) Configuration on page 3539](#) for details).

Configure Data Management on the Compute Nodes

Data management allows jobs' data to be staged in/out or to and from the server and compute nodes.

- For shared filesystems (i.e., NFS, DFS, AFS, etc.) use the `$usecp` parameter in the `mom_priv/config` files to specify how to map a user's home directory.

(Example: `$usecp gridmaster.tmx.com:/home /home`)

- For local, non-shared filesystems, rcp or scp must be configured to allow direct copy without prompting for passwords (key authentication, etc.)

Update TORQUE Server Configuration

On the TORQUE server, append the list of newly configured compute nodes to the `TORQUE_HOME/server_priv/nodes` file:

```
server_priv/nodes
computenode001.cluster.org
computenode002.cluster.org
computenode003.cluster.org
```

Start the pbs_mom Daemons on Compute Nodes

- Next start the pbs_mom daemon on each compute node by running the pbs_mom executable.

Run the trqauthd daemon to run client commands (see [Configuring trqauthd for Client Commands on page 3297](#)). This enables running client commands.

Verify Correct TORQUE Installation

The pbs_server daemon was started on the TORQUE server when the `torque.setup` file was executed or when it was manually configured. It must now be restarted so it can reload the updated configuration changes.

```
# shutdown server
> qterm # shutdown server

# start server
> pbs_server

# verify all queues are properly configured
> qstat -q

# view additional server configuration
> qmgr -c 'p s'

# verify all nodes are correctly reporting
> pbsnodes -a

# submit a basic job
> echo "sleep 30" | qsub

# verify jobs display
> qstat
```

At this point, the job will not start because there is no scheduler running. The scheduler is enabled in the next step below.

Enable the Scheduler

Selecting the cluster scheduler is an important decision and significantly affects cluster utilization, responsiveness, availability, and intelligence. The default

TORQUE scheduler, `pbs_sched`, is very basic and will provide poor utilization of your cluster's resources. Other options, such as Maui Scheduler or Moab Workload Manager are highly recommended. If using Maui/Moab, see [Moab-TORQUE Integration Guide on page 1377](#). If using `pbs_sched`, start this daemon now.

i If you are installing ClusterSuite, TORQUE and Moab were configured at installation for interoperability and no further action is required.

Startup/Shutdown Service Script for TORQUE/Moab (OPTIONAL)

Optional startup/shutdown service scripts are provided as an example of how to run TORQUE as an OS service that starts at bootup. The scripts are located in the `contrib/init.d/` directory of the TORQUE tarball you downloaded. In order to use the script you must:

- Determine which `init.d` script suits your platform the best.
- Modify the script to point to TORQUE's install location. This should only be necessary if you used a non-default install location for TORQUE (by using the `--prefix` option of `./configure`).
- Place the script in the `/etc/init.d/` directory.
- Use a tool like `chkconfig` to activate the start-up scripts or make symbolic links (`S99moab` and `K15moab`, for example) in desired runtimes (`/etc/rc.d/rc3.d/` on Redhat, etc.).

Appendix M: BLCR Acceptance Tests

This section contains a description of the testing done to verify the functionality of the BLCR implementation. For details, see these topics:

- [Test Environment on page 3595](#)
- [Test 1 - Basic Operation on page 3595](#)
- [Test 2 - Persistence of Checkpoint Images on page 3597](#)
- [Test 3 - Restart After Checkpoint on page 3598](#)
- [Test 4 - Multiple Checkpoint/Restart on page 3599](#)
- [Test 5 - Periodic Checkpoint on page 3599](#)
- [Test 6 - Restart from Previous Image on page 3600](#)

Test Environment

All these tests assume the following test program and shell script, `test.sh`.

```
#include
int main( int argc, char *argv[] )
{
    int i;

    for (i=0; i<100; i++)
    {
        printf("i = %d\n", i);
        fflush(stdout);
        sleep(1);
    }
}
#!/bin/bash

/home/test/test
```

Related Topics

[Appendix M: BLCR Acceptance Tests on page 3594](#)

Test 1 - Basic Operation

Introduction

This test determines if the proper environment has been established.

Test Steps

Submit a test job and the issue a hold on the job.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
```

Possible Failures

Normally the result of `qhold` is nothing. If an error message is produced saying that `qhold` is not a supported feature then one of the following configuration errors might be present.

- The TORQUE images may have not be configured with `--enable-blcr`
- BLCR support may not be installed into the kernel with `insmod`.
- The config script in `mom_priv` may not exist with `$checkpoint_script` defined.
- The config script in `mom_priv` may not exist with `$restart_script` defined.

- The config script in `mom_priv` may not exist with `$checkpoint_run_exe` defined.
- The scripts referenced in the config file may not exist.
- The scripts referenced in the config file may not have the correct permissions.

Successful Results

If no configuration was done to specify a specific directory location for the checkpoint file, the default location is off of the TORQUE directory, which in my case is `/var/spool/torque/checkpoint`.

Otherwise, go to the specified directory for the checkpoint image files. This was done by either specifying an option on job submission, i.e. `-c dir=/home/test` or by setting an attribute on the execution queue. This is done with the command `qmgr -c 'set queue batch checkpoint_dir=/home/test'`.

Doing a directory listing shows the following.

```
# find /var/spool/torque/checkpoint
/var/spool/torque/checkpoint
/var/spool/torque/checkpoint/999.xxx.yyy.CK
/var/spool/torque/checkpoint/999.xxx.yyy.CK/ckpt.999.xxx.yyy.1205266630
# find /var/spool/torque/checkpoint |xargs ls -l
-r----- 1 root root 543779 2008-03-11 14:17
/var/spool/torque/checkpoint/999.xxx.yyy.CK/ckpt.999.xxx.yyy.1205266630

/var/spool/torque/checkpoint:
total 4
drwxr-xr-x 2 root root 4096 2008-03-11 14:17 999.xxx.yyy.CK

/var/spool/torque/checkpoint/999.xxx.yyy.CK:
total 536
-r----- 1 root root 543779 2008-03-11 14:17 ckpt.999.xxx.yyy.1205266630
```

Doing a `qstat -f` command should show the job in a held state, *job_state* = *H*. Note that the attribute `checkpoint_name` is set to the name of the file seen above.

If a checkpoint directory has been specified, there will also be an attribute *checkpoint_dir* in the output of `qstat -f`.

```

$ qstat -f
Job Id: 999.xxx.yyy
  Job_Name = test.sh
  Job_Owner = test@xxx.yyy
  resources_used.cput = 00:00:00
  resources_used.mem = 0kb
  resources_used.vmem = 0kb
  resources_used.walltime = 00:00:06
  job_state = H
  queue = batch
  server = xxx.yyy
  Checkpoint = u

[Appendix M: BLCR Acceptance Tests on page 3594](#)

Test 2 - Persistence of Checkpoint Images

Introduction

This test determines if the checkpoint files remain in the default directory after the job is removed from the TORQUE queue.

Note that this behavior was requested by a customer but in fact may not be the right thing to do as it leaves the checkpoint files on the execution node. These will gradually build up over time on the node being limited only by disk space. The right thing would seem to be that the checkpoint files are copied to the user's home directory after the job is purged from the execution node.

Test Steps

Assuming the steps of Test 1 (see [Test 1 - Basic Operation on page 3595](#)), delete the job and then wait until the job leaves the queue after the completed job hold time. Then look at the contents of the default checkpoint directory to see if the files are still there.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
> qdel 999
> sleep 100
> qstat
>
> find /var/spool/torque/checkpoint
... files ...
```

Possible Failures

The files are not there, did Test 1 actually pass?

Successful Results

The files are there.

Related Topics

[Appendix M: BLCR Acceptance Tests on page 3594](#)

Test 3 - Restart After Checkpoint

Introduction

This test determines if the job can be restarted after a checkpoint hold.

Test Steps

Assuming the steps of Test 1 (see [Test 1 - Basic Operation on page 3595](#)), issue a [qrsls](#) command. Have another window open into the `/var/spool/torque/spool` directory and tail the job.

Successful Results

After the `qrsls`, the job's output should resume.

Related Topics

[Appendix M: BLCR Acceptance Tests on page 3594](#)

Test 4 - Multiple Checkpoint/Restart

Introduction

This test determines if the checkpoint/restart cycle can be repeated multiple times.

Test Steps

Start a job and then while tailing the job output, do multiple [qhold](#)/[qrls](#) operations.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
> qrls 999
> qhold 999
> qrls 999
> qhold 999
> qrls 999
```

Successful results

After each [qrls](#), the job's output should resume. Also tried "while true; do [qrls](#) 999; [qhold](#) 999; done" and this seemed to work as well.

Test 5 - Periodic Checkpoint

Introduction

This test determines if automatic periodic checkpoint will work.

Test Steps

Start the job with the option `-c enabled,periodic,interval=1` and look in the checkpoint directory for checkpoint images to be generated about every minute.

```
> qsub -c enabled,periodic,interval=1 test.sh
999.xxx.yyy
```

Successful Results

After each `qrls`, the job's output should resume. Also tried "while true; do `qrls 999`; `qhold 999`; done" and this seemed to work as well.

Test 6 - Restart from Previous Image

Introduction

This test determines if the job can be restarted from a previous checkpoint image.

Test Steps

Start the job with the option `-c enabled,periodic,interval=1` and look in the checkpoint directory for checkpoint images to be generated about every minute. Do a `qhold` on the job to stop it. Change the attribute `checkpoint_name` with the `qalter` command. Then do a `qrls` to restart the job.

```
> qsub -c enabled,periodic,interval=1 test.sh
999.xxx.yyy
> qhold 999
> qalter -W checkpoint_name=ckpt.999.xxx.yyy.1234567
> qrls 999
```

Successful Results

The job output file should be truncated back and the count should resume at an earlier number.
