<b>Welcome</b> .....	<b>xxiii</b>
<b>Moab HPC Suite – Basic Edition release notes</b> .....	<b>1</b>
Moab HPC Suite – Basic Edition 8.0.0 release notes .....	1
New features .....	1
Differences .....	5
Installation and upgrade information .....	6
Known issues .....	7
Resolved issues .....	8
Key documentation changes .....	9
<b>Installation and Configuration</b> .....	<b>11</b>
Requirements .....	11
Manual installation .....	17
Installation .....	17
Preparing for installation .....	17
Installing TORQUE .....	23
Installing Moab Workload Manager .....	27
Installing Moab Web Services .....	31
Additional configuration .....	35
Configuring SSL in Tomcat .....	35
Setting up OpenLDAP on CentOS 6 .....	36
Moab Workload Manager configuration options .....	42
Trusting servers in Java .....	44
Upgrading .....	45
Upgrading MongoDB .....	45
Upgrading TORQUE .....	45
Upgrading Moab Workload Manager .....	47
Upgrading MWS .....	50
RPM installation .....	54
Installing Moab HPC Suite – Basic Edition .....	54
Configuration .....	59
Configuring TORQUE .....	59
Configuring Moab Workload Manager .....	61
Configuring Moab Web Services .....	62
Installing Insight .....	65
Installing Viewpoint .....	69
Additional configuration .....	71

Configuring SSL in Tomcat .....	71
Setting up OpenLDAP on CentOS 6 .....	71
Trusting servers in Java .....	77
Troubleshooting .....	78
Component documentation .....	86
<b>Moab Workload Manager .....</b>	<b>89</b>
Moab Workload Manager overview .....	89
Philosophy .....	89
Value of a Batch System .....	90
Philosophy and Goals .....	91
Workload .....	92
Scheduler Basics .....	94
Initial Moab Configuration .....	94
Layout of Scheduler Components .....	96
Scheduling Environment .....	98
Scheduling Dictionary .....	104
Scheduling Iterations and Job Flow .....	111
Configuring the Scheduler .....	114
Credential Overview .....	117
Job Attributes/Flags Overview .....	144
Scheduler Commands .....	151
Status Commands .....	153
Job Management Commands .....	154
Reservation Management Commands .....	155
Policy/Configuration Management Commands .....	156
End-user Commands .....	156
Commands .....	157
checkjob .....	157
checknode .....	169
mcredctl .....	174
mdiag .....	177
mdiag -a .....	180
mdiag -b .....	181
mdiag -c .....	181
mdiag -f .....	185
mdiag -g .....	187
mdiag -j .....	187
mdiag -n .....	188
mdiag -t .....	195
mdiag -p .....	195

mdiag -q .....	198
mdiag -r .....	199
mdiag -R .....	203
mdiag -S .....	208
mdiag -s .....	209
mdiag -T .....	209
mdiag -u .....	211
mjobctl .....	212
mnodectl .....	229
moab .....	235
mrmctl .....	236
mrsvctl .....	238
mschedctl .....	264
mshow .....	271
mshow -a .....	272
mshow -a .....	283
msub .....	286
Applying the msub submit filter .....	303
Submitting Jobs via msub in XML .....	305
mvectl (Moab Virtual Container Control) .....	309
mvmctl .....	314
showbf .....	318
showq .....	321
showhist.moab.pl .....	331
showres .....	336
showstart .....	342
showstate .....	345
showstats .....	347
showstats -f .....	359
TIMESPEC .....	362
Deprecated commands .....	362
canceljob .....	362
changeparam .....	363
diagnose .....	363
releasehold .....	364
releaseres .....	366
resetstats .....	366

runjob .....	367
sethold .....	368
setqos .....	369
setres .....	370
setspri .....	374
showconfig .....	375
Prioritizing Jobs and Allocating Resources .....	376
Job Prioritization .....	377
Priority Overview .....	377
Job Priority Factors .....	378
Fairshare Job Priority Example .....	388
Common Priority Usage .....	390
Prioritization Strategies .....	392
Manual Job Priority Adjustment .....	393
Node Allocation Policies .....	393
Node Access Policies .....	403
Node Availability Policies .....	404
Task Distribution Policies .....	411
Managing Fairness - Throttling Policies, Fairshare, and Allocation Management .....	411
Fairness Overview .....	411
Usage Limits/Throttling Policies .....	414
Fairshare .....	432
Sample FairShare Data File .....	445
Charging a Workflow .....	446
Controlling Resource Access - Reservations, Partitions, and QoS Facilities .....	450
Advance Reservations .....	450
Reservation Overview .....	450
Administrative Reservations .....	455
Standing Reservations .....	457
Reservation Policies .....	457
Configuring and Managing Reservations .....	460
Personal Reservations .....	491
Partitions .....	494
Quality of Service (QoS) Facilities .....	498
Optimizing Scheduling Behavior – Backfill and Node Sets .....	507
Optimization Overview .....	507
Backfill .....	508
Node Set Overview .....	514
Evaluating System Performance - Statistics, Profiling, Testing, and Simulation .....	521
Moab Performance Evaluation Overview .....	521
Accounting: Job and System Statistics .....	521
Testing New Versions and Configurations .....	523

Answering What If? Questions with the Simulator .....	524
General Job Administration .....	525
Job Holds .....	525
Job Priority Management .....	526
Suspend/Resume Handling .....	527
Checkpoint/Restart Facilities .....	528
Job Dependencies .....	528
Job Defaults and Per Job Limits .....	530
General Job Policies .....	531
Using a Local Queue .....	539
Job Deadlines .....	542
Job Arrays .....	545
General Node Administration .....	552
Node Location .....	553
Node Attributes .....	556
Node Specific Policies .....	566
Managing Shared Cluster Resources (Floating Resources) .....	567
Managing Node State .....	571
Managing Consumable Generic Resources .....	573
Enabling Generic Metrics .....	575
Enabling Generic Events .....	578
Resource Managers and Interfaces .....	584
Resource Manager Overview .....	585
Resource Manager Configuration .....	588
Resource Manager Extensions .....	618
PBS Resource Manager Extensions .....	647
Adding New Resource Manager Interfaces .....	649
Managing Resources Directly with the Native Interface .....	650
Utilizing Multiple Resource Managers .....	661
License Management .....	663
Resource Provisioning .....	665
Managing Networks .....	666
Intelligent Platform Management Interface .....	669
Resource Manager Translation .....	672
Troubleshooting and System Maintenance .....	673
Internal Diagnostics/Diagnosing System Behavior and Problems .....	673
Logging Overview .....	676
Object Messages .....	682
Notifying Administrators of Failures .....	684
Issues with Client Commands .....	685
Tracking System Failures .....	686
Problems with Individual Jobs .....	688
Diagnostic Scripts .....	689
Improving User Effectiveness .....	691

User Feedback Loops .....	691
User Level Statistics .....	692
Enhancing Wallclock Limit Estimates .....	693
Job Start Time Estimates .....	693
Providing Resource Availability Information .....	694
Collecting Performance Information on Individual Jobs .....	694
Cluster Analysis, Testing, and Simulation .....	694
Testing New Releases and Policies .....	695
Testing New Middleware .....	699
Configuring Resources for Simulation .....	701
Workload Event Format .....	702
Interactive Simulation Tutorial .....	712
Checking the Queue Status .....	712
Determining Why Jobs Are Not Running .....	713
Controlling Iterations .....	714
Managing Reservations Applying to the Queue .....	715
Verifying Fair Scheduling .....	721
Taking the System Down for Maintenance .....	722
Green computing .....	723
Green computing overview .....	723
How-to's .....	733
Deploying Adaptive Computing IPMI scripts .....	733
Choosing which nodes Moab powers on or off .....	735
Enabling green computing .....	736
Adjusting green pool size .....	740
Handling power-related events .....	740
Maximizing scheduling efficiency .....	741
Putting idle nodes in power-saving states .....	742
Troubleshooting green computing .....	742
Object triggers .....	745
About object triggers .....	745
How-to's .....	747
Creating a trigger .....	748
Creating VM triggers .....	751
Using a trigger to send email .....	752
Using a trigger to execute a script .....	754
Using a trigger to perform internal Moab actions .....	754
Requiring an object threshold for trigger execution .....	755
Enabling job triggers .....	755
Modifying a trigger .....	756
Viewing a trigger .....	757
Checkpointing a trigger .....	757

References .....	758
Job triggers .....	758
Node triggers .....	759
Reservation triggers .....	761
Resource manager triggers .....	762
Scheduler triggers .....	763
Threshold triggers .....	764
Trigger components .....	765
Trigger exit codes .....	773
Node maintenance example .....	773
Environment creation example .....	774
Trigger variables .....	775
About trigger variables .....	775
How-to's .....	776
Setting and receiving trigger variables .....	776
Externally injecting variables into job triggers .....	777
Exporting variables to parent objects .....	777
Requiring variables from generations of parent objects .....	778
Requesting name space variables .....	778
References .....	779
Dependency trigger components .....	779
Trigger variable comparison types .....	779
Internal variables .....	780
Miscellaneous .....	781
User Feedback Overview .....	781
Enabling High Availability Features .....	783
Malleable Jobs .....	785
Identity Managers .....	786
Generic System Jobs .....	790
Database Configuration .....	793
SQLite3 .....	793
Connecting to a MySQL Database with an ODBC Driver .....	794
Connecting to a PostgreSQL Database with an ODBC Driver .....	797
Connecting to an Oracle Database with an ODBC Driver .....	799
Installing the Oracle Instant Client .....	806
Migrating Your Database to Newer Versions of Moab .....	808
Importing Statistics from stats/DAY.* to the Moab Database .....	815
Accelerators .....	815
Scheduling GPUs .....	816
Using GPUs with NUMA .....	816
NVIDIA GPUs .....	817

GPU Metrics .....	820
Intel® Xeon Phi™ Coprocessor Configuration .....	822
Intel® Xeon Phi™ Co-processor Metrics .....	827
Preemption .....	828
About preemption .....	828
How-to's .....	830
Canceling jobs with preemption .....	830
Checkpointing jobs with preemption .....	833
Requeueing jobs with preemption .....	834
Suspending jobs with preemption .....	837
Using owner preemption .....	840
Using QoS preemption .....	844
References .....	845
Manual preemption commands .....	845
Preemption flags .....	846
PREEMTPOLICY types .....	848
Simple example of preemption .....	848
Testing and troubleshooting preemption .....	852
Job templates .....	853
About job templates .....	853
How-to's .....	854
Creating job templates .....	854
Viewing job templates .....	855
Applying templates based on job attributes .....	855
Requesting job templates directly .....	856
Creating workflows with job templates .....	857
References .....	858
Job template extension attributes .....	858
Job template matching attributes .....	870
Job template examples .....	870
Job template workflow examples .....	871
Moab Workload Manager for Grids .....	872
Grid Basics .....	873
Grid Configuration Basics .....	881
Centralized Grid Management (Master/Slave) .....	882
Hierarchal Grid Management .....	882
Localized Grid Management .....	884
Resource Control and Access .....	885
Workload Submission and Control .....	888
Reservations in the Grid .....	888
Grid Usage Policies .....	889
Grid Scheduling Policies .....	891
Grid Credential Management .....	893
Grid Data Management .....	895

Grid Security .....	900
Grid Diagnostics and Validation .....	900
Data staging .....	901
About data staging .....	901
How-to's .....	903
Configuring the SSH keys for the data staging transfer script .....	903
Configuring data staging .....	905
Staging data to or from a shared file system .....	907
Staging data to or from a shared file system in a grid .....	911
Configuring the \$CLUSTERHOST variable .....	915
Staging data to or from a compute node .....	916
Configuring data staging with advanced options .....	920
References .....	922
Sample user job script .....	922
Appendices .....	923
Appendix A: Moab Parameters .....	923
Appendix B: Multi-OS Provisioning .....	1079
Event Dictionary .....	1098
Appendix D: Adjusting Default Limits .....	1213
Appendix E: Security .....	1217
Appendix F: Initial Moab Testing .....	1225
Appendix G: Integrating Other Resources with Moab .....	1227
Compute Resource Managers .....	1228
Moab-TORQUE Integration Guide .....	1228
TORQUE/PBS Integration Guide - RM Access Control .....	1231
TORQUE/PBS Config - Default Queue Settings .....	1232
Moab-SLURM Integration Guide .....	1232
Installation Notes for Moab and TORQUE for Cray .....	1236
Provisioning Resource Managers .....	1252
Validating an xCAT Installation for Use with Moab .....	1252
Hardware Integration .....	1255
Moab-NUMA Integration Guide .....	1255
Appendix H: Interfacing with Moab (APIs) .....	1259
Appendix I: Considerations for Large Clusters .....	1263
Appendix J: Configuring Moab as a Service .....	1268
Appendix K: Migrating from 3.2 .....	1269
Appendix R: Node Allocation Plug-in Developer Kit .....	1272
Appendix S: Scalable Systems Software Specification .....	1278
Scalable Systems Software Job Object Specification .....	1278
Scalable Systems Software Resource Management and Accounting Protocol (SSSRMAP) Mes- sage Format .....	1314

Scalable Systems Software Node Object Specification .....	1338
Scalable Systems Software Resource Management and Accounting Protocol (SSSRMAP) Wire Protocol .....	1347
Appendix W: Moab Resource Manager Language Interface Overview .....	1363
W.1 Moab Resource Manager Language Data Format .....	1363
W.2 Managing Resources with SLURM .....	1372
W.3 Moab RM Language Socket Protocol Description .....	1383
SCHEDCFG flags .....	1389

## **Moab Web Services .....** 1395

Moab Web Services overview .....	1395
Setup .....	1395
Moab Web Services setup .....	1395
Configuring Moab Web Services .....	1395
Setting up MWS security .....	1410
Securing the connection with Moab .....	1411
Securing the connection with MongoDB .....	1411
Securing client connections to MWS .....	1412
Securing the LDAP connection .....	1416
Securing the connection with the message queue .....	1417
Version and build information .....	1418
Access control .....	1420
About access control .....	1420
Access control .....	1420
API documentation .....	1423
About the API .....	1423
RESTful web services .....	1423
Data format .....	1425
Global URL parameters .....	1425
Requesting specific API versions .....	1428
Responses and return codes .....	1429
Error messages .....	1432
Pre and post-processing hooks .....	1434
Authentication .....	1443
System events .....	1444
Resources .....	1446
Resources introduction .....	1446
Access control lists (ACLs) .....	1448
Accounting .....	1451
Accounting Accounts .....	1451
Accounting Allocations .....	1455
Accounting Charge rates .....	1459
Accounting Funds .....	1463
Accounting Liens .....	1473
Accounting Organizations .....	1477

Accounting Quotes .....	1480
Accounting Transactions .....	1483
Accounting Usage records .....	1488
Accounting Users .....	1502
Credentials .....	1506
Diagnostics .....	1521
Distinct .....	1526
Events .....	1528
Images .....	1536
Job arrays .....	1545
Jobs .....	1547
Job templates .....	1569
Metric types .....	1571
Nodes .....	1573
Notification conditions .....	1580
Notifications .....	1585
Permissions .....	1593
Plugins .....	1599
Plugin types .....	1607
Policies .....	1611
Fairshare .....	1618
Principals .....	1627
Priority .....	1633
Reports .....	1636
Reservations .....	1646
Resource types .....	1654
Roles .....	1655
Standing reservations .....	1661
Reporting framework .....	1665
Overview of reporting framework .....	1665
Example report (CPU Utilization) .....	1668
Plugins .....	1672
About Moab Web Services plugins .....	1672
Plugin overview .....	1673
Plugin introduction .....	1673
Lifecycle states .....	1675
Events .....	1676
Custom web services .....	1676
Utility services .....	1677
Data consolidation .....	1677
Routing .....	1679
Plugin developer's guide .....	1679
Requirements .....	1680
Dynamic methods .....	1681

Logging .....	1682
in messaging .....	1683
Configuration .....	1685
Configuration constraints .....	1686
Individual datastore .....	1694
Exposing web services .....	1696
Reporting state data .....	1698
Controlling lifecycle .....	1701
Accessing MWS REST resources .....	1702
Creating events and notifications .....	1704
Handling events .....	1711
Handling exceptions .....	1713
Managing SSL connections .....	1714
Utilizing services or custom "helper" classes .....	1715
Packaging plugins .....	1720
Example plugin types .....	1729
Moab Workload Manager resource manager integration .....	1730
Configuring Moab Workload Manager .....	1731
Resource manager queries .....	1735
Plugin type management .....	1737
Listing plugin types .....	1737
Displaying plugin types .....	1738
Plugin type documentation .....	1738
Add or update plugin types .....	1739
Plugin management .....	1742
Listing plugins .....	1742
Creating a plugin .....	1742
Displaying a plugin .....	1743
Modifying a plugin .....	1744
Deleting a plugin .....	1745
Monitoring and lifecycle controls .....	1745
Setting default plugin configuration .....	1747
Plugin services .....	1747
Job RM service .....	1748
Moab REST service .....	1748
Node RM service .....	1750
Plugin control service .....	1750
Plugin datastore service .....	1752
Plugin event service .....	1755
SSL service .....	1757
Storage RM service .....	1757
Virtual machine RM service .....	1757
Plugin types .....	1758
Power Management Plugin .....	1758

<b>TORQUE Resource Manager .....</b>	<b>2541</b>
Introduction .....	2541
Overview .....	2543
TORQUE installation overview .....	2544
TORQUE architecture .....	2544
Installing TORQUE .....	2544
Compute nodes .....	2549
Enabling TORQUE as a service .....	2550
Initializing/Configuring TORQUE on the server (pbs_server) .....	2551
Specifying compute nodes .....	2553
Configuring TORQUE on compute nodes .....	2554
Configuring ports .....	2555
Configuring trqauthd for client commands .....	2556
Finalizing configurations .....	2558
Advanced configuration .....	2558
Customizing the install .....	2558
Server configuration .....	2566
Manual setup of initial server configuration .....	2571
Server node file configuration .....	2572
Basic node specification .....	2572
Specifying virtual processor count for a node .....	2572
Specifying GPU count for a node .....	2573
Specifying node features (node properties) .....	2573
Testing server configuration .....	2574
TORQUE on NUMA systems .....	2576
TORQUE NUMA configuration .....	2576
Building TORQUE with NUMA support .....	2576
TORQUE Multi-MOM .....	2580
Multi-MOM configuration .....	2580
Stopping pbs_mom in Multi-MOM mode .....	2582
Submitting and managing jobs .....	2582

Job submission .....	2583
Multiple job submission .....	2584
Managing multi-node jobs .....	2585
Requesting resources .....	2586
Requesting generic resources .....	2593
Requesting floating resources .....	2593
Requesting other resources .....	2594
Exported batch environment variables .....	2594
Enabling trusted submit hosts .....	2596
Example submit scripts .....	2596
Job files .....	2597
Monitoring jobs .....	2599
Canceling jobs .....	2599
Job preemption .....	2600
Keeping completed jobs .....	2600
Job checkpoint and restart .....	2601
Introduction to BLCR .....	2601
Configuration files and scripts .....	2602
Starting a checkpointable job .....	2609
Checkpointing a job .....	2610
Restarting a job .....	2610
Acceptance tests .....	2611
Job exit status .....	2611
Service jobs .....	2615
Submitting service jobs .....	2616
Submitting service jobs in MCM .....	2616
Managing service jobs .....	2616
Managing nodes .....	2617
Adding nodes .....	2617
Node properties .....	2618
Changing node state .....	2618
Changing node power states .....	2619
Host security .....	2621
Linux cpuset support .....	2623
Scheduling cores .....	2624
Geometry request configuration .....	2624
Geometry request usage .....	2625
Geometry request considerations .....	2625
Scheduling accelerator hardware .....	2625
Setting server policies .....	2626
Queue configuration .....	2626
Queue attributes .....	2626
Example queue configuration .....	2637
Setting a default queue .....	2638

Mapping a queue to subset of resources .....	2638
Creating a routing queue .....	2638
Server high availability .....	2640
Setting min_threads and max_threads .....	2652
Integrating schedulers for TORQUE .....	2653
Configuring data management .....	2653
SCP setup .....	2653
Generating SSH key on source host .....	2654
Copying public SSH key to each destination host .....	2654
Configuring the SSH daemon on each destination host .....	2655
Validating correct SSH configuration .....	2655
Enabling bi-directional SCP access .....	2655
Compiling TORQUE to support SCP .....	2656
Troubleshooting .....	2656
NFS and other networked filesystems .....	2656
File stage-in/stage-out .....	2657
MPI (Message Passing Interface) support .....	2658
MPICH .....	2658
Open MPI .....	2659
Resources .....	2660
Accounting records .....	2662
Job logging .....	2664
Job log location and name .....	2664
Enabling job logs .....	2664
Troubleshooting .....	2665
Host resolution .....	2666
Firewall configuration .....	2666
TORQUE log files .....	2666
Using "tracejob" to locate job failures .....	2668
Using GDB to locate job failures .....	2670
Other diagnostic options .....	2670
Stuck jobs .....	2671
Frequently asked questions (FAQ) .....	2672
Compute node health check .....	2677
Configuring MOMs to launch a health check .....	2678

# Welcome

Welcome to *Moab HPC Suite – Basic Edition 8.0.0*, which lets you...

This guide is intended for...

The following sections will help you quickly get started with Moab HPC Suite:

## About Moab HPC Suite

Gives an overview about Moab HPC Suite basics.

## Installing Moab HPC Suite

Instructs on how to install Moab HPC Suite.

## Configuring Moab HPC Suite

Explains how to configure and set up Moab HPC Suite.

## Common Moab HPC Suite tasks

Contains helpful task-based information for the most common Moab HPC Suite functions.

## Moab HPC Suite references

Contains useful examples, configurations, use cases and references relating to Moab HPC Suite use and setup.

# Moab HPC Suite – Basic Edition release notes

## Moab HPC Suite – Basic Edition 8.0.0 release notes

The release notes file contains the following sections:

- [New features on page 1](#)
- [Differences on page 5](#)
- [Installation and upgrade information on page 6](#)
- [Known issues on page 7](#)
- [Resolved issues on page 8](#)
- [Key documentation changes on page 9](#)

## New features

The following is a summary of key new features in Basic.

- [Moab Workload Manager on page 1](#)
- [Moab Web Services on page 4](#)
- [TORQUE Resource Manager on page 5](#)

### Moab Workload Manager

#### *Data staging*

The old method of data staging has been deprecated in Moab Workload Manager 8.0.0 and will be removed from the product in a future release.

Moab data staging has undergone a major redesign in 8.0.0. Consequently, Moab includes several new features that improve the data staging experience. These features include the following:

- Moab data staging system jobs, separately schedulable from the user job, that increase system performance and utilization by not reserving compute nodes during input or output data-staging

unless a compute node's local file system is involved.

- New `msub` options that are required to submit data staging jobs. At least one of `--stagein`, `--stageinfile`, `--stageout`, and/or `--stageoutfile` is required to stage data for your job.
  - `--stagein` and `--stageout` specify individual files and/or directories to stage in or out, respectively.
  - `--stageinfile` and `--stageoutfile` specify the path to an individual file that contain the paths of files and/or directories to stage in or out, respectively.
- `--stageinsize` and `--stageoutsize` options that give Moab an estimate of the size of the files or directories to stage in or out, respectively, so it can more accurately schedule the associated data staging jobs. For more information, see "[msub](#)".
- A customizable reference data staging job submit filter that sums the size of all input files and passes the sum to Moab. It uses the `--stageinsize` option so you do not have to estimate an input data size and Moab can more accurately estimate wallclock time when scheduling the input data staging system job. For more information, see "[Configuring data staging](#)".
- Customizable reference scripts that use `scp` or `rsync` to stage data (`/opt/moab/tools/data-staging/ds_move_scp` and `/opt/moab/tools/data-staging/ds_move_rsync`, respectively). The scripts work in an out-of-the-box environment, but you should modify one or both to work with your unique environment. You can use the reference scripts as a guide to create your own script that supports data staging with a different Linux file transfer utility or commercial file transfer utility, such as one from Aspera.
- The ability to set generic metrics on partitions (for more information, see "[Per-Partition Settings](#)").
  - The new `DATASTAGINGBANDWIDTH_MBITS_PER_SEC` metric, required for data staging, specifies the transfer rate of the partition in megabits per second. Moab uses it and the `--stageinsize` and/or `--stageoutsize` `msub` options submitted with the job to estimate the wallclock time for better scheduling of the input and output data staging system jobs.
  - The new metric can be dynamically updated by a resource manager or configured by an administrator.
- When you run `checkjob -v` on a data staging job, Moab returns the source and destination of data staging files and their total size. See "[checkjob](#)" for more information.
- Advanced configuration options allow you to rename the default template, support multiple file transfer script utilities in a grid on a per-partition basis, configure a notification email to be sent after a data staging job completes, add a non-default template via `msub`, and use `msub` to return all job IDs in the workflow at submission time. This is useful when you dynamically generate user workflows using scripts that must create dependencies on data-staging system jobs (when input or output data-staging has completed, for example), not the user job. For more information, see "[Configuring data staging with advanced options](#)".

The features associated with data staging in previous Moab releases have been deprecated in this release and will be removed in the next. For more information about data staging in Moab Workload Manager, see "[About data staging](#)".

### *CPU frequency control*

Moab can now ask the resource manager to change the CPU frequency on allocated nodes for submitted jobs. The request is made with the new [CPULOCK](#) resource manager extension. A user can specify a desired clock frequency in megahertz, a Linux power governor policy name, or an ACPI performance state (P-state) number.

The [mjobctl -m](#) command has been updated to allow modification of the requested CPU frequency on an already submitted job.

CPULOCK has also been added as a job template extension. The job template extension overrides the job script CPULOCK extension and the job submission CPULOCK option.

### *Improved Performance and Scalability*

Moab 8.0.0 includes new multi-threaded scheduling routines and is now compiled with optimizations enabled (-O). These improvements should increase scalability, efficiency, and performance for the majority of sites. The size of the thread pool can be throttled using the [THREADPOOLSIZE](#) parameter.

### *Finer-grained Logging Timestamps*

The timestamps in the Moab logs now include milliseconds, which can be helpful with higher [LOGLEVEL](#) settings.

### *Deleting checkpoint file doesn't reset IDs*

Moab now persists counters for job and reservation IDs to an external file (`<moab home>/counters`), in addition to persisting the counters to checkpoints. The new external counter file is created during installation. On startup, Moab reads the ID counters from either or both sources and uses the maximum of the two values that it sees as the resumption point for new IDs. This means that you can safely delete a checkpoint file without causing your IDs to be reset.

If both the external counter file and the checkpoint file are missing, Moab refuses to start. This is a precaution to protect the integrity of a relational database or external processes that rely on the IDs. If you need to override this behavior, you can do so by manually creating a new external counter file that starts IDs at an arbitrary number.

### *CANCELFAILEDDEPENDENCYJOBS scheduler flag*

The new [CANCELFAILEDDEPENDENCYJOBS](#) scheduler flag automatically cancels dependency jobs that will never run because of an unmet requirement. For more information, see [Job Dependencies](#).

### *Reduction in command processing time*

If your system's scheduling cycle regularly takes longer than the [CLIENTTIMEOUT](#) value, you can configure Moab to fork a copy of itself that will respond to certain information-only client commands (`checkjob`, `showbf`, and `showstart`). This enables you to run intense diagnostic commands while Moab is in the middle of its scheduling process. For more information, see [Reduce command processing time](#).

### *New --workflowjobids option for msub*

A new `--workflowjobids` option for the `msub` command returns all the job IDs, including data-staging system job IDs, in a data-staging workflow at submission time (Moab creates an internal workflow for

jobs submitted with data-staging options). For more information, see [Configuring data staging with advanced options](#).

### *NAMI interface improvements*

The Native Accounting Manager Interface now implements all charge policies and chargeable properties implemented by the MAM Accounting Manager Interface.

### *New support diagnostic script*

The `support.diag.pl` script used for gathering information for Adaptive support representatives has been deprecated with the 8.0.0 release. Use the new `support-diag.py` script instead. For more information, see [Diagnostic Scripts](#).

## Moab Web Services

### *PAM authentication support*

Support for PAM (pluggable authentication module) has been added to MWS. PAM treats the user as if it is local to the machine doing the authenticating, and it uses whatever the user is authenticating with, whether it be LDAP or NIS. For information about configuring PAM with MWS, see [PAM \(pluggable authentication module\) configuration using mws-config.groovy](#).

There is a security risk when authenticating local users through your PAM configuration. This behavior is highly discouraged and is not supported by Adaptive Computing.

### *OAuth authentication support*

Support for OAuth has been added to MWS. OAuth allows trusted client applications to securely delegate authentication to MWS. Once MWS has authenticated a user by verifying the username and password in LDAP, PAM, or NIS, MWS returns an access token to the client. The client then presents this access token to MWS to access resources. For information about configuring PAM with MWS, see [OAuth configuration using mws-config.groovy](#).

### *Node power management plugin*

The MWS power management plugin acts as a power resource manager; it monitors the power states of the nodes in the Node Configuration File using the TORQUE `pbsnodes` command and a query script. The plugin also allows you to customize the power state of each node when it should be "turned off." For more information, see the documentation included with the plugin in Moab Web Services.

### *Fairshare policy added to MWS Policies object*

The Moab "fairshare" policy has been added to the Policies object in MWS. With this addition, you can get fairshare policy information and make fairshare policy modifications through the MWS API. For more information, see .

### *Modifiable attributes added to the MWS job resource*

You can now use MWS to modify an idle job's system priority, the nodes that the job requests, and the resources per task required for the job. For more information, see [Modify job attributes](#).

### *View and modify single credentials*

You can now query a single credential in MWS. Additionally, you can modify a credential's fields and use the change-mode parameter to modify the credential's list fields. For more information, see [Credentials](#).

### *View and modify scheduler priorities*

You can now query and modify the scheduler priorities through the Priority resource in MWS. For more information, see [Priority](#).

## TORQUE Resource Manager

### *CPU frequency control*

TORQUE can now set the CPU frequency on requested nodes for submitted jobs. The request is made with the new resource extension. A user can specify a desired clock frequency in megahertz, a Linux power governor policy name, or an ACPI performance state (P-state) number.

The `qalter -l` command has been updated to allow modification of the requested CPU frequency on an already submitted job.

The `pass_cpuclock` server parameter was added which allows administrators to track, but not grant, the CPU frequency request portion of a job submission.

### *qrerun all command*

When you execute the `qrerun all` command, you will be prompted for confirmation. TORQUE will then place all running jobs in a queued state without contacting the MOMs. You should only use this when the entire cluster is down and you cannot contact it.

### *Node power state control*

TORQUE can now set the power state of a node. Depending on the hardware and software capabilities of the node, TORQUE can set the power state to Running, Standby, Suspend, Hibernate, or Shutdown. A [new option](#) was added to the `pbsnodes` command to make this work. The syntax of the command is:

```
pbsnodes -m [running|standby|suspend|hibernate|shutdown] <space delimited list of nodes to alter>
```

In order to wake a node from a low-power state, Wake-on-LAN must be supported and configured on the node. For more information, see [Changing node power states](#).

## Differences

This section contains differences in previously existing features that require a change in configuration or routine.

- [Moab HPC Suite on page 6](#)
- [Moab Workload Manager on page 6](#)
- [Moab Web Services on page 6](#)

- [TORQUE Resource Manager on page 6](#)
- [Differences on page 5](#)

## Moab HPC Suite

### PostgreSQL 9.3 repository

The PostgreSQL 9.3 repository information has been moved from the AC.repo file in /etc/yum.repos.d/ to its own file. Please make sure to use the newer AC.repo file to avoid duplicate repository entries for PostgreSQL 9.3.

## Moab Workload Manager

## Moab Web Services

## TORQUE Resource Manager

# Installation and upgrade information

## Installing Moab HPC Suite – Basic Edition 8.0.0

Please see [Installing the RPMs](#) for Basic for manual or RPM-based installation instructions, respectively.

## Installing TORQUE 5.0.0

### Installing TORQUE 5.0.0 on RHEL 5

TORQUE 5.0.0 requires the download of boost version 1.36 or later header files in order to build on most RHEL 5 installations. TORQUE 5.0.0 needs the `unordered_map` from the boost library. This did not become part of the boost standard until boost version 1.36. Standard RHEL 5 installations only have boost version 1.33.1. TORQUE 5.0.0 has added a configure option named `--with-boost-path`. This option allows the user to be able to download a newer version of boost without the need to install boost.

You can download a new boost library from [www.boost.org](http://www.boost.org). Extract the tarball to a directory of your choosing. When you are configuring TORQUE you then add the `--with-boost-path=<boost_path>` to the configuration line. The `boost_path` is the location where you unzipped the boost library. Within the unzipped files is a directory named `boost`. This directory contains the `.hpp` files with the needed

boost classes. Once the `--with-boost-path` option has been added to the configuration line you can continue to install TORQUE as per the installation guide.

Note that this procedure is not required on RHEL 6 and later versions.

## Upgrading to Moab HPC Suite – Basic Edition 8.0.0

**i** Upgrading an RPM-based installation of the Moab HPC Suite does not work correctly in 8.0.0. See [Known issues on page 7](#) for more information and tips.

Please see [Upgrading Moab Workload Manager](#) for Basic for upgrade instructions.

The Moab database schema has been updated for 8.0.0:

Table name	New additions	Changes
<b>Nodes</b>	<ul style="list-style-type: none"> <li>CPUClock (VARCHAR (64))</li> </ul>	<ul style="list-style-type: none"> <li>Column name "Partition" changed to "PartitionName". The word "partition" became a reserved word as of MySQL 5.6</li> </ul>
<b>Requests</b>	<ul style="list-style-type: none"> <li>CPUClock (VARCHAR (64))</li> </ul>	n/a
<b>NodeStats</b>	<ul style="list-style-type: none"> <li>CPUClock integer</li> <li>CPUMaxClock integer</li> <li>CPUMinClock integer</li> </ul>	n/a
<b>Reservations</b>	n/a	<ul style="list-style-type: none"> <li>Column name "Partition" changed to "PartitionName". The word "partition" became a reserved word as of MySQL 5.6</li> </ul>

To migrate your database schema to the newest version, see [Migrating Your Database to Newer Versions of Moab](#).

## Known issues

The following are known issues in Basic. Following each issue description is an associated issue number in parentheses.

- Connecting Moab to MySQL via ODBC can cause Moab to slow down. You can work around this issue by creating the tables with the old storage engine (ENGINE = MyISAM). Also note that other factors will also affect DB performance, such as the type of DB connection (remote vs. local), the DB server's hardware specifications, Moab's configuration for how much to write to the DB (see REALTIMEDBOBJECTS), etc (MOAB-6316).
- Sites that used RPMs to install Moab HPC Suite will not be able to upgrade to 8.0.0 RPMs until 7.2.9 is released. The issue exists in all pre-8.0 RPMs and cannot be worked around without uninstalling the suite. Thank you for your patience as we work to resolve these upgrade issues. Until the issues are addressed, we suggest a fresh installation (either [manual](#) or [RPM](#)) on a separate machine (MOAB-7192).
- Verification and validation of the Moab 8.0.0 integration with Oracle 12c is not yet complete (AC-7407).
- When you submit jobs to Moab with a proxy user but no group specified via MWS, Moab uses the root group rather than the group of the proxy user (WS-2111).
- When you submit jobs with MWS, you must set the commandFile field to the absolute path of the job script on the MWS server. MWS must have read access to the file given in commandFile. Submitting remote job scripts (that is, including the script as part of the JSON payload) is not currently supported (WS-2112).
- Jobs may linger in an exiting state on MOMs with 12 or more cores when multiple jobs start exiting at the same time. Eventually, the jobs clear but it may take several seconds or even minutes to clear them all (TRQ-2408).

## Resolved issues

The following is a list of some key bugs fixed in Basic. Following each issue description is an associated issue number in parentheses.

- **The scan\_for\_terminated action in TORQUE affected the speed of main\_loop.** The scan\_for\_terminated action in TORQUE has been placed on its own thread so that the MOM will be able to service incoming requests in a timely manner (TRQ-2408).
- **When the queue contained more than 50,000 jobs, TORQUE slowed down substantially.** TORQUE no longer slows down with a large number of jobs in the queue (TRQ-2345).
- **When pbs\_server had a high load, it would get stuck polling.** pbs\_server no longer gets stuck polling under these conditions (TRQ-2620).
- **When a job with a dependent job was deleted with qdel, TORQUE did not clean up the dependent job.** TORQUE now removes the dependent job when you delete its parent (TRQ-2621).
- **When a lot of jobs were run at once, one job would get stuck in an exiting state.** This error no longer occurs (TRQ-2622).
- **The afterok dependency did not work as expected.** afterok now works correctly (TRQ-2626).

- **When running a large amount of jobs, the server would crash during job recycle.** The crash no longer occurs (TRQ-2628).
- **pbsdsh required FQDNs even when they were working in pbs\_server.** The short names in pbs\_server are now enough to run pbsdsh (TRQ-2632).
- **A deadlock would occur on job\_save failure.** This error no longer occurs (TRQ-2645).
- **Asynchronous job starts queued in TORQUE but not yet serviced caused Moab to reschedule jobs that would eventually run.** A new job sub-state in TORQUE prevents this from occurring (TRQ-2715).

## Key documentation changes

This section lists some key documentation changes made for Moab HPC Suite – Basic Edition 8.0.0. Following each change description is a link to the affected page and an associated issue number if applicable.

Features new to this release have been documented but are not listed on this page. For information about those new features and links to their respective documentation, see [New features on page 1](#).

- [Moab Suite on page 9](#)
- [TORQUE Resource Manager on page 9](#)

### Moab Suite

#### [Additions](#)

#### [Removals](#)

- The "Scheduling Jobs When VMs Exist" topic has been removed from Prioritizing Jobs and Allocating Resources. Obsolete feature (DOC-1905)
- The VMUSAGE as been removed from the "Cloud-specific job template attributes" topic. Obsolete feature (DOC-1905).

#### [Improvements](#)

# Installation and Configuration

## Requirements

There are many different ways to install and configure Moab HPC Suite. Each environment has its own set of requirements and preferences. The following installation instructions are intended to help an administrator understand how each of the Moab HPC Suite components interact and how to install and configure each one. Two approaches have been documented: the “Manual installation” and the “RPM installation”. Only one approach is required for installation; do not try to follow both sets of instructions on a single system.

The diagram below provides a general topology of the Moab HPC Suite.

Please note the following:

- Moab Accounting Manager is available only with the Moab HPC Enterprise Suite.
- Smaller environments may elect to consolidate the TORQUE Head Node with the Moab Head Node, including PBS Server in the list of components installed on the Moab Head Node.
- The Requirements section gives further clarification regarding what each component requires.
- Although Moab Workload Manager and Moab Accounting Manager may share the same database instance, it is not a requirement. Two database instances may be used, one for each component. See the Requirements section for more information about what databases are supported.
- Larger systems will require more dedicated resources for each component, in which case it may be necessary to move individual components from the Moab Head Node (i.e. databases, Moab Accounting Manager, and/or Viewpoint) to their own respective servers.
- The Message Queue component is fulfilled by [ZeroMQ™](#). The libraries are provided with the components that use the message queue and are enabled via configuration; no special installation is necessary.

## Where to Start

1. Begin by reading the Requirements section below. Whether installing manually or with RPMs, it is important to be familiar with the hardware and software requirements.
2. Decide whether you will perform a manual installation or an RPM installation.

The manual installation provides advantages to administrators who want to pick and choose what components to install and administrators who want non-standard configure options. The RPM installation provides advantages to administrators who want a fairly standard installation.

 Code samples have been provided for convenience. Some code samples provide sample passwords (i.e. “changeme!”). We strongly recommend that you do not use these passwords during installation, as using the documented passwords could introduce unnecessary security vulnerabilities into your system.

Then follow the appropriate installation instructions.

3. The “Additional Configuration” section in both the manual and the RPM installation instructions provide additional information and instructions for optional, but recommended configurations (i.e. Configuring SSL in Tomcat, etc.).
4. Refer to [Troubleshooting on page 78](#) for assistance in addressing common problems during installation and configuration.
5. Refer to [Component documentation on page 86](#) for links to additional administrator and reference guides.

## Requirements

### Moab HPC Suite

#### Hardware Requirements

The following are the minimum hardware requirements for an average environment. Larger environments should consider allocating more resources and/or spreading components across multiple servers. Please consult the table below for recommendations:

Type	# of Compute Nodes	Jobs/week	Minimum Requirements (combine TORQUE & Moab head nodes on one server)	Recommended Requirements (targeting minimum number of servers)
Proof of Concept / Small Demo	50	<1k	<b>Moab+TORQUE Head Node:</b> <ul style="list-style-type: none"> <li>• 4 Intel/AMD x86-64 cores</li> <li>• At least 8 GB RAM</li> <li>• At least 100 GB dedicated disk space</li> </ul>	Same as minimum
Medium	500	<100k	<b>Moab+TORQUE Head Node:</b> <ul style="list-style-type: none"> <li>• 8 Intel/AMD x86-64 cores</li> <li>• At least 16 GB RAM</li> <li>• At least 512 GB dedicated disk space</li> </ul>	<b>Moab+TORQUE Head Node:</b> <ul style="list-style-type: none"> <li>• 16 Intel/AMD x86-64 cores</li> <li>• At least 32 GB RAM</li> <li>• At least 1 TB dedicated disk space</li> </ul>

Type	# of Compute Nodes	Jobs/week	Minimum Requirements (combine TORQUE & Moab head nodes on one server)	Recommended Requirements (targeting minimum number of servers)
Medium with High Throughput or Larger	>500	>100k	<p><b>Moab Head Node:</b></p> <ul style="list-style-type: none"> <li>• 8 Intel/AMD x86-64 cores</li> <li>• At least 16 GB RAM</li> <li>• At least 512 GB dedicated disk space</li> </ul> <p><b>TORQUE Head Node:</b></p> <ul style="list-style-type: none"> <li>• 8 Intel/AMD x86-64 cores</li> <li>• At least 16 GB RAM</li> <li>• At least 512 GB dedicated disk space</li> </ul>	We recommend separating components onto separate servers where possible (some components should not be separated; see Requirements below). Specific requirements around the intended configuration and use of Moab HPC Suite will help determine suite topology and resource allocation.

Please note the following:

- All requirements above (minimum and recommended) target a minimum number of management servers. Administrators are encouraged to separate the TORQUE and Moab head nodes where possible for better results, especially when High Throughput is enabled.
- Although many factors may have an impact on performance (network bandwidth, intended use and configuration, etc.), we consider High Throughput as something that makes a significant enough difference between minimum and recommended hardware requirements to merit mention in the table above.
- Moab and TORQUE are both multi-threaded and perform better with more processors.
- Regarding disk space, consideration should be given to requirements related to log files, log depth, number of jobs/nodes/reservations (more objects impact database journal size), average number of events generated (more events take more space), etc.

### *Software Requirements*

The installation documentation provides more details regarding how to install and configure the following software requirements. The information provided below is for your information only. No action is necessary.

Software requirements are listed per-component rather than suite-wide to make it easier for administrators who wish to install components on separate servers.

## **TORQUE**

### *Supported Operating Systems*

- CentOS 6.5 or later
- Red Hat 6.5 or later
- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

**i** CentOS 5.9, Red Hat 5.9 and Scientific Linux 5.9 are supported, largely to continue support for clusters where the compute nodes operating systems cannot be upgraded. We recommend that the TORQUE head node run on the supported operating systems listed above.

### *Software Requirements*

- libxml2-devel package (package name may vary)
- openssl-devel package (package name may vary)
- Tcl/Tk version 8 or later if you plan to build the GUI portion of TORQUE or use a Tcl based scheduler
- If you use [cpuset](#), libhwloc 1.1 or later is required (for TORQUE 4.0.0 and later)

If you build TORQUE from source (i.e. clone from github), the following additional software is required:

- gcc
- gcc-c++
- A posix compatible version of make
- libtool 1.5.22
- boost-devel 1.36.0

## **Moab Workload Manager**

### *Supported Operating Systems*

- CentOS 6.5 or later
- Red Hat 6.5 or later

- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

#### *Software Requirements*

- [libcurl](#)
- Perl 5.8.8 or later
- perl-cpan (package name may vary)
- libxml2-devel (package name may vary)
- *(Optional)* MySQL, PostgreSQL, or Oracle with ODBC driver (see [Database Configuration on page 793](#) for details)

#### *Supported Resource Managers*

- TORQUE 5.0.0
- SLURM

### **Moab Accounting Manager**

MAM is commonly installed on the same host as Moab Workload Manager; however, in some cases you might obtain better performance by installing them on separate hosts.

#### *Supported Operating Systems*

- CentOS 6.5 or later
- Red Hat 6.5 or later
- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

#### *Software Requirements*

- gcc
- perl-suidperl
- httpd
- mod\_ssl
- rrdtool
- Perl modules (see Installing for more details)

#### *Depends On (not necessarily on the same server)*

MAM uses an RDBMS as a back end.

- Moab® Workload Manager 8.0.0
- PostgreSQL 7.2 or later

## Moab Web Services

MWS should be installed on the same host as Moab® Workload Manager.

### Supported Operating Systems

- CentOS 6.5 or later
- Red Hat 6.5 or later
- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

### Software Requirements

- Moab® Workload Manager 8.0.0
- Apache Tomcat™ 6
- Oracle® Java® 7 Runtime Environment

**i** Oracle Java 7 Runtime Environment is the recommended Java environment, but Oracle Java 6 is also supported. All other versions of Java, including OpenJDK/IcedTea, GNU Compiler for Java, and so on cannot run Moab Web Services.

- MongoDB® 2.4.x

*Depends On (not necessarily on the same server)*

- OpenLDAP or PAM (see [Configuring Moab Web Services on page 1395](#))

# Manual installation

## Installation

### Preparing for installation

The installation process of the Moab HPC Suite includes installing the separate components in the suite. This guide contains detailed instructions for installing each component.

**i** Many individual components have dependencies on other components (see [Requirements on page 11](#)). However, if you do not require a certain component (Moab Web Services, for example), you do not have to install it.

The install instructions for each component include information about system requirements and dependencies. Some include prerequisite instructions that you will need to complete before you begin the install. Please read this information carefully, and make sure you have installed all the dependencies and packages that are necessary in order to avoid errors during the Moab HPC Suite install process.

**i** Because many system-level files and directories are accessed during the installation, the instructions in this guide should be executed with root privileges.

You will see that the instructions execute commands as the root user. Please note that the same commands will work for a non-root user with the `sudo` command.

To install the Moab HPC Suite, install the packages in the following order:

1. Install the TORQUE and Moab Workload Manager dependencies (see the [dependency installation instructions](#) below).
2. Install TORQUE (see [Installing TORQUE on page 2544](#)).
3. Install Moab Workload Manager (see [Installing Moab Workload Manager on page 27](#)).
4. Install Moab Web Services (see [Installing Moab Web Services on page 31](#)).

**i** Once you have finished installing the Moab HPC Suite and Moab is running, you can perform an RPM-based installation of the optional Insight and Viewpoint components.

## Install TORQUE and Moab Workload Manager dependencies

You must install the following dependencies in order to use TORQUE and Moab Workload Manager:

- libxml2-devel package (package name may vary)
- openssl-devel package (package name may vary)
- boost-devel package (package name may vary)
- ANSI C compiler. The native C compiler is recommended if it is ANSI; otherwise use `gcc`.

Use the following commands to install the required dependencies and packages.

- **RHEL, CentOS, and Scientific Linux:**

```
[root]# yum install make perl-CPAN libxml2-devel openssl-devel boost-devel gcc gcc-c++
```

- **SLES:**

Before installing the dependencies, do the following:

1. Verify that you have a licensed installation of SLES 11 SP3.
2. Download the [SuSE Linux Enterprise 11 Software Development Kit e-Media Kit](#) and add the ISO to the repository.

```
[root]# zypper install make libxml2-devel libopenssl-devel boost-devel gcc gcc-c++ git-core automake
```

## Install Java

You must install the 64-bit RPM version of Oracle® Java® 7 Runtime Environment if you are installing Moab Web Services.

**i** Oracle Java 7 Runtime Environment is the recommended Java environment, but Oracle Java 6 is also supported. All other versions of Java, including OpenJDK/IcedTea, GNU Compiler for Java, and so on cannot run Moab Web Services.

Do the following:

- Download the *Linux x64 RPM* version of Oracle Java SE 7 JRE. (Go to the [Oracle Java 7 download page](#), copy the URL to the *Linux x64 RPM* version, then run the following command.)

```
[root]# wget <URL> -O jre-7-linux-x64.rpm
```

To verify that the download was successful, run the following on the RPM before installation:

```
[root]# rpm -qip jre-7-linux-x64.rpm
```

- Run the following to install Java 7:

```
[root]# rpm -Uh jre-7-linux-x64.rpm
```

## Install Tomcat

You must install Tomcat if you are installing Moab Web Services.

- **RHEL, CentOS, and Scientific Linux:**

```
[root]# yum install tomcat6
```

- **SLES:**

```
[root]# zypper ar --refresh -r
http://download.opensuse.org/evergreen/11.4/openSUSE:Evergreen:11.4.repo
[root]# zypper in tomcat6
[root]# zypper mr -d openSUSE_Evergreen_11.4
```

## Opening ports

A few ports need to be available through your firewall so components of the suite can communicate with each other. Some features of some components might need additional ports configured. The individual component documentation indicates when additional ports are needed.

The ports required for basic suite functionality are:

- 7112: Default, configurable port needed for Moab Accounting Manager client-server communication
- 443: Needed for Moab Accounting Manager web GUI (https)
- 8080: Needed for Moab Web Services web portal (http)

## To open ports in your firewall

- **Use iptables for Red Hat-based distributions:**

```
[root]# iptables-save > /tmp/iptables.mod
[root]# vi /tmp/iptables.mod

# Add the following lines immediately *before* the line matching
# "-A INPUT -j REJECT --reject-with icmp-host-prohibited"
-A INPUT -p tcp --dport 7112 -j ACCEPT
-A INPUT -p tcp --dport 443 -j ACCEPT
-A INPUT -p tcp --dport 8080 -j ACCEPT

[root]# iptables-restore < /tmp/iptables.mod
[root]# service iptables save
```

- **Use SuSEfirewall2 for SuSE-based distributions:**

```
[root]# vi /etc/sysconfig/SuSEfirewall2

FW_SERVICES_EXT_TCP="443 7112 8080"

[root]# service SuSEfirewall2_setup restart
```

## Install MongoDB

You must install MongoDB if you are installing Moab Web Services.

### To install and enable MongoDB

1. Install MongoDB.

- **RHEL and CentOS, and Scientific Linux:**

Create a file called `/etc/yum.repos.d/10gen.repo` and add the following lines.

```
[10gen]
name=MongoDB Repository
baseurl=http://downloads-distro.mongodb.org/repo/redhat/os/x86_64
gpgcheck=0
enabled=1
```

Install `mongo-10gen-server`.

```
[root]# yum install mongo-10gen-server --exclude mongodb-org,mongodb-org-server
```

- **SLES:**

```
[root]# zypper ar
http://download.opensuse.org/repositories/server:/database/SLE_11_SP3
OpenSuseDatabase
[root]# zypper install mongodb
```

## 2. Start MongoDB.

- **RHEL and CentOS, and Scientific Linux:**

```
[root]# chkconfig mongod on
[root]# service mongod start
```

- **SLES:**

```
[root]# chkconfig mongod on
[root]# service mongod start
```

**i** There may be a short delay (approximately 3 minutes) for Mongo to start the first time.

**i** If you see errors while running the `chkconfig` command, make sure that `/sbin` is in your `PATH` environment variable, then run `chkconfig` again.

```
export PATH=/sbin:$PATH
```

## 3. Prepare the MongoDB database by doing the following:

## a. Add the required MongoDB users.

**i** The passwords used below (`secret1`, `secret2`, and `secret3`) are examples. Choose your own passwords for these users.

```
[root]# mongo
> use admin;
> db.addUser("admin_user", "secret1");
> db.auth ("admin_user", "secret1");

> use moab;
> db.addUser("moab_user", "secret2");
> db.addUser("mws_user", "secret3", true);

> use mws;
> db.addUser("mws_user", "secret3");
> exit
```

**i** Because the `admin_user` has read and write rights to the `admin` database, it also has read and write rights to all other databases. See [Control Access to MongoDB Instances with Authentication](#) for more information.

## b. Enable authentication in MongoDB.

- **RHEL and CentOS, and Scientific Linux:**

```
[root]# vi /etc/mongod.conf

auth = true

[root]# service mongod restart
```

- **SLES:**

```
[root]# vi /etc/mongodb.conf
auth = true

[root]# service mongodb restart
```

 On SLES machines, auth = true is enabled by default.

## Install PostgreSQL

### To install PostgreSQL

1. Install and initialize PostgreSQL.

#### CentOS, RHEL, and Scientific Linux

```
[root]# yum install postgresql-server
[root]# service postgresql initdb
```

#### SLES

```
[root]# zypper install postgresql-server
[root]# service postgresql start
```

2. Configure trusted connections.

 Edit or add a "host" line in the pg\_hba.conf file for the interface from which the server(s) (for example, Moab Workload Manager and/or Moab Accounting Manager) will be connecting to the database and ensure that it specifies a secure password-based authentication method (for example, md5).

```
[root]# vi /var/lib/pgsql/data/pg_hba.conf

# IPv4 local connections:
host    all             all             127.0.0.1/32      md5
# IPv6 local connections:
host    all             all             :::1/128         md5
```

3. Configure PostgreSQL to accept connections from your host.

```
[root]# vi /var/lib/pgsql/data/postgresql.conf

# Uncomment the listen addresses line in the configuration:

listen_addresses = 'localhost'          # what IP address(es) to listen on;
```

4. Start or restart the database.

```
[root]# chkconfig postgresql on
[root]# service postgresql restart
```

## Related topics

- [Welcome on page xxiii](#)

# Installing TORQUE

These instructions describe how to install and start TORQUE.

## Requirements

### *Supported Operating Systems*

- CentOS 6.5 or later
- Red Hat 6.5 or later
- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

CentOS 5.9, Red Hat 5.9 and Scientific Linux 5.9 are supported, largely to continue support for clusters where the compute nodes operating systems cannot be upgraded. We recommend that the TORQUE head node run on the supported operating systems listed above.

### *Software Requirements*

- libxml2-devel package (package name may vary)
- openssl-devel package (package name may vary)
- Tcl/Tk version 8 or later if you plan to build the GUI portion of TORQUE or use a Tcl based scheduler
- If you use [cpuset](#), libhwloc 1.1 or later is required (for TORQUE 4.0.0 and later)

If you build TORQUE from source (i.e. clone from github), the following additional software is required:

- gcc
- gcc-c++
- A posix compatible version of make
- libtool 1.5.22
- boost-devel 1.36.0

## Prerequisites

- TORQUE requires certain ports to be open for essential communication:
  - For client communication to `pbs_server`, all privileged ports must be open (ports under 1024).
  - For `pbs_server` communication to `pbs_mom`, the default port is 15003.
  - For `pbs_mom` to `pbs_server`, the default port is 15001.

For more information on how to configure the ports that TORQUE uses for communication, see [Configuring ports on page 2555](#).

**i Important:** If you intend to use TORQUE 5.0.0 with Moab, you must run Moab version 8.0.0 or later. TORQUE 5.0.0 will not work with versions earlier than Moab 8.0.0.

- Make sure your host (with the correct IP address) is in your `/etc/hosts` file.
- The `libxml2-devel`, `openssl-devel`, and `boost-devel` packages must be installed (These packages should already be installed from following the steps in the [Preparing for installation on page 17](#)).

### RHEL 6.5 and CentOS 6.5, and Scientific Linux 6.5:

```
[root]# yum install openssl-devel libtool-devel libxml2-devel boost-devel gcc gcc-c++
```

### SLES

```
[root]# zypper install openssl-devel libtool-devel libxml2-devel boost-devel gcc gcc-c++
```

### RHEL 5 and CentOS 5, and Scientific Linux 5:

```
[root]# yum install openssl-devel libtool-devel libxml2-devel gcc gcc-c++
```

**i Important:** TORQUE requires Boost version 1.36.0 or greater. The `boost-devel` package provided with RHEL 5, CentOS 5, and Scientific Linux 5 is older than this requirement. A new option, `--with-boost-path` has been added to configure (see [Customizing the install on page 2558](#) in the *TORQUE Administrator Guide* for more information). This allows you to point TORQUE to a specific version of boost during make. One way to compile TORQUE without installing Boost is to simply download the Boost version you plan to use from: <http://www.boost.org/users/history/>. Next, untar Boost—you do not need to build it or install it. When you run TORQUE configure, use the `--with-boost-path` option pointed to the extracted Boost directory.

## To install TORQUE

1. Switch the user to root.

```
[user]$ su -
```

2. Download the latest 5.0.0 build from the [Adaptive Computing](#) website. It can also be downloaded via command line.
  - a. Clone the source from github. If you clone the source from github, the `libtool` package must be installed.

**i** If you are using CentOS 5, use these instructions for installing `libtool`:

```
[root]# cd /tmp
[root]# wget http://ftpmirror.gnu.org/libtool/libtool-2.4.2.tar.gz
[root]# tar -xzvf libtool-2.4.2.tar.gz
[root]# cd libtool-2.4.2
[root]# ./configure --prefix=/usr
[root]# make
[root]# make install
[root]# cd /tmp
[root]# git clone https://github.com/adaptivecomputing/torque.git -b
5.0.0 5.0.0
[root]# cd 5.0.0
[root]# ./autogen.sh
```

```
# RHEL 6 and Scientific Linux 6:
[root]# yum install git libtool
```

```
# SLES:
[root]# zypper install libtool
```

```
[root]# git clone https://github.com/adaptivecomputing/torque.git -b 5.0.0 5.0.0
[root]# cd 5.0.0
[root]# ./autogen.sh
```

- b. Get the tarball source distribution.

```
[root]# wget http://www.adaptivecomputing.com/download/torque/torque-
5.0.0.tar.gz -O torque-5.0.0.tar.gz

[root]# tar -xzvf torque-5.0.0.tar.gz
[root]# cd torque-5.0.0/
```

3. Run each of the following commands in order.

```
[root]# ./configure
[root]# make
[root]# make install
```

For information on what options are available to customize the `./configure` command, see [Customizing the install on page 2558](#).

4. Configure the `trqauthd` daemon to start automatically at system boot.

```

* If RHEL distribution, do the following *
[root]# cp contrib/init.d/trqauthd /etc/init.d/
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start

* If SLES distribution, do the following *
[root]# cp contrib/init.d/suse.trqauthd /etc/init.d/trqauthd
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start

```

5. The `make packages` command can be used to create self-extracting packages that can be copied and executed on your nodes. For information on creating packages and deploying them, see [Compute nodes on page 2549](#).

You will also want to scp the `init.d` scripts to the compute nodes and install them there.

6. Verify that the `/var/spool/torque/server_name` file exists and contains the correct name of the server.

```
[root]# echo <pbs_server's_hostname> > /var/spool/torque/server_name
```

7. By default, TORQUE installs all binary files to `/usr/local/bin` and `/usr/local/sbin`. Make sure the path environment variable includes these directories for both the installation user and the root user.

```
[root]# export PATH=/usr/local/bin:/usr/local/sbin:$PATH
```

8. Initialize `serverdb` by executing the `torque.setup` script.

```
[root]# ./torque.setup root
```

9. Add nodes to the `/var/spool/torque/server_priv/nodes` file. For information on syntax and options for specifying compute nodes, see [Specifying compute nodes on page 2553](#).
10. Configure the MOMs if necessary (see [Configuring TORQUE on compute nodes on page 2554](#) in the TORQUE Administrator Guide).
11. Configure `pbs_server` and `pbs_mom` to start automatically at system boot, and then start their daemons.

```

* If RHEL distribution, do the following *
[root]# cp contrib/init.d/pbs_server contrib/init.d/pbs_mom /etc/init.d
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom
[root]# service pbs_server restart
[root]# service pbs_mom start

* If SLES distribution, do the following *
[root]# cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
[root]# cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom
[root]# service pbs_server restart
[root]# service pbs_mom start

```

### Related topics

- [Installing Moab Workload Manager on page 27](#)
- [Component documentation on page 86](#)

## Installing Moab Workload Manager

These instructions describe how to install and start Moab Workload Manager (Moab).

### Dependencies and packages installation

Use the following commands to install the required Moab Workload Manager dependencies and packages (listed in the [Installing Moab Workload Manager](#) section above).

#### RHEL, CentOS, and Scientific Linux:

```

[root]# yum update
[root]# yum install make libcurl perl-CPAN libxml2-devel

```

#### SLES:

```

[root]# zypper update
[root]# zypper install make curl libxml2-devel

```

### Optional: To build a custom RPM

1. Install rpm-build.

```

[root]# yum install rpm-build

```

2. Download the latest Moab build (moab-*<version>*-*<OS>*.tar.gz) from the [Adaptive Computing website](#).

**i** The variable marked *<version>* is the desired version of the suite; for example, 8.0-2014061017-8f96ac8d would be Moab 8.0 revision 2014061017 at changeset 8f96ac8d. The variable marked *<OS>* indicates which OS the build was designed for.

3. Untar the downloaded package.

4. Change directories into the untarred directory.
5. Edit the `./moab.spec` file for RPM customization.
6. Run `./rpm-build`.
7. Locate the custom RPM in `rpm/RPMS/x86_64`.

## To install Moab Workload Manager

1. Download the latest Moab build (`moab-<version>-<OS>.tar.gz`) from the [Adaptive Computing website](#).

**i** The variable marked `<version>` is the desired version of the suite; for example, `8.0-2014061017-8f96ac8d` would be Moab 8.0 revision 2014061017 at changeset 8f96ac8d. The variable marked `<OS>` indicates which OS the build was designed for.

2. As the root user, run each of the following commands in order.

```
[root]# tar xzvf moab-<version>-<OS>.tar.gz
[root]# cd moab-<version>-<OS>
```

3. Configure Moab. For a complete list of `./configure` options, use `./configure --help` or refer to [Moab Workload Manager configuration options on page 42](#) for a list of commonly used options.

It is strongly recommended that you configure Moab with the `--with-init` and `--with-profile` options. The `--with-profile` option makes it easier to execute Moab commands (see step 8). The `--with-init` option allows Moab to automatically start at OS startup (see step 11).

```
[root]# ./configure <options>
```

4. (Only if you are using green computing, or if you are using a resource manager other than TORQUE) Run the `make perldeps` command to install the necessary perl modules using CPAN. When first running CPAN, you will be asked for configuration information. It is recommended that you choose an automatic configuration. You will be prompted to provide input during module installation; running the `make perldeps` command with a script is not recommended.

```
[root]# make perldeps
```

5. Install Moab.

```
[root]# make install
```

6. (ONLY if installing on non-RHEL distributions)

Copy the appropriate `init.d` file, set the permissions on it, and configure Moab to start automatically at system boot.

```
* If SLES distribution, do the following *
[root]# cp OS/SLES/etc/init.d/moab /etc/init.d/moab

[root]# chmod 755 /etc/init.d/moab
[root]# chkconfig --add moab
```

7. Modify the Moab configuration file.

```
[root]# vi /opt/moab/etc/moab.cfg
```

Do the following:

- a. Verify that **SUBMITCMD** is set up for your TORQUE resource manager and that it points to a valid qsub executable. For example:

```
RMCFG[torque] SUBMITCMD=/usr/local/bin/qsub
```

If you use a SLURM resource manager, see [Moab-SLURM Integration Guide](#) for configuration information. If you use a NATIVE resource manager, see [Managing Resources Directly with the Native Interface](#) for configuration information.

- b. *ONLY* if you are using Moab Web Services, add *tomcat* to the list of administrator **USERS**. For example:

```
ADMINCFG[1] USERS=root,tomcat
```

8. If you configured with the `./configure --with-profile` option, source the following file to add the Moab executable directories to your current shell `$PATH` environment.

```
[root]# . /etc/profile.d/moab.sh
```

9. Copy your license file into the same directory as `moab.cfg` (`/opt/moab/etc/` by default). For example:

```
[root]# cp moab.lic $MOABHOMEDIR/etc/moab.lic
```

To verify the current status of your license, use `moab --about`.

Moab checks the status of the license every day just after midnight. At 60 and 45 days before, and daily from 30 days before license expiration to and including the license expiration date, Moab sends an e-mail to all level 1 administrators informing them of the pending Moab license expiration. A log record is also made of the upcoming expiration event. For the notifications to occur correctly, you must enable administrator email notification (see "[Notifying Administrators of Failures on page 684](#)" in the Moab Workload Manager Administrator Guide) and `moab.cfg` must contain email addresses for level 1 administrators. For example:

```
ADMINCFG[1] USERS=u1,u2,u3[,...]

USERCFG[u1] EMAILADDRESS=u1@company.com
USERCFG[u2] EMAILADDRESS=u2@company.com
USERCFG[u3] EMAILADDRESS=u3@company.com

MAILPROGRAM DEFAULT
```

**i** Moab will not run without a license. For information about obtaining a trial license, please contact [Adaptive Computing](#).

10. Start Moab.

```
[root]# chkconfig moab on
[root]# service moab start
```

11. Submit a sleep job as a non-root user and verify the job is running.

```
[root]# su - user
[user]$ echo sleep 150 | msub
[user]$ showq
[user]$ exit
```

12. Connecting Moab to MongoDB

If you will be installing Moab Web Services, connect Moab to MongoDB using the following instructions:

 The `USEDATABASE` parameter is unrelated to the MongoDB configuration.

- a. Set the **MONGOSERVER** parameter in `/opt/moab/etc/moab.cfg` to the MongoDB server hostname. Use localhost as the hostname if Moab and MongoDB are hosted on the same server.

```
MONGOSERVER <host>[:<port>]
```

If your **MONGOSERVER** host is set to anything other than localhost, edit the `/etc/mongod.conf` file on the MongoDB server host and either comment out any `bind_ip` parameter or set it to the correct IP address:

```
# Listen to local interface only. Comment out to listen on all interfaces.
#bind_ip=127.0.0.1
```

- b. In the `/opt/moab/etc/moab-private.cfg` file, set the **MONGOUSER** and **MONGOPASSWORD** parameters to the MongoDB `moab_user` credentials you set (for details, see [Install MongoDB on page 20](#)).

```
MONGOUSER      moab_user
MONGOPASSWORD  secret2
```

- c. Verify that Moab is able to connect to MongoDB.

```
[root]# service moab restart
[root]# mdiag -S
...
Mongo connection (localhost) is up (credentials are set)
...
```

13. Securing communication using secret keys

- a. (required) Moab and MWS use Message Authentication Codes (MAC) to ensure messages have not been altered or corrupted in transit. Generate a key and store the result in `/opt/moab/etc/.moab.key`:

```
[root]# service moab stop
[root]# dd if=/dev/urandom count=18 bs=1 2>/dev/null | base64 >
/opt/moab/etc/.moab.key
[root]# chown root:root /opt/moab/etc/.moab.key
[root]# chmod 400 /opt/moab/etc/.moab.key
[root]# service moab start
```

The key you specify in the `.moab.key` file is the same key you must also specify in the `moab.secretKey` property when installing and configuring MWS (see [Installing Moab Web Services on page 31](#)).

- b. (optional) Moab supports message queue security using AES. This feature requires a Base64-encoded 16-byte (128-bit) shared secret. Generate a key and append the result to `/opt/moab/etc/moab-private.cfg`:

```
[root]# service moab stop
[root]# echo "MESSAGEQUEUESECRETKEY $(dd if=/dev/urandom count=16 bs=1
2>/dev/null | base64)" >> /opt/moab/etc/moab-private.cfg
[root]# service moab start
```

The key you specify in the `moab-private.cfg` file is the same key you must also specify in the `moab.messageQueue.secretKey` property when installing and configuring MWS (see [Installing Moab Web Services](#)).

**i** If MWS is configured to encrypt the message queue and Moab is not (or vice versa), then MWS will ignore the messages from Moab. Furthermore, all attempts to access the MWS service resource will fail.

- c. (optional) Verify that encryption is on for the ZeroMQ connection.

```
[root]# mdiag -S|grep 'ZeroMQ MWS'
ZeroMQ MWS connection is bound on port 5570 (encryption is on)
```

## Installing Moab Web Services

These instructions describe how to install Moab Web Services (MWS).

### To install Moab Web Services

**i** You must deploy Moab Web Services on the same server as Moab Workload Manager.

1. Verify Moab is installed and configured as desired (for details, see [Installing Moab Workload Manager](#)).
2. Start Moab.

```
[root]# service moab start
```

3. Create the MWS home directory and subdirectories (for more information, see the "[Configuration on page 1772](#)" section of the Moab Web Services Reference Guide).

**i** The default location for the MWS home directory is `/opt/mws`. These instructions assume the default location.

Here is a sample script for this setup:

```
[root]# mkdir -p \
/opt/mws/etc/mws.d \
/opt/mws/hooks \
/opt/mws/log \
/opt/mws/plugins \
/opt/mws/spool/hooks \
/opt/mws/utils
[root]# chown -R tomcat:tomcat /opt/mws # Depending on your OS, the Tomcat username
might be tomcat6.
[root]# chmod -R 555 /opt/mws
[root]# chmod u+w \
/opt/mws/log \
/opt/mws/plugins \
/opt/mws/spool \
/opt/mws/spool/hooks \
/opt/mws/utils
```

4. Download the latest MWS build (`mws-<version>.tar.gz`) from the [Adaptive Computing](#) website.
5. Extract the contents of the MWS download tarball into a temporary directory. For example:

```
[root]# mkdir /tmp/mws-install
[root]# cd /tmp/mws-install
[root]# tar xvzf $HOME/Downloads/mws-8.0.0.tar.gz
```

6. Copy the extracted utility files to the utility directory created above and give the tomcat user ownership of the directory.

```
[root]# cd /tmp/mws-install/mws-8.0.0/utils
[root]# cp * /opt/mws/utils
[root]# chown tomcat:tomcat /opt/mws/utils/*
```

7. Set up the MWS configuration files. In the extracted directory are several configuration files.

- a. Copy `mws-config.groovy` to `/opt/mws/etc`.

```
[root]# cd /tmp/mws-install/mws-8.0
[root]# cp mws-config.groovy /opt/mws/etc
```

- b. Copy the appropriate suite-specific file to `/opt/mws/etc/mws.d`. Pick from the files matching filename `mws-config-*.groovy` in `/tmp/mws-install/mws-8.0`.

```
[root]# cp mws-config-<your suite choice>.groovy /opt/mws/etc/mws.d
```

- c. Give the Tomcat user read access to `/opt/mws/etc/mws-config.groovy` and `/opt/mws/etc/mws.d/mws-config-*.groovy`.

```
[root]# chown tomcat:tomcat /opt/mws/etc/mws-config.groovy
[root]# chown tomcat:tomcat /opt/mws/etc/mws.d/mws-config-<your suite
choice>.groovy
[root]# chmod u+r /opt/mws/etc/mws-config.groovy
[root]# chmod u+r /opt/mws/etc/mws.d/mws-config-<your suite choice>.groovy
```

d. In the `/opt/mws/etc/mws-config.groovy` file, change these settings:

- **moab.secretKey:** Must match the Moab secret key you generated earlier (contained in `/opt/moab/etc/.moab.key`).
- **auth.defaultUser.username:** Any value you like, or leave as is.
- **auth.defaultUser.password:** Any value you like, but choose a strong password.
- **moab.messageQueue.secretKey:** Add this property to configure the message queue security key in MWS.

 The key you specify must be encoded in [Base64](#), and must match *exactly* the key specified in the **MESSAGEQUEUESECRETKEY** when installing Moab Workload Manager (see [Installing Moab Workload Manager](#) on page 27).

 Important: If MWS is configured to encrypt the message queue and Moab is not (or vice versa) then the messages from Moab will be ignored. Furthermore, all attempts to access the MWS service resource will fail.

```
[root]# vi /opt/mws/etc/mws-config.groovy

// Replace <ENTER-KEY-HERE> with the contents of /opt/moab/etc/.moab.key.
moab.secretKey = "<ENTER-KEY-HERE>"
moab.server = "localhost"
moab.port = 42559

// Replace <ENTER-KEY-HERE> with the value of MESSAGEQUEUESECRETKEY in
/opt/moab/etc/moab-private.cfg.

moab.messageQueue.secretKey = "<ENTER-KEY-HERE>"

// Change these to be whatever you like.

auth.defaultUser.username = "moab-admin"
auth.defaultUser.password = "changeme!"
```

 If you do not change **auth.defaultUser.password**, your MWS will not be secure (because anyone reading these instructions would be able to log into your MWS). Here are some [tips](#) for choosing a good password.

e. Do *one* of the following:

**i** You can configure only one authentication method in `mws-config.groovy`—LDAP or PAM, but not both. If you have configured both LDAP and PAM, MWS defaults to using LDAP.

If you need multiple authentication methods, you must add them to your local PAM configuration. See your distribution documentation for details.

- If you are configuring an MWS connection to your LDAP server, add the following parameters to `/opt/mws/etc/mws-config.groovy`:

```
ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.directory.type = "OpenLDAP Using InetOrgPerson Schema"
```

*This is just an example LDAP connection. Be sure to use the appropriate domain controllers (dc) and common names (cn) for your environment.*

**i** If you followed the Adaptive Computing tutorial, [Setting up OpenLDAP on CentOS 6 on page 71](#), your `ldap.directory.type` should be set to "OpenLDAP Using InetOrgPerson Schema." However, the use of other schemas is supported. For more information see [LDAP Configuration using mws-config.groovy on page 1402](#).

**i** To see how to configure a secure connection to the LDAP server, see [Securing the LDAP connection on page 1416](#).

- If you are configuring MWS to use PAM, add the the `pam.configuration.service` parameter to the `mws-config.groovy` file. For example:

```
pam.configuration.service = "login"
```

*This is just an example PAM configuration file name. Make sure you specify the name of the configuration file you want MWS to use.*

**i** For more information about PAM configuration with MWS, see [PAM \(pluggable authentication module\) configuration using mws-config.groovy on page 1405](#).

**⚠** There is a security risk when authenticating local users through your PAM configuration. This behavior is highly discouraged and not supported by Adaptive Computing.

- f. Add the `grails.mongo.username` and `grails.mongo.password` parameters to the `mws-config.groovy` file. Use the MWS credentials you added to MongoDB in the [Preparing for installation on page 17](#) section.

```
...  
grails.mongo.username = "mws_user"  
grails.mongo.password = "secret3"
```

- 8. Add the following lines to the end of `/etc/tomcat6/tomcat6.conf`:

```
CATALINA_OPTS="-DMWS_HOME=/opt/mws -Xms256m -Xmx3g -XX:MaxPermSize=384m -  
Dfile.encoding=UTF8"  
JAVA_HOME="/usr/java/latest"
```

**i** Some Linux distributions use `/etc/default/tomcat6` or `/etc/sysconfig/tomcat6` instead of `/etc/tomcat6/tomcat6.conf`.

- 9. Deploy the `mws.war` file and start Tomcat.

```
[root]# chkconfig tomcat6 on  
[root]# service tomcat6 stop  
[root]# cp /tmp/mws-install/mws-8.0.0/mws.war /usr/share/tomcat6/webapps  
[root]# service tomcat6 start
```

- 10. Navigate to `http://localhost:8080/mws/` in a web browser to verify that MWS is running (you will see some sample queries and a few other actions).
- 11. Log in to MWS to verify that your credentials are working. (Your login credentials are the `auth.defaultUser.username` and `auth.defaultUser.password` values you set in the `/opt/mws/etc/mws-config.groovy` file.)

**i** If you encounter problems, or if the application does not seem to be running, see the steps in [Moab Web Services issues](#) on page 82.

## Additional configuration

### Configuring SSL in Tomcat

To configure SSL in Tomcat, please refer to the Apache Tomcat [documentation](#).

## Related topics

## Setting up OpenLDAP on CentOS 6

These instructions are intended to help first-time LDAP administrators get up and running. The following procedures contain instructions for getting started using OpenLDAP on a CentOS 6 system. For more complete information on how to set up OpenLDAP see the [OpenLDAP documentation](#).

- [Installing and configuring OpenLDAP on Centos 6 on page 36](#)
- [Adding an organizational unit \(OU\) on page 40](#)
- [Adding a user on page 40](#)
- [Adding a group on page 41](#)
- [Adding a user to a group on page 41](#)

**i** Adaptive Computing is not responsible for creating, maintaining, or supporting customer LDAP or Active Directory configurations.

## Installing and configuring OpenLDAP on Centos 6

First, you will need to install OpenLDAP. These instructions explain how you can do this on a CentOS 6 system.

### To install and configure OpenLDAP on Centos 6

1. Run the following command:

```
[root]# yum -y install openldap openldap-clients openldap-servers
```

2. Generate a password hash to be used as the admin password. This password hash will be used when you create the root user for your LDAP installation. For example:

```
[root]# slappasswd
New password : p@ssw0rd
Re-enter new password : p@ssw0rd
{SSHA}5lPFVw19zeh7LT53hQH69znpj8TuBrLv
```

3. Add the root user and the root user's password hash to the OpenLDAP configuration in the `olcDatabase={2}bdb.ldif` file. The root user will have permissions to add other users, groups, organizational units, etc. Do the following:

- a. Run this command:

```
[root]# cd /etc/openldap/slapd.d/cn=config
[root]# vi olcDatabase=\{2\}bdb.ldif
```

- b. If the **olcRootPW** attribute does not already exist, create it. Then set the value to be the hash you created from `slappasswd`. For example:

```
olcRootPW: {SSHA}51PFVw19zeh7LT53hQH69znzj8TuBrLv
...
```

4. While editing this file, change the distinguished name (DN) of the **olcSuffix** to something appropriate. The suffix typically corresponds to your DNS domain name, and it will be appended to the DN of every other LDAP entry in your LDAP tree.

For example, let's say your company is called Acme Corporation, and that your domain name is "acme.com." You might make the following changes to the `olcDatabase={2}bdb.ldif` file:

```
olcSuffix: dc=acme,dc=com
...
olcRootDN: cn=Manager,dc=acme,dc=com
...
olcRootPW: {SSHA}51PFVw19zeh7LT53hQH69znzj8TuBrLv
...
```

 Throughout the following examples in this topic, you will see `dc=acme,dc=com`. "acme" is only used as an example to illustrate what you would use as your own domain controller if your domain name was "acme.com." You should replace any references to "acme" with your own organization's domain name.

 Do not set the cn of your root user to "root" (`cn=root,dc=acme,dc=com`), or OpenLDAP will have problems.

5. Modify the DN of the root user in the `olcDatabase={1}monitor.ldif` file to match the **olcRootDN** line in the `olcDatabase={2}bdb.ldif` file. Do the following:

- a. Run this command to edit the `olcDatabase={2}bdb.ldif` file:

```
[root]# vi olcDatabase=\{1\}monitor.ldif
```

- b. Modify the **olcAccess** line so that the **dn.base** matches the **olcRootDN** from the `olcDatabase={2}bdb.ldif` file. (In this example, **dn.base** should be "cn=Manager,dc=acme,dc=com".)

```
olcAccess: {0}to * by
dn.base="gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth" read by
dn.base="cn=Manager,dc=acme,dc=com" read by * none
```

- c. Now the root user for your LDAP is `cn=Manager,dc=acme,dc=com`. The root user's password is the password that you entered using `slappasswd` (see step 2), which, in this example, is **p@ssw0rd**
6. Hide the password hashes from users who should not have permission to view them.

 A full discussion on configuring access control in OpenLDAP is beyond the scope of this tutorial. For help, see [the OpenLDAP Access Control documentation](#).

- a. Run this command to edit the `olcDatabase\=\{2\}bdb.ldif` file:

```
[root]# vi olcDatabase\=\{2\}bdb.ldif
```

- b. Add the following two lines to the end of the file to restrict users from viewing other users' password hashes.

```
olcAccess: {0}to attrs=userPassword by self write by
dn.base="cn=Manager,dc=acme,dc=com" write by anonymous auth by * none
olcAccess: {1}to * by dn.base="cn=Manager,dc=acme,dc=com" write by self write by
* read
```

*These lines allow a user to read and write his or her own password. It also allows a manager to read and write anyone's password. Anyone, including anonymous users, is allowed to view non-password attributes of other users.*

7. Make sure that OpenLDAP is configured to start when the machine starts up, and start the OpenLDAP service.

```
[root]# chkconfig slapd on
[root]# service slapd start
```

8. Now, you must manually create the "dc=acme,dc=com" LDAP entry in your LDAP tree.

An LDAP directory is analogous to a tree. Nodes in this tree are called LDAP "entries" and may represent users, groups, organizational units, domain controllers, or other objects. The attributes in each entry are determined by the LDAP schema. In this tutorial we will build entries based on the `InetOrgPerson` schema (which ships with OpenLDAP by default).

In order to build our LDAP tree we must first create the root entry. Root entries are usually a special type of entry called a domain controller (DC). Because we are assuming that the organization is called Acme Corporation, and that the domain is "acme.com," we will create a domain controller LDAP entry called `dc=acme,dc=com`. Again, you will need to replace "acme" with your organization's domain name. Also note that `dc=acme,dc=com` is what is called an LDAP distinguished name (DN). An LDAP distinguished name uniquely identifies an LDAP entry.

Do the following:

- a. Create a file called `acme.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi acme.ldif
```

- b. Add the following lines in `acme.ldif`:

```
dn: dc=acme,dc=com
objectClass: dcObject
objectClass: organization
dc: acme
o : acme
```

- c. Now add the contents of this file to LDAP. Run this command:

```
[root]# ldapadd -f acme.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

- d. Verify that your entry was added correctly.

```
[root]# ldapsearch -x -LLL -b dc=acme,dc=com
dn: dc=acme,dc=com
objectClass: dcObject
objectClass: organization
dc: acme
o: acme
```

9. Run the following:

```
[root]# sudo iptables -L
[root]# sudo service iptables save
```

10. By default, the CentOS 6 firewall will block external requests to OpenLDAP. In order to allow MWS to access LDAP, you will have to configure your firewall to allow connections on port 389. (Port 389 is the default LDAP port.)

Configuring your firewall is beyond the scope of this tutorial; however, it may be helpful to know that the default firewall on CentOS is a service called `iptables`. (For more information, see the documentation on [iptables](#).) In the most basic case, you may be able to add a rule to your firewall that accepts connections to port 389 by doing the following:

- a. Edit your `iptables` file:

```
[root]# vi /etc/sysconfig/iptables
```

- b. Add the following line *after* all the **ACCEPT** lines but *before* any of the **REJECT** lines in your `iptables` file:

```
# ... lines with ACCEPT should be above
-A INPUT -p tcp --dport 389 -j ACCEPT
# .. lines with REJECT should be below
```

For example, here is a sample `iptables` file with this line added:

```
*filter
:INPUT ACCEPT [0:0]
:FORWARD ACCEPT [0:0]
:OUTPUT ACCEPT [0:0]
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
-A INPUT -p icmp -j ACCEPT
-A INPUT -i lo -j ACCEPT
-A INPUT -m state --state NEW -m tcp -p tcp --dport 22 -j ACCEPT
-A INPUT -p tcp --dport 389 -j ACCEPT
-A INPUT -j REJECT --reject-with icmp-host-prohibited
-A FORWARD -j REJECT --reject-with icmp-host-prohibited

COMMIT
```

- c. Now reload `iptables`.

```
[root]# service iptables reload
```

**i** Although providing instructions is beyond the scope of this tutorial, it is also highly recommended that you set up OpenLDAP to use SSL or TLS security to prevent passwords and other sensitive data from being sent in plain text. For information on how to do this, see the [OpenLDAP TLS documentation](#).

Now that you have installed and set up Open LDAP, you are ready to add organizational units (see [Adding an organizational unit \(OU\) on page 40](#)).

## Adding an organizational unit (OU)

These instructions will describe how to populate the LDAP tree with organizational units (OUs), groups, and users, all of which are different types of LDAP entries. The examples that follow also presume an InetOrgPerson schema, because the InetOrgPerson schema is delivered with OpenLDAP by default.

### To add an organizational unit (OU) entry to the LDAP tree

In this example, we are going to add an OU called "Users."

1. Create a temporary file called `users.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi users.ldif
```

2. Add these lines to `users.ldif`:

```
dn: ou=Users,dc=acme,dc=com
objectClass: organizationalUnit
ou: Users
```

3. Add the contents of `users.ldif` file to LDAP.

```
[root]# ldapadd -f users.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a user

### To add a user to LDAP

In this example, we will add a user named "Bob Jones" to LDAP inside the "Users" OU.

1. Create a temporary file called `bob.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi bob.ldif
```

2. Add these lines to `bob.ldif`:

```
dn: cn=Bob Jones,ou=Users,dc=acme,dc=com
cn: Bob Jones
sn: Jones
objectClass: inetOrgPerson
userPassword: p@ssw0rd
uid: bjones
```

3. Add the contents of bob.ldif file to LDAP.

```
[root]# ldapadd -f bob.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a group

### To add a group to LDAP

In this example, we will add a group called "Engineering" to LDAP inside the "Users" OU.

1. Create a temporary file called engineering.ldif. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the /tmp folder.)

```
[root]# cd /tmp
[root]# vi engineering.ldif
```

2. Add these lines to engineering.ldif:

```
dn: cn=Engineering,ou=Users,dc=acme,dc=com
cn: Engineering
objectClass: groupOfNames
member: cn=Bob Jones,ou=Users,dc=acme,dc=com
```

3. Add the contents of engineering.ldif file to LDAP.

```
[root]# ldapadd -f engineering.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a user to a group

### To add a user to an LDAP group

In this example, we will add an LDAP member named "Al Smith" to the "Engineering" LDAP group. This example assumes that user, Al Smith, has already been added to LDAP.

**i** Before you add a user to an LDAP group, the user must first be added to LDAP. For more information, see [Adding a user on page 40](#).

1. Create a temporary file called addUserToGroup.ldif. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the /tmp folder.)

```
[root]# cd /tmp
[root]# vi addUserToGroup.ldif
```

2. Add these lines to addUserToGroup.ldif:

```
dn: cn=Engineering,ou=Users,dc=acme,dc=com
changetype: modify
add: member
member: cn=Al Smith,ou=Users,dc=acme,dc=com
```

3. Now add the contents of addUserToGroup.ldif file to LDAP.

```
[root]# ldapadd -f addUserToGroup.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Moab Workload Manager configuration options

The following is a list of commonly used configure options. For a complete list, use `./configure --help` when configuring Moab.

Option	Description	Example
<b>--with-flexlm</b>	Causes Moab to install the <code>license.mon.flexLM.pl</code> script in the <code>/opt/moab/tools</code> directory. For more information about this script, see the <a href="#">Interfacing to FLEXlm on page 653</a> section in the Moab Administrator Guide.	<pre>[root]# ./configure --with-flexlm</pre>
<b>--with-homedir</b>	Specifies the location of the Moab configuration directory and the MOABHOMEDIR environment variable. The default location is <code>/opt/moab</code> .  <b>i</b> MOABHOMEDIR is automatically set on some distributions during installation, when the <code>--with-profile</code> option is enabled.	<pre>[root]# ./configure --with-homedir=/var/moab</pre> <i>The Moab HPC Suite home directory will be <code>/var/moab</code> instead of the default <code>/opt/moab</code>.</i>

Option	Description	Example
<p><b>--with-init</b></p>	<p>Enables the installation of a distribution-specific <code>/etc/init.d/moab</code> service startup script.</p> <p>This option is required if you want to install this script onto a new system. If you do not set this option, you must manually set up the Moab daemon service.</p> <p>The startup script is located at <code>OS/EL/etc/init.d/moab</code>.</p> <div data-bbox="506 688 857 968" style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> The TORQUE and Moab HPC Suite initialization scripts are provided in the <code>contrib/init.d</code> directory as a courtesy and may be modified at your discretion to work on your system.</p> </div>	<pre data-bbox="906 317 1432 363" style="border: 1px dashed gray; padding: 5px;">[root]# ./configure --with-init</pre>
<p><b>--prefix</b></p>	<p>Specifies the location of the binaries and libraries of the Moab install.</p> <p>The default location is <code>/opt/moab</code>.</p>	<pre data-bbox="906 1020 1432 1066" style="border: 1px dashed gray; padding: 5px;">[root]# ./configure --prefix=/usr/local</pre>
<p><b>--with-profile</b></p>	<p>Enables the installation of distribution-specific <code>/etc/profile.d/moab.[c]sh</code> setup script for bash and cshell.</p> <p>The <code>MOABHOMEDIR</code>, <code>PERL5LIB</code>, <code>PATH</code> and <code>MANPATH</code> environment variables are setup to specify where the new moab configuration, scripts, binaries and man pages reside. If you do not set this option, these scripts are not installed, and you must manually perform this set up.</p> <p>The environment setup scripts are located at <code>OS/EL/etc/profile.d/moab.[c]sh</code>.</p>	<pre data-bbox="906 1230 1432 1276" style="border: 1px dashed gray; padding: 5px;">[root]# ./configure --with-profile</pre>

Option	Description	Example
<b>--with-am</b>	<p>Specifies that you want to configure Moab with Moab Accounting Manager.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> There is a similar <code>--with-torque</code> option that configures Moab with TORQUE, but you do not need to specify this option if you install the "torque" tarball version.</p> </div>	<pre>[root]# ./configure --with-am</pre>

## Trusting servers in Java

### Prerequisites

Some of these instructions refer to `JAVA_HOME`, which must point to the same directory that Tomcat uses. To set `JAVA_HOME`, do this:

```
[root]# source /etc/tomcat6/tomcat6.conf
```

Your system administrator might have defined Tomcat's `JAVA_HOME` in a different file.

### Retrieve the server's X.509 public certificate

To retrieve the server's certificate, use the following command:

```
[root]# $JAVA_HOME/bin/keytool -printcert -rfc -sslserver <servername>:<port> > /tmp/public.cert.pem
```

Replace `<servername>` with the server's host name and `<port>` with the secure port number. The default port for https is 443. The default port for ldaps is 636. If successful, `/tmp/public.cert.pem` contains the server's public certificate. Otherwise, `/tmp/public.cert.pem` contains an error message. This message is typical: `keytool error: java.lang.Exception: No certificate from the SSL server`. This message suggests that the server name or port is incorrect. Consult your IT department to determine the correct server name and port.

### Add the server's certificate to Java's keystore

Java stores trusted certificates in a database known as the keystore. Because each new version of Java has its own keystore, you need to add the server certificate to the Java keystore (using the steps below) every time you install a new version of Java.

Java's keystore is located at `$JAVA_HOME/lib/security/cacerts`. If Tomcat's `JAVA_HOME` points to a JDK, then the keystore is located at `$JAVA_HOME/jre/lib/security/cacerts`. To add the server certificate to the keystore, run the following command:

```
[root]# $JAVA_HOME/bin/keytool -import -trustcacerts -file /tmp/public.cert.pem -alias
<servername> -keystore $JAVA_HOME/lib/security/cacerts
```

You will be prompted for the keystore password, which is "changeit" by default.

**i** Your system administrator might have changed this password.

After you've entered the keystore password, you'll see the description of the server's certificate. At the end of the description it prompts you to trust the certificate.

```
Trust this certificate? [no]:
```

Type **yes** and press **Enter** to add the certificate to the keystore.

## Upgrading

### Upgrading MongoDB

Adaptive Computing strongly recommends upgrading MongoDB to version 2.4. Support for environments using MongoDB 2.0 is now deprecated and will be removed in future releases. Please refer to [docs.mongodb.org](https://docs.mongodb.org) for instructions on how to upgrade MongoDB. Note that you must pay close attention to the information regarding instances with `auth` enabled (as this is the recommended setup for Moab HPC Suite).

```
[root]# service mongod stop
[root]# yum remove mongo20-10gen-server mongo20-10gen
[root]# yum install mongo-10gen-server --exclude mongodb-org,mongodb-org-server
[root]# service mongod start
```

**i** Note that the settings in the `/etc/mongod.conf` file were saved in `/etc/mongod.conf.rpmsave` while removing MongoDB 2.0. You may need to be restore any custom settings after MongoDB 2.4 is installed in the new `/etc/mongod.conf` file (for example, "auth = true").

After upgrading to MongoDB 2.4, you should verify that the MongoDB credentials were preserved:

```
[root]# mongo -u mws_user mws -p
MongoDB shell version: 2.4.8
connecting to: mws
> show collections
event
mongeez
permission
...
```

### Upgrading TORQUE

TORQUE 5.0.0 is not backward compatible with versions of TORQUE prior to 4.0. When you upgrade to TORQUE 5.0.0, all MOM and server daemons must be upgraded at the same time.

The job format is compatible between 5.0.0 and previous versions of TORQUE. Any queued jobs will upgrade to the new version with the exception of job arrays in TORQUE 2.4 and earlier. It is not recommended to upgrade TORQUE while jobs are in a running state.

## Job arrays

Job arrays from TORQUE version 2.5 and 3.0 are compatible with TORQUE 5.0.0. Job arrays were introduced in TORQUE version 2.4 but modified in 2.5. If upgrading from TORQUE 2.4, you need to make sure all job arrays are complete before upgrading.

## serverdb

The `pbs_server` configuration is saved in the file `$TORQUE_HOME/server_priv/serverdb`. When running TORQUE 4.1.0 or later for the first time, this file converts from a binary file to an XML-like format. This format can be used by TORQUE versions 2.5 and 3.0, but not earlier versions. Back up the `$TORQUE_HOME/server_priv/serverdb` file before moving to TORQUE 4.1.0 or later.

## Jobs

Before upgrading the system, all running jobs must complete. To prevent queued jobs from starting, nodes can be set to offline or all queues can be disabled. Once all running jobs are complete, the upgrade can be made. Remember to allow any job arrays in version 2.4 to complete before upgrading. Queued array jobs will be lost.

## Cray

For upgrading TORQUE to 5.0.0 on a Cray system, refer to the [Installation Notes for Moab and TORQUE for Cray on page 1236](#) in Appendix G of the Moab Workload Manager Administrator Guide.

## To upgrade TORQUE

1. Shut down TORQUE.

```
[root]# qterm
[root]# momctl -s

* If running TORQUE 4.6.0 or later *
[root]# trqauthd -d

*If running a version of TORQUE earlier than 4.6.0 *
[root]# ps -efw | grep trqauthd
root      1487      1  0 Dec18 ?          00:00:00 /usr/sbin/trqauthd
adaptive 4830  4374  0 15:07 pts/0    00:00:00 grep trqauthd

[root]# kill -9 1487
```

2. Back up your `server_priv` directory.

```
[root]# tar -cvf backup.tar.gz $TORQUE_HOME/server_priv
```

3. If not already installed, install the Boost C++ headers.

```
[root]# yum install boost-devel
```

**i** For SLES, use `zypper install <package names>` instead of `yum install <package names>`.

#### 4. Install the latest TORQUE tarball.

```
[root]# cd /tmp
[root]# tar xzvf torque-5.0.0-<build number>.tar.gz
[root]# cd torque-5.0.0-<build number>
[root]# ./configure
[root]# make
[root]# make install
```

#### 5. If not already done, configure `pbs_server` and `pbs_mom` to start automatically at system boot.

```
* If Debian distribution, do the following *
[root]# cp contrib/init.d/debian.pbs_server /etc/init.d/pbs_server
[root]# cp contrib/init.d/debian.pbs_mom /etc/init.d/pbs_mom
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom

* If SLES distribution, do the following *
[root]# cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
[root]# cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom

* If RHEL distribution, do the following *
[root]# cp contrib/init.d/pbs_server contrib/init.d/pbs_mom /etc/init.d
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom
```

#### 6. Start the services.

```
[root]# service trqauthd start
[root]# service pbs_mom start
[root]# service pbs_server start
```

#### 7. Check the status of jobs in the queue and perform other checks for errors.

```
[root]# qstat
[root]# grep -i error /var/spool/torque/server_logs/*
[root]# grep -i error /var/spool/torque/mom_logs/*
```

## Upgrading Moab Workload Manager

The following instructions will guide you through a 6.1.x, 7.0.x, 7.1.x, 7.2.x, or 7.5.0 to 8.0.0 upgrade. Depending on which version of Moab you are presently running, upgrade instructions may vary, so unless otherwise noted, all instructions assume use of a RHEL operating system; notes for SLES users are added in appropriate places.

You might want to [test](#) the newest version of Moab on your system (before making the new version live) to verify your policies, scripts, and queues work the way you want them to.

If you are also upgrading TORQUE from an older version (pre-4.0), you may encounter a problem where Moab HPC Suite core files are regularly created in `/opt/moab`. This can be caused by old TORQUE library files used by Moab that try to authorize with the old TORQUE `pbs_iff` authorization daemon. You can resolve the problem by removing the old version library files from `/usr/local/lib`.

**i** Because many system-level files and directories are accessed during the installation, the instructions in this guide should be executed with root privileges.

You will see that the instructions execute commands as the root user. Please note that the same commands will work for a non-root user with the `sudo` command.

## To upgrade Moab

1. Untar the distribution file. For example:

```
[root]# tar -xzvf moab-<version>-<OS>.tar.gz
```

2. Change directory into the extracted directory.
3. Verify `/etc/yum.repos.d/epel.repo` exists and has the following lines. If not, create it and add these lines.

```
[epel]
name=Extra Packages for Enterprise Linux 6 - x86_64
mirrorlist=http://mirrors.fedoraproject.org/mirrorlist?repo=epel-6&arch=x86_64
failovermethod=priority
enabled=1
gpgcheck=1
gpgkey=http://download.fedoraproject.org/pub/epel/RPM-GPG-KEY-EPEL-6
```

**i** SLES users must add a repository to YaST. The URL of the repository is [http://download.opensuse.org/repositories/server:/database/SLE\\_11\\_SP2/](http://download.opensuse.org/repositories/server:/database/SLE_11_SP2/).

4. Configure the installation package.

Use the same configure options as when Moab was installed previously. If you cannot remember which options were used previously, check the `config.log` file in the directory where the previous version of Moab was installed from.

For a complete list of configure options, use `./configure --help`.

5. Stop Moab.

```
[root]# mschedctl -k
moab will be shutdown immediately
```

**i** While Moab is down, all currently running jobs continue to run on the nodes, the job queue remains intact, and new jobs cannot be submitted to Moab.

6. Before proceeding to the following steps, consider backing up your Moab Workload Manager home directory (`/opt/moab/` by default).

- If you use ODBC, you must upgrade to the 8.0.0 schema. See [Migrating Your Database to Newer Versions of Moab on page 808](#) for more information.
- Run the `make perldeps` command to install the necessary perl modules using CPAN (and install CPAN if you have not already done so). When first running CPAN, you will be asked for configuration information. It is recommended that you choose an automatic configuration. You will be prompted to provide input during module installation; running the `make perldeps` command with a script is not recommended.

```
[root]# yum install cpan
[root]# make perldeps
```

- Install Moab.

```
[root]# make install
```

**i** Default configuration files are installed during `make install`. Existing configuration files are not overwritten and the new files are given a `.dist` extension.

- Verify the version number is correct before starting the new server version.

```
[root]# moab --about

Defaults:  server=:42559  cfgdir=/opt/moab  vardir=/opt/moab
Build dir:  /tmp/develop
Build host: crom
Build date: Mon Jun 16 16:00:00 MST 2014
Build args: NA
Compiler Flags:  -D_M64 -D_BUILDDATETIME="2014061616" -DMUSEWEBSERVICES -
DMUSEZEROMQ -DMUSEMONGODB -DMMAX_GRES=512 -DMMAX_RANGE=2048 -DMMAX_TASK=32768 -fPIC
-gdwarf-3 -Wall -Wextra -DVALGRIND -x c++ -std=c++11 -DDMAX_PJOB=512 -D_GNU_SOURCE
Compiled as little endian.
Version: moab server master (revision 2014061616, changeset
90ce9f804ddd09b061238e438ecb4d117cc83e81)
Copyright (C) 2000-2014 by Adaptive Computing Enterprises, Inc. All Rights
Reserved.
```

- If you are upgrading from Moab Workload Manager 7.5 or earlier and use Moab Accounting Manager with the native interface, (`AMCFG[...] TYPE=native`), locate the entries in `moab.cfg` with the following form:

```
AMCFG[mam] *URL=exec:/// $HOME/tools/mam/*.*.mam.pl
```

Replace the matching entries with the following:

```
AMCFG[mam] CREATEURL=exec://$TOOLSDIR/mam/usage.quote.mam.pl
AMCFG[mam] STARTURL=exec://$TOOLSDIR/mam/usage.reserve.mam.pl
AMCFG[mam] PAUSEURL=exec://$TOOLSDIR/mam/usage.charge.mam.pl
AMCFG[mam] UPDATEURL=exec://$TOOLSDIR/mam/usage.charge.mam.pl
AMCFG[mam] RESUMEURL=exec://$TOOLSDIR/mam/usage.reserve.mam.pl
AMCFG[mam] ENDURL=exec://$TOOLSDIR/mam/usage.charge.mam.pl
AMCFG[mam] DELETEURL=exec://$TOOLSDIR/mam/lien.delete.mam.pl
```

- Start Moab.

```
[root]# moabd
```

- If you will be using Moab Web Services, you must configure a secret key. See [Securing communication using secret keys on page 30](#).

## Upgrading MWS

### Context

Before upgrading MWS, we recommend you upgrade to Java 7 and MongoDB 2.4. To upgrade Java, repeat the [Java installation instructions](#). To upgrade MongoDB, see [Upgrading MongoDB on page 45](#).

It is highly recommended that you perform a full database backup before updating your database. This can be done using the `mongodump` utility documented in the [MongoDB documentation](#).

### To perform an MWS upgrade

- Extract the contents of the MWS download tarball into a temporary directory. For example:

```
[root]# mkdir /tmp/mws-install
[root]# cd /tmp/mws-install
[root]# tar xvzf mws-8.0.0.tar.gz
[root]# cd /tmp/mws-install/mws-8.0.0
```

- Stop Tomcat, re-deploy `mws.war`, and remove the exploded `mws` directory.

```
# CentOS 6 example

[root]# service tomcat6 stop
[root]# cp /tmp/mws-install/mws-8.0.0/mws.war /usr/share/tomcat6/webapps
[root]# rm -rf /usr/share/tomcat6/webapps/mws
```

- Create the MWS home directory and subdirectories (for more information, see the "[Configuration on page 1772](#)" section of the *Moab Web Services Reference Guide*).

The default location for the MWS home directory is `/opt/mws`. These instructions assume the default location.

Here is a sample script for this setup:

```
[root]# mkdir -p \  
  /opt/mws/etc/mws.d \  
  /opt/mws/hooks \  
  /opt/mws/log \  
  /opt/mws/plugins \  
  /opt/mws/spool/hooks \  
  /opt/mws/utils  
[root]# chown -R tomcat:tomcat /opt/mws # Depending on your OS, the Tomcat username  
might be tomcat6.  
[root]# chmod -R 555 /opt/mws  
[root]# chmod u+w \  
  /opt/mws/log \  
  /opt/mws/plugins \  
  /opt/mws/spool \  
  /opt/mws/spool/hooks \  
  /opt/mws/utils
```

4. Copy the extracted utility files to the utility directory created above and give the tomcat user ownership of the directory.

```
[root]# cd /tmp/mws-install/mws-8.0.0/utils  
[root]# cp * /opt/mws/utils  
[root]# chown tomcat:tomcat /opt/mws/utils/*
```

5. Set up the MWS configuration files. In the extracted directory are several configuration files.
  - a. Merge the `/opt/mws/etc/mws-config.groovy.rpmnew` file with the old `/opt/mws/etc/mws-config.groovy` file by editing `/opt/mws/etc/mws-config.groovy`. (Note the addition of the "auditAppender" in the default logging configuration of `/opt/mws/etc/mws-config.groovy.rpmnew`.)

**i** If necessary, open port 5570 in the firewall.

Note that the **mws.suite** parameter and the **mam.\*** parameters have been moved to a suite-specific file in `/opt/mws/etc/mws.d/` and do not need to exist in `/opt/mws/etc/mws-config.groovy`.

Also note the new **\*messageQueue** parameters in `/opt/mws/etc/mws-config.groovy.rpmnew`. These are required and the value for **moab.messageQueue.secretKey** should match the value located in `/opt/moab/etc/moab-private.cfg`. If you have not yet configured a secret key, see [Securing communication using secret keys on page 30](#).

- b. Copy the `mws-config-hpc.groovy` file to `/opt/mws/etc/mws.d`.
  - c. Give the Tomcat user read access to `/opt/mws/etc/mws-config.groovy` and `/opt/mws/etc/mws.d/mws-config-*.groovy`.
6. Upgrade the schema of the `mws` database in MongoDB.

**!** You *must* perform this step, regardless of whether you upgraded MongoDB to version 2.4 or not.

Run the database migration script provided with MWS. (It is safe to run this script more than once. If for any reason, errors occur during the execution of the script, run it again.)

```
[root]# mongo -u mws_user mws /opt/mws/utils/db-migrate.js -p
```

**i** The script might take several minutes to execute.

7. Start Tomcat.

```
[root]# service tomcat6 start
```

8. Visit <http://localhost:8080/mws/> in a web browser to verify that MWS is running again.

You will see some sample queries and a few other actions.

9. Log into MWS to verify configuration. (The credentials are the values of **auth.defaultUser.username** and **auth.defaultUser.password** set in `/opt/mws/etc/mws-config.groovy`.)

**i** If you encounter problems, or if MWS does not seem to be running, see the steps in [Troubleshooting on page 78](#).

# RPM installation

## Installing Moab HPC Suite – Basic Edition

**i** The RPM installation only supports installation on Red Hat 6.5, CentOS 6.5 or Scientific Linux 6.5. Use the [Manual installation](#) instructions if installing on other supported operating systems.

**i** Because many system-level files and directories are accessed during the installation, the instructions in this guide should be executed with root privileges.

You will see that the instructions execute commands as the root user. Please note that the same commands will work for a non-root user with the `sudo` command.

## Dependencies and packages installation

### Install Java

Install the *Linux x64 RPM* version of Oracle® Java® 7 Runtime Environment.

**i** Oracle Java 7 Runtime Environment is the recommended Java environment, but Oracle Java 6 is also supported. All other versions of Java, including OpenJDK/IcedTea, GNU Compiler for Java, and so on cannot run Moab Web Services.

Do the following:

1. Download the *Linux x64 RPM* version of Oracle Java SE 7 JRE. (Go to the [Oracle Java 7 download page](#), copy the URL to the *Linux x64 RPM* version, then run the following command.)

```
[root]# wget <URL> -O jre-7-linux-x64.rpm
```

To verify that the download was successful, run the following on the RPM before installation:

```
[root]# rpm -qip jre-7-linux-x64.rpm
```

2. Run the following to install Java 7:

```
[root]# rpm -Uh jre-7-linux-x64.rpm
```

### Opening ports

A few ports need to be available through your firewall so components of the suite can communicate with each other. Some features of some components might need additional ports configured. The individual component documentation indicates when additional ports are needed.

- 8080: Needed for Moab Web Services web portal (http)

## To open ports in your firewall

- Use **iptables** for Red Hat-based distributions:

```
[[root]# iptables-save > /tmp/iptables.mod
[root]# vi /tmp/iptables.mod

# Add the following lines immediately *before* the line matching
# "-A INPUT -j REJECT --reject-with icmp-host-prohibited"
-A INPUT -p tcp --dport 8080 -j ACCEPT

[root]# iptables-restore < /tmp/iptables.mod
[root]# service iptables save
```

- Use **SuSEfirewall12** for SuSE-based distributions:

```
[root]# vi /etc/sysconfig/SuSEfirewall12

FW_SERVICES_EXT_TCP="8080"

[root]# service SuSEfirewall12_setup restart
```

## Installing the RPM suite

**i** If you want to build a custom RPM for component documentation (Moab Workload Manager, Moab Web Services or Moab Accounting Manager, refer to the Manual Installation Guide and follow instructions in the respective component.

### To install the RPM suite

1. If you are upgrading from a previous installation of Moab, back up your `/opt/moab/tools` directory to prevent losing modifications made to the perl scripts. If you are performing a clean installation of Moab HPC Suite, skip this step.

```
[root]# tar czf backup-tools.tar.gz /opt/moab/tools
```

2. Download the latest 8.0.0 RPM suite tarball (`moab-hpc-basic-suite-<version>-<timestamp>-<OS>.tar.gz`, for example) from the [Adaptive Computing](#) website.
3. Untar the downloaded package.

```
[root]# tar xzf moab-hpc-basic-suite-<version>-<timestamp>-<OS>.tar.gz
```

4. Change directories into the untarred directory.

**i** Consider reviewing the README file for additional details on using the RPM distribution tarball.

5. Install the suite repositories. The `-y` option installs with the default settings for the RPM suite.

**i** For a description of the options of the repository installer script, run:

```
[root]# ./install-rpm-repos.sh -h
```

```
[root]# ./install-rpm-repos.sh [<repository-directory>] [-y]
```

**i** If the installation returns the following warning line:

```
Warning: RPMDB altered outside of yum.
```

This is normal and can safely be ignored.

The [*<repository-directory>*] option is the directory where you want to copy the RPMs. If no argument is given, run "install-rpm-repos.sh -h" and note the default directory location. If the [*<repository-directory>*] already exists, RPMs will be added to the existing directory. No files are overwritten in [*<repository-directory>*]. A repository file is also created in `/etc/yum.repos.d/` and points to the [*<repository-directory>*] location.

For ease in repository maintenance, the install script fails if Adaptive Computing RPMs are copied to different directories. If a non-default [*<repository-directory>*] is specified, please use the same directory for future updates.

The script installs the `createrepo` package and its dependencies. You must answer "y" to all the questions in order for the RPM install of the suite to work. Additionally, the script installs the EPEL and 10gen repositories.

## 6. Test the repository:

```
[root]# yum search moab
```

If no error is given, the repository is correctly installed. The output will look similar to the following (varying slightly depending on the suite and build type):

```
...
moab-hpc-basic-suite.noarch : Moab HPC Basic Suite virtual package
moab-perl-RRDs.noarch : Moab RRDs
moab-tomcat-config.x86_64 : Tomcat Configuration for Moab Viewpoint and Web
Services
moab-verify-oracle-java.noarch : Java Validator for Moab Viewpoint and Web Services
moab-web-services.x86_64 : Moab Web Services
moab-workload-manager.x86_64 : Moab Workload Manager
moab-workload-manager-client.x86_64 : Moab Workload Manager Client
moab-workload-manager-common.x86_64 : Moab Workload Manager Common Files
moab-perl-data.noarch : Perl Configuration for perl packages by Adaptive Computing
moab-torque-client.x86_64 : TORQUE Client
moab-torque-common.x86_64 : TORQUE Common Files
moab-torque-devel.x86_64 : TORQUE Development Files
moab-torque-mom.x86_64 : TORQUE MOM agent
moab-torque-server.x86_64 : TORQUE Server
moab-web-services-hpc-configuration.x86_64 : MWS configuration for HPC
moab-workload-manager-hpc-configuration.x86_64 : MWM configuration for HPC
```

## 7. Install the suite package.

```
[root]# yum install moab-hpc-basic-suite
```

**i** If you encounter the following error:

```
...
--> Finished Dependency Resolution
krb5-workstation-1.6.1-62.el5.x86_64 from installed has depsolving problems
--> Missing Dependency: krb5-libs = 1.6.1-62.el5 is needed by package
krb5-workstation-1.6.1-62.el5.x86_64 (installed)
krb5-workstation-1.6.1-62.el5.x86_64 from installed has depsolving problems
--> Missing Dependency: krb5-libs = 1.6.1-62.el5 is needed by package
krb5-workstation-1.6.1-62.el5.x86_64 (installed)
Error: Missing Dependency: krb5-libs = 1.6.1-62.el5 is needed by package
krb5-workstation-1.6.1-62.el5.x86_64 (installed)
You could try using --skip-broken to work around the problem
You could try running: package-cleanup --problems
package-cleanup --dupes
rpm -Va --nofiles --nodigest
```

Install the `krb5-workstation` package, then execute the install suite package again.

```
[root]# yum install krb5-workstation
[root]# yum install moab-hpc-basic-suite
```

**i** If you encounter CURL library errors, make sure you are installing the correct version for your OS.

## 8. Install and prepare the MongoDB database by doing the following:

- a. Install `mongo-10gen-server`.

```
[root]# yum install mongo-10gen-server --exclude mongodb-org,mongodb-org-server
```

- b. Start MongoDB.

**RHEL and CentOS, and Scientific Linux:**

```
[root]# chkconfig mongod on
[root]# service mongod start

[ OK ]
```

**i** If using versions of MongoDB older than 2.4.8 you might see connection errors when trying to execute the Mongo shell, such as "Error: couldn't connect to server 127.0.0.1:27017 at src/mongo/shell/mongo.js:145".

- c. Add the required MongoDB users.

**i** The passwords used below (`secret1`, `secret2`, and `secret3`) are examples. Choose your own passwords for these users.

```
[root]# mongo
> use admin;
> db.addUser("admin_user", "secret1");
> db.auth("admin_user", "secret1");

> use moab;
> db.addUser("moab_user", "secret2");
> db.addUser("mws_user", "secret3", true);

> use mws;
> db.addUser("mws_user", "secret3");
> exit
```

**i** Because the `admin_user` has read and write permissions to the `admin` database, it also has read and write permissions to all other databases. See [Control Access to MongoDB Instances with Authentication](#) for more information.

- d. Enable authentication in MongoDB.

#### **RHEL and CentOS, and Scientific Linux:**

```
[root]# vi /etc/mongod.conf

auth = true

[root]# service mongod restart
```

## Installing PostgreSQL

If you plan to use Moab Workload Manager with ODBC, you must install a PostgreSQL database.

### To install PostgreSQL

1. Install and initialize PostgreSQL.

#### **CentOS, RHEL, and Scientific Linux**

```
[root]# yum install postgresql-server
[root]# service postgresql initdb
```

#### **SLES**

```
[root]# zypper install postgresql-server
[root]# service postgresql start
```

2. Configure trusted connections.

**i** Edit or add a "host" line in the `pg_hba.conf` file for the interface from which the server(s) (for example, Moab Workload Manager and/or Moab Accounting Manager) will be connecting to the database and ensure that it specifies a secure password-based authentication method (for example, md5).

```
[root]# vi /var/lib/pgsql/data/pg_hba.conf
# IPv4 local connections:
host    all             all             127.0.0.1/32      md5
# IPv6 local connections:
host    all             all             ::1/128           md5
```

### 3. Configure PostgreSQL to accept connections from your host.

```
[root]# vi /var/lib/pgsql/data/postgresql.conf
# Uncomment the listen addresses line in the configuration:
listen_addresses = 'localhost'          # what IP address(es) to listen on;
```

### 4. Start or restart the database.

```
[root]# chkconfig postgresql on
[root]# service postgresql restart
```

## Configuration

### Configuring TORQUE

These instructions describe how to configure and start TORQUE.

## Prerequisites

- TORQUE requires certain ports to be open for essential communication:
  - For client communication to `pbs_server`, all privileged ports must be open (ports under 1024).
  - For `pbs_server` communication to `pbs_mom`, the default port is 15003.
  - For `pbs_mom` to `pbs_server`, the default port is 15001.

For more information on how to configure the ports that TORQUE uses for communication, see [Configuring ports on page 2555](#).

**i Important:** If you intend to use TORQUE 5.0.0 with Moab, you must run Moab version 8.0.0 or later. TORQUE 5.0.0 will not work with versions earlier than Moab 8.0.0.

- Make sure your host (with the correct IP address) is in your `/etc/hosts` file.

## To configure TORQUE

1. Add nodes to the `/var/spool/torque/server_priv/nodes` file. For information on syntax and options for specifying compute nodes, see [Managing nodes on page 2617](#).
2. Start the servers.

```
[root]# service trqauthd start
[root]# service pbs_server start
[root]# service pbs_mom start
```

## To configure MOMs

1. To set up the MOMs, in the directory of the unpackaged tarball, copy the `torque-common` and `torque-mom` RPM files to each MOM node.

```
[root]# scp RPMs/moab-torque-common-*.rpm <mom-node>
[root]# scp RPMs/moab-torque-mom-*.rpm <mom-node>
```

2. On each MOM node, install the RPMs, making sure that `torque-mom-common` is installed first.

```
[root]# ssh root@<mom-node>
[root]# yum install moab-torque-common-*.rpm moab-torque-mom-*.rpm
```

3. By default, on each MOM node, the `/var/spool/torque/server_name` file contains the hostname of the current host. If `pbs_server` is running on another host, change the name.

```
[root]# echo <pbs_server's_hostname> > /var/spool/torque/server_name
```

4. Edit the `/var/spool/torque/mom_priv/config` file on each node. This file is identical for all compute nodes and can be created on the head node and distributed in parallel to all systems.

```
[root]# vi /var/spool/torque/mom_priv/config
$pbsserver      headnode      # hostname running pbs server
$logevent       225           # bitmap of which events to log
```

- [Installing Moab HPC Suite - Basic Edition on page 54](#)
- [Configuring Moab Workload Manager on page 61](#)
- [Component documentation on page 86](#)

## Configuring Moab Workload Manager

These instructions describe how to configure and start Moab Workload Manager (Moab).

### To configure Moab Workload Manager

1. Source the following file to add the Moab executable directories to your current shell `$PATH` environment.

```
[root]# . /etc/profile.d/moab.sh
```

2. Copy your license file into the same directory as `moab.cfg` (`/opt/moab/etc/` by default). For example:

```
[root]# cp moab.lic $MOABHOMEDIR/etc/moab.lic
```

To verify the current status of your license, use `moab --about`.

Moab checks the status of the license every day just after midnight. At 60 and 45 days before, and daily from 30 days before license expiration to and including the license expiration date, Moab sends an e-mail to all level 1 administrators informing them of the pending Moab license expiration. A log record is also made of the upcoming expiration event. For the notifications to occur correctly, you must enable administrator email notification (see "[Notifying Administrators of Failures on page 684](#)" in the Moab Workload Manager Administrator Guide) and `moab.cfg` must contain email addresses for level 1 administrators. For example:

```
ADMINCFG[1]  USERS=u1,u2,u3[,...]
USERCFG[u1]  EMAILADDRESS=u1@company.com
USERCFG[u2]  EMAILADDRESS=u2@company.com
USERCFG[u3]  EMAILADDRESS=u3@company.com
MAILPROGRAM DEFAULT
```

Moab will not run without a license. For information about obtaining a trial license, please contact [Adaptive Computing](#).

3. Start Moab.

```
[root]# chkconfig moab on
[root]# service moab start
```

- If you have a resource manager configured, submit a sleep job as a non-root user and verify the job is running.

**i** If you do not have a resource manager configured, skip this step. For TORQUE, you can configure a basic queue.

```
qmgr -c "set server scheduling=true"
qmgr -c "create queue batch queue_type=execution"
qmgr -c "set queue batch started=true"
qmgr -c "set queue batch enabled=true"
qmgr -c "set queue batch resources_default.nodes=1"
qmgr -c "set queue batch resources_default.walltime=3600"
qmgr -c "set server default_queue=batch"
```

```
[root]# su - moab
[moab]$ echo sleep 150 | msub
[moab]$ showq
[moab]$ exit
```

## 5. Connecting Moab to MongoDB

If you will be installing Moab Web Services, connect Moab to MongoDB using the following instructions:

**i** The `USEDATABASE` parameter is unrelated to the MongoDB configuration.

- In `/opt/moab/etc/moab.cfg`, set the **MONGOSERVER** parameter to the correct location of the MongoDB server. By default, Moab assumes it is on the same server.

```
MONGOSERVER <host>[:<port>]
```

- In the `/opt/moab/etc/moab-private.cfg` file, set the **MONGOUSER** and **MONGOPASSWORD** parameters to the MongoDB `moab_user` credentials you set.

```
MONGOUSER      moab_user
MONGOPASSWORD  secret2
```

- Verify that Moab is able to connect to MongoDB.

```
[root]# service moab restart
[root]# mdiag -S
...
Mongo connection (localhost) is up (credentials are set)
...
```

- [Configuring TORQUE on page 59](#)
- [Component documentation on page 86](#)

## Configuring Moab Web Services

These instructions describe how to configure Moab Web Services (MWS).

## To configure Moab Web Services

### 1. Start Moab.

```
[root]# service moab start
```

### 2. Set up the MWS configuration file.

#### a. In the `/opt/mws/etc/mws-config.groovy` file, change these settings:

- **auth.defaultUser.username:** Any value you like, or leave as is.
- **auth.defaultUser.password:** Any value you like, but choose a strong password.

```
[root]# vi /opt/mws/etc/mws-config.groovy

// Change these to be whatever you like.
auth.defaultUser.username = "moab-admin"
auth.defaultUser.password = "changeme!"
```

If you do not change **auth.defaultUser.password**, your MWS will not be secure (because anyone reading these instructions would be able to log into your MWS). Here are some [tips](#) for choosing a good password.

#### b. Do *one* of the following:

- If you are configuring an MWS connection to your LDAP server, add the following parameters:

```
ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.directory.type = "OpenLDAP Using InetOrgPerson Schema"
```

*This is just an example LDAP connection. Be sure to use the appropriate domain controllers (dc) and common names (cn) for your environment.*

If you followed the Adaptive Computing tutorial, [Setting up OpenLDAP on CentOS 6 on page 71](#), your **ldap.directory.type** should be set to "OpenLDAP Using InetOrgPerson Schema." However, the use of other schemas is supported. For more information see [LDAP Configuration using mws-config.groovy on page 1402](#).

To see how to configure a secure connection to the LDAP server, see [Securing the LDAP connection on page 1416](#).

- If you are configuring MWS to use PAM, add the the **pam.configuration.service** parameter to the `mws-config.groovy` file. For example:

```
pam.configuration.service = "login"
```

*This is just an example PAM configuration file name. Make sure you specify the name of the configuration file you want MWS to use.*

**i** For more information about PAM configuration with MWS, see [PAM \(pluggable authentication module\) configuration using mws-config.groovy](#) on page 1405.

**!** There is a security risk when authenticating local users through your PAM configuration. This behavior is highly discouraged and not supported by Adaptive Computing.

**i** You can configure only one authentication method in `mws-config.groovy`—LDAP or PAM, but not both. If you have configured both LDAP and PAM, MWS defaults to using LDAP. If you need multiple authentication methods, you must add them to your local PAM configuration. See your distribution documentation for details.

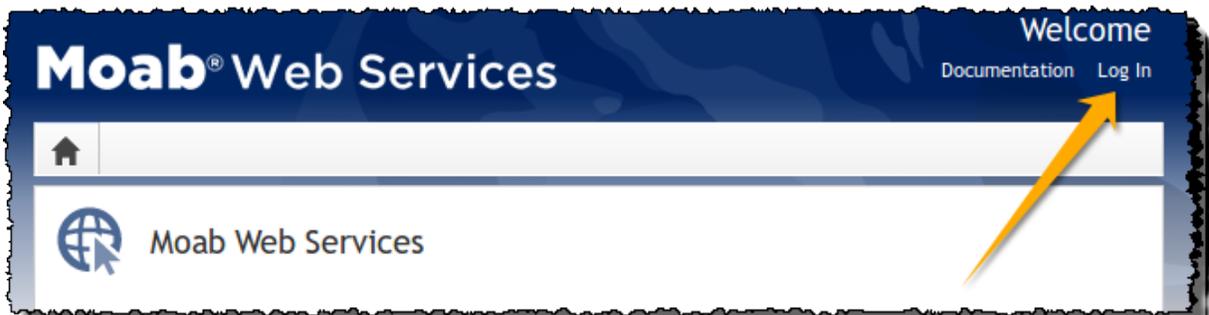

- c. Add the `grails.mongo.username` and `grails.mongo.password` parameters to the `mws-config.groovy` file. Use the MWS credentials you added to MongoDB in the [Installing Moab HPC Suite - Basic Edition](#) on page 54 section.

```
...
grails.mongo.username = "mws_user"
grails.mongo.password = "secret3"
```

3. Start or restart Tomcat.

```
[root]# chkconfig tomcat6 on
[root]# service tomcat6 restart
```

4. Navigate to `http://localhost:8080/mws/` in a web browser to verify that MWS is running (you will see some sample queries and a few other actions).
5. Log in to MWS to verify that your credentials are working. (Your login credentials are the `auth.defaultUser.username` and `auth.defaultUser.password` values you set in the `/opt/mws/etc/mws-config.groovy` file.)

**i** If you encounter problems, or if the application does not seem to be running, see the steps in [Moab Web Services issues on page 82](#)

## Installing Insight

### Context

Because Insight accumulates data for one cluster at a time, one Insight daemon should service one Moab instance. However, you can configure PostgreSQL to aggregate data using database replication mechanisms if you want cross-cluster .

**i** Moab Workload Manager and Insight both tend to heavily consume system resources. Therefore, we strongly recommend that the Insight daemon and the Moab Workload Manager server run on separate servers. For these installation instructions, the "Moab server" refers to one server and the "Insight server" refers to another server.

### Requirements

- Software:
  - 64-bit Linux server
  - RedHat or CentOS version 6.5 or greater
  - Sun® Java® 7 JRE
  - Postgres 9.3
- Hardware:
  - At least 8 cores
  - 8 GB of RAM
  - A dedicated 1 Gbit channel between Insight and Moab
  - 128 GB local SSD for swap
  - At least 512 GB disk

### To install Insight

1. Install Moab 8.0.0 or later on the Moab server.
2. Install Java 7 JRE on the Insight server. See [Install Java on page 54](#) for more information.
3. On the Insight server, download the latest 8.0.0 RPM suite tarball (moab-hpc-basic-suite-*<version>*-*<timestamp>*-*<OS>*.tar.gz, for example) from the [Adaptive Computing](#) website.
4. On the Insight server, untar the downloaded package.

```
[root]# tar xzf moab-hpc-basic-suite-<version>-<timestamp>-<OS>.tar.gz
```

5. On the Insight server, change directories into the untarred directory.

6. On the Insight server, install the suite repositories. The `-y` option installs with the default settings for the RPM suite.

**i** For a description of the options of the repository installer script, run:

```
[root]# ./install-rpm-repos.sh -h
```

```
[root]# ./install-rpm-repos.sh [<repository-directory>] [-y]
```

**i** If the installation returns the following warning line:

```
Warning: RPMDB altered outside of yum.
```

This is normal and can safely be ignored.

The script installs the `createrepo` package and its dependencies. You must answer "y" to all the questions in order for the RPM install of the suite to work. Additionally, the script installs the EPEL and 10gen repositories.

7. On the Insight server, install the Insight RPM. This will also install PostgreSQL.

```
[root]# yum install moab-insight
```

**i** If the installation returns the following warning line:

```
warning: rpmts_HdrFromFdno: Header V4 RSA/SHA1 Signature, key ID
952741e1: NOKEY
```

```
Retrieving key from file:///opt/adaptive-rpm-repository/key/GPG_
ADAPTIVE_COMPUTING_INC_EL_6_KEY
```

```
Importing GPG key 0x952741E1:
```

```
Userid: "Adaptive Computing Enterprises, Inc. (EL 6 key)
<info@adaptivecomputing.com>"
```

```
From : /opt/adaptive-rpm-repository/key/GPG_ADAPTIVE_COMPUTING_INC_EL_
6_KEY
```

This is normal. You can safely input `y` and continue.

8. On the Insight server, set up the PostgreSQL database.

- a. Initialize PostgreSQL.

```
[root]# /etc/init.d/postgresql-9.3 initdb
```

- b. Enable TCP connections instead of locally authenticated connections.

```
[root]# sed -i '/^host/s/ident/md5/' /var/lib/pgsql/9.3/data/pg_hba.conf
```

- c. If you are also using MWS, enable remote TCP connections.

```
[root]# echo 'host all all 0.0.0.0/32 md5' >> /var/lib/pgsql/9.3/data/pg_hba.conf
```

If you only want to enable access on one network interface, use the network interface IP address instead of 0.0.0.0.

- d. Start PostgreSQL.

```
[root]# service postgresql-9.3 start
```

- e. Switch to a PostgreSQL super-user. You will run the remaining commands in this step as that user.

```
[root]# su - postgres
```

- f. Create the Insight user and databases.

```
psql
CREATE USER moab_insight WITH PASSWORD 'changeme!';
CREATE DATABASE moab_insight WITH OWNER=moab_insight;
CREATE DATABASE moab_insight_reference WITH OWNER=moab_insight;
\q
```

- g. Initialize the `moab_insight` database. This sets up event triggers so that database schema validation works correctly in Insight.

```
psql moab_insight -f /opt/insight/db/initialize.sql
```

- h. If you are also using MWS, create and grant permissions for the MWS user to the database.

```
psql -d moab_insight
CREATE USER mws WITH PASSWORD 'changeme!';
GRANT SELECT ON ALL TABLES IN SCHEMA public TO mws;
ALTER DEFAULT PRIVILEGES IN SCHEMA public GRANT SELECT ON TABLES TO mws;
\q
```

9. On the Moab server, configure Moab's connection to Insight.

- a. In `/opt/moab/etc/moab.cfg`, configure the `INSIGHTENDPOINT` parameter so that Moab can connect to the Insight database.

```
INSIGHTENDPOINT <hostname>[:<port>]
```

`<hostname>` is the server where Insight is located. `<port>` is optional and `<hostname>` is required.

- b. Restart Moab in order for the new `INSIGHTENDPOINT` parameter to take affect.

```
service moab restart
```

- c. Verify that Moab is properly configured to connect to Insight.

```
mdiag -S | grep Insight
```

You should see something similar to the following:

```
[root]# mdiag -S | grep Insight
ZeroMQ Insight connection is bound on port 5574 (reliability port 5575) on host
* using Insight endpoint <the insight hostname displays here>:5568
encryption is on)
ZeroMQ Insight reliable message delivery is using store file(s) up to 1024 MB in
/opt/moab/spool/insight_store/
```

10. configure the message queue secret key so that Moab can connect to the Insight database.

```
INSIGHTENDPOINT <hostname>[:<port>]
```

*<hostname>* is the server where Insight is located. *<port>* is optional and *<hostname>* is required.

11. On the Insight server, configure the `moab.host` and `messageQueue.secretKey` parameters in the Insight configuration file `/opt/insight/etc/config.groovy`.

```
moab.host = "<moab server>"
messageQueue.secretKey = "<secret key>"
```

The *<secret key>* must match the secret key configured in `moab-private.cfg` on the Moab server for the **MESSAGEQUEUESECRETKEY** configuration parameter. See [Appendix A: Moab Parameters on page 923](#) in Moab Workload Manager for parameter information.

12. On the Insight server, verify that Insight and PostgreSQL run on startup.

```
[root]# chkconfig insight on
[root]# chkconfig postgresql-9.3 on
```

13. On the Insight server, start Insight.

```
[root]# service insight start
```

# Installing Viewpoint

## Requirements

### Hardware requirements:

- Dual or Quad core Intel/AMD x86-64 processor
- At least 4 GB of RAM
- At least 20 GB disk space

### Supported operating systems:

Viewpoint has been tested on the following variants of Linux:

- CentOS (6.5)
- RHEL (6.5)
- Scientific Linux (6.5)

### Supported browsers:

To run Moab Viewpoint, you must use one of these web browsers:

- Mozilla Firefox 25+
- Internet Explorer 10+
- Chrome 35+

**i** The new user interface was built on Django, a forward-thinking web framework, which relies heavily on Python; thus, HPC administrators should install Viewpoint only on systems with standard system level Python installed. The system you select for Viewpoint should not have any modifications made to its default Python installation.

## To install Viewpoint

**i** Only an RPM-based installation is supported for installing Moab Viewpoint. If you are installing Moab Viewpoint on the same server as you have installed other Moab HPC Suite RPMs, then steps 1 through 4 may be skipped. If you are installing Moab Viewpoint on a server where you used manual installation instructions to install Moab HPC Suite components, then steps 1 through 4 are necessary to install Moab Viewpoint.

1. On the Viewpoint server, download the latest 8.0.0 RPM suite tarball (`moab-hpc-basic-suite-<version>-<timestamp>-<OS>.tar.gz`, for example) from the [Adaptive Computing website](#).
2. On the Viewpoint server, untar the downloaded package.

```
[root]# tar xzf moab-hpc-basic-suite-<version>-<timestamp>-<OS>.tar.gz
```

3. On the Viewpoint server, change directories into the untarred directory.

- On the Viewpoint server, install the suite repositories. The `-y` option installs with the default settings for the RPM suite.

**i** For a description of the options of the repository installer script, run:

```
[root]# ./install-rpm-repos.sh -h
```

```
[root]# ./install-rpm-repos.sh [<repository-directory>] [-y]
```

**i** If the installation returns the following warning line:

```
Warning: RPMDB altered outside of yum.
```

This is normal and can safely be ignored.

The script installs the `createrepo` package and its dependencies. You must answer "y" to all the questions in order for the RPM install of the suite to work. Additionally, the script installs the EPEL and 10gen repositories.

- On the Viewpoint server, install the Viewpoint RPM. This will also install Apache Server and several Python packages (see the [Requirements on page 69](#) for details):

```
[root]# yum install viewpoint
```

- (Optional) The Viewpoint RPM installs an `/etc/httpd/conf.d/viewpoint.conf` file for Apache. Administrators can configure virtual hosts as required. Virtual host configurations should be made within this file. See <http://httpd.apache.org/docs/2.2/vhosts/> for more details.
  - Start the Apache service.
- ```
[root]# chkconfig httpd on
[root]# service httpd start
```
- Navigate your browser to the Viewpoint Login page `http://<viewpoint_server>/`.
  - Log in with the default credentials. The default user name is `moab-admin` and the default password is `changeme!`.
  - Proceed to About Configuration.

## Additional configuration

### Configuring SSL in Tomcat

To configure SSL in Tomcat, please refer to the Apache Tomcat [documentation](#).

Related topics

### Setting up OpenLDAP on CentOS 6

These instructions are intended to help first-time LDAP administrators get up and running. The following procedures contain instructions for getting started using OpenLDAP on a CentOS 6 system. For more complete information on how to set up OpenLDAP see the [OpenLDAP documentation](#).

- [Installing and configuring OpenLDAP on Centos 6 on page 71](#)
- [Adding an organizational unit \(OU\) on page 75](#)
- [Adding a user on page 76](#)
- [Adding a group on page 76](#)
- [Adding a user to a group on page 77](#)

Adaptive Computing is not responsible for creating, maintaining, or supporting customer LDAP or Active Directory configurations.

### Installing and configuring OpenLDAP on Centos 6

First, you will need to install OpenLDAP. These instructions explain how you can do this on a CentOS 6 system.

#### To install and configure OpenLDAP on Centos 6

1. Run the following command:

```
[root]# yum -y install openldap openldap-clients openldap-servers
```

2. Generate a password hash to be used as the admin password. This password hash will be used when you create the root user for your LDAP installation. For example:

```
[root]# slappasswd
New password : p@ssw0rd
Re-enter new password : p@ssw0rd
{SSHA}5lPFVw19zeh7LT53hQH69znzj8TuBrLv
```

3. Add the root user and the root user's password hash to the OpenLDAP configuration in the `olcDatabase={2}bdb.ldif` file. The root user will have permissions to add other users, groups,

organizational units, etc. Do the following:

- a. Run this command:

```
[root]# cd /etc/openldap/slapd.d/cn=config
[root]# vi olcDatabase=\{2\}bdb.ldif
```

- b. If the **olcRootPW** attribute does not already exist, create it. Then set the value to be the hash you created from `slappasswd`. For example:

```
olcRootPW: {SSHA}51PFVw19zeh7LT53hQH69znzj8TuBrLv
...
```

4. While editing this file, change the distinguished name (DN) of the **olcSuffix** to something appropriate. The suffix typically corresponds to your DNS domain name, and it will be appended to the DN of every other LDAP entry in your LDAP tree.

For example, let's say your company is called Acme Corporation, and that your domain name is "acme.com." You might make the following changes to the `olcDatabase={2}bdb.ldif` file:

```
olcSuffix: dc=acme,dc=com
...
olcRootDN: cn=Manager,dc=acme,dc=com
...
olcRootPW: {SSHA}51PFVw19zeh7LT53hQH69znzj8TuBrLv
...
```

Throughout the following examples in this topic, you will see `dc=acme,dc=com`. "acme" is only used as an example to illustrate what you would use as your own domain controller if your domain name was "acme.com." You should replace any references to "acme" with your own organization's domain name.

Do not set the cn of your root user to "root" (`cn=root,dc=acme,dc=com`), or OpenLDAP will have problems.

5. Modify the DN of the root user in the `olcDatabase={1}monitor.ldif` file to match the **olcRootDN** line in the `olcDatabase={2}bdb.ldif` file. Do the following:

- a. Run this command to edit the `olcDatabase={2}bdb.ldif` file:

```
[root]# vi olcDatabase=\{1\}monitor.ldif
```

- b. Modify the **olcAccess** line so that the **dn.base** matches the **olcRootDN** from the `olcDatabase={2}bdb.ldif` file. (In this example, **dn.base** should be "cn=Manager,dc=acme,dc=com".)

```
olcAccess: {0}to * by
dn.base="gidNumber=0+uidNumber=0,cn=peercred,cn=external,cn=auth" read by
dn.base="cn=Manager,dc=acme,dc=com" read by * none
```

- c. Now the root user for your LDAP is `cn=Manager,dc=acme,dc=com`. The root user's password is the password that you entered using `slappasswd` (see step 2), which, in this example, is **p@ssw0rd**
6. Hide the password hashes from users who should not have permission to view them.

**i** A full discussion on configuring access control in OpenLDAP is beyond the scope of this tutorial. For help, see [the OpenLDAP Access Control documentation](#).

- a. Run this command to edit the `olcDatabase=\{2\}bdb.ldif` file:

```
[root]# vi olcDatabase=\{2\}bdb.ldif
```

- b. Add the following two lines to the end of the file to restrict users from viewing other users' password hashes.

```
olcAccess: {0}to attrs=userPassword by self write by
dn.base="cn=Manager,dc=acme,dc=com" write by anonymous auth by * none
olcAccess: {1}to * by dn.base="cn=Manager,dc=acme,dc=com" write by self write by
* read
```

*These lines allow a user to read and write his or her own password. It also allows a manager to read and write anyone's password. Anyone, including anonymous users, is allowed to view non-password attributes of other users.*

7. Make sure that OpenLDAP is configured to start when the machine starts up, and start the OpenLDAP service.

```
[root]# chkconfig slapd on
[root]# service slapd start
```

8. Now, you must manually create the "dc=acme,dc=com" LDAP entry in your LDAP tree.

An LDAP directory is analogous to a tree. Nodes in this tree are called LDAP "entries" and may represent users, groups, organizational units, domain controllers, or other objects. The attributes in each entry are determined by the LDAP schema. In this tutorial we will build entries based on the `InetOrgPerson` schema (which ships with OpenLDAP by default).

In order to build our LDAP tree we must first create the root entry. Root entries are usually a special type of entry called a domain controller (DC). Because we are assuming that the organization is called Acme Corporation, and that the domain is "acme.com," we will create a domain controller LDAP entry called `dc=acme,dc=com`. Again, you will need to replace "acme" with your organization's domain name. Also note that `dc=acme,dc=com` is what is called an LDAP distinguished name (DN). An LDAP distinguished name uniquely identifies an LDAP entry.

Do the following:

- a. Create a file called `acme.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi acme.ldif
```

- b. Add the following lines in `acme.ldif`:

```
dn: dc=acme,dc=com
objectClass: dcObject
objectClass: organization
dc: acme
o : acme
```

- c. Now add the contents of this file to LDAP. Run this command:

```
[root]# ldapadd -f acme.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

- d. Verify that your entry was added correctly.

```
[root]# ldapsearch -x -LLL -b dc=acme,dc=com
dn: dc=acme,dc=com
objectClass: dcObject
objectClass: organization
dc: acme
o: acme
```

9. Run the following:

```
[root]# sudo iptables -L
[root]# sudo service iptables save
```

10. By default, the CentOS 6 firewall will block external requests to OpenLDAP. In order to allow MWS to access LDAP, you will have to configure your firewall to allow connections on port 389. (Port 389 is the default LDAP port.)

Configuring your firewall is beyond the scope of this tutorial; however, it may be helpful to know that the default firewall on CentOS is a service called `iptables`. (For more information, see the documentation on [iptables](#).) In the most basic case, you may be able to add a rule to your firewall that accepts connections to port 389 by doing the following:

- a. Edit your `iptables` file:

```
[root]# vi /etc/sysconfig/iptables
```

- b. Add the following line *after* all the **ACCEPT** lines but *before* any of the **REJECT** lines in your `iptables` file:

```
# ... lines with ACCEPT should be above
-A INPUT -p tcp --dport 389 -j ACCEPT
# .. lines with REJECT should be below
```

For example, here is a sample `iptables` file with this line added:

```
*filter
:INPUT ACCEPT [0:0]
:FORWARD ACCEPT [0:0]
:OUTPUT ACCEPT [0:0]
-A INPUT -m state --state ESTABLISHED,RELATED -j ACCEPT
-A INPUT -p icmp -j ACCEPT
-A INPUT -i lo -j ACCEPT
-A INPUT -m state --state NEW -m tcp -p tcp --dport 22 -j ACCEPT
-A INPUT -p tcp --dport 389 -j ACCEPT
-A INPUT -j REJECT --reject-with icmp-host-prohibited
-A FORWARD -j REJECT --reject-with icmp-host-prohibited

COMMIT
```

c. Now reload iptables.

```
[root]# service iptables reload
```

Although providing instructions is beyond the scope of this tutorial, it is also highly recommended that you set up OpenLDAP to use SSL or TLS security to prevent passwords and other sensitive data from being sent in plain text. For information on how to do this, see the [OpenLDAP TLS documentation](#).

Now that you have installed and set up Open LDAP, you are ready to add organizational units (see [Adding an organizational unit \(OU\) on page 75](#)).

## Adding an organizational unit (OU)

These instructions will describe how to populate the LDAP tree with organizational units (OUs), groups, and users, all of which are different types of LDAP entries. The examples that follow also presume an InetOrgPerson schema, because the InetOrgPerson schema is delivered with OpenLDAP by default.

### To add an organizational unit (OU) entry to the LDAP tree

In this example, we are going to add an OU called "Users."

1. Create a temporary file called `users.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi users.ldif
```

2. Add these lines to `users.ldif`:

```
dn: ou=Users,dc=acme,dc=com
objectClass: organizationalUnit
ou: Users
```

3. Add the contents of `users.ldif` file to LDAP.

```
[root]# ldapadd -f users.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a user

### To add a user to LDAP

In this example, we will add a user named "Bob Jones" to LDAP inside the "Users" OU.

1. Create a temporary file called `bob.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi bob.ldif
```

2. Add these lines to `bob.ldif`:

```
dn: cn=Bob Jones,ou=Users,dc=acme,dc=com
cn: Bob Jones
sn: Jones
objectClass: inetOrgPerson
userPassword: p@ssw0rd
uid: bjones
```

3. Add the contents of `bob.ldif` file to LDAP.

```
[root]# ldapadd -f bob.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a group

### To add a group to LDAP

In this example, we will add a group called "Engineering" to LDAP inside the "Users" OU.

1. Create a temporary file called `engineering.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi engineering.ldif
```

2. Add these lines to `engineering.ldif`:

```
dn: cn=Engineering,ou=Users,dc=acme,dc=com
cn: Engineering
objectClass: groupOfNames
member: cn=Bob Jones,ou=Users,dc=acme,dc=com
```

3. Add the contents of `engineering.ldif` file to LDAP.

```
[root]# ldapadd -f engineering.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

## Adding a user to a group

### To add a user to an LDAP group

In this example, we will add an LDAP member named "Al Smith" to the "Engineering" LDAP group. This example assumes that user, Al Smith, has already been added to LDAP.

**i** Before you add a user to an LDAP group, the user must first be added to LDAP. For more information, see [Adding a user on page 76](#).

1. Create a temporary file called `addUserToGroup.ldif`. (You can delete this file once its content has been added to LDAP, so in this example, we will create it in the `/tmp` folder.)

```
[root]# cd /tmp
[root]# vi addUserToGroup.ldif
```

2. Add these lines to `addUserToGroup.ldif`:

```
dn: cn=Engineering,ou=Users,dc=acme,dc=com
changetype: modify
add: member
member: cn=Al Smith,ou=Users,dc=acme,dc=com
```

3. Now add the contents of `addUserToGroup.ldif` file to LDAP.

```
[root]# ldapadd -f addUserToGroup.ldif -D cn=Manager,dc=acme,dc=com -w p@ssw0rd
```

Related topics

## Trusting servers in Java

### Prerequisites

Some of these instructions refer to `JAVA_HOME`, which must point to the same directory that Tomcat uses. To set `JAVA_HOME`, do this:

```
[root]# source /etc/tomcat6/tomcat6.conf
```

Your system administrator might have defined Tomcat's `JAVA_HOME` in a different file.

### Retrieve the server's X.509 public certificate

To retrieve the server's certificate, use the following command:

```
[root]# $JAVA_HOME/bin/keytool -printcert -rfc -sslserver <servername>:<port> >
/tmp/public.cert.pem
```

Replace `<servername>` with the server's host name and `<port>` with the secure port number. The default port for https is 443. The default port for ldaps is 636. If successful, `/tmp/public.cert.pem` contains the server's public certificate. Otherwise, `/tmp/public.cert.pem` contains an error message. This

message is typical: `keytool error: java.lang.Exception: No certificate from the SSL server`. This message suggests that the server name or port is incorrect. Consult your IT department to determine the correct server name and port.

## Add the server's certificate to Java's keystore

Java stores trusted certificates in a database known as the keystore. Because each new version of Java has its own keystore, you need to add the server certificate to the Java keystore (using the steps below) every time you install a new version of Java.

Java's keystore is located at `$JAVA_HOME/lib/security/cacerts`. If Tomcat's `JAVA_HOME` points to a JDK, then the keystore is located at `$JAVA_HOME/jre/lib/security/cacerts`. To add the server certificate to the keystore, run the following command:

```
[root]# $JAVA_HOME/bin/keytool -import -trustcacerts -file /tmp/public.cert.pem -alias
<servername> -keystore $JAVA_HOME/lib/security/cacerts
```

You will be prompted for the keystore password, which is "changeit" by default.

 Your system administrator might have changed this password.

After you've entered the keystore password, you'll see the description of the server's certificate. At the end of the description it prompts you to trust the certificate.

```
Trust this certificate? [no]:
```

Type `yes` and press **Enter** to add the certificate to the keystore.

# Troubleshooting

This page details some common problems and general solutions. It contains these sections:

- [General issues on page 78](#)
- [Moab Web Services issues on page 82](#)

## General issues

- [Moab error: "cannot determine local hostname" on page 79](#)
- [Moab error: "Moab will now exit due to license file not found" on page 79](#)
- [Other Moab issues on page 79](#)
- [Where do I change my passwords? on page 80](#)

### Moab error: "cannot determine local hostname"

```
# service moab start
Starting moab: ERROR:      cannot determine local hostname - node is misconfigured
                        [FAILED]
```

If you encounter this error when starting Moab, check the `/opt/moab/etc/moab.cfg` file to make sure a valid host is configured. For example:

```
...
SCHEDCFG[Moab]                SERVER=<moab-hostname>:42559
...
```

Also check `/etc/hosts` to be sure the host name resolves, at least with localhost:

```
...
127.0.0.1    <moab-hostname> localhost localhost.localdomain localhost4
localhost4.localhostdomain4
...
```

### Moab error: "Moab will now exit due to license file not found"

```
# service moab start
Starting moab: Moab will now exit due to license file not found
Please contact Adaptive Computing (sales@adaptivecomputing.com) to get a license
for your system
                        [FAILED]
```

If you encounter this error when starting Moab, make sure your Moab license file is named **moab.lic** and is located in the `/opt/moab/etc/` directory.

Also make sure the license is not expired. The expiration date is listed in the license file. For example:

```
# cat /opt/moab/etc/moab.lic
...
# Expires after Tue Dec 31 10:43:46 2013
...
```

### Other Moab issues

Please see "Troubleshooting and System Maintenance" in the *Moab Workload Manager Administrator Guide*.

[Where do I change my passwords?](#)

**MWS super user username and password**

The default username and password for MWS are **moab-admin** and **changeme!** (respectively).

To change the username and/or the password for the MWS super user:

1. Stop the tomcat6 and moab services.

```
[root]# service moab stop
[root]# service tomcat6 stop
```

2. Change the respective values in the following files:

- /opt/mws/etc/mws-config.groovy:

```
auth.defaultUser.username = "moab-admin"
auth.defaultUser.password = "changeme!"
```

- /opt/moab/etc/moab-private.cfg:

```
CLIENTCFG[RM:mws] USERNAME=moab-admin PASSWORD=changeme!
```

- /opt/moab/etc/cloud.cfg:

```
CONFIG[default] MWS_USERNAME=moab-admin
CONFIG[default] MWS_PASSWORD=changeme!
```

3. Start the tomcat6 service.

```
[root]# service tomcat6 start
```

4. Start the moab service.

```
[root]# service moab start
```

**MongoDB passwords**

To change the passwords for MongoDB:

1. Stop the tomcat6 and moab services.

```
[root]# service moab stop
[root]# service tomcat6 stop
```

2. Change the passwords for the MongoDB accounts (i.e., **moab\_user** and/or **mws\_user**). For instructions, see the [MongoDB documentation](#).

3. Edit the password values in the following files:

- /opt/moab/etc/moab-private.cfg:

```
MONGouser moab_user
MONGOPASSWORD secret2
```

- /opt/mws/etc/mws-config.groovy:

```
// MongoDB configuration.  
grails.mongo.username = "mws_user"  
grails.mongo.password = "secret3"
```

4. Start the tomcat6 service.

```
[root]# service tomcat6 start
```

5. Start the moab service.

```
[root]# service moab start
```

## Moab Web Services issues

If something goes wrong with MWS, look in the following files:

- The MWS log file. By default this is `/opt/mws/log/mws.log`.
- The Tomcat `catalina.out` file, usually in `/var/log/tomcat6` or `$CATALINA_HOME/logs`.

**i** If you remove the `log4j` configuration from `mws-config.groovy`, MWS writes its log files to `java.io.tmpdir`. For Tomcat, `java.io.tmpdir` is generally set to `$CATALINA_BASE/temp` or `CATALINA_TMPDIR`.

Here is a list of some errors and their fixes:

- [MongoDB: Errors during MWS startup on page 83](#)
- [MongoDB: Out of semaphores to get db connection on page 85](#)
- [MongoDB: Connection wait timeout after 120000 ms on page 85](#)
- [java.lang.OutOfMemoryError: Java heap space on page 85](#)
- [java.lang.OutOfMemoryError: PermGen space on page 86](#)
- [SEVERE: Context \[/mws\] startup failed due to previous errors on page 86](#)
- [Moab Reached Maximum Number of Concurrent Client Connections on page 86](#)

[MongoDB: Errors during MWS startup](#)

If the application fails to start and gives error messages such as these:

```
Error creating bean with name 'mongoDatastore'
can't say something; nested exception is com.mongodb.MongoException
```

```
ERROR    grails.app.services.com.ace.mws.ErrorService    0
Error encountered while attempting to authenticate account or query database;
the MongoDB server is not available. Please verify connection to server
'/127.0.0.1:27017' and that MongoDB is running.
```

MongoDB is most likely not running, or the MongoDB host and port are misconfigured.

In this case, there are a few things to verify:

- (Not relevant if MongoDB is installed on a separate server) **Is MongoDB installed?**

Run the following commands to assess whether MongoDB is installed on the current server.

```
$ mongo
-bash: mongo: command not found
```

To remedy, install MongoDB, start the `mongod` service and then restart the `tomcat6` service. See [Preparing for installation on page 17](#) or [Installing Moab HPC Suite - Basic Edition on page 54](#) for more information on how to install and configure MongoDB in the manual installation guide or the RPM-based installation guide, respectively.

- (Only relevant if MongoDB is installed on a separate server) **Is MWS configured to connect to the remote MongoDB server?**

Run the following commands to assess whether MongoDB is installed on the current server.

```
[root]# cat /opt/mws/etc/mws-config.groovy | grep 'grails.mongo'
// grails.mongo.username = "mws_user"
// grails.mongo.password = "<ENTER-KEY-HERE>"
// grails.mongo.host = "127.0.0.1"
// grails.mongo.port = 27017
```

Make sure that the `grails.mongo.*` options are configured in `/opt/mws/etc/mws-config.groovy` for the remote MongoDB server and then restart the `tomcat6` service.

```
[root]# service tomcat6 restart
```

- **Is MWS configured to authenticate with MongoDB, and is MongoDB configured to enforce authentication?**

Run the following commands to assess the relevant MWS and MongoDB configurations.

```
[root]# cat /opt/mws/etc/mws-config.groovy | grep 'grails.mongo'
// grails.mongo.username = "mws_user"
// grails.mongo.password = "<ENTER-KEY-HERE>"

[root]# cat /etc/mongod.conf | grep 'auth'
#noauth = true
auth = true
```

The configuration above is problematic because the `grails.mongo` credentials are commented out in the `/opt/mws/etc/mws-config.groovy` file while MongoDB is

configured to enforce authentication ("auth = true"). Similar connection issues will exist if the `grails.mongo` parameters do not match the credentials configured for the "mws\_user" on both the `mws` and `moab` databases in MongoDB.

(For upgrade scenarios only) If the application fails to start and gives the following message in `/opt/mws/etc/log/mws.log`:

```
java.lang.Exception: The db-migrate.js script has not yet been run. Please see the
upgrade section of the installation guide for instructions.
```

Then the `db-migrate.js` script must be run to update the schema of the `mws` database in MongoDB.

### MongoDB: Out of semaphores to get db connection

To resolve this error, adjust the values of `connectionsPerHost` or `threadsAllowedToBlockForConnectionMultiplier` by adding them to `mws-config.groovy`. Example:

```
grails.mongo.options.connectionsPerHost = 60
grails.mongo.options.threadsAllowedToBlockForConnectionMultiplier = 10
```

For more information on these options, refer to these documents:

- "Configuration" (in the Moab Web Services *Reference Guide*), which briefly discusses a few MongoDB driver options.
- The [MongoOptions](#) documentation, which contains full details on all MongoDB driver options.

**i** You must restart Tomcat after adding, removing, or changing `grails.mongo.options` parameters.

As shipped, `mws-config.groovy` does not contain any `grails.mongo.options` parameters. To adjust their values, you need to add them to `mws-config.groovy`.

The default value of `connectionsPerHost` is normally 10, but MWS sets it internally to 50.

The default value of `threadsAllowedToBlockForConnectionMultiplier` is 5.

Any of the options listed in `MongoOptions` can be specified in `mws-config.groovy`. Just use the prefix `grails.mongo.options` as shown above.

### MongoDB: Connection wait timeout after 120000 ms

See [MongoDB: Out of semaphores to get db connection](#) above.

### java.lang.OutOfMemoryError: Java heap space

Increase the size of the heap using JVM options `-Xms` and `-Xmx`. Here are the suggested values:

```
CATALINA_OPTS="-DMWS_HOME=/opt/mws -Xms256m-Xmx3g -XX:MaxPermSize=384m"
```

- `-Xms`: Set initial Java heap size.
- `-Xmx`: Set maximum Java heap size.

### java.lang.OutOfMemoryError: PermGen space

Increase the size of the permanent generation using JVM option **-XX:MaxPermSize**. Here are the suggested values:

```
CATALINA_OPTS="-DMWS_HOME=/opt/mws -Xms256m -Xmx3g -XX:MaxPermSize=384m"
```

### SEVERE: Context [/mws] startup failed due to previous errors

If `catalina.out` contains this error, look in `/opt/mws/log/mws.log` and `/opt/mws/log/stacktrace.log` for more details on the error.

Also ensure that the `/opt/mws/etc/mws-config.groovy` file can be read by the Tomcat user. The permissions should appear as follows:

```
$ ls -al /opt/mws/etc/mws-config.groovy
-r----- 1 tomcat tomcat 4056 Dec  4 12:07 mws-config.groovy
```

### Moab Reached Maximum Number of Concurrent Client Connections

When this error message is encountered, simply add a new line to the `moab.cfg` file:

```
CLIENTMAXCONNECTIONS 256
```

This will change the Moab configuration when Moab is restarted. Run the following command to immediately use the new setting:

```
[root]# changeparam CLIENTMAXCONNECTIONS 256
```

 The number **256** above may be substituted for the desired maximum number of Moab client connections.

## Component documentation

The individual components of the suite have more options and allow for more configuration than can be contained in this guide. Refer to the individual component guides for more information.

# Moab Workload Manager

## Moab Workload Manager overview

Moab Workload Manager is a highly advanced scheduling and management system designed for clusters, grids, and on-demand/utility computing systems. At a high level, Moab applies site policies and extensive optimizations to orchestrate jobs, services, and other workload across the ideal combination of network, compute, and storage resources. Moab enables true adaptive computing allowing compute resources to be customized to changing needs and failed systems to be automatically fixed or replaced. Moab increases system resource availability, offers extensive cluster diagnostics, delivers powerful QoS/SLA features, and provides rich visualization of cluster performance through advanced statistics, reports, and charts.

Moab works with virtually all major resource management and resource monitoring tools. From hardware monitoring systems like IPMI to provisioning systems and storage managers, Moab takes advantage of domain expertise to allow these systems to do what they do best, importing their state information and providing them with the information necessary to better do their job. Moab uses its global information to coordinate the activities of both resources and services, which optimizes overall performance in-line with high-level mission objectives.

## Philosophy

The scheduler's purpose is to optimally use resources in a convenient and manageable way. System users want to specify resources, obtain quick turnaround on their jobs, and have reliable resource allocation. On the other hand, administrators want to understand both the workload and the resources available. This includes current state, problems, and statistics—information about what is happening that is transparent to the end-user. Administrators need an extensive set of options to enable management enforced policies and tune the system to obtain desired statistics.

There are other systems that provide batch management; however, Moab is unique in many respects. Moab matches jobs to nodes, dynamically reprovisions nodes to satisfy workload, and dynamically modifies workload to better take advantage of available nodes. Moab allows sites to fully visualize cluster and user behavior. It can integrate and orchestrate resource monitors, databases, identity managers, license managers, networks, and storage systems, thus providing a cohesive view of the cluster—a cluster that fully acts and responds according to site mission objectives.

Moab can dynamically adjust security to meet specific job needs. Moab can create real and virtual clusters on demand and from scratch that are custom-tailored to a specific request. Moab can integrate visualization services, web farms and application servers; it can create powerful grids of disparate clusters. Moab maintains complete accounting and auditing records, exporting this data to information services on command, and even providing professional billing statements to cover all used resources and services.

Moab provides user- and application-centric web portals and powerful graphical tools for monitoring and controlling every conceivable aspect of a cluster's objectives, performance, workload, and usage. Moab is unique in its ability to deliver a powerful user-centric cluster with little effort. Its design is focused on ROI, better use of resources, increased user effectiveness, and reduced staffing requirements.

This chapter contains these sections:

- [Value of a Batch System on page 90](#)
- [Philosophy and Goals on page 91](#)
- [Workload on page 92](#)

## Value of a Batch System

Batch systems provide centralized access to distributed resources through mechanisms for submitting, launching, and tracking jobs on a shared resource. This greatly simplifies use of the cluster's distributed resources, allowing users a *single system image* in terms of managing jobs and aggregate compute resources available. Batch systems should do much more than just provide a global view of the cluster, though. Using compute resources in a fair and effective manner is complex, so a scheduler is necessary to determine when, where, and how to run jobs to optimize the cluster. Scheduling decisions can be categorized as follows:

- [Traffic Control](#)
- [Mission Policies](#)
- [Optimizations](#)

### Traffic Control

A scheduler must prevent jobs from interfering. If jobs contend for resources, cluster performance decreases, job execution is delayed, and jobs may fail. Thus, the scheduler tracks resources and dedicates requested resources to a particular job, which prevents use of such resources by other jobs.

### Mission Policies

Clusters and other HPC platforms typically have specific purposes; to fulfill these purposes, or mission goals, there are usually rules about system use pertaining to who or what is allowed to use the system. To be effective, a scheduler must provide a suite of policies allowing a site to *map* site mission policies into scheduling behavior.

## Optimizations

The compute power of a cluster is a limited resource; over time, demand inevitably exceeds supply. Intelligent scheduling decisions facilitate higher job volume and faster job completion. Though subject to the constraints of the traffic control and mission policies, the scheduler must use whatever freedom is available to maximize cluster performance.

## Philosophy and Goals

Managers want high system utilization and the ability to deliver various qualities of service to various users and groups. They need to understand how available resources are delivered to users over time. They also need administrators to tune *cycle delivery* to satisfy the current site mission objectives.

Determining a scheduler's success is contingent upon establishing metrics and a means to measure them. The value of statistics is best understood if optimal statistical values are known for a given environment, including workload, resources, and policies. That is, if an administrator could determine that a site's typical workload obtained an average queue time of 3.0 hours on a particular system, that would be a useful *statistic*; however, if an administrator knew that through proper tuning the system could deliver an average queue time of 1.2 hours with minimal negative side effects, that would be valuable *knowledge*.

Moab development relies on extensive feedback from users, administrators, and managers. At its core, it is a tool designed to *manage* resources and provide meaningful information about what is actually happening on the system.

## Management Goals

A manager must ensure that a cluster fulfills the purpose for which it was purchased, so a manager must deliver cycles to those projects that are most critical to the success of the funding organizations.

Management tasks to fulfill this role may include the following:

- Define cluster mission objectives and performance criteria
- Evaluate current and historical cluster performance
- Instantly graph delivered service

## Administration Goals

An administrator must ensure that a cluster is effectively functioning within the bounds of the established mission goals. Administrators translate goals into cluster policies, identify and correct cluster failures, and train users in best practices. Given these objectives, an administrator may be tasked with each of the following:

- Maximize utilization and cluster responsiveness
- Tune fairness policies and workload distribution
- Automate time-consuming tasks
- Troubleshoot job and resource failures

- Instruct users of available policies and in their use regarding the cluster
- Integrate new hardware and cluster services into the batch system

## End-user Goals

End-users are responsible for learning about the resources available, the requirements of their workload, and the policies to which they are subject. Using this understanding and the available tools, they find ways to obtain the best possible responsiveness for their own jobs. A typical end-user may have the following tasks:

- Manage current workload
- Identify available resources
- Minimize workload response time
- Track historical usage
- Identify effectiveness of prior submissions

## Workload

Moab can manage a broad spectrum of compute workload types, and it can optimize all four workload types within the same cluster simultaneously, delivering on the objectives most important to each workload type. The workload types include the following:

- [Batch Workload](#)
- [Interactive Workload](#)
- [Calendar Workload](#)
- [Service Workload](#)

### Batch Workload

Batch workload is characterized by a *job* command file that typically describes all critical aspects of the needed compute resources and execution environment. With a batch job, the job is submitted to a job queue, and is run somewhere on the cluster as resources become available. In most cases, the submitter will submit multiple batch jobs with no execution time constraints and will process the job results as they become available.

Moab can enforce rich policies defining how, when, and where batch jobs run to deliver compute resources to the most important workload and provide general SLA guarantees while maximizing system utilization and minimizing average response time.

### Interactive Workload

Interactive workload differs from batch in that requestors are interested in immediate response and are generally waiting for the interactive request to be executed before going on to other activities. In many cases, interactive submitters will continue to be *attached* to the interactive job, routing keystrokes and

other input into the job and seeing both output and error information in real-time. While interactive workload may be submitted within a job file, commonly, it is routed into the cluster via a web or other graphical terminal and the end-user may never even be aware of the underlying use of the batch system.

For managing interactive jobs, the focus is usually on setting aside resources to guarantee immediate execution or at least a minimal wait time for interactive jobs. Targeted service levels require management when mixing batch and interactive jobs. Interactive and other jobs types can be dynamically steered in terms of what they are executing as well as in terms of the quantity of resources required by the application. Moab can apply dynamic or malleable job facilities to dynamically grow and shrink jobs as needed to meet these changing constraints.

## Calendar Workload

Calendar workload must be executed at a particular time and possibly in a regular periodic manner. For such jobs, time constraints range from flexible to rigid. For example, some calendar jobs may need to complete by a certain time, while others must run exactly at a given time each day or each week.

Moab can schedule the future and can thus guarantee resource availability at needed times to allow calendar jobs to run as required. Furthermore, Moab provisioning features can locate or temporarily create the needed compute environment to properly execute the target applications.

## Service Workload

Moab can schedule and manage both individual applications and long-running or persistent services. Service workload processes externally-generated transaction requests while Moab provides the distributed service with needed resources to meet target backlog or response targets to the service. Examples of service workload include parallel databases, web farms, and visualization services. Moab can apply cluster, [grid](#), or dynamically-generated on-demand resources to the service.

When handling service workload, Moab observes the application in a highly abstract manner. Using the [JOB\\_CFG](#) parameter, aspects of the service jobs can be discovered or configured with attributes describing them as resource consumers possessing response time, backlog, state metrics, and associated QoS targets. In addition, each application can specify the type of compute resource required (OS, arch, memory, disk, network adapter, data store, and so forth) as well as the support environment (network, storage, external services, and so forth).

If the QoS response time/backlog targets of the application are not being satisfied by the current resource allocation, Moab evaluates the needs of this application against all other site mission objectives and workload needs and determines what it must do to locate or create (that is, provision, customize, secure) the needed resources. With the application resource requirement specification, a site may also indicate proximity/locality constraints, partition policies, ramp-up/ramp-down rules, and so forth.

Once Moab identifies and creates appropriate resources, it hands these resources to the application via a site customized URL. This URL can be responsible for whatever application-specific hand-shaking must be done to launch and initialize the needed components of the distributed application upon the new resources. Moab engages in the hand-off by providing needed context and resource information and by launching the URL at the appropriate time.

## Initial Moab Configuration

### Configuring an RPM-based install of Moab

When Moab is installed via an RPM source, such as with the Moab HPC Suite or Moab Cloud Suite, the `moab.cfg` file contains only one directive - an `#IMPORT` line that imports all the configuration files in `/opt/moab/etc`. The usual configuration settings that are normally contained in `moab.cfg` have been moved to `moab-server.cfg`. Moab still reads the `moab.cfg` file and, due to the `#INCLUDE` directive, reads in all the other configuration files as well.

To configure Moab in the case of an RPM install, you can modify the `moab.cfg` file, the `moab-server.cfg` file, or any of the configuration files that are read in by `moab.cfg` such as the accounting manager configuration file (`am.cfg`) or the resource manager configuration file (`rm.cfg`).

The RPMs allow for a client install of Moab, instead of a server install. In this instance, the `moab-server.cfg` file is replaced with a `moab-client.cfg` file. The server and client RPMs cannot be installed on the same machine.

### Basic configuration of Moab

After Moab is installed, there may be minor configuration remaining within the primary configuration file, `moab.cfg`. While the `configure` script automatically sets these parameters, sites may choose to specify additional parameters. If the values selected in `configure` are satisfactory, then this section may be safely ignored.

The parameters needed for proper initial startup include the following:

| Parameter                | Instructions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">SCHEDCFG</a> | <p>The <b>SCHEDCFG</b> parameter specifies how the Moab server will execute and communicate with client requests. The <b>SERVER</b> attribute allows Moab client commands to locate the Moab server and is specified as a URL or in <code>&lt;HOST&gt;[:&lt;PORT&gt;]</code> format. For example:</p> <pre>SCHEDCFG[orion] SERVER=cw.psu.edu</pre> <p>Specifying the server in the Moab configuration file is optional. If nothing is specified, <code>gethostname()</code> is called. You can restart Moab and run <code>mdiag -S</code> to confirm that the correct host name is specified.</p> <p><b>i</b> The <b>SERVER</b> attribute can also be set using the environment variable <b>\$MOABSERVER</b>. Using this variable allows you to quickly change to the Moab server that client commands will connect to.</p> <pre>&gt; export MOABSERVER=cluster2:12221</pre>                                                                                                             |
| <a href="#">ADMINCFG</a> | <p>Moab provides role-based security enabled via multiple levels of admin access. Users who are to be granted full control of all Moab functions should be indicated by setting the <b>ADMINCFG[1]</b> parameter. The first user in this <b>USERS</b> attribute list is considered the <i>primary</i> administrator. It is the ID under which Moab will execute. For example, the following may be used to enable users <i>greg</i> and <i>thomas</i> as level 1 admins:</p> <pre>ADMINCFG[1] USERS=greg,thomas</pre> <p><b>i</b> Moab may only be launched by the primary administrator user ID.</p> <p><b>i</b> The primary administrator should be configured as a manager/operator/administrator in every resource manager with which Moab will interface.</p> <p><b>i</b> If the <code>msub</code> command will be used, then "root" <i>must</i> be the primary administrator.</p> <p><b>i</b> Moab's home directory and contents should be owned by the primary administrator.</p> |
| <a href="#">RMCFG</a>    | <p>For Moab to properly interact with a resource manager, the interface to this resource manager must be defined as described in the <a href="#">Resource Manager Configuration Overview</a>. Further, it is important that the primary Moab administrator also be a resource manager administrator within each of those systems. For example, to interface to a <b>TORQUE</b> resource manager, the following may be used:</p> <pre>RMCFG[torque1] TYPE=pbs</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Layout of Scheduler Components

Moab is initially unpacked into a simple one-deep directory structure. What follows demonstrates the default layout of scheduler components; some of the files (such as log and statistics files) are created while Moab runs.

- \* `$(MOABHOMEDIR)` (default is `/opt/moab` and can be modified via the `--with-homedir` parameter during `./configure`) contains the following files:

| Filename                        | Description                                                          |
|---------------------------------|----------------------------------------------------------------------|
| <b>.moab.ck</b>                 | Checkpoint file                                                      |
| <b>.moab.pid</b>                | Lock file                                                            |
| <b>moab.lic</b>                 | License file                                                         |
| <b>contrib/</b>                 | Directory containing contributed code and plug-ins                   |
| <b>docs/</b>                    | Directory for documentation                                          |
| <b>etc/</b>                     | Directory for configuration files                                    |
| <b>moab.cfg</b>                 | General configuration file                                           |
| <b>moab.dat</b>                 | Configuration file generated by <a href="#">Moab Cluster Manager</a> |
| <b>moab-private.cfg</b>         | Secure configuration file containing private information             |
| <b>lib/</b>                     | Directory for library files (primarily for <code>tools/</code> )     |
| <b><a href="#">log/</a></b>     | Directory for log files                                              |
| <b><a href="#">moab.log</a></b> | Log file                                                             |
| <b>moab.log.1</b>               | Previous log file                                                    |

| Filename                 | Description                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">stats/</a>   | Directory for statistics files: <ul style="list-style-type: none"> <li>◦ <code>events.&lt;date&gt;</code> - event files</li> <li>◦ <code>{DAY WEEK MONTH YEAR}.&lt;date&gt;</code> - usage profiling data</li> <li>◦ <code>FS.&lt;PARTITION&gt;.&lt;epochtime&gt;</code> - fairshare usage data</li> </ul> |
| <a href="#">samples/</a> | Directory for sample configuration files, simulation trace files, etc.                                                                                                                                                                                                                                     |

- `$ (MOABINSTDIR)` (default is `/opt/moab` and can be modified via the `--prefix` parameter during `./configure`) contains the following files:

| Filename               | Description                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#">bin/</a>   | Directory for client commands (for example, <a href="#">showq</a> , <a href="#">setres</a> , etc.) |
| <a href="#">sbin/</a>  | Directory for server daemons                                                                       |
| <a href="#">moab</a>   | Moab binary                                                                                        |
| <a href="#">tools/</a> | Directory for resource manager interfaces and local scripts                                        |

- `/etc/moab.cfg` - If the Moab home directory cannot be found at startup, this file is checked to see if it declares the Moab home directory. If a declaration exists, the system checks the declared directory to find Moab. The syntax is: `MOABHOMEDIR=<DIRECTORY>`.

If you want to run Moab from a different directory other than `/opt/moab` but did not use the `--with-homedir` parameter during `./configure`, you can set the `$MOABHOMEDIR` environment variable, declare the home directory in the `/etc/moab.cfg` file, or use the `-C` command line option when using the Moab server or client commands to specify the configuration file location.

When Moab runs, it creates a log file, `moab.log`, in the `log/` directory and creates a statistics file in the `stats/` directory with the naming convention `events.WWW_MMM_DD_YYYY` (for example, `events.Sat_Oct_10_2009`). Additionally, a checkpoint file, `.moab.ck`, and lock file, `.moab.pid`, are maintained in the Moab home directory.

## Layout of Scheduler Components with Integrated Database Enabled

If [USEDATABASE INTERNAL](#) is configured, the layout of scheduler components varies slightly. The `.moab.ck` file and usage profiling data (`stat/{DAY|WEEK|MONTH|YEAR}.<date>`) are stored in the `moab.db` database. In addition, the event information is stored in both event files: (`stat/events.<date>`) and `moab.db`.

Moab functions by manipulating a number of elementary objects, including jobs, nodes, reservations, QoS structures, resource managers, and policies. Multiple minor elementary objects and composite objects are also used; these objects are defined in the [scheduling dictionary](#).

## Jobs

Job information is provided to the Moab scheduler from a resource manager such as Loadleveler, PBS, Wiki, or LSF. Job attributes include ownership of the job, [job state](#), amount and type of resources required by the job, and a wallclock limit indicating how long the resources are required. A job consists of one or more [task groups](#), each of which requests a number of resources of a given type; for example, a job may consist of two task groups, the first asking for a single master task consisting of *1 IBM SP node with at least 512 MB of RAM* and the second asking for a set of slave tasks such as *24 IBM SP nodes with at least 128 MB of RAM*. Each task group consists of one or more [tasks](#) where a task is defined as the minimal independent unit of resources. By default, each task is equivalent to one processor. In SMP environments, however, users may wish to tie one or more processors together with a certain amount of memory and other resources.

## Job States

The job's *state* indicates its current status and eligibility for execution and can be any of the values listed in the following tables:

Table 3-1: Pre-execution states

| State            | Definition                                                                                                                                                                                                                                                                                     |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Deferred</b>  | Job that has been held by Moab due to an inability to schedule the job under current conditions. Deferred jobs are held for <a href="#">DEFERTIME</a> before being placed in the idle queue. This process is repeated <a href="#">DEFERCOUNT</a> times before the job is placed in batch hold. |
| <b>Hold</b>      | Job is idle and is not eligible to run due to a user, (system) administrator, or batch system <i>hold</i> (also, <a href="#">batchhold</a> , <a href="#">systemhold</a> , <a href="#">userhold</a> ).                                                                                          |
| <b>Idle</b>      | Job is currently queued and eligible to run but is not executing (also, <b>notqueued</b> ).                                                                                                                                                                                                    |
| <b>NotQueued</b> | The job has not been queued.                                                                                                                                                                                                                                                                   |
| <b>Unknown</b>   | Moab cannot determine the state of the job.                                                                                                                                                                                                                                                    |

Table 3-2: Execution states

| State            | Definition                                                                                                                                                                                            |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Starting</b>  | Batch system has attempted to start the job and the job is currently performing <i>pre-start</i> tasks that may include provisioning resources, staging data, or executing system pre-launch scripts. |
| <b>Running</b>   | Job is currently executing the user application.                                                                                                                                                      |
| <b>Suspended</b> | Job was running but has been suspended by the scheduler or an administrator; user application is still in place on the allocated compute resources, but it is not executing.                          |

Table 3-3: Post-execution states

| State            | Definition                                                                                                                                                                                                                                                           |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Completed</b> | Job has completed running without failure.                                                                                                                                                                                                                           |
| <b>Removed</b>   | Job has run to its requested walltime successfully but has been canceled by the scheduler or resource manager due to exceeding its walltime or violating another policy; includes jobs canceled by users or administrators either before or after a job has started. |

| State          | Definition                                                    |
|----------------|---------------------------------------------------------------|
| <b>Vacated</b> | Job canceled after partial execution due to a system failure. |

## Task Group (or Req)

A job *task group* (or req) consists of a request for a single type of resources. Each task group consists of the following components:

| Component                    | Description                                                                                                                                                                                |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Task Definition</b>       | A specification of the elementary resources that compose an individual task.                                                                                                               |
| <b>Resource Constraints</b>  | A specification of conditions that must be met for resource matching to occur. Only resources from nodes that meet <i>all</i> resource constraints may be allocated to the job task group. |
| <b>Task Count</b>            | The number of task instances required by the task group.                                                                                                                                   |
| <b>Task List</b>             | The list of nodes on which the task instances are located.                                                                                                                                 |
| <b>Task Group Statistics</b> | Statistics tracking resource utilization.                                                                                                                                                  |

## Nodes

Moab recognizes a node as a collection of resources with a particular set of associated attributes. This definition is similar to the traditional notion of a node found in a Linux cluster or supercomputer wherein a node is defined as one or more CPUs, associated memory, and possibly other compute resources such as local disk, swap, network adapters, and software licenses. Additionally, this node is described by various attributes such as an architecture type or operating system. Nodes range in size from small uniprocessor PCs to large symmetric multiprocessing (SMP) systems where a single node may consist of hundreds of CPUs and massive amounts of memory.

In many cluster environments, the primary source of information about the configuration and status of a compute node is the [resource manager](#). This information can be augmented by additional information sources including node monitors and information services. Further, extensive node policy and node configuration information can be specified within Moab via the graphical tools or the configuration file. Moab aggregates this information and presents a comprehensive view of the node configuration, usages, and state.

While a node in Moab in most cases represents a standard compute host, nodes may also be used to represent more generalized resources. The GLOBAL node possesses floating resources that are available cluster wide, and created virtual nodes (such as network, software, and data nodes) track and allocate resource usage for other resource types.

For additional node information, see [General Node Administration](#).

## Advance Reservations

An advance reservation dedicates a block of specific resources for a particular use. Each reservation consists of a list of resources, an access control list, and a time range for enforcing the access control list. The reservation ensures the matching nodes are used according to the access controls and policy constraints within the time frame specified. For example, a reservation could reserve 20 processors and 10 GB of memory for users Bob and John from Friday 6:00 a.m. to Saturday 10:00 p.m. Moab uses advance reservations extensively to manage backfill, guarantee resource availability for active jobs, allow service guarantees, support deadlines, and enable metascheduling. Moab also supports both regularly recurring reservations and the creation of dynamic one-time reservations for special needs. Advance reservations are described in detail in the [Advance Reservations](#) overview.

## Policies

A configuration file specifies policies controls how and when jobs start. Policies include job prioritization, fairness policies, fairshare configuration policies, and scheduling policies.

## Resources

Jobs, nodes, and reservations all deal with the abstract concept of a resource. A resource in the Moab world is one of the following:

| Resource          | Description                                             |
|-------------------|---------------------------------------------------------|
| <b>processors</b> | Specify with a simple count value                       |
| <b>memory</b>     | Specify real memory or RAM in megabytes (MB)            |
| <b>swap</b>       | Specify virtual memory or <i>swap</i> in megabytes (MB) |
| <b>disk</b>       | Specify local disk in megabytes (MB)                    |

In addition to these elementary resource types, there are two higher level resource concepts used within Moab: [Task](#) and the processor equivalent, or [\(PE\)](#).

## Task

A task is a collection of elementary resources that must be allocated together within a single [node](#). For example, a task may consist of one processor, 512 MB of RAM, and 2 GB of local disk. A key aspect of a task is that the resources associated with the task must be allocated as an atomic unit, without spanning node boundaries. A task requesting 2 processors cannot be satisfied by allocating 2 uniprocessor nodes, nor can a task requesting 1 processor and 1 GB of memory be satisfied by allocating 1 processor on 1 node and memory on another.

In Moab, when jobs or reservations request resources, they do so in terms of tasks typically using a task count and a task definition. By default, a task maps directly to a single processor within a job and maps to a full node within reservations. In all cases, this default definition can be overridden by specifying a new task definition.

Within both jobs and reservations, depending on task definition, it is possible to have multiple tasks from the same job mapped to the same node. For example, a job requesting 4 tasks using the default task definition of 1 processor per task, can be satisfied by 2 dual processor nodes.

## PE

The concept of the processor equivalent, or PE, arose out of the need to translate multi-resource consumption requests into a scalar value. It is not an elementary resource but rather a derived resource metric. It is a measure of the actual impact of a set of requested resources by a job on the total resources available system wide. It is calculated as follows:

$$PE = \text{MAX}(\text{ProcsRequestedByJob} / \text{TotalConfiguredProcs}, \text{MemoryRequestedByJob} / \text{TotalConfiguredMemory}, \text{DiskRequestedByJob} / \text{TotalConfiguredDisk}, \text{SwapRequestedByJob} / \text{TotalConfiguredSwap}) * \text{TotalConfiguredProcs}$$

For example, if a job requested 20% of the total processors and 50% of the total memory of a 128-processor MPP system, only two such jobs could be supported by this system. The job is essentially using 50% of all available resources since the system can only be scheduled to its most constrained resource - memory in this case. The processor equivalents for this job should be 50% of the processors, or PE = 64.

Another example: Assume a homogeneous 100-node system with 4 processors and 1 GB of memory per node. A job is submitted requesting 2 processors and 768 MB of memory. The PE for this job would be calculated as follows:

$$PE = \text{MAX}(2 / (100 * 4), 768 / (100 * 1024)) * (100 * 4) = 3.$$

This result makes sense since the job would be consuming 3/4 of the memory on a 4-processor node.

The calculation works equally well on homogeneous or heterogeneous systems, uniprocessor or large SMP systems.

## Class (or Queue)

A class (or queue) is a logical container object that implicitly or explicitly applies policies to jobs. In most cases, a class is defined and configured within the resource manager and associated with one or more of the following attributes or constraints:

| Attribute                     | Description                                                                                            |
|-------------------------------|--------------------------------------------------------------------------------------------------------|
| <b>Default Job Attributes</b> | A queue may be associated with a default job duration, default size, or default resource requirements. |

| Attribute               | Description                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Host Constraints</b> | A queue may constrain job execution to a particular set of hosts.                                                                                         |
| <b>Job Constraints</b>  | A queue may constrain the attributes of jobs that may be submitted, including setting limits such as max wallclock time and minimum number of processors. |
| <b>Access List</b>      | A queue may constrain who may submit jobs into it based on such things as user lists and group lists.                                                     |
| <b>Special Access</b>   | A queue may associate special privileges with jobs including adjusted job priority.                                                                       |

As stated previously, most resource managers allow full class configuration within the resource manager. Where additional class configuration is required, the [CLASSCFG](#) parameter may be used.

Moab tracks class usage as a consumable resource allowing sites to limit the number of jobs using a particular class. This is done by monitoring class initiators that may be considered to be a ticket to run in a particular class. Any compute node may simultaneously support several types of classes and any number of initiators of each type. By default, nodes will have a one-to-one mapping between class initiators and configured processors. For every job task run on the node, one class initiator of the appropriate type is consumed. For example, a 3-processor job submitted to the class "batch" consumes three batch class initiators on the nodes where it runs.

Using queues as consumable resources allows sites to specify various policies by adjusting the class initiator to node mapping. For example, a site running serial jobs may want to allow a particular 8-processor node to run any combination of batch and special jobs subject to the following constraints:

- Only 8 jobs of any type allowed simultaneously.
- No more than 4 special jobs allowed simultaneously.

To enable this policy, the site may set the node's [MAXJOB](#) policy to 8 and configure the node with 4 special class initiators and 8 batch class initiators.

In virtually all cases, jobs have a one-to-one correspondence between processors requested and class initiators required. However, this is not a requirement, and with special configuration, sites may choose to associate job tasks with arbitrary combinations of class initiator requirements.

In displaying class initiator status, Moab signifies the type and number of class initiators available using the format [[<CLASSNAME>:<CLASSCOUNT>](#)]. This is most commonly seen in the output of node status commands indicating the number of configured and available class initiators, or in job status commands when displaying class initiator requirements.

## Resource Manager (RM)

While other systems may have more strict interpretations of a resource manager and its responsibilities, Moab's multi-resource manager support allows a much more liberal interpretation. In essence, any object that can provide environmental information and environmental control can be used

as a resource manager, including sources of resource, workload, credential, or policy information such as scripts, peer services, databases, web services, hardware monitors, or even flat files. Likewise, Moab considers to be a resource manager any tool that provides control over the cluster environment whether that be a license manager, queue manager, checkpoint facility, provisioning manager, network manager, or storage manager.

Moab aggregates information from multiple unrelated sources into a larger more complete world view of the cluster that includes all the information and control found within a standard resource manager such as [TORQUE](#), including node, job, and queue management services. For more information, see the [Resource Managers and Interfaces](#) overview.

### Arbitrary Resource

Nodes can also be configured to support various arbitrary resources. Use the [NODECFG](#) parameter to specify information about such resources. For example, you could configure a node to have *256 MB RAM, 4 processors, 1 GB Swap, and 2 tape drives*.

## Scheduling Dictionary

| Account                   |                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b>         | A credential also known as "project ID." Multiple users may be associated a single account ID and each user may have access to multiple accounts. (See <a href="#">credential</a> definition and <a href="#">ACCOUNTCFG</a> parameter.)                                                                                                                                                                               |
| <b>Example</b>            | <code>ACCOUNT=hgc13</code>                                                                                                                                                                                                                                                                                                                                                                                            |
| ACL (Access Control List) |                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Definition</b>         | In the context of scheduling, an access control list is used and applied much as it is elsewhere. An ACL defines what credentials are required to access or use particular objects. The principal objects to which ACLs are applied are <a href="#">reservations</a> and <a href="#">QoSs</a> . ACLs may contain both allow and deny statements, include wildcards, and contain rules based on multiple object types. |
| <b>Example</b>            | Reservation META1 contains 4 access statements. <ul style="list-style-type: none"> <li>• Allow jobs owned by user "john" or "bob "</li> <li>• Allow jobs with QoS "premium"</li> <li>• Deny jobs in class "debug"</li> <li>• Allow jobs with a duration of less than 1 hour</li> </ul>                                                                                                                                |

| Allocation        |                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A logical, scalar unit assigned to users on a credential basis, providing access to a particular quantity of compute resources. Allocations are consumed by jobs associated with those credentials. |
| <b>Example</b>    | <code>ALLOCATION=30000</code>                                                                                                                                                                       |

| Class             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | (See <a href="#">Queue</a> ) A class is a logical container object that holds jobs allowing a site to associate various constraints and defaults to these jobs. Class access can also be tied to individual nodes defining whether a particular node will accept a job associated with a given class. Class based access to a node is denied unless explicitly allowed via resource manager configuration. Within Moab, classes are tied to jobs as a <a href="#">credential</a> . |
| <b>Example</b>    | job "cw.073" is submitted to class batch<br>node "cl02" accepts jobs in class batch<br>reservation weekend allows access to jobs in class batch                                                                                                                                                                                                                                                                                                                                    |

| CPU               |                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A single processing unit. A CPU is a consumable resource. Nodes typically consist of one or more CPUs. (same as <a href="#">processor</a> ) |

| Credential        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | An attribute associated with <a href="#">jobs</a> and other objects that determines object identity. In the case of schedulers and resource managers, credential based policies and limits are often established. At submit time, jobs are associated with a number of credentials such as <a href="#">user</a> , <a href="#">group</a> , <a href="#">account</a> , <a href="#">QoS</a> , and <a href="#">class</a> . These job credentials subject the job to various polices and grant it various types of access. In most cases, credentials set both the privileges of the job and the ID of the actual job <a href="#">executable</a> . |
| <b>Example</b>    | Job "cw.24001" possesses the following credentials:<br><code>USER=john;GROUP=staff;ACCOUNT=[NONE];<br/>QOS=[DEFAULT];CLASS=batch</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Disk              |                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A quantity of local disk available for use by batch jobs. Disk is a <a href="#">consumable resource</a> . |

## Execution Environment

**Definition** A description of the environment in which the executable is launched. This environment may include attributes such as the following:

- an executable
- command line arguments
- input file
- output file
- local user ID
- local group ID
- process resource limits

**Example** Job "cw.24001" possesses the following execution environment:

```
EXEC=/bin/sleep;ARGS="60";
INPUT=[NONE];OUTPUT=[NONE];
USER=loadl;GROUP=staff;
```

## Fairshare

**Definition** A mechanism that allows historical resource utilization information to be incorporated into job priority decisions.

## Fairness

**Definition** The access to shared compute resources that each user is granted. Access can be equal or based on factors such as historical resource usage, political issues, and job value.

## Group

**Definition** A [credential](#) typically directly mapping to a user's UNIX group ID.

## Job

**Definition** The fundamental object of resource consumption. A job contains the following components:

- A list of required [consumable resources](#)
- A list of [resource constraints](#) controlling which resources may be allocated to the job
- A list of [job constraints](#) controlling where, when, and how the job should run
- A list of [credentials](#)
- An [execution environment](#)

## Job Constraints

### Definition

A set of conditions that must be fulfilled for the job to start. These conditions are far reaching and may include one or more of the following:

- When the job may run. (After time X, within Y minutes.)
- Which resources may be allocated. (For example, node must possess at least 512 MB of RAM, run only in partition or Partition C, or run on HostA and HostB.)
- Starting job relative to a particular event. (Start after job X successfully completes.)

### Example

```
RELEASETIME>='Tue Feb 12, 11:00AM'
DEPEND=AFTERANY:cw.2004
NODEMEMORY==256MB
```

## Memory

### Definition

A quantity of physical memory (RAM). Memory is provided by compute nodes. It is required as a constraint or consumed as a consumable resource by jobs. Within Moab, memory is tracked and reported in megabytes (MB).

### Example

Node "node001" provides the following resources:

```
PROCS=1, MEMORY=512, SWAP=1024
```

"Job cw.24004" consumes the following resources per task:

```
PROCS=1, MEMORY=256
```

## Node

### Definition

A node is the fundamental object associated with compute resources. Each node contains the following components:

- A list of [consumable resources](#)
- A list of [node attributes](#)

## Node Attribute

### Definition

A node attribute is a non-quantitative aspect of a node. Attributes typically describe the node itself or possibly aspects of various node resources such as processors or memory. While it is probably not optimal to aggregate node and resource attributes together in this manner, it is common practice. Common node attributes include processor architecture, operating system, and processor speed. Jobs often specify that resources be allocated from nodes possessing certain node attributes.

### Example

```
ARCH=AMD, OS=LINUX24, PROCSPEED=950
```

| Node Feature      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A node feature is a <a href="#">node attribute</a> that is typically specified locally via a configuration file. Node features are opaque strings associated with the node by the resource manager that generally only have meaning to the end-user, or possibly to the scheduler. A node feature is commonly associated with a subset of nodes allowing end-users to request use of this subset by requiring that resources be allocated from nodes with this feature present. In many cases, node features are used to extend the information provided by the resource manager. |
| <b>Example</b>    | <pre>FEATURE=s950,pIII,geology</pre> <p><i>This may be used to indicate that the node possesses a 950 MHz Pentium III processor and that the node is owned by the Geology department.</i></p>                                                                                                                                                                                                                                                                                                                                                                                     |

| Processor         |                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A processing unit. A processor is a consumable resource. Nodes typically consist of one or more processors. (same as CPU) |

| Quality of Service (QoS) |                                                                    |
|--------------------------|--------------------------------------------------------------------|
| <b>Definition</b>        | An object that provides special services, resources, and so forth. |

| Queue             |                              |
|-------------------|------------------------------|
| <b>Definition</b> | (see <a href="#">Class</a> ) |

| Reservation       |                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | An object that reserves a specific collection or resources for a specific timeframe for use by jobs that meet specific conditions. |
| <b>Example</b>    | Reserve 24 processors and 8 GB of memory from time T1 to time T2 for use by user X or jobs in the class batch.                     |

| Resource          |                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | Hardware, generic resources such as software, and features available on a node, including memory, disk, swap, and processors. |

## Resource, Available

### Definition

A compute node's [configured](#) resources minus the *maximum* of the sum of the resources [utilized](#) by all job tasks running on the node and the resources [dedicated](#); that is,  $R_{Available} = R_{Configure} - \text{MAX}(R_{Dedicated}, R_{Utilized})$ .

In most cases, resources utilized will be associated with compute jobs that the batch system has started on the compute nodes, although resource consumption may also come from the operating system or *rogue* processes outside of the batch system's knowledge or control. Further, in a well-managed system, utilized resources are less than or equal to dedicated resources and when exceptions are detected, one or more [usage-based limits](#) are activated to [preempt](#) the jobs violating their requested resource usage.

### Example

Node "cl003" has 4 processors and 512 MB of memory. It is executing 2 tasks of job "clserver.0041" that are using 1 processor and 60 MB of memory each. One processor and 250 MB of memory are reserved for user "jsmith" but are not currently in use.

Resources available to user jsmith on node "cl003":

- 2 processors
- 392 MB memory

Resources available to a user other than jsmith on node "cl003":

- 1 processor
- 142 MB memory

## Resource, Configured

### Definition

The total amount of [consumable resources](#) that are available on a compute node for use by job tasks.

### Example

Node "cl003" has 4 processors and 512 MB of memory. It is executing 2 tasks of job "clserver.0041" that are using 1 processor and 60 MB of memory each. One processor and 250 MB of memory are reserved for user "jsmith" but are not currently in use.

Configured resources for node "cl003":

- 4 processors
- 512 MB memory

### Resource, Consumable

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | <p>Any object that can be used (that is, consumed and thus made unavailable to another job) by, or dedicated to a job is considered to be a resource. Common examples of resources are a node's physical memory or local disk. As these resources may be given to one job and thus become unavailable to another, they are considered to be consumable. Other aspects of a node, such as its operating system, are not considered to be consumable since its use by one job does not preclude its use by another. Note that some node objects, such as a network adapter, may be dedicated under some operating systems and resource managers and not under others. On systems where the network adapter cannot be dedicated and the network usage per job cannot be specified or tracked, network adapters are not considered to be resources, but rather attributes.</p> <p>Nodes possess a specific quantity of consumable resources such as real memory, local disk, or processors. In a resource management system, the node manager may choose to report only those configured resources available to batch jobs. For example, a node may possess an 80-GB hard drive but may have only 20 GB dedicated to batch jobs. Consequently, the resource manager may report that the node has 20 GB of local disk available when idle. Jobs may explicitly request a certain quantity of consumable resources.</p> |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Resource, Constraint

|                   |                                                                                                                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | <p>A resource constraint imposes a rule on which resources can be used to match a resource request. Resource constraints either specify a required quantity and type of resource or a required node attribute. All resource constraints must be met by any given node to establish a match.</p> |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Resource, Dedicated

|                   |                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | <p>A job may request that a block of resources be dedicated while the job is executing. At other times, a certain number of resources may be reserved for use by a particular user or group. In these cases, the scheduler is responsible for guaranteeing that these resources, <a href="#">utilized</a> or not, are set aside and made unavailable to other jobs.</p>                              |
| <b>Example</b>    | <p>Node "cl003" has 4 processors and 512 MB of memory. It is executing 2 tasks of job "clserver.0041" that are using 1 processor and 60 MB of memory each. One processor and 250 MB of memory are reserved for user "jsmith" but are not currently in use.</p> <p>Dedicated resources for node "cl003":</p> <ul style="list-style-type: none"> <li>• 1 processor</li> <li>• 250 MB memory</li> </ul> |

### Resource, Utilized

|                   |                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | <p>All <a href="#">consumable</a> resources actually used by all job tasks running on the compute node.</p> |
|-------------------|-------------------------------------------------------------------------------------------------------------|

## Resource, Utilized

|                |                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Example</b> | <p>Node "cl003" has 4 processors and 512 MB of memory. It is executing 2 tasks of job "clserver.0041" that are using 1 processor and 60 MB of memory each. One processor and 250 MB of memory are reserved for user "jsmith" but are not currently in use.</p> <p>Utilized resources for node "cl003":</p> <ul style="list-style-type: none"> <li>• 2 processors</li> <li>• 120 MB memory</li> </ul> |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Swap

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | A quantity of virtual memory available for use by batch jobs. Swap is a consumable resource provided by nodes and consumed by jobs. |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|

## Task

|                   |                                               |
|-------------------|-----------------------------------------------|
| <b>Definition</b> | An atomic collection of consumable resources. |
|-------------------|-----------------------------------------------|

## User, Global

|                   |                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Definition</b> | The user credential used to provide access to functions and resources. In local scheduling, global user IDs map directly to local user IDs. |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------|

## User, Local

|                   |                                                                      |
|-------------------|----------------------------------------------------------------------|
| <b>Definition</b> | The user credential under which the job executable will be launched. |
|-------------------|----------------------------------------------------------------------|

## Workload

|                   |                   |
|-------------------|-------------------|
| <b>Definition</b> | Generalized term. |
|-------------------|-------------------|

# Scheduling Iterations and Job Flow

- [Scheduling Iterations](#)
  - [Update State Information](#)
  - [Handle User Requests](#)

- [Perform Next Scheduling Cycle](#)
- [Detailed Job Flow](#)
  - [Determine Basic Job Feasibility](#)
  - [Prioritize Jobs](#)
  - [Enforce Configured Throttling Policies](#)
  - [Determine Resource Availability](#)
  - [Allocate Resources to Job](#)
  - [Launch Job](#)

## Scheduling Iterations

In any given scheduling iteration, many activities take place, examples of which are listed below:

- [Refresh reservations](#)
- [Schedule reserved jobs](#)
- [Schedule priority jobs](#)
- [Backfill jobs](#)
- [Update statistics](#)
- [Update State Information](#)
- [Handle User Requests](#)
- [Perform Next Scheduling Cycle](#)

### Update State Information

Each iteration, the scheduler contacts the resource manager(s) and requests up-to-date information on compute resources, workload, and policy configuration. On most systems, these calls are to a centralized resource manager daemon that possesses all information. Jobs may be reported as being in any of the following states listed in the [job state](#) table.

### Handle User Requests

User requests include any call requesting state information, configuration changes, or job or resource manipulation commands. These requests may come in the form of user client calls, peer daemon calls, or process signals.

### Perform Next Scheduling Cycle

Moab operates on a polling/event driven basis. When all scheduling activities complete, Moab processes user requests until a new resource manager event is received or an internal event is generated. Resource manager events include activities such as a new job submission or completion of an active job, addition of new node resources, or changes in resource manager policies. Internal events include

administrator [schedule](#) requests, reservation activation/deactivation, or the expiration of the [RMPOLLINTERVAL](#) timer.

## Detailed Job Flow

### Determine Basic Job Feasibility

The first step in scheduling is determining which jobs are feasible. This step eliminates jobs that have job holds in place, invalid job states (such as Completed, Not Queued, Deferred), or unsatisfied preconditions. Preconditions may include stage-in files or completion of preliminary job steps.

### Prioritize Jobs

With a list of feasible jobs created, the next step involves [determining the relative priority](#) of all jobs within that list. A priority for each job is calculated based on job attributes such as job owner, job size, and length of time the job has been queued.

### Enforce Configured Throttling Policies

Any configured [throttling policies](#) are then applied constraining how many jobs, nodes, processors, and so forth are allowed on a per credential basis. Jobs that violate these policies are not considered for scheduling.

### Determine Resource Availability

For each job, Moab attempts to locate the required compute resources needed by the job. For a match to be made, the node must possess all node attributes specified by the job and possess adequate available resources to meet the "TasksPerNode" job constraint. (Default "TasksPerNode" is 1.) Normally, Moab determines that a node has adequate resources if the resources are *neither utilized by nor dedicated to* another job using the calculation.

$R.Available = R.Configured - MAX(R.Dedicated, R.Utilized)$ .

The [NODEAVAILABILITYPOLICY on page 1000](#) parameter can be modified to adjust this behavior.

### Allocate Resources to Job

If adequate resources can be found for a job, the [node allocation policy](#) is then applied to select the best set of resources. These allocation policies allow selection criteria such as speed of node, type of reservations, or excess node resources to be figured into the allocation decision to improve the performance of the job and maximize the freedom of the scheduler in making future scheduling decisions.

### Launch Job

With the resources selected and task distribution mapped, the scheduler then contacts the resource manager and informs it where and how to launch the job. The resource manager then initiates the actual job executable.

## Configuring the Scheduler

- [Adjusting Server Behavior](#)
  - [Logging](#)
  - [Checkpointing](#)
  - [Client Interface](#)
  - [Scheduler Mode](#)
  - [Configuring a job ID offset on page 116](#)

Scheduler configuration is maintained using the flat text configuration file `moab.cfg`. All configuration file entries consist of simple `<PARAMETER> <VALUE>` pairs that are whitespace delimited. Parameter names are not case sensitive but `<VALUE>` settings are. Some parameters are array values and should be specified as `<PARAMETER>[<INDEX>]` (Example: `QOSCFG[hiprio] PRIORITY=1000`); the `<VALUE>` settings may be integers, floats, strings, or arrays of these. Some parameters can be specified as arrays wherein index values can be numeric or alphanumeric strings. If no array index is specified for an array parameter, an index of zero (0) is assumed. The example below includes both array based and non-array based parameters:

```
SCHEDCFG[cluster2] SERVER=head.c2.org MODE=NORMAL
LOGLEVEL 6
LOGDIR /var/tmp/moablog
```

See the [parameters](#) documentation for information on specific parameters.

The `moab.cfg` file is read when Moab is started up or recycled. Also, the `mschedctl -m` command can be used to reconfigure the scheduler at any time, updating some or all of the configurable parameters dynamically. This command can be used to modify parameters either permanently or temporarily. For example, the command `mschedctl -m LOGLEVEL 3` will temporarily adjust the scheduler log level. When the scheduler restarts, the log level restores to the value stored in the Moab configuration files. To adjust a parameter permanently, the option `--flags=persistent` should be set.

At any time, the current server parameter settings may be viewed using the `mschedctl -l` command.

### Adjusting Server Behavior

Most aspects of Moab behavior are configurable. This includes both scheduling policy behavior and daemon behavior. In terms of configuring server behavior, the following realms are most commonly modified.

#### Logging

Moab provides extensive and highly configurable logging facilities controlled by parameters.

| Parameter              | Description                        |
|------------------------|------------------------------------|
| <a href="#">LOGDIR</a> | Indicates directory for log files. |

| Parameter                               | Description                                        |
|-----------------------------------------|----------------------------------------------------|
| <a href="#"><u>LOGFACILITY</u></a>      | Indicates scheduling facilities to track.          |
| <a href="#"><u>LOGFILE</u></a>          | Indicates path name of log file.                   |
| <a href="#"><u>LOGFILEMAXSIZE</u></a>   | Indicates maximum size of log file before rolling. |
| <a href="#"><u>LOGFILEROLLDEPTH</u></a> | Indicates maximum number of log files to maintain. |
| <a href="#"><u>LOGLEVEL</u></a>         | Indicates verbosity of logging.                    |

## Checkpointing

Moab checkpoints its internal state. The checkpoint file records statistics and attributes for jobs, nodes, reservations, users, groups, classes, and almost every other scheduling object.

| Parameter                                       | Description                                                                                                                                        |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#"><u>CHECKPOINTEXPIRATIONTIME</u></a> | Indicates how long unmodified data should be kept after the associated object has disappeared; that is, job priority for a job no longer detected. |
| <a href="#"><u>CHECKPOINTFILE</u></a>           | Indicates path name of checkpoint file.                                                                                                            |
| <a href="#"><u>CHECKPOINTINTERVAL</u></a>       | Indicates interval between subsequent checkpoints.                                                                                                 |

## Client Interface

The Client interface is configured using the [SCHEDCFG](#) parameter. Most commonly, the attributes **SERVER** and **PORT** must be set to point client commands to the appropriate Moab server. Other parameters such as [CLIENTTIMEOUT](#) may also be set.

## Scheduler Mode

The scheduler mode of operation is controlled by setting the **MODE** attribute of the [SCHEDCFG](#) parameter. The following modes are allowed:

| Mode               | Description                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>INTERACTIVE</b> | Moab interactively confirms each scheduling action before taking any steps. (See <a href="#"><u>interactive mode overview</u></a> for more information.) |

| Mode              | Description                                                                                                                                                                                                                                                                                                                                        |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MONITOR</b>    | Moab observes cluster and workload performance, collects statistics, interacts with allocation management services, and evaluates failures, but it does not actively alter the cluster, including job migration, workload scheduling, and resource provisioning. (See <a href="#">monitor mode overview</a> for more information.)                 |
| <b>NORMAL</b>     | Moab actively schedules workload according to mission objectives and policies; it creates reservations; starts, cancels, preempts, and modifies jobs; and takes other scheduling actions.                                                                                                                                                          |
| <b>SIMULATION</b> | Moab obtains <a href="#">workload</a> and <a href="#">resource</a> information from specified simulation trace files and schedules the defined virtual environment.                                                                                                                                                                                |
| <b>SINGLESTEP</b> | Moab behaves as in <a href="#">NORMAL</a> mode but will only schedule a single iteration and then exit.                                                                                                                                                                                                                                            |
| <b>SLAVE</b>      | Moab behaves as in <a href="#">NORMAL</a> mode but will only start a job when explicitly requested by a trusted <a href="#">grid peer</a> service or <a href="#">administrator</a> .                                                                                                                                                               |
| <b>TEST</b>       | Moab behaves as in <a href="#">NORMAL</a> mode, will make reservations, and scheduling decisions, but will then only log scheduling actions it would have taken if running in <a href="#">NORMAL</a> mode. In most cases, "TEST" mode is identical to <a href="#">MONITOR</a> mode. (See <a href="#">test mode overview</a> for more information.) |

## Configuring a job ID offset

Moab assigns job IDs as integers in numeric order as jobs are submitted, starting with 1. In some situations, you might want to offset the integer at which Moab starts to assign job IDs in your system.

This example describes how you would offset the job IDs in a compound system consisting of Site A, Site B, and Site C, each of which runs its own instance of Moab. Users belonging to any of the sites can submit jobs to their own site and to the other two. To simplify aggregation of usage records from the three sites, offset the job IDs for Site B to a starting value higher than the expected total lifetime value for the system; in this example, to **20000000**. Likewise, set Site C to 20,000,000 more, or **40000000**. To do so, set the **MINJOBID** attribute of **SCHEDCFG** in each system's `moab.cfg` to the offset value. To ensure that Moab will never use the same job ID for two different sites, also set **MAXJOBID**. If the Moab job naming process ever reaches the **MAXJOBID**, it will start over again with the **MINJOBID**.

```
SCHEDCFG[moab] SERVER=moab_siteA:4244 MAXJOBID=19999999
```

```
SCHEDCFG[moab] SERVER=moab_siteB:4344 MINJOBID=20000000 MAXJOBID=39999999
```

```
SCHEDCFG[moab] SERVER=moab_siteC:4444 MINJOBID=40000000 MAXJOBID=59999999
```

When users submit jobs to Moab using [msub on page 286](#), Moab selects the job ID in numeric order, starting with 1 in Site A, 20000000 in Site B, and 40000000 in Site C.

If the compound system in this example uses TORQUE as its resource manager and users submit jobs directly to TORQUE using [qsub](#), TORQUE assigns the job ID instead of Moab. In this case, you should also

offset the TORQUE job IDs by setting the [next\\_job\\_number on page 2779](#) server parameter of Site B and Site C to `20000000` and `40000000`, respectively.

```
$user qmgr "set server next_job_number=20000000"
```

```
$user qmgr "set server next_job_number=40000000"
```

**i** TORQUE job ID limits will allow you to use the 20,000,000 offset scheme for up to 4 sites.

## Credential Overview

Moab supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features. There are five types of credentials - [user](#), [group](#), [account](#), [class](#), and [QoS](#). While the credentials have many similarities, each plays a slightly different role.

- [General Credential Attributes](#)
- [User Credential](#)
- [Group Credential](#)
- [Account \(or Project\) Credential](#)
- [Class \(or Queue\) Credential](#)
- [QoS Credential](#)

## General Credential Attributes

Internally, credentials are maintained as objects. Credentials can be created, destroyed, queried, and modified. They are associated with jobs and requests providing access and privileges. Each credential type has the following attributes:

- [Priority Settings](#)
- [Usage Limits](#)
- [Service Targets](#)
- [Credential and Partition Access](#)
- [Statistics](#)
- [Credential Defaults, State and Configuration Information](#)

All credentials represent a form of identity, and when applied to a job, express ownership. Consequently, jobs are subject to policies and limits associated with their owners.

## Credential Priority Settings

Each credential may be assigned a priority using the **PRIORITY** attribute. This priority affects a job's total credential priority factor as described in the [Priority Factors](#) section. In addition, each credential may also specify priority weight offsets, which adjust priority weights that apply to associated jobs. These priority weight offsets include [FSWEIGHT](#) (See [Priority-Based Fairshare](#) for more information.), [QTWEIGHT](#), and [XFWEIGHT](#).

For example:

```
# set priority weights
CREDWEIGHT 1
USERWEIGHT 1
CLASSWEIGHT 1
SERVICEWEIGHT 1
XFACTORWEIGHT 10
QUEUETIMEWEIGHT 1000
# set credential priorities
USERCFG[john] PRIORITY=200
CLASSCFG[batch] PRIORITY=15
CLASSCFG[debug] PRIORITY=100
QOFCFG[bottomfeeder] QTWEIGHT=-50 XFWEIGHT=100
ACCOUNTCFG[topfeeder] PRIORITY=100
```

## Credential Usage Limits

Usage limits constrain which jobs may run, which jobs may be considered for scheduling, and what quantity of resources each individual job may consume. With usage limits, policies such as [MAXJOB](#), [MAXNODE](#), and [MAXMEM](#) may be enforced against both idle and active jobs. Limits may be applied in any combination as shown in the example below where usage limits include 32 active processors per group and 12 active jobs for user *john*. For a job to run, it must satisfy the most limiting policies of all associated credentials. The [Throttling Policy](#) section documents credential usage limits in detail.

```
GROUPCFG[DEFAULT] MAXPROC=32 MAXNODE=100
GROUPCFG[staff] MAXNODE=200
USERCFG[john] MAXJOB=12
```

## Service Targets

Credential service targets allow jobs to obtain special treatment to meet usage or response time based metrics. Additional information about service targets can be found in the [Fairshare](#) section.

## Credential and Partition Access

Access to partitions and to other credentials may be specified on a per credential basis with credential [access lists](#), [default credentials](#), and credential [membership lists](#).

### Credential Access Lists

You can use the **ALIST**, **PLIST**, and **QLIST** attributes (shown in the following table) to specify the list of credentials or partitions that a given credential may access.

| Credential       | Attribute                                                                           |
|------------------|-------------------------------------------------------------------------------------|
| <b>Account</b>   | <b>ALIST</b> (allows credential to access specified list of accounts)               |
| <b>Partition</b> | <b>PLIST</b> (allows credential to access specified list of partitions)             |
| <b>QoS</b>       | <b>QLIST</b> (allows credential to access specified list of <a href="#">QoSes</a> ) |

*Example 3-1:*

```
USERCFG[bob]    ALIST=jupiter,quantum
USERCFG[steve] ALIST=quantum
```

**i** Account-based access lists are only enforced if using an allocation manager or if the **ENFORCEACCOUNTACCESS** parameter is set to "TRUE."

*Assigning Default Credentials*

Use the **\*DEF** attribute (shown in the following table) to specify the default credential or partition for a particular credential.

| Credential     | Attribute                               |
|----------------|-----------------------------------------|
| <b>Account</b> | <b>ADEF</b> (specifies default account) |
| <b>Class</b>   | <b>CDEF</b> (specifies default class)   |
| <b>QoS</b>     | <b>QDEF</b> (specifies default QoS)     |

*Example 3-2:*

```
# user bob can access accounts a2, a3, and a6. If no account is explicitly requested,
# his job will be assigned to account a3
USERCFG[bob]    ALIST=a2,a3,a6 ADEF=a3
# user steve can access accounts a14, a7, a2, a6, and a1. If no account is explicitly
# requested, his job will be assigned to account a2
USERCFG[steve] ALIST=a14,a7,a2,a6,a1 ADEF=a2
```

*Specifying Credential Membership Lists*

As an alternate to specifying access lists, administrators may also specify membership lists. This allows a credential to specify who can access it rather than allowing each credential to specify which credentials it can access. Membership lists are controlled using the **MEMBERULIST**, **EXCLUDEUSERLIST** and **REQUIREDUSERLIST** attributes, shown in the following table:

| Credential          | Attribute                                                            |
|---------------------|----------------------------------------------------------------------|
| User                | ---                                                                  |
| Account, Group, QoS | <b>MEMBERULIST</b>                                                   |
| Class               | <a href="#">EXCLUDEUSERLIST</a> and <a href="#">REQUIREDUSERLIST</a> |

Example 3-3:

```
# account omega3 can only be accessed by users johnh, stevek, jenp
ACCOUNTCFG[omega3] MEMBERULIST=johnh,stevek,jenp
```

Example 3-4: Controlling Partition Access on a Per User Basis

A site may specify the user john may access partitions atlas, pluto, and zeus and will default to partition pluto. To do this, include the following line in the configuration file:

```
USERCFG[john] PLIST=atlas,pluto,zeus
```

Example 3-5: Controlling QoS Access on a Per Group Basis

A site may also choose to allow everyone in the group staff to access QoS standard and special with a default QoS of standard. To do this, include the following line in the configuration file:

```
GROUPCFG[staff] QLIST=standard,special QDEF=standard
```

Example 3-6: Controlling Resource Access on a Per Account Basis

An organization wants to allow everyone in the account omega3 to access nodes 20 through 24. To do this, include the following in the configuration file:

```
ACCOUNTCFG[omega3] MEMBERULIST=johnh,stevek,jenp
SRCFG[omega3] HOSTLIST=r:20-24 ACCOUNTLIST=omega3
```

## Credential Statistics

Full statistics are maintained for each credential instance. These statistics record current and historical resource usage, level of service delivered, accuracy of requests, and many other aspects of workload. Note, though, that you must explicitly enable credential statistics as they are not tracked by default. You can enable credential statistics by including the following in the configuration file:

```
USERCFG[DEFAULT]          ENABLEPROFILING=TRUE
GROUPCFG[DEFAULT]        ENABLEPROFILING=TRUE
ACCOUNTCFG[DEFAULT]      ENABLEPROFILING=TRUE
CLASSCFG[DEFAULT]        ENABLEPROFILING=TRUE
QOSCFG[DEFAULT]          ENABLEPROFILING=TRUE
```

## Job Defaults, Credential State, and General Configuration

Credentials may apply defaults and force job configuration settings via the following parameters:

| COMMENT            |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Associates a comment string with the target credential.                                                                           |
| <b>Example</b>     | <pre>USERCFG[steve] COMMENT='works for boss, provides good service' CLASSCFG[i3] COMMENT='queue for I/O intensive workload'</pre> |

| HOLD               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>Specifies a hold should be placed on all jobs associated with the target credential.</p> <div style="border: 1px solid black; padding: 5px; margin: 5px 0;"> <p><b>i</b> The order in which this <b>HOLD</b> attribute is evaluated depends on the following credential precedence: <b>USERCFG</b>, <b>GROUPCFG</b>, <b>ACCOUNTCFG</b>, <b>CLASSCFG</b>, <b>QOSCFG</b>, <b>USERCFG</b> <i>[DEFAULT]</i>, <b>GROUPCFG</b> <i>[DEFAULT]</i>, <b>ACCOUNTCFG</b> <i>[DEFAULT]</i>, <b>CLASSCFG</b> <i>[DEFAULT]</i>, <b>QOSCFG</b> <i>[DEFAULT]</i>.</p> </div> |
| <b>Example</b>     | <pre>GROUPCFG[bert] HOLD=yes</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| JOBFLAGS           |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Description</b> | Assigns the specified <a href="#">job flag</a> to all jobs with the associated credential. |
| <b>Example</b>     | <pre>CLASSCFG[batch] JOBFLAGS=suspendable QOSCFG[special] JOBFLAGS=restartable</pre>       |

| NOSUBMIT           |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Description</b> | Specifies whether jobs belonging to this credential can submit jobs using <code>msub</code> . |
| <b>Example</b>     | <pre>ACCOUNTCFG[general] NOSUBMIT=TRUE CLASSCFG[special] NOSUBMIT=TRUE</pre>                  |

| OVERRUN            |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Specifies the amount of time a job may exceed its wallclock limit before being terminated. (Only applies to user and class credentials.) |
| <b>Example</b>     | <pre>CLASSCFG[bigmem] OVERRUN=00:15:00</pre>                                                                                             |

| VARIABLE           |                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Specifies attribute-value pairs associated with the specified credential. These variables may be used in triggers and other interfaces to modify system behavior. |
| <b>Example</b>     | <pre>GROUPCFG[staff] VARIABLE='nocharge=true'</pre>                                                                                                               |

Credentials may carry additional configuration information. They may specify that detailed statistical profiling should occur, that submitted jobs should be held, or that corresponding jobs should be marked as preemptible.

## User Credential

The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

As the fundamental credential, the user credential has a number of unique attributes.

- [Role](#)
- [Email Address](#)
- [Disable Moab User Email](#)

### Role

Moab supports role-based authorization, mapping particular roles to collections of specific users. See the [Security](#) section for more information.

### Email Address

Facilities exist to allow user notification in the event of job or system failures or under other general conditions. This attribute allows these notifications to be mailed directly to the target user.

```
USERCFG[sally] EMAILADDRESS=sally@acme.com
```

### Disable Moab User Email

You can disable Moab email notifications for a specific user.

```
USERCFG[john] NOEMAIL=TRUE
```

## Group Credential

The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-

to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.

With many resource managers such as TORQUE, PBSPro, and LSF, the group associated with a job is either the user's active primary group as specified within the operating system or a group that is explicitly requested at job submission time. When a secondary group is requested, the user's default group and associated policies are not taken into account. Also note that a job may only run under one group. If more constraining policies are required for these systems, an alternate aggregation scheme such as the use of [Account](#) or [QOS](#) credentials is recommended.

To submit a job as a secondary group, refer to your local resource manager's job submission options. For TORQUE users, see the `group_list=g_list` option of the [qsub -W](#) command.

## Account Credential

The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes. User-to-accounting mapping may be obtained from a resource manager or allocation manager, or you can configure it directly within Moab. Access to an account can be controlled via the **ALIST** and **ADEF** credential attributes specified via the [Identity Manager](#) or the `moab.cfg` file.

The **MANAGERS** attribute (applicable only to the account and [class](#) credentials) allows an administrator to assign a user the ability to manage jobs inside the credential, as if the user is the job owner.

### Example 3-7: MANAGERS Attribute

```
ACCOUNTCFG [general]   MANAGERS=ops
ACCOUNTCFG [special]  MANAGERS=stevep
```

If a user is able to access more than one account, the desired account can be specified at job submission time using the resource-manager specific attribute. For example, with [TORQUE](#) this is accomplished using the `-A` argument to the [qsub](#) command.

### Example 3-8: Enforcing Account Usage

Job-to-account mapping can be enforced using the **ALIST** attribute and the [ENFORCEACCOUNTACCESS](#) parameter.

```
USERCFG [john]        ALIST=proj1,proj3
USERCFG [steve]       ALIST=proj2,proj3,proj4
USERCFG [brad]        ALIST=proj1
USERCFG [DEFAULT]    ALIST=proj2
ENFORCEACCOUNTACCESS TRUE
...
```

## Class Credential

- [Class Job Defaults](#)
- [Per Job Min/Max Limits](#)
- [Resource Access](#)
- [Class Membership Constraints](#)

- [Attributes Enabling Class Access to Other Credentials](#)
- [Special Class Attributes \(such as Managers and Job Prologs\)](#)
- [Setting Default Classes](#)
- [Creating a Remap Class](#)
- [Class Attribute Overview](#)
- [Enabling Queue Complex Functionality](#)

The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab. Class attributes include the following:

- [Job Defaults](#)
- [Per Job Min/Max Limits](#)
- [Resource Access Constraints](#)
- [Class Membership Constraints](#)
- [Attributes Enabling Class Access to Other Credentials](#)
- [Special Class Attributes](#)

**i** When using [SLURM](#), Moab classes have a one-to-one relationship with SLURM partitions of the same name.

**i** For all classes configured in Moab, a resource manager queue with the same name should be created.

**i** When TORQUE reports a new queue to Moab a class of the same name is automatically applied to all nodes.

### Class Job Defaults

Classes can be assigned to a default [job template](#) that can apply values to job attributes not explicitly specified by the submitter. Additionally, you can specify shortcut attributes from the table that follows:

| Attribute           | Description           |
|---------------------|-----------------------|
| <b>DEFAULT.ATTR</b> | Job Attribute         |
| <b>DEFAULT.DISK</b> | Required Disk (in MB) |

| Attribute               | Description                           |
|-------------------------|---------------------------------------|
| <b>DEFAULT.EXT</b>      | Job RM Extension                      |
| <b>DEFAULT.FEATURES</b> | Required Node Features/Properties     |
| <b>DEFAULT.GRES</b>     | Required Consumable Generic Resources |
| <b>DEFAULT.MEM</b>      | Required Memory/RAM (in MB)           |
| <b>DEFAULT.NODESET</b>  | Node Set Specification                |
| <b>DEFAULT.PROC</b>     | Required Processor Count              |
| <b>DEFAULT.TPN</b>      | Tasks Per Node                        |
| <b>DEFAULT.WCLIMIT</b>  | Wallclock Limit                       |

**i** Defaults set in a class/queue of the resource manager will override the default values of the corresponding class/queue specified in Moab.

**i** [RESOURCELIMITPOLICY](#) must be configured in order for the **CLASSCFG** limits to take effect.

Example 3-9:

```
CLASSCFG [batch] DEFAULT.DISK=200MB DEFAULT.FEATURES=prod DEFAULT.WCLIMIT=1:00:00
CLASSCFG [debug] DEFAULT.FEATURES=debug DEFAULT.WCLIMIT=00:05:00
```

### Per Job Min/Max Limits

Classes can be assigned a minimum and a maximum [job template](#) that constrains resource requests. Jobs submitted to a particular queue must meet the resource request constraints of these templates. If a job submission exceeds these limits, the entire job submission fails.

| Limit                   | Description                   |
|-------------------------|-------------------------------|
| <b>MAX.ARRAYSUBJOBS</b> | Max Allowed Jobs in an Array  |
| <b>MAX.CPUTIME</b>      | Max Allowed Utilized CPU Time |
| <b>MAX.NODE</b>         | Max Allowed Node Count        |

| Limit              | Description                     |
|--------------------|---------------------------------|
| <b>MAX.PROC</b>    | Max Allowed Processor Count     |
| <b>MAX.PS</b>      | Max Requested Processor-Seconds |
| <b>MIN.NODE</b>    | Min Allowed Node Count          |
| <b>MIN.PROC</b>    | Min Allowed Processor Count     |
| <b>MIN.PS</b>      | Min Requested Processor-Seconds |
| <b>MIN.TPN</b>     | Min Tasks Per Node              |
| <b>MIN.WCLIMIT</b> | Min Requested Wallclock Limit   |
| <b>MAX.WCLIMIT</b> | Max Requested Wallclock Limit   |

**i** The parameters listed in the preceding table are for classes and PARCFG only, not users, accounts, groups or QoSes, and they function on a per-job basis. The **MAX.\*** and **MIN.\*** parameters are different from the **MAXJOB**, **MAXNODE**, and **MAXMEM** parameters described earlier in [Credential Usage Limits](#).

## Resource Access

Classes may be associated with a particular set of compute resources. Consequently, jobs submitted to a given class may only use listed resources. This may be handled at the [resource manager](#) level or via the [CLASSCFG HOSTLIST](#) attribute.

## Class Membership Constraints

Classes may be configured at either the resource manager or scheduler level to only allow select users and groups to access them. Jobs that do not meet these criteria are rejected. If specifying class membership/access at the resource manager level, see the respective resource manager documentation. Moab automatically detects and enforces these constraints. If specifying class membership/access at the scheduler level, use the **REQUIREDUSERLIST** or **EXCLUDEUSERLIST** attributes of the [CLASSCFG](#) parameter.

**i** Under most resource managers, jobs must always be a member of one and only one class.

## Attributes Enabling Class Access to Other Credentials

Classes may be configured to allow jobs to access other credentials such as QoSs and Accounts. This is accomplished using the [QDEF](#), [QLIST](#), [ADEF](#), and [ALIST](#) attributes.

## Special Class Attributes

The class object also possesses a few unique attributes including [JOBPROLOG](#), [JOBPILOG](#), [RESFAILPOLICY](#), and [DISABLEAM](#) attributes described in what follows:

### MANAGERS

Users listed via the **MANAGERS** parameter are granted full control over all jobs submitted to or running within the specified class.

```
# allow john and steve to cancel and modify all jobs submitted to the class/queue
special
CLASSCFG[special] MANAGERS=john,steve
```

In particular, a class manager can perform the following actions on jobs within a class/queue:

- view/diagnose job ([checkjob](#))
- cancel, requeue, suspend, resume, and checkpoint job ([mjobctl](#))
- modify job ([mjobctl](#))

### JOBPROLOG

The **JOBPROLOG** class performs a function similar to the resource manager level job prolog feature; however, there are some key differences:

- Moab prologs execute on the head node; resource manager prologs execute on the nodes allocated to the job.
- Moab prologs execute as the primary Moab administrator, resource manager prologs execute as root.
- Moab prologs can incorporate cluster environment information into their decisions and actions. (See [Valid Variables](#).)
- Unique Moab prologs can be specified on a per class basis.
- Job start requests are not sent to the resource manager until the Moab job prolog is successfully completed.
- Error messages generated by a Moab prolog are attached to jobs and associated objects; stderr from prolog script is attached to job.
- Moab prologs have access to Moab internal and peer services.

Valid epilog and prolog variables are:

| Variable      | Description                    |
|---------------|--------------------------------|
| <b>\$TIME</b> | Time that the trigger launches |
| <b>\$HOME</b> | Moab home directory            |

| Variable            | Description                        |
|---------------------|------------------------------------|
| <b>\$USER</b>       | User name the job is running under |
| <b>\$JOBID</b>      | Unique job identifier              |
| <b>\$HOSTLIST</b>   | Entire host list for job           |
| <b>\$MASTERHOST</b> | Master host for job                |

The **JOBPROLOG** class attribute allows a site to specify a unique per-class action to take before a job is allowed to start. This can be used for environmental provisioning, pre-execution resource checking, security management, and other functions. Sample uses may include enabling a VLAN, mounting a global file system, installing a new application or virtual node image, creating dynamic storage partitions, or activating job specific software services.

**i** A prolog is considered to have failed if it returns a negative number. If a prolog fails, the associated job will not start.

**i** If a prolog executes successfully, the associated epilog is guaranteed to start, even if the job fails for any reason. This allows the epilog to undo any changes made to the system by the prolog.

### Job Prolog Examples

```
# explicitly specify prolog arguments for special epilog
CLASSCFG[special] JOBPROLOG='$TOOLSDIR/specialprolog.pl $JOBID $HOSTLIST'
# use default prolog arguments for batch prolog
CLASSCFG[batch] JOBPROLOG=$TOOLSDIR/batchprolog.pl
```

### JOBEPILOG

The Moab epilog is nearly identical to the prolog in functionality except that it runs after the job completes within the resource manager but before the scheduler releases the allocated resources for use by subsequent jobs. It is commonly used for job clean-up, file transfers, signaling peer services, and undoing other forms of resource customization.

**i** An epilog is considered to have failed if it returns a negative number. If an epilog fails, the associated job will be annotated and a message will be sent to administrators.

### RESFAILPOLICY

This policy allows specification of the action to take on a per-class basis when a failure occurs on a node allocated to an actively running job. See the [Node Availability Overview](#) for more information.

## DISABLEAM

You can disable allocation management for jobs in specific classes by setting the **DISABLEAM** class attribute to **TRUE**. For all jobs outside of the specified classes, allocation enforcement will continue to be enforced.

```
# do not enforce allocations on low priority and debug jobs
CLASSCFG[lowprio]  DISABLEAM=TRUE
CLASSCFG[debug]    DISABLEAM=TRUE
```

## Setting Default Classes

In many cases, end-users do not want to be concerned with specifying a job class/queue. This is often handled by defining a default class. Whenever a user does not explicitly submit a job to a particular class, a default class, if specified, is used. In resource managers such as [TORQUE](#), this can be done at the resource manager level and its impact is transparent to the scheduler. The default class can also be enabled within the scheduler on a per resource manager or per user basis. To set a resource manager default class within Moab, use the **DEFAULTCLASS** attribute of the [RMCFG](#) parameter. For per user defaults, use the **CDEF** attribute of the [USERCFG](#) parameter.

## Creating a Remap Class

If a single default class is not adequate, Moab provides more flexible options with the [REMAPCLASS](#) parameter. If this parameter is set and a job is submitted to the remap class, Moab attempts to determine the final class to which a job belongs based on the resources requested. If a remap class is specified, Moab compares the job's requested nodes, processors, memory, and node features with the class's corresponding minimum and maximum resource limits. Classes are searched in the order in which they are defined; when the first match is found, Moab assigns the job to that class.

Because Moab remaps at job submission, updates you make to job requirements after submission will not cause any class changes. Moab does not restart the process.

In order to use **REMAPCLASS**, you must specify a **DEFAULTCLASS**. For example:

```
RMCFG[internal] DEFAULTCLASS=batch
```

In the example that follows, a job requesting 4 processors and the node feature *fast* are assigned to the class *quick*.

```
# You must specify a default class in order to use remap classes
RMCFG[internal]   DEFAULTCLASS=batch

# Jobs submitted to "batch" should be remapped
REMAPCLASS       batch

# stevens only queue
CLASSCFG[stevens] REQ.FEATURES=stevens REQUIREDUSERLIST=stevens,steven2

# Special queue for I/O nodes
CLASSCFG[io]      MAX.PROC=8 REQ.FEATURES=io

# General access queues
CLASSCFG[quick]   MIN.PROC=2 MAX.PROC=8 REQ.FEATURES=fast|short
CLASSCFG[medium]  MIN.PROC=2 MAX.PROC=8
CLASSCFG[DEFAULT] MAX.PROC=64
...
```

The following parameters can be used to remap jobs to different classes:

- **MIN.PROC**
- **MAX.PROC**
- **MIN.WCLIMIT**
- **MAX.WCLIMIT**
- **REQ.FEATURES**
- **REQ.FLAGS=INTERACTIVE**
- **REQUIREDUSERLIST**

If the parameter [REMAPCLASSLIST](#) is set, then only the listed classes are searched and they are searched in the order specified by this parameter. If none of the listed classes are valid for a particular job, that job retains its original class.

**i** The remap class only works with resource managers that allow dynamic modification of a job's assigned class/queue.

**i** If default credentials are specified on a remap class, a job submitted to that class will inherit those credentials. If the destination class has different default credentials, the new defaults override the original settings. If the destination class does not have default credentials, the job maintains the defaults inherited from the remap class.

## Class Attribute Overview

The following table enumerates the different parameters for **CLASSCFG**.

**i** Setting **DEFAULT.\*** on a class does not assign resources or features to that class. Rather, it specifies resources that jobs will inherit when they are submitted to the class without their own resource requests. To configure features, use [NODECFG](#).

**DEFAULT.ATTR**

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <b>Format</b>      | <ATTRIBUTE>[,<ATTRIBUTE>]...                        |
| <b>Description</b> | One or more comma-delimited generic job attributes. |
| <b>Example</b>     | ---                                                 |

**DEFAULT.DISK**

|                    |                                         |
|--------------------|-----------------------------------------|
| <b>Format</b>      | <INTEGER>                               |
| <b>Description</b> | Default amount of requested disk space. |
| <b>Example</b>     | ---                                     |

**DEFAULT.EXT**

|                    |                           |
|--------------------|---------------------------|
| <b>Format</b>      | <STRING>                  |
| <b>Description</b> | Default job RM extension. |
| <b>Example</b>     | ---                       |

**DEFAULT.FEATURESDEFAULT.EXT**

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | Comma-delimited list of features.                                                                                             |
| <b>Description</b> | Default list of requested <a href="#">node features</a> (a.k.a, node properties). This only applies to compute resource reqs. |
| <b>Example</b>     | ---                                                                                                                           |

**DEFAULT.GRES**

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Format</b>      | <STRING>[<COUNT>][,<STRING>[<COUNT>]]...                                         |
| <b>Description</b> | Default list of per task required <a href="#">consumable generic resources</a> . |

| DEFAULT.GRES   |                                               |
|----------------|-----------------------------------------------|
| <b>Example</b> | <code>CLASSCFG[viz] DEFAULT.GRES=viz:2</code> |

| DEFAULT.MEM        |                                     |
|--------------------|-------------------------------------|
| <b>Format</b>      | <INTEGER> (in MB)                   |
| <b>Description</b> | Default amount of requested memory. |
| <b>Example</b>     | ---                                 |

| DEFAULT.NODE       |                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <INTEGER>                                                                                                                                                                                                                                            |
| <b>Description</b> | Default required node count.                                                                                                                                                                                                                         |
| <b>Example</b>     | <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"><code>CLASSCFG[viz] DEFAULT.NODE=5</code></div> <p>When a user submits a job to the <code>viz</code> class without a specified node count, the job is assigned 5 nodes.</p> |

| DEFAULT.NODESET    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <SETTYPE>:<SETATTR>[:<SETLIST>[,<SETLIST>]...]                                                                                         |
| <b>Description</b> | Default <a href="#">node set</a> .                                                                                                     |
| <b>Example</b>     | <div style="border: 1px dashed gray; padding: 5px;"><code>CLASSCFG [amd]<br/>DEFAULT.NODESET=ONEOF:FEATURE:ATHLON,OPTERON</code></div> |

| DEFAULT.PROC       |                                         |
|--------------------|-----------------------------------------|
| <b>Format</b>      | <INTEGER>                               |
| <b>Description</b> | Default number of requested processors. |
| <b>Example</b>     | ---                                     |

**DEFAULT.TPN**

|                    |                                   |
|--------------------|-----------------------------------|
| <b>Format</b>      | <INTEGER>                         |
| <b>Description</b> | Default number of tasks per node. |
| <b>Example</b>     | ---                               |

**DEFAULT.WCLIMIT**

|                    |                          |
|--------------------|--------------------------|
| <b>Format</b>      | <INTEGER>                |
| <b>Description</b> | Default wallclock limit. |
| <b>Example</b>     | ---                      |

**EXCL.FEATURES**

|                    |                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | Comma- or pipe-delimited list of node features.                                                                                                                                                |
| <b>Description</b> | Set of excluded (disallowed) features. If delimited by commas, reject job if all features are requested; if delimited by the pipe symbol ( ), reject job if at least one feature is requested. |
| <b>Example</b>     | <code>CLASSCFG[intel] EXCL.FEATURES=ATHLON,AMD</code>                                                                                                                                          |

**EXCL.FLAGS**

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Format</b>      | Comma-delimited list of <a href="#">job flags</a> .                             |
| <b>Description</b> | Set of excluded (disallowed) job flags. Reject job if any listed flags are set. |
| <b>Example</b>     | <code>CLASSCFG[batch] EXCL.FLAGS=INTERACTIVE</code>                             |

**EXCLUDEUSERLIST**

|               |                                |
|---------------|--------------------------------|
| <b>Format</b> | Comma-delimited list of users. |
|---------------|--------------------------------|

| EXCLUDEUSERLIST    |                                              |
|--------------------|----------------------------------------------|
| <b>Description</b> | List of users not permitted access to class. |
| <b>Example</b>     | ---                                          |

| FORCENODEACCESSPOLICY |                                                                                                                                                                                                             |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>         | one of <i>SINGLETASK</i> , <i>SINGLEJOB</i> , <i>SINGLEUSER</i> , or <i>SHARED</i>                                                                                                                          |
| <b>Description</b>    | Node access policy associated with queue. If set, this value overrides any per job settings specified by the user at the job level. (See <a href="#">Node Access Policy</a> overview for more information.) |
| <b>Example</b>        | <code>CLASSCFG [batch] FORCENODEACCESSPOLICY=SINGLEJOB</code>                                                                                                                                               |

| FSCAP              |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Format</b>      | <DOUBLE>[%]                                           |
| <b>Description</b> | See <a href="#">fairshare policies</a> specification. |
| <b>Example</b>     | ---                                                   |

| FSTARGET           |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Format</b>      | <DOUBLE>[%]                                           |
| <b>Description</b> | See <a href="#">fairshare policies</a> specification. |
| <b>Example</b>     | ---                                                   |

| HOSTLIST           |                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <a href="#">Host expression</a> , or comma-delimited list of hosts or host ranges.                                                            |
| <b>Description</b> | List of hosts associated with a class. If specified, Moab constrains the availability of a class to only nodes listed in the class host list. |

## HOSTLIST

|                |                                                     |
|----------------|-----------------------------------------------------|
| <b>Example</b> | <code>CLASSCFG[batch] HOSTLIST=r:abs[45-113]</code> |
|----------------|-----------------------------------------------------|

## JOBPILOG

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <STRING>                                                                                                                          |
| <b>Description</b> | Scheduler level job epilog to be run after job is completed by resource manager. (See <a href="#">special class attributes</a> .) |
| <b>Example</b>     | ---                                                                                                                               |

## JOBFLAGS

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Format</b>      | Comma-delimited list of job flags.                                            |
| <b>Description</b> | See the <a href="#">flag overview</a> for a description of legal flag values. |
| <b>Example</b>     | <code>CLASSCFG[batch] JOBFLAGS=restartable</code>                             |

## JOBPROLOG

|                    |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <STRING>                                                                                                                         |
| <b>Description</b> | Scheduler level job prolog to be run before job is started by resource manager. (See <a href="#">special class attributes</a> .) |
| <b>Example</b>     | ---                                                                                                                              |

## MANAGERS

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <USER>[,<USER>]..                                                                                                               |
| <b>Description</b> | Users allowed to control, cancel, preempt, and modify jobs within class/queue. (See <a href="#">special class attributes</a> .) |
| <b>Example</b>     | <code>CLASSCFG[fast] MANAGERS=root,kerry,e43</code>                                                                             |

| MAXJOB             |                                              |
|--------------------|----------------------------------------------|
| <b>Format</b>      | <INTEGER>                                    |
| <b>Description</b> | Maximum number of jobs allowed in the class. |
| <b>Example</b>     | ---                                          |

| MAXPROCPERNODE           |                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Form-<br/>at</b>      | <INTEGER>                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Descri-<br/>ption</b> | Maximum number of processors requested per node. May optionally include node names to articulate which nodes have a specific limit.                                                                                                                                                                                                                                                             |
| <b>Exam-<br/>ple</b>     | <pre>CLASSCFG[cpu] MAXPROCPERNODE=20 # When using this class, limit 20 for all nodes</pre> <pre>CLASSCFG[cpu] MAXPROCPERNODE[n1,n2]=20 MAXPROCPERNODE[n3]=10 # When using this class, limit 20 for n1 &amp; n2 and limit 10 for n3</pre> <pre>CLASSCFG[cpu] MAXPROCPERNODE[n1,n2]=20 MAXPROCPERNODE=10 # When using this class, limit 20 for n1 &amp; n2 and limit 10 for all other nodes</pre> |

| MAX.CPUTIME        |                                    |
|--------------------|------------------------------------|
| <b>Format</b>      | <INTEGER>                          |
| <b>Description</b> | Maximum allowed utilized CPU time. |
| <b>Example</b>     | ---                                |

| MAX.NODE           |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <INTEGER>                                                                                                                 |
| <b>Description</b> | Maximum number of requested nodes per job. (Also used when <a href="#">REMAPCLASS</a> is set to correctly route the job.) |

## MAX.NODE

## Example

```
CLASSCFG[batch] MAX.NODE=64
```

Deny jobs requesting over 64 nodes access to the class *batch*.

## MAX.PROC

## Format

<INTEGER>

## Description

Maximum number of requested processors per job. (Also used when [REMAPCLASS](#) is set to correctly route the job.)

## Example

```
CLASSCFG[small] MAX.PROC[USER]=3,6
```

## MAX.PS

## Format

<INTEGER>

## Description

Maximum requested processor-seconds.

## Example

---

## MAX.WCLIMIT

## Format

[[[DD:]HH:]MM:]SS

## Description

Maximum allowed wallclock limit per job. (Also used when [REMAPCLASS](#) is set to correctly route the job.)

## Example

```
CLASSCFG[long] MAX.WCLIMIT=96:00:00
```

## MIN.NODE

## Format

<INTEGER>

## Description

Minimum number of requested nodes per job. (Also used when [REMAPCLASS](#) is set to correctly route the job.)

| MIN.NODE       |                                                                                                                    |
|----------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Example</b> | <pre>CLASSCFG[dev] MIN.NODE=16</pre> <p>Jobs must request at least 16 nodes to be allowed to access the class.</p> |

| MIN.PROC           |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <INTEGER>                                                                                                                      |
| <b>Description</b> | Minimum number of requested processors per job. (Also used when <a href="#">REMAPCLASS</a> is set to correctly route the job.) |
| <b>Example</b>     | <pre>CLASSCFG[dev] MIN.PROC=32</pre> <p>Jobs must request at least 32 processors to be allowed to access the class.</p>        |

| MIN.PS             |                                      |
|--------------------|--------------------------------------|
| <b>Format</b>      | <INTEGER>                            |
| <b>Description</b> | Minimum requested processor-seconds. |
| <b>Example</b>     | ---                                  |

| MIN.TPN            |                                          |
|--------------------|------------------------------------------|
| <b>Format</b>      | <INTEGER>                                |
| <b>Description</b> | Minimum required tasks per node per job. |
| <b>Example</b>     | ---                                      |

| MIN.WCLIMIT        |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | [[[DD:]HH:]MM:]SS                                                                                                        |
| <b>Description</b> | Minimum required wallclock limit per job. (Also used when <a href="#">REMAPCLASS</a> is set to correctly route the job.) |

## MIN.WCLIMIT

**Example** ---

## NODEACCESSPOLICY

**Format** one of *SINGLETASK*, *SINGLEJOB*, *SINGLEUSER*, or *SHARED*

**Description** Default node access policy associated with queue. This value will be overridden by any per job settings specified by the user at the job level. (See [Node Access Policy](#) overview.)

**Example** `CLASSCFG [batch] NODEACCESSPOLICY=SINGLEJOB`

## PARTITION

**Format** <STRING>

**Description** Partition name where jobs associated with this class must run.

**Example** `CLASSCFG [batch] PARTITION=p12`

## PRIORITY

**Format** <INTEGER>

**Description** Priority associated with the class. (See [Priority](#) overview.)

**Example** `CLASSCFG [batch] PRIORITY=1000`

## QDEF

**Format** <QOSID>

**Description** Default QoS for jobs submitted to this class. You may specify a maximum of four **QDEF** entries per credential. Any QoS specified after the fourth will not be accepted.

 In addition to classes, you may also specify **QDEF** for accounts, groups, and users.

| QDEF           |                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Example</b> | <pre>CLASSCFG[batch] QDEF=base</pre> <p>Jobs submitted to class <i>batch</i> that do not explicitly request a QoS will have the QoS <i>base</i> assigned.</p> |

| QLIST              |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Format</b>      | <QOSID>[,<QOSID>]..                                                |
| <b>Description</b> | List of accessible QoSs for jobs submitted to this class.          |
| <b>Example</b>     | <pre>CLASSCFG[batch] QDEF=base QLIST=base,fast,special,bigio</pre> |

| REQ.FEATURES       |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | Comma- or pipe-delimited list of node features.                                                                                                     |
| <b>Description</b> | Set of required features. If delimited by commas, all features are required; if delimited by the pipe symbol ( ), at least one feature is required. |
| <b>Example</b>     | <pre>CLASSCFG[amd] REQ.FEATURES=ATHLON,AMD</pre>                                                                                                    |

| REQ.FLAGS          |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Format</b>      | REQ.FLAGS can be used with only the INTERACTIVE flag. |
| <b>Description</b> | Sets the INTERACTIVE flag on jobs in this class.      |
| <b>Example</b>     | <pre>CLASSCFG[orion] REQ.FLAGS=INTERACTIVE</pre>      |

| REQUIREDACCOUNTLIST |                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------|
| <b>Format</b>       | Comma-delimited list of accounts.                                                                     |
| <b>Description</b>  | List of accounts allowed to access and use a class (analogous to <i>*LIST</i> for other credentials). |

### REQUIREDACCOUNTLIST

**Example**

```
CLASSCFG[jasper] REQUIREDACCOUNTLIST=testers,development
```

### REQUIREDUSERLIST

**Format**

Comma-delimited list of users.

**Description**

List of users allowed to access and use a class (analogous to **\*LIST** for other credentials).

**Example**

```
CLASSCFG[jasper] REQUIREDUSERLIST=john,u13,steve,guest
```

### REQUIREDQOSLIST

**Format**

Comma-delimited list of QoSs

**Description**

List of QoSs allowed to access and use a class (analogous to **\*LIST** for other credentials).

The number of unique QoSs is limited by the Moab Maximum ACL limit, which defaults to 32.

**Example**

```
CLASSCFG[jasper] REQUIREDQOSLIST=hi,lo
```

### SYSPRIO

**Format**

<INTEGER>

**Description**

Value of [system priority](#) applied to every job submitted to this class.

**Example**

```
CLASSCFG[special] SYSPRIO=100
```

### WCOVERRUN

**Format**

[[[DD:]HH:]MM:]SS

| WCOVERRUN          |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Description</b> | Tolerated amount of time beyond the specified wallclock limit. |
| <b>Example</b>     | ---                                                            |

## Enabling Queue Complex Functionality

Queue complexes allow an organization to build a hierarchy of queues and apply certain limits and rules to collections of these queues. Moab supports this functionality in two ways. The first way, queue mapping, is very simple but limited in functionality. The second method provides very rich functionality but requires more extensive configuration using the Moab hierarchical fairshare facility.

### Queue Mapping

Queue mapping allows collections of queues to be mapped to a parent credential object against which various limits and policies can be applied, as in the following example.

```

QOSCFG[general]   MAXIJOB[USER]=14  PRIORITY=20
QOSCFG[prio]     MAXIJOB[USER]=8   PRIORITY=2000
# group short, med, and long jobs into 'general' QOS
CLASSCFG[short]  QDEF=general FSTARGET=30
CLASSCFG[med]    QDEF=general FSTARGET=40
CLASSCFG[long]   QDEF=general FSTARGET=30 MAXPROC=200
# group interactive and debug jobs into 'prio' QOS
CLASSCFG[inter]  QDEF=prio
CLASSCFG[debug]  QDEF=prio
CLASSCFG[premier] PRIORITY=10000

```

## QoS Credential

The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoSs differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.

QoS access and QoS defaults can be mapped to users, groups, accounts, and classes, allowing limited service offering for key users. As mentioned, these services focus around increasing access to special scheduling capabilities & additional resources and improving job responsiveness. At a high level, unique QoS attributes can be broken down into the following:

- [Usage Limit Overrides](#)
- [Service Targets](#)
- [Privilege Flags](#)

- [Charge Rate](#)
- [Access Controls](#)

## QoS Usage Limit Overrides

All credentials allow specification of job limits. In such cases, jobs are constrained by the most limiting of all applicable policies. With QoS override limits, however, jobs are limited by the override, regardless of other limits specified.

## QoS Service Targets

Service targets cause the scheduler to take certain job-related actions as various responsiveness targets are met. Targets can be set for either job queue time or job expansion factor and cause priority adjustments, reservation enforcement, or preemption activation. In strict service centric organizations, Moab can be configured to trigger various events and notifications in the case of failure by the cluster to meet responsiveness targets.

## QoS Privilege Flags

QoSs can provide access to special capabilities. These capabilities include preemption, job deadline support, backfill, next to run priority, guaranteed resource reservation, resource provisioning, dedicated resource access, and many others. See the complete list in the [QoS Facility Overview](#) section.

## QoS Charge Rate

Associated with the QoSs many privileges is the ability to assign end-users costs for the use of these services. This charging can be done on a per-QoS basis and may be specified for both dedicated and use-based resource consumption. The [Per QoS Charging](#) section covers more details on QoS level costing configuration while the Charging and Allocation Management section provides more details regarding general single cluster and multi-cluster charging capabilities.

## QoS Access Controls

QoS access control can be enabled on a per QoS basis using the [MEMBERULIST](#) attribute or specified on a *per-requestor* basis using the [QDEF](#) and [QLIST](#) attributes of the [USERCFG](#), [GROUPCFG](#), [ACCOUNTCFG](#), and [CLASSCFG](#) parameters. See [Managing QoS Access](#) for more detail.

# Job Attributes/Flags Overview

## Job Attributes

| FLAGS               |                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | <FLAG>[:<FLAG>]...                                                                                                                                                                                |
| <b>Default:</b>     | ---                                                                                                                                                                                               |
| <b>Description:</b> | Specifies job specific flags.                                                                                                                                                                     |
| <b>Example:</b>     | <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 5px;"> <pre>FLAGS=ADVRES:RESTARTABLE</pre> </div> <p><i>The job can restart and should only utilize reserved resources.</i></p> |

| PLIST*              |                                                                                                                                                                                                                                               |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | <PARTITION_NAME>[^ &]<br>[:<PARTITION_NAME>[^ &]]...                                                                                                                                                                                          |
| <b>Default:</b>     | <i>[ALL]</i>                                                                                                                                                                                                                                  |
| <b>Description:</b> | Specifies the list of partitions the object can access. If no partition list is specified, the object is granted default access to all partitions.                                                                                            |
| <b>Example:</b>     | <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 5px;"> <pre>PLIST=OldSP:Cluster1:O3K</pre> </div> <p><i>The object can access resources located in the <i>OldSP</i>, <i>Cluster1</i>, and/or <i>O3K</i> partitions.</i></p> |

| QDEF                |                                                       |
|---------------------|-------------------------------------------------------|
| <b>Format:</b>      | <QOS_NAME>                                            |
| <b>Default:</b>     | <i>[DEFAULT]</i>                                      |
| <b>Description:</b> | Specifies the default QOS associated with the object. |

| QDEF            |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| <b>Example:</b> | <pre>QDEF=premium</pre> <p><i>The object is assigned the default QoS premium.</i></p> |

| QLIST*              |                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | <QOS_NAME>[^ &]<br>[:<QOS_NAME>[^ &]]...                                                                                                   |
| <b>Default:</b>     | <QDEF>                                                                                                                                     |
| <b>Description:</b> | Specifies the list of QoSs the object can access. If no QoS list is specified, the object is granted access only to its default partition. |
| <b>Example:</b>     | <pre>QLIST=premium:express:bottomfeeder</pre> <p><i>The object can access any of the 3 QoSs listed.</i></p>                                |

**i** By default, jobs may access QoSs based on the 'logical or' of the access lists associated with all job credentials. For example, a job associated with user "John," group "staff," and class "batch" may utilize QoSs accessible by any of the individual credentials. Thus the job's QoS access list, or QLIST, equals the 'or' of the user, group, and class QLIST's. (i.e., JOBQLIST = USERQLIST | GROUPQLIST | CLASSQLIST). If the ampersand symbol, '&', is associated with any list, this list is logically and'd with the other lists. If the carat symbol, '^', is associated with any object QLIST, this list is exclusively set, regardless of other object access lists using the following order of precedence user, group, account, QOS, and class. These special symbols affect the behavior of both QOS and partition access lists.

## Job Flags

| ADVRES              |                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | ADVRES[:<RESID>]                                                                                                                                         |
| <b>Default:</b>     | Use available resources where ever found, whether inside a reservation or not.                                                                           |
| <b>Description:</b> | Specifies the job may only utilize accessible, reserved resources. If <RESID> is specified, only resources in the specified reservation may be utilized. |

## ADVRES

**Example:**

```
FLAGS=ADVRES:MET.A.1
```

*The job may only utilize resources located in the **META.1** reservation.*

## ARRAYJOBPARLOCK

**Format:**

---

**Default:**

---

**Description:**

Specifies that the job array being submitted should not span across multiple partitions. This locks all sub jobs of the array to a single partition. If you want to lock all job arrays to a single partition, specify the [ARRAYJOBPARLOCK](#) parameter in `moab.cfg` to force this behavior on a global scale.

**Example:**

```
> msub -t moab.[1-5]%3 -l walltime=30,flags=arrayjobparlock
```

## ARRAYJOBPARSPAN

**Format:**

---

**Default:**

---

**Description:**

Specifies that the job array being submitted should span across multiple partitions. This is the default behavior in Moab, unless the [ARRAYJOBPARLOCK](#) parameter is specified in `moab.cfg`. This job flag overrides the **ARRAYJOBPARLOCK** parameter so that job arrays can be allowed to span multiple partitions at submit time.

**Example:**

```
> msub -t moab.[1-5]%3 -l walltime=30,flags=arrayjobparspan
```

## GRESONLY

**Format:**

GRESONLY

**Default:**

False

**Description:**

Uses no compute resources such as processors, memory, and so forth; uses only generic resources.

## GRESONLY

**Example:**

```
> msub -l gres=matlab,walltime=300
```

## IGNIDLEJOBRSV

**Format:**

IGNIDLEJOBRSV

**Default:**

N/A

**Description:**

Only applies to QOS. **IGNIDLEJOBRSV** allows jobs to start without a guaranteed walltime. Instead, it overlaps the idle reservations of real jobs and is preempted 2 minutes before the real job starts.

**Example:**

```
QOSCFG[standby] JOBFLAGS=IGNIDLEJOBRSV
```

## NOQUEUE

**Format:**

NOQUEUE

**Default:**

Jobs remain queued until they are able to run

**Description:**

Specifies that the job should be removed if it is unable to allocate resources and start execution immediately.

**Example:**

```
FLAGS=NOQUEUE
```

*The job should be removed unless it can start running at submit time.*

This functionality is identical to the resource manager extension [QUEUEJOB:FALSE](#).

## NORMSTART

**Format:**

NORMSTART

**Default:**

Moab passes jobs to a resource manager to schedule.

**Description:**

Specifies that the job is an internal system job and will not be started via an RM.

| NORMSTART       |                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------|
| <b>Example:</b> | <pre>FLAGS=NORMSTART</pre> <p><i>The job begins running in Moab without a corresponding RM job.</i></p> |

| NOVMMIGRATE        |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | NOVMMIGRATE                                                                                                                                     |
| <b>Default</b>     | Moab can migrate the VM associated with the job.                                                                                                |
| <b>Description</b> | Specifies that Moab may not migrate the VM that the job sets up.                                                                                |
| <b>Example</b>     | <pre>msub -l walltime=INFINITY,template=VMTracking,os=linux,nodes=h3,jobflags=novmmigrate</pre> <p><i>Moab will not migrate the new VM.</i></p> |

| PREEMPTEE           |                                                                                                                           |
|---------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | PREEMPTEE                                                                                                                 |
| <b>Default:</b>     | Jobs may not be preempted by other jobs                                                                                   |
| <b>Description:</b> | Specifies that the job may be <a href="#">preempted</a> by other jobs which have the <b>PREEMPTOR</b> flag set.           |
| <b>Example:</b>     | <pre>FLAGS=PREEMPTEE</pre> <p><i>The job may be preempted by other jobs which have the <b>PREEMPTOR</b> flag set.</i></p> |

| PREEMPTOR           |                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | PREEMPTOR                                                                                                |
| <b>Default:</b>     | Jobs may not preempt other jobs                                                                          |
| <b>Description:</b> | Specifies that the job may <a href="#">preempt</a> other jobs which have the <b>PREEMPTEE</b> flag set . |

| PREEMPTOR       |                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Example:</b> | <pre>FLAGS=PREEMPTOR</pre> <p><i>The job may preempt other jobs which have the <b>PREEMPTEE</b> flag set.</i></p> |

| PURGEONSUCCESSONLY |                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | PURGEONSUCCESSONLY                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>     | Completed jobs are sent to a queue for a short period of time before Moab purges them from the system.                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | Specifies that Moab should only purge the job from the completed queue if it completed successfully. If the job failed, Moab will keep it in the queue indefinitely to allow you to restart it at any time. This flag is particularly useful for setup and take down jobs in job workflows. See <a href="#">Creating workflows with job templates on page 857</a> for more information. |
| <b>Example</b>     | <pre>FLAGS=PURGEONSUCCESSONLY</pre> <p><i>If the job fails, Moab will not purge it from the completed job queue.</i></p>                                                                                                                                                                                                                                                                |

| RESTARTABLE         |                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | RESTARTABLE                                                                                                   |
| <b>Default:</b>     | Jobs may not be restarted if preempted.                                                                       |
| <b>Description:</b> | Specifies jobs can be <i>requeued</i> and later restarted if <a href="#">preempted</a> .                      |
| <b>Example:</b>     | <pre>FLAGS=RESTARTABLE</pre> <p><i>The associated job can be preempted and restarted at a later date.</i></p> |

| SUSPENDABLE    |             |
|----------------|-------------|
| <b>Format:</b> | SUSPENDABLE |

| SUSPENDABLE         |                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Default:</b>     | Jobs may not be suspended if preempted.                                                                     |
| <b>Description:</b> | Specifies jobs can be <i>suspended</i> and later resumed if <a href="#">preempted</a> .                     |
| <b>Example:</b>     | <pre>FLAGS=SUSPENDABLE</pre> <p><i>The associated job can be suspended and resumed at a later date.</i></p> |

| SYSTEMJOB           |                                                                 |
|---------------------|-----------------------------------------------------------------|
| <b>Format:</b>      | SYSTEMJOB                                                       |
| <b>Default:</b>     | N/A                                                             |
| <b>Description:</b> | Creates an internal system job that does not require resources. |
| <b>Example:</b>     | <pre>FLAGS=SYSTEMJOB</pre>                                      |

| WIDERSVSEARCHALGO   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format:</b>      | <BOOLEAN>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default:</b>     | ---                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description:</b> | When Moab is determining when and where a job can run, it either searches for the most resources or the longest range of resources. In almost all cases searching for the longest range is ideal and returns the soonest starttime. In some rare cases, however, a particular job may need to search for the most resources. In those cases this flag can be used to have the job find the soonest starttime. The flag can be specified at submit time, or you can use <a href="#">mjobctl -m</a> to modify the job after it has been submitted. See the <a href="#">RSVSEARCHALGO</a> parameter. |
| <b>Example:</b>     | <pre>&gt; msub -l flags=widersvsearchalgo &gt; mjobctl -m flags+=widersvsearchalgo job.1</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

# Scheduler Commands

## Moab Commands

| Command                                 | Description                                                          |
|-----------------------------------------|----------------------------------------------------------------------|
| <a href="#"><u>checkjob</u></a>         | Provide detailed status report for specified job                     |
| <a href="#"><u>checknode</u></a>        | Provide detailed status report for specified node                    |
| <a href="#"><u>mcredctl</u></a>         | Controls various aspects about the credential objects within Moab    |
| <a href="#"><u>mdiag</u></a>            | Provide diagnostic reports for resources, workload, and scheduling   |
| <a href="#"><u>mjobctl</u></a>          | Control and modify job                                               |
| <a href="#"><u>mnodectl</u></a>         | Control and modify nodes                                             |
| <a href="#"><u>moab</u></a>             | Control the Moab daemon                                              |
| <a href="#"><u>mrmctl</u></a>           | Query and control resource managers                                  |
| <a href="#"><u>mrsvctl</u></a>          | Create, control and modify reservations                              |
| <a href="#"><u>mschedctl</u></a>        | Modify scheduler state and behavior                                  |
| <a href="#"><u>mshow</u></a>            | Displays various diagnostic messages about the system and job queues |
| <a href="#"><u>mshow -a</u></a>         | Query and show available system resources                            |
| <a href="#"><u>msub</u></a>             | Scheduler job submission                                             |
| <a href="#"><u>mvcctl</u></a>           | Create, modify, and delete VCs                                       |
| <a href="#"><u>mvmctl</u></a>           | Create, control and modify VMs                                       |
| <a href="#"><u>showbf</u></a>           | Show current resource availability                                   |
| <a href="#"><u>showhist.moab.pl</u></a> | Show past job information                                            |

| Command                             | Description                                          |
|-------------------------------------|------------------------------------------------------|
| <a href="#"><u>showq</u></a>        | Show queued jobs                                     |
| <a href="#"><u>showres</u></a>      | Show existing reservations                           |
| <a href="#"><u>showstart</u></a>    | Show estimates of when job can/will start            |
| <a href="#"><u>showstate</u></a>    | Show current state of resources                      |
| <a href="#"><u>showstats</u></a>    | Show usage statistics                                |
| <a href="#"><u>showstats -f</u></a> | Show various tables of scheduling/system performance |

## Moab command options

For many Moab commands, you can use the following options to specify that Moab will run the command in a different way or different location from the configured default. These options do not change your settings in the configuration file; they override the settings for this single instance of the command.

| Option                                | Description                                                                                                                                               |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>--about</b>                        | Displays build and version information and the status of your Moab license                                                                                |
| <b>--help</b>                         | Displays usage information about the command                                                                                                              |
| <b>--host=&lt;server-HostName&gt;</b> | Causes Moab to run the client command on the specified host                                                                                               |
| <b>--loglevel=&lt;logLevel&gt;</b>    | Causes Moab to write log information to STDERR as the client command is running. For more information, see <a href="#">Logging Overview on page 676</a> . |
| <b>--msg=&lt;message&gt;</b>          | Causes Moab to annotate the action in the <a href="#">event log</a>                                                                                       |
| <b>--port=&lt;server-Port&gt;</b>     | Causes Moab to run the command using the port specified                                                                                                   |
| <b>--timeout=&lt;seconds&gt;</b>      | Sets the maximum time that the client command will wait for a response from the Moab server                                                               |

| Option           | Description                                            |
|------------------|--------------------------------------------------------|
| <b>--version</b> | Displays version information                           |
| <b>--xml</b>     | Causes Moab to return the command output in XML format |

## Commands Providing Maui Compatibility

The following commands are deprecated. Click the link for respective deprecated commands to see the updated replacement command for each.

| Command                            | Description                                                                          |
|------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#"><u>canceljob</u></a>   | Cancel job                                                                           |
| <a href="#"><u>changeparam</u></a> | Change in memory parameter settings                                                  |
| <a href="#"><u>diagnose</u></a>    | Provide diagnostic report for various aspects of resources, workload, and scheduling |
| <a href="#"><u>releasehold</u></a> | Release job defers and holds                                                         |
| <a href="#"><u>releaseres</u></a>  | Release reservations                                                                 |
| <a href="#"><u>runjob</u></a>      | Force a job to run immediately                                                       |
| <a href="#"><u>sethold</u></a>     | Set job holds                                                                        |
| <a href="#"><u>setqos</u></a>      | Modify job QOS settings                                                              |
| <a href="#"><u>setres</u></a>      | Set an admin/user reservation                                                        |
| <a href="#"><u>setspri</u></a>     | Adjust job/system priority of job                                                    |
| <a href="#"><u>showconfig</u></a>  | Show current scheduler configuration                                                 |

## Status Commands

The status commands organize and present information about the current state and historical statistics of the scheduler, jobs, resources, users, and accounts. The following table presents the primary status commands and flags.

| Command                                                         | Description                                                                                                                                                                |
|-----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#"><u>checkjob</u></a>                                 | Displays detailed job information such as job state, resource requirements, environment, constraints, credentials, history, allocated resources, and resource utilization. |
| <a href="#"><u>checknode</u></a>                                | Displays detailed node information such as node state, resources, attributes, reservations, history, and statistics.                                                       |
| <a href="#"><u>mdiag -f</u></a>                                 | Displays summarized fairshare information and any unexpected fairshare configuration.                                                                                      |
| <a href="#"><u>mdiag -j</u></a>                                 | Displays summarized job information and any unexpected job state.                                                                                                          |
| <a href="#"><u>mdiag -n</u></a>                                 | Displays summarized node information and any unexpected node state.                                                                                                        |
| <a href="#"><u>mdiag -p</u></a>                                 | Displays summarized job priority information.                                                                                                                              |
| <a href="#"><u>mschedctl</u></a><br><a href="#"><u>-f</u></a>   | Resets internal statistics.                                                                                                                                                |
| <a href="#"><u>showstats</u></a><br><a href="#"><u>-f</u></a>   | Displays various aspects of scheduling performance across a job duration/job size matrix.                                                                                  |
| <a href="#"><u>showq [-r]-</u></a><br><a href="#"><u>i]</u></a> | Displays various views of currently queued active, idle, and non-eligible jobs.                                                                                            |
| <a href="#"><u>showstats</u></a><br><a href="#"><u>-g</u></a>   | Displays current and historical usage on a per group basis.                                                                                                                |
| <a href="#"><u>showstats</u></a><br><a href="#"><u>-u</u></a>   | Displays current and historical usage on a per user basis.                                                                                                                 |
| <a href="#"><u>showstats</u></a><br><a href="#"><u>-v</u></a>   | Displays high level current and historical scheduling statistics.                                                                                                          |

## Job Management Commands

Moab shares job management tasks with the resource manager. Typically, the scheduler only modifies scheduling relevant aspects of the job such as partition access, job priority, charge account, and hold state. The following table covers the available job management commands. The [Commands Overview](#) lists all available commands.

| Command                               | Description                                                                                                                               |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#"><u>canceljob</u></a>      | Cancels existing job.                                                                                                                     |
| <a href="#"><u>checkjob</u></a>       | Displays job state, resource requirements, environment, constraints, credentials, history, allocated resources, and resource utilization. |
| <a href="#"><u>mdiag -j</u></a>       | Displays summarized job information and any unexpected job state.                                                                         |
| <a href="#"><u>releasehold -a</u></a> | Removes job holds or deferrals.                                                                                                           |
| <a href="#"><u>runjob</u></a>         | Starts job immediately, if possible.                                                                                                      |
| <a href="#"><u>sethold</u></a>        | Sets hold on job.                                                                                                                         |
| <a href="#"><u>setqos</u></a>         | Sets/modifies QoS of existing job.                                                                                                        |
| <a href="#"><u>setspri</u></a>        | Adjusts job/system priority of job.                                                                                                       |

## Reservation Management Commands

Moab exclusively controls and manages all advance reservation features including both standing and administrative reservations. The following table covers the available reservation management commands.

| Command                           | Description                                                           |
|-----------------------------------|-----------------------------------------------------------------------|
| <a href="#"><u>mdiag -r</u></a>   | Displays summarized reservation information and any unexpected state. |
| <a href="#"><u>mrsvctl</u></a>    | Reservation control.                                                  |
| <a href="#"><u>mrsvctl -r</u></a> | Removes reservations.                                                 |
| <a href="#"><u>mrsvctl -c</u></a> | Creates an administrative reservation.                                |
| <a href="#"><u>showres</u></a>    | Displays information regarding location and state of reservations.    |

## Policy/Configuration Management Commands

Moab allows dynamic modification of most scheduling parameters allowing new scheduling policies, algorithms, constraints, and permissions to be set at any time. Changes made via Moab client commands are temporary and are overridden by values specified in Moab configuration files the next time Moab is shut down and restarted. The following table covers the available configuration management commands.

| Command                             | Description                                                                |
|-------------------------------------|----------------------------------------------------------------------------|
| <a href="#"><u>mschedctl -l</u></a> | Displays triggers, messages, and settings of all configuration parameters. |
| <a href="#"><u>mschedctl</u></a>    | Controls the scheduler (behavior, parameters, triggers, messages).         |
| <a href="#"><u>mschedctl -m</u></a> | Modifies system values.                                                    |

## End-user Commands

While the majority of Moab commands are tailored for use by system administrators, a number of commands are designed to extend the knowledge and capabilities of end-users. The following table covers the commands available to end-users.

**i** When using Active Directory as a central authentication mechanism, all nodes must be reported with a different name when booted in both Linux and Windows (for instance, `node01-1` for Linux and `node01` for Windows). If a machine account with the same name is created for each OS, the most recent OS will remove the previously-joined machine account. The nodes must report to Moab with the same hostname. This can be done by using aliases (adding all node names to the `/etc/hosts` file on the system where Moab is running) and ensuring that the Linux resource manager reports the node with its global name rather than the Linux-specific one (`node01` rather than `node01-1`).

| Command                           | Description                                                                                                                               |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#"><u>canceljob</u></a>  | Cancels existing job.                                                                                                                     |
| <a href="#"><u>checkjob</u></a>   | Displays job state, resource requirements, environment, constraints, credentials, history, allocated resources, and resource utilization. |
| <a href="#"><u>msub</u></a>       | Submit a new job.                                                                                                                         |
| <a href="#"><u>releaseres</u></a> | Releases a <a href="#"><u>user reservation</u></a> .                                                                                      |

| Command                          | Description                                                                                        |
|----------------------------------|----------------------------------------------------------------------------------------------------|
| <a href="#"><u>setres</u></a>    | Create a <a href="#"><u>user reservation</u></a> .                                                 |
| <a href="#"><u>showbf</u></a>    | Shows resource availability for jobs with specific resource requirements.                          |
| <a href="#"><u>showq</u></a>     | Displays detailed prioritized list of active and idle jobs.                                        |
| <a href="#"><u>showstart</u></a> | Shows estimated start time of idle jobs.                                                           |
| <a href="#"><u>showstats</u></a> | Shows detailed usage statistics for users, groups, and accounts, to which the end-user has access. |

## Commands

### checkjob

#### Synopsis

checkjob [[exact:jobid](#)] [[-l policylevel](#)] [[-n nodeid](#)] [[-q qosid](#)] [[-r reservationid](#)] [[-v](#)] [[--flags=future](#)] [[--blocking](#)] [jobid](#)

#### Overview

checkjob displays detailed job [state](#) information and diagnostic output for a specified job. Detailed information is available for queued, blocked, active, and recently completed jobs. The checkjob command shows the master job of an array as well as a summary of array sub-jobs, but does not display all sub-jobs. Use [checkjob -v](#) to display all job-array sub-jobs.

#### Access

This command can be run by level 1-3 Moab administrators for any job. Also, end users can use checkjob to view the status of their own jobs.

## Arguments

| --blocking         |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | --blocking                                                                                                        |
| <b>Description</b> | Do not use cache information in the output. The --blocking flag retrieves results exclusively from the scheduler. |
| <b>Example</b>     | <pre>&gt; checkjob -v --blocking 1234</pre> <p><i>Display real time data about job 1234.</i></p>                  |

| --flags            |                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | --flags=future                                                                                                                                                      |
| <b>Description</b> | Evaluates future eligibility of job (ignore current resource state and usage limitations).                                                                          |
| <b>Example</b>     | <pre>&gt; checkjob -v --flags=future 6235</pre> <p><i>Display reasons why idle job is blocked ignoring node state and current node utilization constraints.</i></p> |

| exact              |                                                   |
|--------------------|---------------------------------------------------|
| <b>Format</b>      | exact:<JOBID>                                     |
| <b>Description</b> | Searches for and returns the exact job ID         |
| <b>Example</b>     | <pre>&gt; checkjob exact:1.job_ dependency1</pre> |

| -l (Policy level) |                                            |
|-------------------|--------------------------------------------|
| <b>Format</b>     | <POLICYLEVEL><br><i>HARD, SOFT, or OFF</i> |

| -l (Policy level)  |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Description</b> | Reports job start eligibility subject to specified throttling policy level. |
| <b>Example</b>     | <pre>&gt; checkjob -l SOFT 6235 &gt; checkjob -l HARD 6235</pre>            |

| -n (NodeID)        |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <NODEID>                                                                                                             |
| <b>Description</b> | Checks job access to specified node and <a href="#">preemption</a> status with regards to jobs located on that node. |
| <b>Example</b>     | <pre>&gt; checkjob -n node113 6235</pre>                                                                             |

| -q (QoS)           |                                             |
|--------------------|---------------------------------------------|
| <b>Format</b>      | <QOSID>                                     |
| <b>Description</b> | Checks job access to specified QoS <QOSID>. |
| <b>Example</b>     | <pre>&gt; checkjob -q special 6235</pre>    |

| -r (Reservation)   |                                                     |
|--------------------|-----------------------------------------------------|
| <b>Format</b>      | <RSVID>                                             |
| <b>Description</b> | Checks job access to specified reservation <RSVID>. |
| <b>Example:</b>    | <pre>&gt; checkjob -r orion.1 6235</pre>            |

**-v (Verbose)**

|                    |                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Sets verbose mode. If the job is part of an array, the <code>-v</code> option shows pertinent array information before the job-specific information (see <a href="#">Example 2</a> and <a href="#">Example 3</a> for differences between standard output and <code>-v</code> output).                                             |
|                    | <div style="background-color: #e6f2ff; border-radius: 5px; padding: 5px;"> <span style="font-size: 1.2em; font-weight: bold; color: #4a7c9c;">i</span> Specifying the double verbose (<code>-v -v</code>) displays additional information about the job. See <a href="#">the Output table</a> for details.                 </div> |
| <b>Example</b>     | <pre>&gt; checkjob -v 6235</pre>                                                                                                                                                                                                                                                                                                  |

## Details

This command allows any Moab administrator to check the detailed status and resource requirements of an active, queued, or recently [completed](#) job. Additionally, this command performs numerous diagnostic checks and determines if and where the job could potentially run. Diagnostic checks include [policy](#) violations, reservation constraints, preemption status, and job to resource mapping. If a job cannot run, a text reason is provided along with a summary of how many nodes are and are not available. If the `-v` flag is specified, a node by node summary of resource availability will be displayed for idle jobs.

### Job Eligibility

If a job cannot run, a text reason is provided along with a summary of how many nodes are and are not available. If the `-v` flag is specified, a node by node summary of resource availability will be displayed for idle jobs. For job level eligibility issues, one of the following reasons will be given:

| Reason                                     | Description                                                                     |
|--------------------------------------------|---------------------------------------------------------------------------------|
| <b>job has hold in place</b>               | one or more job holds are currently in place                                    |
| <b>insufficient idle procs</b>             | there are currently not adequate processor resources available to start the job |
| <b>idle procs do not meet requirements</b> | adequate idle processors are available but these do not meet job requirements   |
| <b>start date not reached</b>              | job has specified a minimum <i>start date</i> which is still in the future      |
| <b>expected state is not idle</b>          | job is in an unexpected state                                                   |
| <b>state is not idle</b>                   | job is not in the idle state                                                    |

| Reason                       | Description                                         |
|------------------------------|-----------------------------------------------------|
| <b>dependency is not met</b> | job depends on another job reaching a certain state |
| <b>rejected by policy</b>    | job start is prevented by a throttling policy       |

If a job cannot run on a particular node, one of the following 'per node' reasons will be given:

| Reason          | Description                                      |
|-----------------|--------------------------------------------------|
| <b>Class</b>    | Node does not allow required job class/queue     |
| <b>CPU</b>      | Node does not possess required processors        |
| <b>Disk</b>     | Node does not possess required local disk        |
| <b>Features</b> | Node does not possess required node features     |
| <b>Memory</b>   | Node does not possess required real memory       |
| <b>Network</b>  | Node does not possess required network interface |
| <b>State</b>    | Node is not Idle or Running                      |

## Reservation Access

The `-r` flag can be used to provide detailed information about job access to a specific reservation

## Preemption Status

If a job is marked as a [preemptor](#) and the `-v` and `-n` flags are specified, `checkjob` will perform a job by job analysis for all jobs on the specified node to determine if they can be preempted.

## Output

The `checkjob` command displays the following job attributes:

| Attribute      | Value    | Description                         |
|----------------|----------|-------------------------------------|
| <b>Account</b> | <STRING> | Name of account associated with job |

| Attribute                           | Value                                                   | Description                                                                                                                                                                             |
|-------------------------------------|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Actual Run Time</b>              | [[[DD:]HH:]MM:]SS                                       | Length of time job actually ran.<br> This info is only displayed in simulation mode.                   |
| <b>Allocated Nodes</b>              | Square bracket delimited list of node and processor ids | List of nodes and processors allocated to job                                                                                                                                           |
| <b>Applied Nodeset**</b>            | <STRING>                                                | Nodeset used for job's node allocation                                                                                                                                                  |
| <b>Arch</b>                         | <STRING>                                                | Node architecture required by job                                                                                                                                                       |
| <b>Attr</b>                         | square bracket delimited list of job attributes         | Job Attributes (i.e. [BACKFILL] [PREEMPT])                                                                                                                                              |
| <b>Available Memory**</b>           | <INTEGER>                                               | The available memory requested by job. Moab displays the relative or exact value by returning a comparison symbol (>, <, >=, <=, or ==) with the value (i.e. Available Memory <= 2048). |
| <b>Available Swap**</b>             | <INTEGER>                                               | The available swap requested by job. Moab displays the relative or exact value by returning a comparison symbol (>, <, >=, <=, or ==) with the value (i.e. Available Swap >= 1024).     |
| <b>Average Utilized Procs*</b>      | <FLOAT>                                                 | Average load balance for a job                                                                                                                                                          |
| <b>Avg Util Resources Per Task*</b> | <FLOAT>                                                 |                                                                                                                                                                                         |
| <b>BecameEligible</b>               | <TIMESTAMP>                                             | The date and time when the job moved from Blocked to Eligible.                                                                                                                          |
| <b>Bypass</b>                       | <INTEGER>                                               | Number of times a lower priority job with a later submit time ran before the job                                                                                                        |

| Attribute                           | Value                                  | Description                                                    |
|-------------------------------------|----------------------------------------|----------------------------------------------------------------|
| <b>User</b>                         | <STRING>                               | Name of user submitting job                                    |
| <b>Utilized Resources Per Task*</b> | <FLOAT>                                |                                                                |
| <b>WallTime</b>                     | [[[DD:]HH:]MM:]SS of [[[DD:]HH:]MM:]SS | Length of time job has been running out of the specified limit |

In the above table, fields marked with an asterisk (\*) are only displayed when set or when the `-v` flag is specified. Fields marked with two asterisks (\*\*) are only displayed when set or when the `-v -v` flag is specified.

*Example 3-10: checkjob 717*

```

> checkjob 717
job 717
State: Idle
Creds: user:jacksond group:jacksond class:batch
WallTime: 00:00:00 of 00:01:40
SubmitTime: Mon Aug 15 20:49:41
  (Time Queued Total: 3:12:23:13 Eligible: 3:12:23:11)
TerminationDate: INFINITY Sat Oct 24 06:26:40
Total Tasks: 1
Req[0] TaskCount: 1 Partition: ALL
Network: --- Memory >= 0 Disk >= 0 Swap >= 0
Opsys: --- Arch: --- Features: ---

IWD: /home/jacksond/moab/moab-4.2.3
Executable: STDIN
Flags: RESTARTABLE,NORMSTART
StartPriority: 5063
Reservation '717' ( INFINITY -> INFINITY Duration: 00:01:40)
Note: job cannot run in partition base (idle procs do not meet requirements : 0 of 1
procs found)
idle procs: 4 feasible procs: 0
Rejection Reasons: [State : 3][ReserveTime : 1]
cannot select job 717 for partition GM (partition GM does not support requested class
batch)

```

*The example job cannot be started for two different reasons.*

- It is temporarily blocked from partition *base* because of node state and node reservation conflicts.
- It is permanently blocked from partition *GM* because the requested class *batch* is not supported in that partition.

**Example 3-11: Using `checkjob` (no `-v`) on a job array master job:**

```

checkjob array.1
job array.1

AName: array
Job Array Info:
  Name: array.1

Sub-jobs:          10
Active:            6 ( 60.0%)
Eligible:          2 ( 20.0%)
Blocked:           2 ( 20.0%)
Complete:          0 (  0.0%)

```

**Example 3-12: Using `checkjob -v` on a job array master job:**

```

$ checkjob -v array.1
job array.1

AName: array
Job Array Info:
  Name: array.1
  1 : array.1.1 : Running
  2 : array.1.2 : Running
  3 : array.1.3 : Running
  4 : array.1.4 : Running
  5 : array.1.5 : Running
  6 : array.1.6 : Running
  7 : array.1.7 : Idle
  8 : array.1.8 : Idle
  9 : array.1.9 : Blocked
 10 : array.1.10 : Blocked

Sub-jobs:          10
Active:            6 ( 60.0%)
Eligible:          2 ( 20.0%)
Blocked:           2 ( 20.0%)
Complete:          0 (  0.0%)

```

**Example 3-13: Using `checkjob -v` on a data staging job**

```

$ checkjob -v moab.14.dsin
job moab.14.dsin

AName: moab.14.dsin
State: Running
Creds: user:fred group:company

# checknode

## Synopsis

```
checknode options nodeID
          ALL
```

## Overview

This command shows detailed state information and statistics for nodes that run jobs.

The following information is returned by this command:

| Name             | Description                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------|
| <b>Disk</b>      | Disk space available                                                                                    |
| <b>Memory</b>    | Memory available                                                                                        |
| <b>Swap</b>      | Swap space available                                                                                    |
| <b>State</b>     | Node state                                                                                              |
| <b>Opsys</b>     | Operating system                                                                                        |
| <b>Arch</b>      | Architecture                                                                                            |
| <b>Adapters</b>  | Network adapters available                                                                              |
| <b>Features</b>  | Features available                                                                                      |
| <b>Classes</b>   | Classes available                                                                                       |
| <b>StateTime</b> | Time node has been in current state in HH:MM:SS notation                                                |
| <b>Downtime</b>  | Displayed only if downtime is scheduled                                                                 |
| <b>Load</b>      | CPU Load (Berkley one-minute load average)                                                              |
| <b>TotalTime</b> | Total time node has been detected since statistics initialization expressed in <i>HH:MM:SS</i> notation |

| Name                       | Description                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UpTime</b>              | Total time node has been in an available (Non-Down) state since statistics initialization expressed in <i>HH:MM:SS</i> notation (percent of time up: UpTime/TotalTime)    |
| <b>ActiveTime</b>          | Total time node has been busy (allocated to active jobs) since statistics initialization expressed in <i>HH:MM:SS</i> notation (percent of time busy: BusyTime/TotalTime) |
| <b>EffNodeAccessPolicy</b> | Configured effective node access policy                                                                                                                                   |

After displaying this information, some analysis is performed and any unusual conditions are reported.

## Access

By default, this command can be run by any Moab Administrator (see [ADMINCFG](#)).

## Parameters

| Name        | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NODE</b> | Node name you want to check. Moab uses regular expressions to return any node that contains the provided argument. For example, if you ran <code>checknode node1</code> , Moab would return information about <code>node1</code> , <code>node10</code> , <code>node100</code> , etc. If you want to limit the results to <code>node1</code> only, you would run <code>checknode "^node1\$"</code> . |

## Flags

| Name         | Description                                                    |
|--------------|----------------------------------------------------------------|
| <b>ALL</b>   | Returns checknode output on all nodes in the cluster.          |
| <b>-h</b>    | Help for this command.                                         |
| <b>-v</b>    | Returns verbose output.                                        |
| <b>--xml</b> | Output in XML format. Same as <a href="#">mdiag -n --xml</a> . |

*Example 3-14: checknode*

```
> checknode P690-032
node P690-032

mcredctl

Synopsis

```
mcredctl [-d credtype[:credid]] [-h credtype:credid] [-l credtype] [-q
{role|limit|profile|accessfrom|accesssto|policies} credtype[:credid]] [--format=xml] [-r
{stats|credits|fairshare} credtype[:credid]] [-t <STARTTIME>[,<ENDTIME>]
```

Overview

The mcredctl command controls various aspects about the credential objects within Moab. It can be used to display configuration, limits, roles, and relationships for various Moab credential objects.

Arguments

**i** In all cases <CREDTYPE> is one of acct, group, user, class, or qos.

**i** In most cases it is necessary to use the --format=xml flag in order to print the output (see examples below for specific syntax requirements).

| -d - DESTROY       |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <TYPE>: <VAL>                                                                                                                 |
| <b>Description</b> | Purge a credential from moab.cfg (does not delete credential from memory).                                                    |
| <b>Example</b>     | <pre>&gt; mcredctl -d user:john</pre> <p><i>All references to <b>USERCFG</b>[john] will be commented out of moab.cfg)</i></p> |

| -h - HOLD          |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Format</b>      | <TYPE>:<VAL>                                                                         |
| <b>Description</b> | Toggles whether a given credentials' jobs should be place on hold or not.            |
| <b>Example</b>     | <pre>&gt; mcredctl -h user:john</pre> <p><i>User [john] will be put on hold.</i></p> |

| -l - LIST          |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <TYPE>                                                                                                                                                                                          |
| <b>Description</b> | List the various sub-objects of the specified credential.                                                                                                                                       |
| <b>Example</b>     | <pre>&gt; mcredctl -l user --format=xml</pre> <p><i>List all users within Moab in XML.</i></p> <pre>&gt; mcredctl -l group --format=xml</pre> <p><i>List all groups within Moab in XML.</i></p> |

| -q - QUERY          |                                                                                                                                                                                                          |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>       | {role   accessfrom   accessto   limit   profile   policies}<br>limit <TYPE><br>policies <TYPE><br>role <USER>:<USERID><br>profile <TYPE>[:<VAL>]<br>accessfrom <TYPE>[:<VAL>]<br>accessto <TYPE>[:<VAL>] |
| <b>Description:</b> | Display various aspects of a credential (formatted in XML)                                                                                                                                               |

**-q - QUERY**

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <b>Example:</b> | <pre>&gt; mcredctl -q role user:bob --format=xml</pre>                                         |
|                 | <i>View user bob's administrative role within Moab in XML</i>                                  |
|                 | <pre>&gt; mcredctl -q limit acct --format=xml</pre>                                            |
|                 | <i>Display limits for all accounts in XML</i>                                                  |
|                 | <pre>&gt; mcredctl -q policies user:bob</pre>                                                  |
|                 | <i>View limits organized by credential for user bob on each partition and resource manager</i> |

**-r - RESET**

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Format</b>      | <TYPE>                                                                             |
| <b>Description</b> | Resets the credential within Moab.                                                 |
| <b>Example</b>     | <pre>&gt; mcredctl -r user:john</pre><br><i>Resets the credential of user john</i> |

**-t - TIMEFRAME**

|                    |                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Format</b>      | <STARTTIME>[,<ENDTIME>]                                                                                             |
| <b>Description</b> | Can be used in conjunction with the -q profile option to display profiling information for the specified timeframe. |
| <b>Example</b>     | <pre>&gt; mcredctl -q profile user -t 14:30_06/20</pre>                                                             |

### Credential Statistics XML Output

Credential statistics can be requested as XML (via the --format=xml argument) and will be written to STDOUT in the following format:

```
> mcredctl -q profile user --format=xml -o time:1182927600,1183013999
<Data>
  <user ...>
    <Profile ...>
    </Profile>
  </user>
</Data>
```

#### Example 3-16: Deleting a group

```
> mcredctl -d group:john
GROUPCFG[john] Successfully purged from config files
```

#### Example 3-17: List users in XML format

```
> mcredctl -l user --format=xml
<Data><user ID="john"></user><user ID="john"></user><user ID="root"></user><user
ID="dev"></user></Data>
```

#### Example 3-18: Display information about a user

```
> mcredctl -q role user:john --format=xml
<Data><user ID="test" role="admin5"></user></Data>
```

[mdiag -g](#) [*groupid*]

[mdiag -G](#) [*Green*]

[mdiag -j](#) [*jobid*] [-t *partition*] [-v] [--blocking]

[mdiag -L](#) [-v] // diagnose usage limits

[mdiag -n](#) [-A *creds*] [-t *partition*] [*nodeid*] [-v]

[mdiag -p](#) [-t *partition*] [-v] // diagnose job priority

[mdiag -q](#) [*qosid*]

`mdiag -r [reservationid] [-v] [-w type=<type>] [--blocking]`

`mdiag -R [resourcemanagename] [-v]`

`mdiag -s [standingreservationid] [--blocking]`

`mdiag -S [-v] // diagnose scheduler`

`mdiag -t [-v] // diagnose partitions`

`mdiag -T [triggerid] [-v] [--blocking]`

`mdiag -u [userid]`

`mdiag [--format=xml]`

## Overview

The `mdiag` command is used to display information about various aspects of the cluster and the results of internal diagnostic tests. In summary, it provides the following:

- current object health and state information
- current object configuration (resources, policies, attributes, etc)
- current and historical performance/utilization information
- reports on recent failure
- object messages

Some `mdiag` options gather information from the Moab cache which prevents them from interrupting the scheduler, but the `--blocking` option can be used to bypass the cache and interrupt the scheduler.

## Arguments

| Argument                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Argument            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-C [file]</b>    | With the vast array of options in the configuration file, the <code>-C</code> option does not validate function, but it does analyze the configuration file for syntax errors including use of invalid parameters, deprecated parameters, and some illegal values. If you start Moab with the <code>-e</code> flag, Moab evaluates the configuration file at startup and quits if an error exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>-e</b>           | Moab will do a query for all events whose <i>eventtime</i> starts at <i>&lt;starttime&gt;</i> and matches the search criteria. This works only when Moab is configured with ODBC MySQL. The syntax is:<br><code>mdiag -e[-w &lt;starttime&gt; &lt;eventtypes&gt; &lt;oidlist&gt; &lt;eidlist&gt; &lt;objectlist&gt;] --xml</code> <ul style="list-style-type: none"> <li>• <i>starttime</i> default is -</li> <li>•</li> <li>• <i>eventtypes</i> default is command delimited, the default is all event types (possible values can be found in the EventType table in the Moab database)</li> <li>• <i>oidlist</i> is a comma-delimited list of object ids, the default is all objects ids</li> <li>• <i>eidlist</i> is a comma-delimited list of specific event ids, the default is all event ids</li> <li>• <i>objectlist</i> is a comma-delimited list of object types, the default is all object types (possible values can be found in the ObjectType table in the Moab database)</li> </ul> |
| <b>-f</b>           | Display <a href="#">fairshare</a> information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>-g [groupid]</b> | display <a href="#">group</a> information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>--format=xml</b>                         | display output in XML format                                                                         |

## XML Output

Information for most of the options can be reported as XML as well. This is done with the command `mdiag -<option> <CLASS_ID> --format=xml`. For example, XML-based class information will be written to STDOUT in the following format:

```
<Data>
  <class <ATTR>="<VAL>" ... >
    <stats <ATTR>="<VAL>" ... >
      <Profile <ATTR>="<VAL>" ... >
        </Profile>
      </stats>
    </class>
  <Data>
  ...
</Data>
```

Of the `mdiag` options, only `-G` and `-L` cannot be reported as XML.

## mdiag -a

## Synopsis

```
mdiag -a [accountid]
```

## Overview

The `mdiag -a` command provides detailed information about the [accounts](#) (aka projects) Moab is currently tracking. This command also allows an administrator to verify correct throttling policies and access provided to and from other credentials.

*Example 3-19: Generating information about accounts*

```
> mdiag -a

### **mdiag -b**

## Synopsis

```
mdiag -b [-l policylevel] [-t partition]
```

## Overview

The `mdiag -b` command returns information about blocked jobs.

### **mdiag -c**

## Synopsis

```
mdiag -c [-v] [classid]
```

## Overview

The `mdiag -c` command provides detailed information about the classes Moab is currently tracking. This command also allows an administrator to verify correct throttling policies and access provided to and from other credentials.

 The term class is used interchangeably with the term queue and generally refers to resource manager queue.

## XML Attributes

Name	Description
<b>ADEF</b>	Accounts a class has access to.
<b>CAPACITY</b>	Number of procs available to the class.
<b>DEFAULT.ATTR</b>	Default attributes attached to a job.
<b>DEFAULT.DISK</b>	Default required disk attached to a job.
<b>DEFAULT.FEATURES</b>	Default required node features attached to a job.
<b>DEFAULT.GRES</b>	Default generic resources attached to a job.
<b>DEFAULT.MEM</b>	Default required memory attached to a job.
<b>DEFAULT.NODESET</b>	Default specified nodeset attached to a job.
<b>DEFAULT.WCLIMIT</b>	Default wallclock limit attached to a job.
<b>EXCL.FEATURES</b>	List of excluded (disallowed) node features.
<b>EXCL.FLAGS</b>	List of excluded (disallowed) job flags.
<b>FSTARGET</b>	The class' fairshare target.
<b>HOLD</b>	If TRUE this credential has a hold on it, FALSE otherwise.
<b>HOSTLIST</b>	The list of hosts in this class.

Name	Description
<b>JOBEPILOG</b>	Scheduler level job epilog to be run after job is completed by resource manager (script path).
<b>JOBFLAGS</b>	Default flags attached to jobs in the class.
<b>JOBPROLOG</b>	Scheduler level job prolog to be run before job is started by resource manager (script path).
<b>ID</b>	The unique ID of this class.
<b>LOGLEVEL</b>	The log level attached to jobs in the class.
<b>MAX.PROC</b>	The max processors per job in the class.
<b>MAX.PS</b>	The max processor-seconds per job in the class.
<b>MAX.WCLIMIT</b>	The max wallclock limit per job in the class.
<b>MAXIJOB</b>	The max idle jobs in the class.
<b>MAXIPROC</b>	The max idle processors in the class.
<b>MAXJOBPERUSER</b>	The max jobs per user.
<b>MAXNODEPERJOB</b>	The max nodes per job.
<b>MAXNODEPERUSER</b>	The max nodes per user.
<b>MAXPROCPERJOB</b>	The max processors per job.
<b>MAXPROCPERNODE</b>	The max processors per node.
<b>MAXPROCPERUSER</b>	The max processors per user.
<b>MIN.NODE</b>	The minimum nodes per job in the class.
<b>MIN.PROC</b>	The minimum processors per job in the class.

Name	Description
<b>MIN.WCLIMIT</b>	The minimum wallclock limit per job in the class.
<b>NODEACCESSPOLICY</b>	The node access policy associated with jobs in the class.
<b>OCDPROCFACTOR</b>	Dedicated processor factor.
<b>OCNODE</b>	Overcommit node.
<b>PRIORITY</b>	The class' associated priority.
<b>PRIORITYF</b>	Priority calculation function.
<b>REQ.FEATURES</b>	Required features for a job to be considered in the class.
<b>REQ.FLAGS</b>	Required flags for a job to be considered in the class.
<b>REQ.IMAGE</b>	Required image for a job to be considered in the class.
<b>REQUIREDUSERLIST</b>	The list of users who have access to the class.
<b>RM</b>	The resource manager reporting the class.
<b>STATE</b>	The class' state.
<b>WCOVERRUN</b>	Tolerated amount of time beyond the specified wallclock limit.

## Example 3-20: Generating information about classes

0.00      ---
batch        1      ---      ---          ---      [A] [B]
70.00      MAXJOB=33:200,250
          MAX.WCLIMIT=10:00:00  MAXPROCPERJOB=128
long         1      ---      low          low      [A]
10.00      MAXJOB=3:100,200
          MAX.WCLIMIT=1:00:00:00  MAXPROCPERJOB=128
fast         100    ---      high         high     [B]
10.00      MAXJOB=8:100,150
          MAX.WCLIMIT=00:30:00  MAXPROCPERJOB=128
bigmem       1      ---      low,high     low      ---
10.00      MAXJOB=1:100,200
          MAXPROCPERJOB=128

```

In the example above, class **fast** has **MAXJOB** soft and hard limits of **100** and **150** respectively and is currently running **8** jobs.

 The Limits column will display limits in the following format:  
<USAGE>:<HARDLIMIT>[,<SOFTLIMIT>]

## Related topics

- [showstats](#) command - display general statistics

**mdiag -f****Synopsis**

```
mdiag -f [-o user|group|acct|qos|class] [--flags=relative] [-w par=<PARTITIONID>]
```

**Overview**

The `mdiag -f` command is used to display at a glance information about the fairshare configuration and historic resource utilization. The fairshare usage may impact job prioritization, job eligibility, or both based on the credential **FSTARGET** and **FSCAP** attributes and by the fairshare priority weights as described in the [Job Prioritization Overview](#). The information presented by this command includes fairshare configuration and credential fairshare usage over time.

The command hides information about credentials which have no fairshare target and no fairshare cap.

If an object type (<OTYPE>) is specified, then only information for that credential type (user, group, acct, class, or qos) will be displayed. If the `relative` flag is set, then per user fairshare usage will be displayed relative to each non-user credential (see the second example below).

 Relative output is only displayed for credentials which have user mappings. For example, if there is no association between classes and users, no relative per user fairshare usage class breakdown will be provided.

Example 3-21: Standard Fairshare Output

**mdiag -g****Synopsis**

```
mdiag -g [groupid]
```

**Overview**

The `mdiag -g` command is used to present information about groups.

**mdiag -j****Synopsis**

```
mdiag -j [jobid] [-t <partition>] [-v] [-w] [--flags=policy] [--xml] [--blocking]
```

## Overview

The `mdiag -j` command provides detailed information about the state of jobs Moab is currently tracking. This command also performs a large number of sanity and state checks. The job configuration and status information, as well as the results of the various checks, are presented by this command. The command gathers information from the Moab cache which prevents it from interrupting the scheduler, but the `--blocking` option can be used to bypass the cache and interrupt the scheduler. If the `-v` (verbose) flag is specified, additional information about less common job attributes is displayed. If `--flags=policy` is specified, information about job templates is displayed.

If used with the `-t <partition>` option on a running job, the only thing `mdiag -j` shows is if the job is running on the specified partition. If used on job that is not running, it shows if the job is able to run on the specified partition.

The `-w` flag enables you to specify specific job states (Such as Running, Completed, Idle, or ALL. See [Job States on page 99](#) for all valid options.) or jobs associated with a given credential (user, acct, class, group, qos). For example:

```
mdiag -j -w user=david           # Displays only David's jobs
mdiag -j -w state=Idle,Running  # Displays only idle or running jobs
```

**i** The `mdiag -j` command does not show all subjobs of an array unless you use `mdiag -j --xml`. In the XML, the master job element contains a child element called `ArraySubJobs` that contains the subjobs in the array. Using `mdiag -j -v --xml` shows the completed sub-jobs as well.

## XML Output

If XML output is requested (via the `--format=xml` argument), XML based node information will be written to STDOUT in the following format:

```
<Data>
  <job ATTR="VALUE" ... > </job>
  ...
</Data>
```

For information about legal attributes, refer to the [XML Attributes](#) table.

**i** To show jobs in XML, use `mdiag -j --xml -w [completed=true|system=true|ALL=true]` to limit or filter jobs. This is for XML use only.

### mdiag -n

## Synopsis

```
mdiag -n [-t partitionid] [-A creds] [-w <CONSTRAINT>] [-v] [--format=xml] [nodeid]
```

## Overview

The `mdiag -n` command provides detailed information about the state of nodes Moab is currently tracking. This command also performs a large number of sanity and state checks. The node configuration and status information as well as the results of the various checks are presented by this command.

## Arguments

Flag	Argument	Description
<b>[-A]</b>	{user group account qos class job}: <OBJECTID>	report if each node is accessible by requested job or credential
<b>[-t]</b>	<partitionid>	report only nodes from specified partition
<b>[-v]</b>	---	show verbose output (do not truncate columns and add columns for additional node attributes)
<b>[-w]</b>	nodestate=drained	display only jobs associated with the specified constraint: nodestate (See <a href="#">DISPLAYFLAGS</a> for more information.)

## Output

This command presents detailed node information in whitespace-delineated fields.

The output of this command can be extensive and the values for a number of fields may be truncated. If truncated, the `-v` flag can be used to display full field content.

## XML Output

If XML output is requested (via the `--format=xml` argument), XML based node information will be written to STDOUT in the following format:

```
mdiag -n --format=xml
<Data>
  <node> <ATTR>="<VAL>" ... </node>
  ...
</Data>
```

## XML Attributes

Name	Description
<b>AGRES</b>	Available generic resources
<b>ALLOCRES</b>	Special allocated resources (like vlans)
<b>ARCH</b>	The node's processor architecture.
<b>AVLCLASS</b>	Classes available on the node.
<b>AVLETIME</b>	Time when the node will no longer be available (used in Utility centers)
<b>AVLSTIME</b>	Time when the node will be available (used in Utility centers)
<b>CFGCLASS</b>	Classes configured on the node
<b>ENABLEPROFILING</b>	If true, a node's state and usage is tracked over time.
<b>FEATURES</b>	A list of comma-separated custom features describing a node.
<b>GEVENT</b>	A user-defined event that allows Moab to perform some action.
<b>GMETRIC</b>	A list of comma-separated consumable resources associated with a node.
<b>GRES</b>	generic resources on the node

Name	Description
<b>HOPCOUNT</b>	How many hops the node took to reach this Moab (used in hierarchical grids)
<b>ISDELETED</b>	Node has been deleted
<b>ISDYNAMIC</b>	Node is dynamic (used in Utility centers)
<b>JOBLIST</b>	The list of jobs currently running on a node.
<b>LOAD</b>	Current load as reported by the resource manager
<b>LOADWEIGHT</b>	Load weight used when calculating node priority
<b>MAXJOB</b>	See <a href="#">Node Policies</a> for details.
<b>MAXJOBPERUSER</b>	See <a href="#">Node Policies</a> for details.
<b>MAXLOAD</b>	See <a href="#">Node Policies</a> for details.
<b>MAXPROC</b>	See <a href="#">Node Policies</a> for details.
<b>MAXPROCPERUSER</b>	See <a href="#">Node Policies</a> for details.
<b>NETWORK</b>	The ability to specify which networks are available to a given node is limited to only a few resource managers. Using the <b>NETWORK</b> attribute, administrators can establish this node to network connection directly through the scheduler. The <a href="#">NODECFG</a> parameter allows this list to be specified in a comma-delimited list.
<b>NODEID</b>	The unique identifier for a node.
<b>NODESTATE</b>	The state of a node.
<b>OS</b>	A node's operating system.
<b>OSLIST</b>	Operating systems the node can run
<b>OSMODACTION</b>	URL for changing the operating system
<b>OWNER</b>	Credential type and name of owner

Name	Description
<b>PARTITION</b>	The partition a node belongs to. See <a href="#">Node Location</a> for details.
<b>POWER</b>	The state of the node's power. Either ON or OFF.
<b>PRIORITY</b>	The fixed node priority relative to other nodes.
<b>PROCSPEED</b>	A node's processor speed information specified in MHz.
<b>RACK</b>	The rack associated with a node's physical location.
<b>RADISK</b>	The total available disk on a node.
<b>RAMEM</b>	The total available memory available on a node.
<b>RAPROC</b>	The total number of processors available on a node.
<b>RASWAP</b>	The total available swap on a node.
<b>RCMEM</b>	The total configured memory on a node.
<b>RCPROC</b>	The total configured processors on a node.
<b>RCSWAP</b>	The total configured swap on a node.
<b>RESCOUNT</b>	Number of reservations on the node
<b>RSVLIST</b>	List of reservations on the node
<b>RESOURCES</b>	Deprecated (use GRES)
<b>RMAccessLIST</b>	A comma-separated list of resource managers who have access to a node.
<b>SIZE</b>	The number of slots or size units consumed by the node.
<b>SLOT</b>	The first slot in the rack associated with the node's physical location.
<b>SPEED</b>	A node's relative speed.
<b>SPEEDWEIGHT</b>	speed weight used to calculate node's priority

Name	Description
<b>STATACTIVETIME</b>	Time node was active
<b>STATMODIFYTIME</b>	Time node's state was modified
<b>STATTOTALTIME</b>	Time node has been monitored
<b>STATUPTIME</b>	Time node has been up
<b>TASKCOUNT</b>	The number of tasks on a node.

**mdiag -t**

## Synopsis

```
mdiag -t [-v] [-v] [partitionid]
```

## Overview

The `mdiag -t` command is used to present configuration, usage, health, and diagnostic information about partitions maintained by Moab. The information presented includes partition name, limits, configured and available resources, allocation weights and policies.

## Examples

*Example 3-24: Standard partition diagnostics*

```
> mdiag -t
Partition Status
...
```

**mdiag -p**

## Synopsis

```
mdiag -p [-t partition] [-v]
```

## Overview

The `mdiag -p` command is used to display at a glance information about the job priority configuration and its effects on the current eligible jobs. The information presented by this command includes priority

weights, priority components, and the percentage contribution of each component to the total job priority.

The command hides information about priority components which have been deactivated (i.e. by setting the corresponding component priority weight to 0). For each displayed priority component, this command gives a small amount of context sensitive information. The following table documents this information. In all cases, the output is of the form `<PERCENT>(<CONTEXT INFO>)` where `<PERCENT>` is the percentage contribution of the associated priority component to the job's total priority.

**i** By default, this command only shows information for jobs which are eligible for immediate execution. Jobs which violate soft or hard policies, or have holds, job dependencies, or other job constraints in place will not be displayed. If priority information is needed for any of these jobs, use the `-v` flag or the `checkjob` command.

## Format

Flag	Name	Format	Default	Description	Example
<code>-v</code>	VERBOSE	---	---	Display verbose priority information. If specified, display priority breakdown information for blocked, eligible, and active jobs. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> By default, only information for eligible jobs is displayed. To view blocked jobs in addition to eligible, run <code>mdiag -p -v -v</code>.</p> </div>	<pre>&gt; mdiag -p -v</pre> <div style="border: 1px dashed black; padding: 5px; margin-top: 10px; text-align: center;"> <i>Display priority summary information for eligible and active jobs</i> </div>

## Output

Priority Component	Format	Description
<b>Target</b>	<code>&lt;PERCENT&gt;()</code>	
<b>QOS</b>	<code>&lt;PERCENT&gt;(&lt;QOS&gt;:&lt;QOSPRI&gt;)</code>	QOS — QOS associated with job QOSPRI — Priority assigned to the QOS

Priority Component	Format	Description
<b>FairShare</b>	<PERCENT> ( <USR>:<GRP>:<ACC>:<QOS>:<CLS>)	<i>USR</i> — user fs usage - user fs target <i>GRP</i> — group fs usage - group fs target <i>ACC</i> — account fs usage - account fs target <i>QOS</i> — QOS fs usage - QOS fs target <i>CLS</i> — class fs usage - class fs target
<b>Service</b>	<PERCENT>(<QT>:<XF>:<Byp>)	<i>QTime</i> — job queue time which is applicable towards priority (in minutes) <i>XF</i> — current theoretical minimum XFactor is job were to start immediately <i>Byp</i> — number of times job was bypassed by lower priority jobs via backfill
<b>Resource</b>	<PERCENT> (<NDE>:<PE>:<PRC>:<MEM>)	<i>NDE</i> — nodes requested by job <i>PE</i> — Processor Equivalents as calculated by all resources requested by job <i>PRC</i> — processors requested by job <i>MEM</i> — real memory requested by job

## Examples

### Example 3-25: `mdiag -p`

```
diagnosing job priority information (partition: ALL)

Job          PRIORITY*  Cred(  QOS)  FS(Accnt)  Serv(QTime)

13703         137     36.6( 50.0) 12.8( 17.6) 50.6( 69.2)
13702         79      1.3(  1.0)  5.7(  4.5) 93.0( 73.4)

Percent Contribution -----  0.9( 0.9)  0.4( 0.4) 98.7( 98.7)

* indicates system prio set on job
```

The `mdiag -p` command only displays information for priority components actually utilized. In the above example, QoS, Account Fairshare, and QueueTime components are utilized in determining a job's priority. Other components, such as Service Targets, and Bypass are not used and thus are not displayed. (See the [Priority Overview](#) for more information) The output consists of a header, a job by job analysis of jobs, and a summary section.

The header provides column labeling and provides configured priority component and subcomponent weights. In the above example, `QOSWEIGHT` is set to 1000 and `FSWEIGHT` is set to 100. When configuring fairshare, a site also has the option of weighting the individual components of a job's overall fairshare, including its user, group, and account fairshare components. In this output, the QoS and account fairshare weights are set to 1.

The job by job analysis displays a job's total priority and the percentage contribution to that priority of each of the priority components. In this example, job 13019 has a total priority of 8699. Both QoS and Fairshare contribute to the job's total priority although these factors are quite small, contributing 0.6% and 0.3% respectively with the fairshare factor being contributed by an account fairshare target. For this job, the dominant factor is the `service` subcomponent `qtime` which is contributing 99.1% of the total priority since the job has been in the queue for approximately 8600 minutes.

At the end of the job by job description, a Totals line is displayed which documents the average percentage contributions of each priority component to the current idle jobs. In this example, the QoS, Fairshare, and Service components contributed an average of 0.9%, 0.4%, and 98.7% to the jobs' total priorities.

### **mdiag -r**

## Synopsis

```
mdiag -r [reservationid] [-v] [-w type=<type>]
```

## Overview

The `mdiag -r` command allows administrators to look at detailed reservation information. It provides the name, type, partition, starttime and endtime, proc and node counts, as well as actual utilization figures. It also provides detailed information about which resources are being used, how many nodes, how much memory, swap, and processors are being associated with each task. Administrators can also view the Access Control Lists for each reservation as well as any flags that may be active in the reservation. The command gathers information from the Moab cache which prevents it from waiting for the scheduler, but the `--blocking` option can be used to bypass the cache and allow waiting for the scheduler.

The `-w` flag filters the output according to the type of reservation. The allowable reservation types are Job, and User.

## Examples

**mdiag -R****Synopsis**

```
mdiag -R [-v] [-V job] [resourcemanagerid]
```

**Overview**

The `mdiag -R` command is used to present information about configured resource managers. The information presented includes name, host, port, state, type, performance statistics and failure

notifications.

## Examples

*Example 3-29:*

```

> $ mdiag -R -v
diagnosing resource managers

RM[internal] State: --- Type: SSS ResourceType: COMPUTE

```

## **mdiag -S**

## **Synopsis**

`mdiag -S [-v] [-v]`

## **Overview**

The `mdiag -S` command is used to present information about the status of the scheduler and grid interface.

This command will report on the following aspects of scheduling:

- **General Scheduler Configuration**
  - Reports short and long term scheduler load
  - Reports detected overflows of node, job, reservation, partition, and other scheduler object tables
- **High Availability**
  - Configuration
  - Reports health of HA primary
  - Reports health of HA backup
- **Scheduling Status**
  - Reports if scheduling is paused
  - Reports if scheduling is stopped
- **System Reservation Status**
  - Reports if global system reservation is active
- **Message Profiling/Statistics Status**
- **Moab scheduling activities (only with `mdiag -S -v -v`)**
  - Activity[JobStart]: Time Moab spends telling the RM to start a job and waiting for a response.
  - Activity[RMResourceLoad]: Time Moab spends querying license managers and nodes.
  - Activity[RMWorkloadLoad]: Time Moab spends querying resource managers about jobs (as opposed to nodes)
  - Activity[Schedule]: Time Moab spends prioritizing jobs and scheduling them onto nodes.
  - Activity[UIProcess]: Time Moab spends handling client commands.

## Examples

### Example 3-30:

```
> mdiag -s
Moab Server running on orion-1:43225 (Mode: NORMAL)
Load(5m)  Sched: 12.27%  RMAAction: 1.16%  RMQuery: 75.30%  User: 0.29%  Idle: 10.98%
Load(24h) Sched: 10.14%  RMAAction: 0.93%  RMQuery: 74.02%  User: 0.11%  Idle: 13.80%
HA Fallback Server: orion-2:43225 (Fallback is Ready)
Note: system reservation blocking all nodes
Message: profiling enabled (531 of 600 samples/5:00 interval)
```

### **mdiag -s**

## Synopsis

```
mdiag -s [reservationid] [-v]>
```

## Overview

The `mdiag -s` command allows administrators to look at detailed standing reservation information. It provides the name, type, partition, starttime and endtime, period, task count, host list, and a list of child instances.

## Examples

### Example 3-31:

```
> mdiag -s
standing reservation overview
RsvID          Type      Par      StartTime      EndTime      Duration      Period
-----
TestSR          User      ---      00:00:00      ---          00:00:00      DAY
  Days:          ALL
  Depth:         2
  RsvList:       testSR.1, testSR.2, testSR.3
  HostExp:       'node1, node2, node4, node8'

test2           User      ---      00:00:00      ---          00:00:00      DAY
  Days:          ALL
  TaskCount:     4
  Depth:         1
  RsvList:       test2.4, test2.5
```

### **mdiag -T**

## Synopsis

```
mdiag -T [triggerid] [-v] [--blocking]
```

## Overview

The `mdiag -T` command is used to present information about each Trigger. The information presented includes Name, State, Action, Event Time. The command gathers information from the Moab cache which prevents it from waiting for the scheduler, but the `-blocking` option can be used to bypass the cache and allow waiting for the scheduler.

## Examples

Example 3-32:

```

> mdiag -T
TrigID          Object ID          Event  AType          ActionDate
State
-----
sched_trig.0    sched:Moab        end    exec           -
Blocked
3              node:node010      threshol  exec           -
Blocked
5              job:Moab.7        preempt  exec           -
Blocked
6              job:Moab.8        preempt  exec           -
Blocked
4*             job:Moab.5        start    exec           -00:00:36
Failure
* indicates trigger has completed

```

**Example 3-33:**

```

> mdiag -T -v
TrigID          Object ID          Event  AType          ActionDate
State
-----
sched_trig.0    sched:Moab        end    exec           -
Blocked
  Name:          sched_trig
  Flags:         globaltrig
  BlockUntil:    INFINITY  ActiveTime:  ---

  Last Execution State: Failure (ExitCode: 0)
  BlockUntil:    00:00:00  ActiveTime:  00:00:00
  Action Data:   $HOME/tools/preemptnotify.pl $OID $OWNER $HOSTNAME
  ALERT: trigger failure detected
  Message:       'exec '/usr/test/moab/tools/preemptnotify.pl' cannot be located or is
not executable'

* indicates trigger has completed

```

**mdiag -u****Synopsis**

```
mdiag -u [userid]
```

**Overview**

The `mdiag -u` command is used to present information about user records maintained by Moab. The information presented includes user name, UID, scheduling priority, default job flags, default QOS level,

List of accessible QOS levels, and list of accessible partitions.

## Examples

Example 3-34:

```

> mdiag -u
evaluating user information

## Overview

The `mjobctl` command controls various aspects of jobs. It is used to submit, cancel, execute, and checkpoint jobs. It can also display diagnostic information about each job. The `mjobctl` command enables the Moab administrator to control almost all aspects of job behavior. See [General Job Administration](#) for more details on jobs and their attributes.

## Format

-c - Cancel	
<b>Format</b>	<a href="#">JOBEXP</a>
<b>Description</b>	Cancel a job. <div style="border: 1px solid #4a6980; border-radius: 10px; padding: 10px; margin-top: 10px;">  Use <a href="#">-w</a> (following a <a href="#">-c</a> flag) to specify job cancellation according to given credentials or job attributes. See <a href="#">-c -w</a> for more information.           </div>
<b>Example:</b>	<pre style="border: 1px dashed #ccc; padding: 10px;"> &gt; mjobctl -c job1045  Cancel job job1045.</pre>

-c -w - Cancel Where	
<b>Format</b>	<ATTR>=<VALUE>  where <ATTR>=[ user   account   qos   class   reqreservation(RsvName)   state (JobState)   job-name(JobName, not job ID)]   partition

**-c -w - Cancel Where**

<b>Description</b>	<p>Cancel a job based on a given credential or job attribute.</p> <p>Use <code>-w</code> following a <code>-c</code> flag to specify job cancellation according to credentials or job attributes. (See examples.)</p> <p>See <a href="#">Job States</a> on page 99 for a list of all valid job states.</p> <p>Also, you can cancel jobs from given partitions using <code>-w partition=&lt;PAR1&gt;[&lt;PAR2&gt;...]</code>; however, you must also either use another <code>-w</code> flag to specify a job or use the standard job expression.</p>
<b>Example</b>	<pre>&gt; mjobctl -c -w state=USERHOLD</pre> <p><i> Cancels all jobs that currently have a USERHOLD on them.</i></p> <pre>&gt; mjobctl -c -w user=user1 -w acct=acct1</pre> <p><i> Cancels all jobs assigned to user1 or acct1.</i></p>

**-C - Checkpoint**

<b>Format</b>	<a href="#">JOBEXP</a>
<b>Description</b>	Checkpoint a job. See <a href="#">Checkpoint/Restart Facilities</a> on page 528 for more information.
<b>Example</b>	<pre>&gt; mjobctl -C job1045</pre> <p><i> Checkpoint job job1045.</i></p>

**-e - Rerun**

<b>Format</b>	JOBID
<b>Description</b>	Rerun the completed TORQUE job. This works only for jobs that are completed and show up in TORQUE as completed. This flag does not work with other resource managers.
<b>Example</b>	<pre>&gt; mjobctl -e job1045</pre> <p><i> Rerun job job1045.</i></p>

-F - Force Cancel	
<b>Format</b>	<u>JOBEXP</u>
<b>Description</b>	Forces a job to cancel and ignores previous cancellation attempts.
<b>Example</b>	<pre>&gt; mjobctl -F job1045</pre> <p><i>Force cancel job job1045.</i></p>

-h - Hold	
<b>Format</b>	<p>&lt;HOLDTYPE&gt;&lt;JOBEXP&gt;</p> <p>&lt;HOLDTYPE&gt; = { user   batch   system   defer   ALL }</p>
<b>Default</b>	user
<b>Description</b>	<p>Set or release a job hold</p> <p>See <a href="#">Job Holds on page 525</a> for more information</p>
<b>Example</b>	<pre>&gt; mjobctl -h user job1045</pre> <p><i>Set a user hold on job job1045.</i></p> <pre>&gt; mjobctl -u all job1045</pre> <p><i>Unset all holds on job job1045.</i></p>

-m - Modify	
<b>Format</b>	<p>&lt;ATTR&gt;{ +=   =   -= } &lt;VAL&gt;</p> <p>&lt;ATTR&gt;={ account   arraylimit   awduration   class   cpuclock   deadline   depend   eeduration   env   features   feature   flags   gres   group   hold   hostlist   jobdisk   jobmem   jobname   job-swap   loglevel   messages   minstarttime   nodecount   notificationaddress   partition   priority   queue   qos   reqreservation   rmxstring   reqattr   reqawduration   sysprio   trig   trigvar   userprio   var   wclimit}</p>

**-m - Modify****Description**

Modify a specific job attribute.

**i** If an `mjobctl -m` attribute can affect how a job starts, then it generally cannot affect a job that is already running. For example, it is not feasible to change the **hostlist** of a job that is already running.

The `userprio` attribute allows you to specify user priority. For job priority, use the `'-p'` flag.

Modification of the job dependency is also communicated to the resource manager in the case of SLURM and PBS/TORQUE.

Adding `--flags=warnifcompleted` causes a warning message to print when a job completes.

To define values for `awduration`, `eeduration`, `minstarttime` (Note that the `minstarttime` attribute performs the same function as [msub -a.](#)), `reqawduration`, and `wclimit`, use the [time spec](#) format.

A non-active job's partition list can be modified by adding or subtracting partitions. Note, though, that when adding or subtracting multiple partitions, each partition must have its own `-m partition{+= | = | -=}name` on the command line. (See example for adding multiple partitions.)

To modify a job's generic resources, use the following format: `gres{ += | = | -= } <gresName>[:<count>].` `<gresName>` is a single resource, not a list. `<count>` is an integer that, if not specified, is assumed to be 1. Modifying a job's generic resources causes Moab to append the new gres (`+=`), subtract the specified gres (`-=`), or clear out all existing generic resources attached to the job and override them with the newly-specified one (`=`).

**-m - Modify****Example**

```
> mjobctl -m reqawduration+=600 1664
```

*Add 10 minutes to the job walltime.*

```
> mjobctl -m eeduration=-1 1664
```

*Reset job's effective queue time, to when the job was submitted.*

```
> mjobctl -m var=Flag1=TRUE 1664
```

*Set the job variable `Flag1` to `TRUE`.*

```
> mjobctl -m notificationaddress="name@server.com"
```

*Sets the notification e-mail address associated with a job to `name@server.com`.*

```
> mjobctl -m partition+=p3 -m partition+=p4 Moab.5
```

*Adds multiple partitions (`p3` and `p4`) to job `Moab.5`.*

```
> mjobctl -m arraylimit=10 sim.25
```

*Changes the concurrently running sub-job limit to 10 for array `sim.25`.*

```
> mjobctl -m gres=matlab:1 job0201
```

*Overrides all generic resources applied to job `job0201` and replaces them with 1 `matlab`.*

```
> mjobctl -m userprio-=100 Moab.4
```

*Reduces the user priority of `Moab.4` by 100.*

**-N - Notify****Format**

```
[signal=]<SIGID>JOBEXP
```

**Description**

Send a signal to all jobs matching the job expression.

**-N - Notify**

<b>Example</b>	<pre>&gt; mjobctl -N INT 1664</pre> <p><i>Send an interrupt signal to job 1664.</i></p> <pre>&gt; mjobctl -N 47 1664</pre> <p><i>Send signal 47 to job 1664.</i></p>
----------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>-n - Name</b>	
<b>Format</b>	
<b>Description</b>	Select jobs by job name.
<b>Example</b>	

<b>-p - Priority</b>	
<b>Format</b>	[+ = -]=<VAL><JOBID> [--flags=relative]
<b>Description</b>	Modify a job's system priority.

**-p - Priority****Example**

Priority is the job priority plus the system priority. Each format affects the job and system priorities differently. Using the format `<VAL><JOBID>` or `+<VAL><JOBID>` will set the system priority to the maximum system priority plus the specified value. Using `+=<VAL><JOBID>` or `<VAL><JOBID> --flags=relative` will relatively increase the job's priority and set the system priority. Using the format `--<VAL> <JOBID>` sets the system priority to 0, and does not change priority based on `<VAL>` (it will not decrease priority by that number).

For the following example, `job1045` has a priority of 10, which is composed of a job priority of 10 and a system priority of 0.

```
> mjobctl -p +1000 job1045
```

*The system priority changes to the max system priority plus 1000 points, ensuring that this job will be higher priority than all normal jobs. In this case, the job priority of 10 is not added, so the priority of `job1045` is now 1000001000.*

```
> mjobctl -p -=1 job1045
```

*The system priority of `job1045` resets to 0. The job priority is still 10, so the overall priority becomes 10.*

```
> mjobctl -p 3 job1045 --flags=relative
```

*Adds 3 points to the relative system priority. The priority for `job1045` changes from 10 to 13.*

**-q - Query**

**Format** [ diag( ALL) | hostlist | starttime | template ] <JOBEXP>

**Description** Query a job.

## -q - Query

### Example

```
> mjobctl -q diag job1045
```

*Query job job1045.*

```
> mjobctl -q diag ALL --format=xml
```

*Query all jobs and return the output in machine-readable XML.*

```
> mjobctl -q starttime job1045
```

*Query starttime of job job1045.*

```
> mjobctl -q template <job>
```

*Query job templates. If the <job> is set to ALL or empty, it will return information for all job templates.*

```
> mjobctl -q wiki <jobName>
```

*Query a job with the output displayed in a WIKI string. The job's name may be replaced with ALL.*

*--flags=completed will only work with the diag option.*

## -r - Resume

### Format

[JOBEXP](#)

### Description

Resume a job.

### Example

```
> mjobctl -r
job1045
```

*Resume
job
job1045.*

## -R - Requeue

### Format

[JOBEXP](#)

**-R - Requeue**

**Description** Requeue a job. Adding `--flags=unmigrate` causes Moab to pull a grid job back to the central scheduler for further evaluation on all valid partitions.

**Example**

```
> mjobctl -R job1045
```

*Requeue job job1045.*

**-s - Suspend**

**Format** [JOBEXP](#)

**Description** Suspend a job. For more information, see [Suspend/Resume Handling](#).

**Example**

```
> mjobctl -s job1045
```

*Suspend job job1045.*

**-u - Unhold**

**Format** [`<TYPE>` [`<TYPE>`]] [JOBEXP](#)  
`<TYPE>` = [ user | system | batch | defer | ALL ]

**Default** ALL

**Description** Release a hold on a job  
 See [Job Holds on page 525](#) for more information.

**Example**

```
> mjobctl -u user,system scrib.1045
```

*Release user and system holds on job scrib.1045.*

**-w - Where**

**Format** [CompletionTime | StartTime][<= | = | >=]<EPOCH\_TIME>

-w - Where	
<b>Description</b>	Add a where constraint clause to the current command. As it pertains to <code>CompletionTime</code>   <code>StartTime</code> , the where constraint only works for completed jobs. <code>CompletionTime</code> filters according to the completed jobs' completion times; <code>StartTime</code> filters according to the completed jobs' start times.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mjobctl -q diag ALL --flags=COMPLETED --format=xml -w CompletionTime&gt;=1246428000 -w CompletionTime&lt;=1254376800</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 10px;"><i>Prints all completed jobs still in memory that completed between July 1, 2009 and October 1, 2009.</i></p>

-x - Execute	
<b>Format</b>	<a href="#">JOBEXP</a>
<b>Description</b>	Execute a job. The <code>-w</code> option allows flags to be set for the job. Allowable flags are, <code>ignorepolicies</code> , <code>ignorenodestate</code> , and <code>ignorersv</code> .
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mjobctl -x job1045</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Execute job job1045.</i></p> <pre style="border: 1px dashed gray; padding: 5px; margin-top: 10px;">&gt; mjobctl -x -w flags=ignorepolicies job1046</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Execute job job1046 and ignore policies, such as MaxJobPerUser.</i></p>

## Parameters

JOB EXPRESSION	
<b>Format</b>	<STRING>

## JOB EXPRESSION

**Description**

The name of a job or a regular expression for several jobs. The flags that support job expressions can use node expression syntax as described in [Node Selection](#). Using `x:` indicates the following string is to be interpreted as a regular expression, and using `r:` indicates the following string is to be interpreted as a range. Job expressions do not work for array sub-jobs.

**i** Moab uses regular expressions conforming to the POSIX 1003.2 standard. This standard is somewhat different than the regular expressions commonly used for filename matching in Unix environments (see man 7 regex). To interpret a job expression as a regular expression, use `x:` or in the Moab configuration file (`moab.cfg`), set the parameter **USEJOBREGEX** to **TRUE** (and take note of the following caution).

**!** If you set **USEJOBREGEX** to **TRUE**, Moab treats all `mjobctl` job expressions as regular expressions regardless of whether wildcards are specified. This should be used with extreme caution since there is high potential for unintended consequences. For example, specifying `canceljob m.1` will not only cancel `m.1`, but also `m.11`, `m.12`, `m.13`, and so on.

**i** In most cases, it is necessary to quote the job expression (for example, `job13[5-9]`) to prevent the shell from intercepting and interpreting the special characters.

**i** The `mjobctl` command accepts a comma delimited list of job expressions. Example usage might be `mjobctl -r job[1-2],job4` or `mjobctl -c job1,job2,job4`.

**Example:**

```
> mjobctl -c "x:80.*"
job '802' cancelled
job '803' cancelled
job '804' cancelled
job '805' cancelled
job '806' cancelled
job '807' cancelled
job '808' cancelled
job '809' cancelled
```

*Cancel all jobs starting with 80.*

```
> mjobctl -m priority+=200 "x:74[3-5]"
job '743' system priority modified
job '744' system priority modified
job '745' system priority modified
```

```
> mjobctl -h x:17.*
# This puts a hold on any job that has a 17 that is followed by an unlimited amount
of any
# character and includes jobs 1701, 17mjk10, and 17DjN_JW-07

> mjobctl -h r:1-17
# This puts a hold on jobs 1 through 17.
```

## XML Output

mjobctl information can be reported as XML as well. This is done with the command `mjobctl -q diag <JOB_ID>`.

### XML Attributes

Name	Description
<b>Account</b>	The account assigned to the job
<b>AllocNodeList</b>	The nodes allocated to the job
<b>Args</b>	The job's executable arguments
<b>AWDuration</b>	The active wall time consumed
<b>BlockReason</b>	The block message index for the reason the job is not eligible
<b>Bypass</b>	Number of times the job has been bypassed by other jobs
<b>Calendar</b>	The job's timeframe constraint calendar
<b>Class</b>	The class assigned to the job
<b>CmdFile</b>	The command file path
<b>CompletionCode</b>	The return code of the job as extracted from the RM
<b>CompletionTime</b>	The time of the job's completion
<b>Cost</b>	The cost of executing the job relative to an allocation manager
<b>CPULimit</b>	The CPU limit for the job
<b>Depend</b>	Any dependencies on the status of other jobs
<b>DRM</b>	The master destination RM
<b>DRMJID</b>	The master destination RM job ID
<b>EEDuration</b>	The duration of time the job has been eligible for scheduling

Name	Description
<b>EFile</b>	The stderr file
<b>Env</b>	The job's environment variables set for execution
<b>EnvOverride</b>	The job's overriding environment variables set for execution
<b>EState</b>	The expected state of the job
<b>EstHistStartTime</b>	The estimated historical start time
<b>EstPrioStartTime</b>	The estimated priority start time
<b>EstRsvStartTime</b>	The estimated reservation start time
<b>ExchList</b>	The excluded host list
<b>Flags</b>	Command delimited list of Moab flags on the job
<b>GAttr</b>	The requested generic attributes
<b>GJID</b>	The global job ID
<b>Group</b>	The group assigned to the job
<b>Hold</b>	The hold list
<b>Holdtime</b>	The time the job was put on hold
<b>HopCount</b>	The hop count between the job's peers
<b>HostList</b>	The requested host list
<b>IFlags</b>	The internal flags for the job
<b>IsInteractive</b>	If set, the job is interactive
<b>IsRestartable</b>	If set, the job is restartable
<b>IsSuspendable</b>	If set, the job is suspendable

Name	Description
<b>IWD</b>	The directory where the job is executed
<b>JobID</b>	The job's batch ID.
<b>JobName</b>	The user-specified name for the job
<b>JobGroup</b>	The job ID relative to its group
<b>LogLevel</b>	The individual log level for the job
<b>MasterHost</b>	The specified host to run primary tasks on
<b>Messages</b>	Any messages reported by Moab regarding the job
<b>MinPreemptTime</b>	The minimum amount of time the job must run before being eligible for preemption
<b>Notification</b>	Any events generated to notify the job's user
<b>OFile</b>	The stdout file
<b>OldMessages</b>	Any messages reported by Moab in the old message style regarding the job
<b>OWCLimit</b>	The original wallclock limit
<b>PAL</b>	The partition access list relative to the job
<b>QueueStatus</b>	The job's queue status as generated this iteration
<b>QoS</b>	The QoS assigned to the job
<b>QoSReq</b>	The requested QoS for the job
<b>ReqAWDuration</b>	The requested active walltime duration
<b>ReqCMaxTime</b>	The requested latest allowed completion time
<b>ReqMem</b>	The total memory requested/dedicated to the job
<b>ReqNodes</b>	The number of requested nodes for the job

Name	Description
<b>ReqProcs</b>	The number of requested procs for the job
<b>ReqReservation</b>	The required reservation for the job
<b>ReqRMType</b>	The required RM type
<b>ReqSMinTime</b>	The requested earliest start time
<b>RM</b>	The master source resource manager
<b>RMXString</b>	The resource manager extension string
<b>RsvAccess</b>	The list of reservations accessible by the job
<b>RsvStartTime</b>	The reservation start time
<b>RunPriority</b>	The effective job priority
<b>Shell</b>	The execution shell's output
<b>SID</b>	The job's system ID (parent cluster)
<b>Size</b>	The job's computational size
<b>STotCPU</b>	The average CPU load tracked across all nodes
<b>SMaxCPU</b>	The max CPU load tracked across all nodes
<b>STotMem</b>	The average memory usage tracked across all nodes
<b>SMaxMem</b>	The max memory usage tracked across all nodes
<b>SRMJID</b>	The source RM's ID for the job
<b>StartCount</b>	The number of the times the job has tried to start
<b>StartPriority</b>	The effective job priority
<b>StartTime</b>	The most recent time the job started executing

Name	Description
<b>State</b>	The state of the job as reported by Moab
<b>StatMSUtl</b>	The total number of memory seconds utilized
<b>StatPSDed</b>	The total number of processor seconds dedicated to the job
<b>StatPSUtl</b>	The total number of processor seconds utilized by the job
<b>StdErr</b>	The path to the stderr file
<b>StdIn</b>	The path to the stdin file
<b>StdOut</b>	The path to the stdout file
<b>StepID</b>	StepID of the job (used with LoadLeveler systems)
<b>SubmitHost</b>	The host where the job was submitted
<b>SubmitLanguage</b>	The RM language that the submission request was performed
<b>SubmitString</b>	The string containing the entire submission request
<b>SubmissionTime</b>	The time the job was submitted
<b>SuspendDuration</b>	The amount of time the job has been suspended
<b>SysPrio</b>	The admin specified job priority
<b>SysMinTime</b>	The system specified min. start time
<b>TaskMap</b>	The allocation taskmap for the job
<b>TermTime</b>	The time the job was terminated
<b>User</b>	The user assigned to the job
<b>UserPrio</b>	The user specified job priority
<b>UtlMem</b>	The utilized memory of the job

Name	Description
<b>UtilProcs</b>	The number of utilized processors by the job
<b>Variable</b>	
<b>VWCTime</b>	The virtual wallclock limit

## Examples

Example 3-35:

```
> mjobctl -q diag ALL --format=xml

## mnodectl

### Synopsis

```
mnodectl -m attr{=|-=}val nodeexp  
mnodectl -q \[cat|diag|profile|wiki\] nodeexp
```

## Overview

Change specified attributes for a given [node expression](#).

## Access

By default, this command can be run by any Moab Administrator.

## Format

-m - Modify	
<b>Format</b>	<p>&lt;ATTR&gt;{= - = +=}&lt;VAL&gt;</p> <p>Where &lt;ATTR&gt; is one of the following:  <a href="#">FEATURES</a>  <a href="#">GEVENT</a>,  <a href="#">GMETRIC</a>,  <a href="#">MESSAGE</a>,  <a href="#">OS</a>,  <a href="#">POWER</a>,  <a href="#">STATE</a>,  <a href="#">VARIABLE</a></p> <p>and -=, except when used for features, clears the attribute instead of decrementing the attribute's value and = indicates that you are specifying a new value to replace the old one(s), if any.</p> <p>When the -= option is used to modify features, it removes the specified features from the node. The += option, which is only available for features, allows you to append additional features to the current list rather than replacing the current list entirely.</p> <div style="border: 1px solid #4a6984; border-radius: 10px; padding: 10px; background-color: #d9e1f2; margin-top: 10px;"> <p><b>i</b> Changing OS and POWER require a Moab Adaptive Computing Suite license and a provisioning resource manager.</p> </div>
<b>Description</b>	Modify the state or attribute of <a href="#">specified</a> node(s)
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 10px;"> &gt; mnodectl -m features+=fastio,highmem node1 &gt; mnodectl -m gevent=cpufail:'cpu02 has failed w/ec:0317' node1 &gt; mnodectl -m gmetric=temp:131.2 node1 &gt; mnodectl -m message='cpufailure:cpu02 has failed w/ec:0317' node1 &gt; mnodectl -m OS=RHAS30 node1 &gt; mnodectl -m power=off node1 &gt; mnodectl -m state=idle node1 &gt; mnodectl -m variable=IP=10.10.10.100,Location=R1S2 node1                     </pre>

-q - Query	
<b>Format</b>	{cat   diag   profile   wiki}

**-q - Query****Description**

Query node categories or node profile information (see [ENABLEPROFILING](#) for nodes).

The diag and profile options must use --xml.

**Example**

```
> mnodectl -q cat ALL
node categorization stats from Mon Jul 10 00:00:00 to Mon Jul 10 15:30:00
Node: moab
  Categories:
                busy: 96.88%

*Query a node with the output displayed in a WIKI string.*

**Parameters**

FEATURES	
<b>Format</b>	<p>&lt;STRING&gt;</p> <p>One of the following:</p> <ul style="list-style-type: none"> <li>• a comma-delimited list of features</li> <li>• [NONE] (to clear features on the node)</li> </ul>
<b>Description</b>	<p>Sets the features on a node.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> These node features will be overwritten when an RM reports features.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">mnodectl -m features=fastio,highmem node1 mnodectl -m features=[NONE] node1</pre>

GEVENT	
<b>Format</b>	<EVENT>:<MESSAGE>
<b>Description</b>	Creates a generic event on the node to which Moab may respond (see <a href="#">Enabling Generic Events</a> ).
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">mnodectl -m gevent=powerfail:'power has failed' node1</pre>

GMETRIC	
<b>Format</b>	<ATTR>:<VALUE>
<b>Description</b>	<p>Sets the value for a generic metric on the node (see <a href="#">Enabling Generic Metrics</a>).</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> When a gmetric set in Moab conflicts with what the resource manager reports, Moab uses the set gmetric until the next time the resource manager reports a different number.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">mnodectl -m gmetric=temp:120 node1</pre>

MESSAGE	
<b>Format</b>	'<MESSAGE>'

## MESSAGE

**Description** Sets a message to be displayed on the node.

**Example**

```
mnodectl -m message='powerfailure: power has failed'
node1
```

## NODEEXP

**Format** *<STRING>*  
Where *<NODEEXP>* is a node name, regex or ALL

**Description** Identifies one or more nodes.

**Example** node1 — applies only to node1  
fr10n\* - all nodes starting with fr10n  
ALL - all known nodes

## OS

**Format** *<STRING>*

**Description** Operating System (see [Resource Provisioning](#)).

**Example**

```
mnodectl node1 -m OS=RHELAS30
```

## POWER

**Format** {off|on}

POWER	
<b>Description</b>	<p>Set the power state of a node. Action will NOT be taken if the node is already in the specified state.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-bottom: 10px;"> <p><b>i</b> If you power off a node, a green policy will try to turn it back on. If you want the node to remain powered off, you must associate a reservation with it.</p> </div> <div style="border: 1px solid #ccc; padding: 5px;"> <p><b>i</b> If you request to power off a node that has active work on it, Moab returns a status indicating that the node is busy (with a job or VM) and will not be powered off. You will see one of these messages:</p> <ul style="list-style-type: none"> <li>• Ignoring node <i>&lt;name&gt;</i>: power ON in process (indicates node is currently powering on)</li> <li>• Ignoring node <i>&lt;name&gt;</i>: power OFF in process (indicates node is currently powering off)</li> <li>• Ignoring node <i>&lt;name&gt;</i>: has active VMs running (indicates the node is currently running active VMs)</li> <li>• Ignoring node <i>&lt;name&gt;</i>: has active jobs running (indicates the node is currently running active jobs)</li> </ul> <p>Once you resolve the activity on the node (by preempting or migrating the jobs or VMs, for example), you can attempt to power the node off again.</p> <p>You can use the <code>--flags=force</code> option to cause a force override. However, doing this will power off the node regardless of whether or not its jobs get migrated or preempted (i.e., you run the risk of losing the VMs/jobs entirely). For example:</p> <div style="border: 1px dashed #ccc; padding: 5px; margin-top: 10px;"> <pre>&gt; mnodectl node1 -m power=off --flags=force</pre> </div> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 5px;"> <pre>&gt; mnodectl node1 -m power=off</pre> </div>

STATE	
<b>Format</b>	{drained idle}
<b>Description</b>	Remove (drained) or add (idle) a node from scheduling.
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 5px;"> <pre>mnodectl node1 -m state=drained</pre> </div> <div style="border: 1px dashed #ccc; padding: 5px;"> <p><i>Moab ignores node1 when scheduling.</i></p> </div>

VARIABLE	
<b>Format</b>	<i>&lt;name&gt;</i> [= <i>&lt;value&gt;</i> ], <i>&lt;name&gt;</i> [= <i>&lt;value&gt;</i> ]..

VARIABLE	
<b>Description</b>	Set a list of variables for a node.
<b>Example</b>	<pre>&gt; mnodectl node1 -m variable=IP=10.10.10.100,Location=R1S2</pre>

## moab

### Synopsis

```
moab --about --help --loglevel=<LOGLEVEL> --version [-c <CONFIG_FILE>] [-C] [-d] [-e] [-h] [-P
<PAUSEDURATION>]] [-R <RECYCLEDURATION>] [-s] [-S <STOPITERATION>]] [-v]
```

### Parameters

Parameter	Description
<b>--about</b>	Displays build environment and version information.
<b>--loglevel</b>	Sets the server loglevel to the specified value.
<b>--version</b>	Displays version information.
<b>-c</b>	Configuration file the server should use.
<b>-C</b>	Clears checkpoint files (.moab.ck, .moab.ck.1).
<b>-d</b>	Debug mode (does not background itself).

Parameter	Description
<b>-e</b>	Forces Moab to exit if there are any errors in the configuration file, if it can't connect to the configured database, or if it can't find these directories: <ul style="list-style-type: none"> <li>• statdir</li> <li>• logdir</li> <li>• spooldir</li> <li>• toolsdir</li> </ul>
<b>-P</b>	Starts Moab in a paused state for the duration specified.
<b>-R</b>	Causes Moab to automatically <a href="#">recycle</a> every time the specified duration transpires.
<b>-s</b>	Starts Moab in the state that was most recently checkpointed.
<b>-S</b>	Suspends/stops scheduling at specified iteration (or at startup if no iteration is specified).
<b>-v</b>	Same as <a href="#">--version</a> .

## mrmctl

### Synopsis

```
mrmctl -f [fobject] {rmName|am:[amid]} mrmctl -l [rmid|am:[amid]] mrmctl -m <attr>=<value> [rmid|am:[amid]] mrmctl -p {rmid|am:[amid]} mrmctl -R {AM|ID}{:RMID}}
```

### Overview

mrmctl allows an admin to query, list, modify, and ping the [resource managers](#) and allocation managers in Moab. mrmctl also allows for a queue (often referred to as a class) to be created for a resource manager.

### Access

By default, this command can be run by level 1 and level 2 Moab administrators (see [ADMINCFG](#)).

### Format

<b>-f - Flush Statistics</b>	
<b>Format</b>	[< <i>fobject</i> >] where <i>fobject</i> is optional and one of messages or stats.

-f - Flush Statistics	
<b>Default</b>	If no <i>object</i> is specified, then reported failures and performance data will be flushed. If no resource manager id is specified, the first resource manager will be flushed.
<b>Description</b>	Clears resource manager statistics. If messages is specified, then reported failures, performance data, and messages will be flushed.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mrmctl -f base</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Moab will clear the statistics for RM base.</i></p>

-l - List	
<b>Format</b>	N/A
<b>Default</b>	All RMs and AMs (when no RM/AM is specified)
<b>Description</b>	List Resource and Allocation Manager(s)
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mrmctl -l</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Moab will list all resource and allocation managers.</i></p>

-m - Modify	
<b>Format</b>	N/A
<b>Default</b>	All RMs and AMs (when no RM/AM is specified).
<b>Description</b>	Modify Resource and Allocation Manager(s).
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mrmctl -m state=disabled peer13</pre>

-p - Ping	
<b>Format</b>	N/A

-p - Ping	
<b>Default</b>	First RM configured.
<b>Description</b>	Ping Resource Manager.
<b>Example</b>	<pre>&gt; mrmctl -p base</pre> <div style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"> <p><i>Moab will ping RM base.</i></p> </div>

-R - Reload	
<b>Format</b>	{AM ID}[:RMID]}
<b>Description</b>	Dynamically reloads server information for the <a href="#">identity manager</a> service if ID is specified; if AM is specified, reloads the allocation manager service.
<b>Example</b>	<pre>&gt; mrmctl -R ID</pre> <p>Reloads the identity manager on demand.</p>

**i** Resource manager interfaces can be enabled/disabled using the modify operation to change the resource manager state as in the following example:

```
# disable active resource manager interface
> mrmctl -m state=disabled torque
# restore disabled resource manager interface
> mrmctl -m state=enabled torque
```

mrsvctl

Synopsis

`mrsvctl -c [-a acl] [-b subtype] [-d duration] [-D description] [-e endtime] [-E] [-f features] [-F flags] [-g rsvgroup] [-h hostexp] [-n name] [-o owner] [-p partition] [-P profile] [-R resources] [-s starttime] [-S setvalue] [-t tasks] [-T trigger] [-V variable] [-x joblist]`

```
mrsvctl -C [-g standing_reservationid] {reservationid}
```

```
mrsvctl -l [{reservationid | -i index}]
```

```
mrsvctl -m <duration|endtime|reqtaskcount|starttime>{=|+=|-}<VAL> <hostexp>{+=|-}<VAL> <variable>
{+=KEY=VAL|-KEY_TO_REMOVE} {reservationid | -i index}
```

```
mrsvctl -q {reservationid | -i index} [--blocking]
```

```
mrsvctl -r {reservationid | -i index}
```

## Overview

`mrsvctl` controls the creation, modification, querying, and releasing of reservations.

The timeframe covered by the reservation can be specified on either an absolute or relative basis. Only jobs with credentials listed in the reservation's access control list can utilize the reserved resources. However, these jobs still have the freedom to utilize resources outside of the reservation. The reservation will be assigned a name derived from the ACL specified. If no reservation ACL is specified, the reservation is created as a system reservation and no jobs will be allowed access to the resources during the specified timeframe (valuable for system maintenance, etc.). See the [Reservation Overview](#) for more information.

Reservations can be viewed using the `-q` flag and can be released using the `-r` flag.

**i** By default, reservations are not exclusive and may overlap with other reservations and jobs. Use the '`-E`' flag to adjust this behavior.

## Access

By default, this command can be run by level 1 and level 2 Moab administrators (see [ADMINCFG](#)).

## Format

-a	
Name	ACL

-a	
<b>Format</b>	<p>&lt;TYPE&gt;==&lt;VAL&gt;[, &lt;TYPE&gt;==&lt;VAL&gt;] . . .</p> <p>Where &lt;TYPE&gt; is one of the following:            ACCT,            CLASS,            DURATION,            GROUP,            JATTR,            PROC,            QOS,            RSV, or            USER</p>
<b>Description</b>	<p>List of limitations for access to the reserved resources (See also: <a href="#">ACL Modifiers</a>).</p>
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mrsvctl -c -h node01 -a USER==john+,CLASS==batch-</pre> <p style="text-align: center; margin-top: 5px;"><i>Moab will make a reservation on node01 allowing access to user john and restricting access from class batch when other resources are available to class batch</i></p> </div> <div style="border: 1px dashed gray; padding: 5px;"> <pre>&gt; mrsvctl -m -a USER-=john system.1</pre> <p style="text-align: center; margin-top: 5px;"><i>Moab will remove user john from the system.1 reservation</i></p> </div>

-a

**Notes**

- When you specify multiple credentials, a user must only match one of them in order to access the reservation. To require one or more of the listed limitations for reservation access, each required specification must end with an asterisk (\*). If a user meets the required limitation(s), he or she has access to the reservation (without meeting any that are not marked required).
- There are three different assignment operators that can be used for modifying most credentials in the ACL. The operator == will reassess the list for that particular credential type. The += operator will append to the list for that credential type, and -= will remove from the list. Two other operators are used to specify DURATION and PROC: >= (greater than) and <= (less than).
- To add multiple credentials of the same type with one command, use a colon to separate them. To separate lists of different credential types, use commas. For example, to reassign the user list to consist of users Joe and Bob, and to append the group MyGroup to the groups list on the system.1 reservation, you could use the command `mrsvctl -m -a USER==Joe:Bob, GROUP+=MyGroup system.1`.
- Any of the ACL modifiers may be used. When using them, it is often useful to put single quotes on either side of the assignment command. For example, `mrsvctl -m -a 'USER==&Joe' system.1`.
- Some flags are mutually exclusive. For example, the ! modifier means that the credential is blocked from the reservation and the & modifier means that the credential must run on that reservation. Moab will take the most recently parsed modifier. Modifiers may be placed on either the left or the right of the argument, so `USER==&JOE` and `USER==JOE&` are equivalent. Moab parses each argument starting from right to left on the right side of the argument, then from left to right on the left side. So, if the command was `USER==!Joe&`, Moab would keep the equivalent of `USER==!Joe` because the ! would be the last one parsed.
- You can set a reservation to have a time limit for submitted jobs using DURATION and the \* modifier. For example, `mrsvctl -m -a 'DURATION<=*1:00:00' system.1` would cause the system.1 reservation to not accept any jobs with a walltime greater than one hour. Similarly, you can set a reservation to have a processor limit using PROC and the \* modifier. `mrsvctl -a 'PROC>=2*' system.2` would cause the system.2 reservation to only allow jobs requesting more than 2 procs to run on it.
- You can verify the ACL of a reservation using the `mdiag -r` command.

```
mrsvctl -m -a 'USER==Joe:Bob, GROUP-=BadGroup, ACCT+=GoodAccount, DURATION<=*1:00:00' system.1
```

*Moab will reassign the USER list to be Joe and Bob, will remove BadGroup from the GROUP list, append GoodAccount to the ACCT list, and only allow jobs that have a submitted walltime of an hour or less on the system.1 reservation.*

**-a**

```
mrsvctl -m -a 'USER==Joe,USER==Bob' system.1
```

*Moab will assign the USER list to Joe, and then reassign it again to Bob. The final result will be that the USER list will just be Bob. To add Joe and Bob, use `mrsvctl -m -a USER==Joe:Bob system.1` or `mrsvctl -m -a USER==Joe,USER+=Bob system.1`.*

**-b**

<b>Name</b>	SUBTYPE
<b>Format</b>	One of the <a href="#">node category</a> values or node category shortcuts.
<b>Description</b>	Add subtype to reservation.
<b>Example</b>	<pre>&gt; mrsvctl -c -b SoftwareMaintenance -t ALL</pre> <p><i>Moab will associate the reserved nodes with the <a href="#">node category</a> SoftwareMaintenance.</i></p>

**-c**

<b>Name</b>	CREATE
<b>Format</b>	<ARGUMENTS>
<b>Description</b>	<p>Creates a reservation.</p> <div style="border: 1px solid black; padding: 5px;"> <p> The <code>-x</code> flag, when used with <code>-F ignjobrsv</code>, lets users create reservations but exclude certain nodes from being part of the reservation because they are running specific jobs. The <code>-F</code> flag instructs <code>mrsvctl</code> to still consider nodes with current running jobs.</p> </div>

-c	
<b>Examples</b>	<pre>&gt; mrsvctl -c -t ALL</pre> <p><i>Moab will create a reservation across all system resources.</i></p> <pre>&gt; mrsvctl -c -t 5 -F ignjobrsv -x moab.5,moab.6</pre> <p><i>Moab will create the reservation while assigning the nodes. Nodes running jobs moab5 and moab6 will not be assigned to the reservation.</i></p> <pre>&gt; mrsvctl -c -d INFINITY</pre> <p><i>Moab will create an infinite reservation.</i></p>

-C	
<b>Name</b>	CLEAR
<b>Format</b>	<RSVID>   -g <SRSVID>
<b>Description</b>	Clears any disabled time slots from standing reservations and allows the recreation of disabled reservations
<b>Example</b>	<pre>&gt; mrsvctl -C -g testing</pre> <p><i>Moab will clear any disabled timeslots from the standing reservation testing.</i></p>

-d	
<b>Name</b>	DURATION
<b>Format</b>	[ [ [DD:]HH:]MM:]SS
<b>Default</b>	INFINITY
<b>Description</b>	Duration of the reservation (not needed if ENDTIME is specified)

**-d**

<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -d 5:00:00</pre> <p><i>Moab will create a reservation on node01 lasting 5 hours.</i></p> <pre>mrsvctl -c -d INFINITY</pre> <p><i>Moab will create a reservation with a duration of INFINITY (no endtime).</i></p>
----------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**-D**

<b>Name</b>	DESCRIPTION
<b>Format</b>	<STRING>
<b>Description</b>	Human-readable description of reservation or purpose
<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -d 5:00:00 -D 'system maintenance to test network'</pre> <p><i>Moab will create a reservation on node01 lasting 5 hours.</i></p>

**-e**

<b>Name</b>	ENDTIME
<b>Format</b>	[HH[:MM[:SS]]][_MO[/DD[/YY]]] or +[[DD:]HH:]MM:]SS
<b>Default</b>	INFINITY
<b>Description</b>	Absolute or relative time reservation will end (not required if Duration specified). ENDTIME also supports an epoch timestamp.

-e	
<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -e +3:00:00</pre> <p><i>Moab will create a reservation on node01 ending in 3 hours.</i></p>

-E	
<b>Name</b>	EXCLUSIVE
<b>Description</b>	When specified, Moab will only create a reservation if there are no other reservations (exclusive or otherwise) which would conflict with the time and space constraints of this reservation. If exceptions are desired, the <a href="#">rsvaccesslist</a> attribute can be set or the <a href="#">ignrsv</a> flag can be used.
<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -E</pre> <p><i>Moab will only create a reservation on node01 if no conflicting reservations are found.</i></p> <div style="border: 1px solid #4a7c9c; padding: 5px; margin-top: 10px;"> <p><b>i</b> This flag is only used at the time of reservation creation. Once the reservation is created, Moab allows jobs into the reservation based on the ACL. Also, once the exclusive reservation is created, it is possible that Moab will overlap it with jobs that match the ACL.</p> </div>

-f	
<b>Name</b>	FEATURES
<b>Format</b>	<STRING>[:<STRING>]...
<b>Description</b>	List of node features which must be possessed by the reserved resources. You can use a backslash and pipe to delimit features to indicate that Moab can use one or the other.
<b>Example</b>	<pre>&gt; mrsvctl -c -h node[0-9] -f fast\ slow</pre> <p><i>Moab will create a reservation on nodes matching the expression and which also have either the feature <i>fast</i> or the feature <i>slow</i>.</i></p>

-F	
<b>Name</b>	FLAGS
<b>Format</b>	<flag>[, <flag>]...
<b>Description</b>	Comma-delimited list of flags to set for the reservation (see <a href="#">Managing Reservations</a> for flags).
<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -F ignstate</pre> <p><i>Moab will create a reservation on node01 ignoring any conflicting node states.</i></p>

-g	
<b>Name</b>	RSVGROUP
<b>Format</b>	<STRING>
<b>Description</b>	For a create operation, create a reservation in this reservation group. For list and modify operations, take actions on all reservations in the specified reservation group. The <code>-g</code> option can also be used in conjunction with the <code>-r</code> option to release a reservation associated with a specified group. See <a href="#">Reservation Group</a> for more information.
<b>Example</b>	<pre>&gt; mrsvctl -c -g staff -h 'node0[1-9]'</pre> <p><i>Moab will create a reservation on nodes matching the <a href="#">node expression</a> given and assign it to the reservation group <code>staff</code>.</i></p>

-h	
<b>Name</b>	HOSTLIST
<b>Format</b>	class:<classname>[,<classname>]... or <STRING> or 'r:<nodeNameStart>[<beginRange>-<endRange>] or ALL

-h	
<b>Description</b>	<p><a href="#">Host expression</a> or a class mapping indicating the nodes which the reservation will allocate.</p> <div style="border: 1px solid #d9534f; padding: 5px; margin-top: 10px;">  When you specify a &lt;STRING&gt;, the HOSTLIST attribute is always treated as a regular expression. foo10 will map to foo10, foo101, foo1006, etc. To request an exact host match, the expression can be bounded by the carat and dollar op expression markers as in ^foo10\$.                 </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mrsvctl -c -h 'r:node0[1-9]'</pre> <p><i>Moab will create a reservation on nodes node01, node02, node03, node04, node05, node06, node07, node08, and node09.</i></p> </div> <div style="border: 1px dashed #ccc; padding: 5px;"> <pre>&gt; mrsvctl -c -h class:batch</pre> <p><i>Moab will create a reservation on all nodes which support class/queue batch.</i></p> </div>

-i	
<b>Name</b>	INDEX
<b>Format</b>	<STRING>
<b>Description</b>	Use the reservation index instead of full reservation ID.
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 5px;"> <pre>&gt; mrsvctl -m -i 1 starttime=+5:00</pre> </div> <div style="border: 1px dashed #ccc; padding: 5px;"> <p><i>Moab will create a reservation on nodes matching the expression given.</i></p> </div>

-l	
<b>Name</b>	LIST
<b>Format</b>	<p>&lt;RSV_ID&gt; or ALL</p> <p>RSV_ID can be the name of a reservation or a regular expression.</p>

-l	
<b>Default</b>	ALL
<b>Description</b>	List reservation(s).
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 5px;"> <pre>&gt; mrsvctl -l system*</pre> </div> <div style="border: 1px dashed gray; padding: 5px;"> <p><i>Moab will list all of the reservations whose names start with system.</i></p> </div>

-m															
<b>Name</b>	MODIFY														
<b>Format</b>	<p>&lt;ATTR&gt;=&lt;VAL&gt;[-m &lt;ATTR2&gt;=&lt;VAL2&gt;]...</p> <p>Where &lt;ATTR&gt; is one of the following:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th colspan="2" style="background-color: #4a7c9c; color: white;">flags</th> </tr> </thead> <tbody> <tr> <td style="background-color: #d9e1f2;"><b>duration</b></td> <td>duration{+ = =}&lt;RELTIME&gt;</td> </tr> <tr> <td style="background-color: #d9e1f2;"><b>endtime</b></td> <td>endtime{+ = =}&lt;RELTIME&gt; or endtime=&lt;ABSTIME&gt;</td> </tr> <tr> <td style="background-color: #d9e1f2;"><b>hostexp</b></td> <td>hostexp{+ = =}&lt;node&gt;[,&lt;node&gt;]</td> </tr> <tr> <td style="background-color: #d9e1f2;"><b>variable</b></td> <td>variable[+=key1=val1 -key_to_remove]</td> </tr> <tr> <td style="background-color: #d9e1f2;"><b>reqtaskcount</b></td> <td>reqtaskcount{+ = =}&lt;TASKCOUNT&gt;</td> </tr> <tr> <td style="background-color: #d9e1f2;"><b>starttime</b></td> <td>starttime{+ = =}&lt;RELTIME&gt; or starttime=&lt;ABSTIME&gt;</td> </tr> </tbody> </table>	flags		<b>duration</b>	duration{+ = =}<RELTIME>	<b>endtime</b>	endtime{+ = =}<RELTIME> or endtime=<ABSTIME>	<b>hostexp</b>	hostexp{+ = =}<node>[,<node>]	<b>variable</b>	variable[+=key1=val1 -key_to_remove]	<b>reqtaskcount</b>	reqtaskcount{+ = =}<TASKCOUNT>	<b>starttime</b>	starttime{+ = =}<RELTIME> or starttime=<ABSTIME>
flags															
<b>duration</b>	duration{+ = =}<RELTIME>														
<b>endtime</b>	endtime{+ = =}<RELTIME> or endtime=<ABSTIME>														
<b>hostexp</b>	hostexp{+ = =}<node>[,<node>]														
<b>variable</b>	variable[+=key1=val1 -key_to_remove]														
<b>reqtaskcount</b>	reqtaskcount{+ = =}<TASKCOUNT>														
<b>starttime</b>	starttime{+ = =}<RELTIME> or starttime=<ABSTIME>														
<b>Description</b>	Modify aspects of a reservation.														

**-m****Example**

```
> mrsvctl -m duration=2:00:00 system.1
```

*Moab sets the duration of reservation `system.1` to be exactly two hours, thus modifying the endtime of the reservation.*

```
> mrsvctl -m starttime+=5:00:00 system.1
```

*Moab advances the starttime of `system.1` five hours from its current starttime (without modifying the duration of the reservation).*

```
> mrsvctl -m endtime-=5:00:00 system.1
```

*Moab moves the endtime of reservation `system.1` ahead five hours from its current endtime (without modifying the starttime; thus, this action is equivalent to modifying the duration of the reservation).*

```
> mrsvctl -m starttime=15:00:00_7/6/08 system.1
```

*Moab sets the starttime of reservation `system.1` to 3:00 p.m. on July 6, 2008.*

```
> mrsvctl -m starttime-=5:00:00 system.1
```

*Moab moves the starttime of reservation `system.1` ahead five hours.*

```
> mrsvctl -m starttime+=5:00:00 system.1
```

*Moab moves the starttime of reservation `system.1` five hours from the current time.*

```
> mrsvctl -m -duration+=5:00:00 system.1
```

*Moab extends the duration of `system.1` by five hours.*

```
> mrsvctl -m flags+=ADVRES system.1
```

*Moab adds the flag `ADVRES` to reservation `system.1`.*

**-m**

```
> mrsvctl -m variable+key1=val1 system.1
```

*Moab adds the variable `key1` with the value `key2` to `system.1`.*

```
> mrsvctl -m variable+=key1=val1 variable+=key2=val2 system.1
```

*Moab adds the variable `key1` with the value `val1`, and variable `key2` with `val2` to `system.1`. (Note that each variable flag requires a distinct `-m` entry.)*

```
> mrsvctl -m variable-=key1 system.1
```

*Moab deletes the variable `key1` from `system.1`.*

```
> mrsvctl -m variable-=key1 -m variable-=key2 system.1
```

*Moab deletes the variables `key1` and `key2` from `system.1`.*

**-m****Notes:**

- Modifying the starttime does not change the duration of the reservation, so the endtime changes as well. The starttime can be changed to be before the current time, but if the change causes the endtime to be before the current time, the change is not allowed.
- Modifying the endtime changes the duration of the reservation as well (and vice versa). An endtime *cannot* be placed before the starttime or before the current time.
- Duration cannot be negative.
- The += and -= operators operate on the time of the reservation (starttime+=5 adds five seconds to the current reservation starttime), while + and - operate on the current time (starttime+5 sets the starttime to five seconds from now).
- If the starttime or endtime specified is before the current time without a date specified, it is set to the next time that fits the command. To force the date, add the date as well. For the following examples, assume that the current time is 9:00 a.m. on March 1, 2007.

```
> mrsvctl -m starttime=8:00:00_3/1/07 system.1
```

*Moab moves system.1's starttime to 8:00 a.m., March 1.*

```
> mrsvctl -m starttime=8:00:00 system.1
```

*Moab moves system.1's starttime to 8:00 a.m., March 2.*

```
> mrsvctl -m endtime=7:00:00 system.1
```

*Moab moves system.1's endtime to 7:00 a.m., March 3. This happens because the endtime must also be after the starttime, so Moab continues searching until it has found a valid time that is in the future and after the starttime.*

```
> mrsvctl -m endtime=7:00:00_3/2/07 system.1
```

*Moab will return an error because the endtime cannot be before the starttime.*

**-n****Name**

NAME

**Format**

&lt;STRING&gt;

-n	
<b>Description</b>	<p>Name for new reservation.</p> <div style="border: 1px solid #004a87; border-radius: 5px; padding: 5px; margin-bottom: 5px;"> <p><b>i</b> If no name is specified, the reservation name is set to first name listed in ACL or SYSTEM if no ACL is specified.</p> </div> <div style="border: 1px solid #004a87; border-radius: 5px; padding: 5px;"> <p><b>i</b> Reservation names may not contain whitespace.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px;"> <pre>mrsvctl -c -h node01 -n John</pre> <p><i>Moab will create a reservation on node01 with the name John.</i></p> </div>

-o	
<b>Name</b>	OWNER
<b>Format</b>	<CREDTYPE>:<CREDID>
<b>Description</b>	Specifies the owner of a reservation. See <a href="#">Reservation Ownership</a> for more information.
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px;"> <pre>mrsvctl -c -h node01 -o USER:user1</pre> <p><i>Moab creates a reservation on node01 owned by user1.</i></p> </div>

-p	
<b>Name</b>	PARTITION
<b>Format</b>	<STRING>
<b>Description</b>	Only allocate resources from the specified partition
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px;"> <pre>mrsvctl -c -p switchB -t 14</pre> <p><i>Moab will allocate 14 tasks from the switchB partition.</i></p> </div>

-P	
<b>Name</b>	PROFILE
<b>Format</b>	<STRING>
<b>Description</b>	Indicates the <a href="#">reservation profile</a> to load when creating this reservation
<b>Example</b>	<pre>mrsvctl -c -P testing2 -t 14</pre> <p><i>Moab will allocate 14 tasks to a reservation defined by the testing2 reservation profile.</i></p>

-q	
<b>Name</b>	QUERY
<b>Format</b>	<RSV_ID> — The <code>-r</code> option accepts <a href="#">x: node regular expressions</a> and <a href="#">r: node range expressions</a> (asterisks (*) are supported wildcards as well).
<b>Description</b>	Get diagnostic information or list all completed reservations. The command gathers information from the Moab cache which prevents it from interrupting the scheduler, but the <code>--blocking</code> option can be used to bypass the cache and interrupt the scheduler.
<b>Example</b>	<pre>mrsvctl -q ALL</pre> <p><i>Moab will query reservations.</i></p> <pre>mrsvctl -q system.1</pre> <p><i>Moab will query the reservation system.1.</i></p>

-r	
<b>Name</b>	RELEASE
<b>Format</b>	<RSV_ID> — The <code>-r</code> option accepts <a href="#">x: node regular expressions</a> and <a href="#">r: node range expressions</a> (asterisks (*) are supported wildcards as well).

-r	
<b>Description</b>	Releases the specified reservation.
<b>Example</b>	<pre>&gt; mrsvctl -r system.1</pre> <p><i>Moab will release reservation system.1.</i></p> <pre>&gt; mrsvctl -r -g idle</pre> <p><i>Moab will release all idle job reservations.</i></p>

-R	
<b>Name</b>	RESOURCES
<b>Format</b>	<p>&lt;tid&gt; or            &lt;RES&gt;=&lt;VAL&gt;[{ + ;}&lt;RES&gt;=&lt;VAL&gt;]...</p> <p>Where &lt;RES&gt; is one of the following:            PROCS,            MEM,            DISK,            SWAP,            GRES</p>
<b>Default</b>	PROCS=-1
<b>Description</b>	<p>Specifies the resources to be reserved per task. (-1 indicates all resources on node)</p> <div style="border: 1px solid #4a7c9c; padding: 5px; background-color: #e6f2ff;"> <p><b>i</b> For GRES resources, &lt;VAL&gt; is specified in the format &lt;GRESNAME&gt;[:&lt;COUNT&gt;]</p> </div>
<b>Example</b>	<pre>&gt; mrsvctl -c -R MEM=100;PROCS=2 -t 2</pre> <p><i>Moab will create a reservation for two tasks with the specified resources.</i></p>

-S	
<b>Name</b>	STARTTIME
<b>Format</b>	[HH[:MM[:SS]]] [_MO[/DD[/YY]]] or +[[[DD:]HH:]MM:]SS
<b>Default</b>	[NOW]
<b>Description</b>	Absolute or relative time reservation will start. STARTTIME also supports an epoch timestamp.
<b>Example</b>	<pre>&gt; mrsvctl -c -t ALL -s 3:00:00_4/4/04</pre> <p><i>Moab will create a reservation on all system resources at 3:00 am on April 4, 2004</i></p> <pre>&gt; mrsvctl -c -h node01 -s +5:00</pre> <p><i>Moab will create a reservation in 5 minutes on node01</i></p> <pre>&gt; mrsvctl -m -s -=5:00 system.1</pre> <p><i>This will decrement the start time by 5 minutes.</i></p>

-S	
<b>Name</b>	SET ATTRIBUTE
<b>Format</b>	<ATTR>=<VALUE> where <ATTR> is one of aaccount — Accountable account agroup — accountable group aqos — accountable QoS auser — accountable user reqarch — required architecture reqmemory — required node memory - in MB reqos — required operating system rsvaccesslist — comma-delimited list of reservations or reservation groups which can be accessed by this reservation request. Because each reservation can access all other reservations by default, you should make any reservation with a specified rsvaccesslist exclusive by setting the <a href="#">-E on page 245</a> flag. This setting gives the otherwise exclusive reservation access to reservations specified in the list.

-S	
<b>Description</b>	Specifies a reservation attribute will be used to create this reservation
<b>Example</b>	<pre>&gt; mrsvctl -c -h node01 -S aqos=high</pre> <p><i>Moab will create a reservation on node01 and will use the QOS high as the accountable credential</i></p>

-t	
<b>Name</b>	TASKS
<b>Format</b>	<INTEGER>[-<INTEGER>]
<b>Description</b>	<p>Specifies the number of tasks to reserve. ALL indicates all resources available should be reserved.</p> <div style="border: 1px solid #005596; padding: 5px; background-color: #e6f2ff;"> <p><b>i</b> If the task value is set to ALL, Moab applies the reservation regardless of existing reservations and exclusive issues. If an integer is used, Moab only allocates accessible resources. If a range is specified Moab attempts to reserve the maximum number of tasks, or at least the minimum.</p> </div>
<b>Example</b>	<pre>&gt; mrsvctl -c -t ALL</pre> <p><i>Moab will create a reservation on all resources.</i></p> <pre>&gt; mrsvctl -c -t 3</pre> <p><i>Moab will create a reservation for three tasks.</i></p> <pre>&gt; mrsvctl -c -t 3-10 -E</pre> <p><i>Moab will attempt to reserve 10 tasks but will fail if it cannot get at least three.</i></p>

-T	
<b>Name</b>	TRIGGER

-T	
<b>Format</b>	<STRING>
<b>Description</b>	Comma-delimited reservation trigger list following format described in the trigger format section of the reservation configuration overview. See <a href="#">Creating a trigger on page 748</a> for more information.
	 To cancel a standing reservation with a trigger, the <b>SRCFG</b> parameter's attribute <a href="#">DEPTH</a> must be set to <i>0</i> .
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">&gt; mrsvctl -c -h node01 -T offset=200,etype=start,atype=exec,action=/tmp/email.sh</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"><i>Moab will create a reservation on node01 and fire the script /tmp/email.sh 200 seconds after it starts</i></p>

-V	
<b>Name</b>	VARIABLE
<b>Format</b>	<name>[=<value>][[:<name>[=<value>]]...]
<b>Description</b>	Semicolon-delimited list of variables that will be set when the reservation is created (See <a href="#">About trigger variables on page 775</a> for more information.). Names with no values will simply be set to <i>TRUE</i> .
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">&gt; mrsvctl -c -h node01 -V \$T1=mac;var2=18.19</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"><i>Moab will create a reservation on node01 and set \$T1 to mac and var2 to 18.19.</i></p>
	 For information on modifying a variable on a reservation, see <a href="#">MODIFY</a> .

-X	
<b>Name</b>	JOBLIST
<b>Format</b>	-x <jobs to be excluded>

-x	
<b>Description</b>	The <code>-x</code> flag, when used with <code>-F ignjobrsv</code> , lets users create reservations but exclude certain nodes that are running the listed jobs. The <code>-F</code> flag instructs <code>mrsvctl</code> to still consider nodes with current running jobs. The nodes are not listed directly.
<b>Example</b>	<pre>&gt; mrsvctl -c -t 5 -F ignjobrsv -x moab.5,moab.6</pre> <p><i>Moab will create the reservation while assigning the nodes. Nodes running jobs <code>moab5</code> and <code>moab6</code> will not be assigned to the reservation.</i></p>

## Parameters

RESERVATION ID	
<b>Format</b>	<STRING>
<b>Description</b>	The name of a reservation or a regular expression for several reservations.
<b>Example</b>	<pre>system*</pre> <p><i>Specifies all reservations starting with <code>system</code>.</i></p>

## Resource Allocation Details

When allocating resources, the following rules apply:

- When specifying tasks, each task defaults to one full compute node unless otherwise specified using the `-R` specification
- When specifying tasks, the reservation will not be created unless all requested resources can be allocated. (This behavior can be changed by specifying `-F besteffort`)
- When specifying tasks or hosts, only nodes in an idle or running state will be considered. (This behavior can be changed by specifying `-F ignstate`)

## Reservation Timeframe Modification

Moab supports dynamically modifying the timeframe of existing reservations. This can be accomplished using the `mrsvctl -m` flag. By default, Moab will perform advanced boundary and resource access to verify that the modification does not result in an invalid scheduler state. However, in certain circumstances administrators may wish to FORCE the modification in spite of any access violations. This can be done using the switch `mrsvctl -m --flags=force` which forces Moab to bypass any access verification and force the change through.

## Extending a reservation by modifying the endtime

The following increases the endtime of a reservation using the += tag:

```
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:35:57  1:11:35:57  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m endtime+=24:00:00 system.1
endtime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:35:22  2:11:35:22  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
```

The following increases the endtime of a reservation by setting the endtime to an absolute time:

```
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:33:18  1:11:33:18  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m endtime=0_11/20 system.1
endtime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:33:05  2:11:33:05  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
```

## Extending a reservation by modifying the duration

The following increases the duration of a reservation using the += tag:

```
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:28:46  1:11:28:46  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m duration+=24:00:00 system.1
duration for rsv 'system.1' changed
>$ showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:28:42  2:11:28:42  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
```

The following increases the duration of a reservation by setting the duration to an absolute time:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:26:41   1:11:26:41  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m duration=48:00:00 system.1
duration for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:26:33   2:11:26:33  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located

```

## Shortening a reservation by modifying the endtime

The following modifies the endtime of a reservation using the `--` tag:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:15:51   2:11:15:51  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m endtime-=24:00:00 system.1
endtime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:15:48   1:11:15:48  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located

```

The following modifies the endtime of a reservation by setting the endtime to an absolute time:

```

$ showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:14:00   2:11:14:00  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m endtime=0_11/19 system.1
endtime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:13:48   1:11:13:48  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located

```

## Shortening a reservation by modifying the duration

The following modifies the duration of a reservation using the `--` tag:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:12:20   2:11:12:20  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m duration-=24:00:00 system.1
duration for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:12:07   1:11:12:07  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located

```

The following modifies the duration of a reservation by setting the duration to an absolute time:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:10:57   2:11:10:57  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m duration=24:00:00 system.1
duration for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:10:50   1:11:10:50  1:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located

```

## Modifying the starttime of a reservation

The following increases the starttime of a reservation using the += tag:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:08:30   2:11:08:30  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m starttime+=24:00:00 system.1
starttime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     1:11:08:22  3:11:08:22  2:00:00:00  1/2      Sun Nov 19
00:00:00
1 reservation located

```

The following decreases the starttime of a reservation using the -= tag:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     11:07:04   2:11:07:04  2:00:00:00  1/2      Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m starttime-=24:00:00 system.1
starttime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
system.1          User -     -12:53:04  1:11:06:56  2:00:00:00  1/2      Fri Nov 17
00:00:00
1 reservation located

```

The following modifies the starttime of a reservation using an absolute time:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P  StartTime
system.1          User -    11:05:31  2:11:05:31  2:00:00:00  1/2  Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m starttime=0_11/19 system.1
starttime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P  StartTime
system.1          User -    1:11:05:18  3:11:05:18  2:00:00:00  1/2  Sun Nov 19
00:00:00
1 reservation located

```

The following modifies the starttime of a reservation using an absolute time:

```

$> showres
ReservationID      Type S      Start      End      Duration  N/P  StartTime
system.1          User -    11:04:04  2:11:04:04  2:00:00:00  1/2  Sat Nov 18
00:00:00
1 reservation located
$> mrsvctl -m starttime=0_11/17 system.1
starttime for rsv 'system.1' changed
$> showres
ReservationID      Type S      Start      End      Duration  N/P  StartTime
system.1          User -    -12:56:02  1:11:03:58  2:00:00:00  1/2  Fri Nov 17
00:00:00
1 reservation located

```

## Examples

- [Basic Reservation on page 262](#)
- [System Maintenance Reservation on page 262](#)
- [Explicit Task Description on page 263](#)
- [Dynamic Reservation Modification on page 263](#)
- [Reservation Modification on page 263](#)
- [Allocating Reserved Resources on page 263](#)
- [Modifying an Existing Reservation on page 263](#)

### Example 3-36: Basic Reservation

Reserve two nodes for use by users john and mary for a period of 8 hours starting in 24 hours

```

> mrsvctl -c -a USER=john,USER=mary -starttime +24:00:00 -duration 8:00:00 -t 2
reservation 'system.1' created

```

### Example 3-37: System Maintenance Reservation

Schedule a system wide reservation to allow a system maintenance on Jun 20, 8:00 AM until Jun 22, 5:00 PM.

```
% mrsvctl -c -s 8:00:00_06/20 -e 17:00:00_06/22 -h ALL
reservation 'system.1' created
```

**Example 3-38: Explicit Task Description**

Reserve one processor and 512 MB of memory on nodes `node003` through node `node006` for members of the group `staff` and jobs in the interactive class

```
> mrsvctl -c -R PROCS=1,MEM=512 -a GROUP=staff,CLASS=interactive -h 'node00[3-6]'
reservation 'system.1' created
```

**Example 3-39: Dynamic Reservation Modification**

Modify reservation `john.1` to start in 2 hours, run for 2 hours, and include `node02` in the hostlist.

```
> mrsvctl -m starttime=+2:00:00,duration=2:00:00,HostExp+=node02
Note: hosts added to rsv system.3
```

**Example 3-40: Reservation Modification**

Remove user `John`'s access to reservation `system.1`

```
> mrsvctl -m -a USER=John system.1 --flags=unset
successfully changed ACL for rsv system.1
```

**Example 3-41: Allocating Reserved Resources**

Allocate resources for group `dev` which are [exclusive](#) except for resources found within reservations `myrinet.3` or `john.6`

```
> mrsvctl -c -E -a group=dev,rsv=myrinet.3,rsv=john.6 -h 'node00[3-6]'
reservation 'dev.14' created
```

Create exclusive network reservation on racks 3 and 4

```
> mrsvctl -c -E -a group=ops -g network -f rack3 -h ALL
reservation 'ops.1' created
> mrsvctl -c -E -a group=ops -g network -f rack4 -h ALL
reservation 'ops.2' created
```

Allocate 64 nodes for 2 hours to new reservation and grant access to reservation `system.3` and all reservations in the reservation group `network`

```
> mrsvctl -c -E -d 2:00:00 -a group=dev -t 64 -S rsvaccesslist=system.3,network
reservation 'system.23' created
```

Allocate 4 nodes for 1 hour to new reservation and grant access to idle job reservations

```
> mrsvctl -c -E -d 1:00:00 -t 4 -S rsvaccesslist=idle
reservation 'system.24' created
```

**Example 3-42: Modifying an Existing Reservation**

Remove user `john` from reservation ACL

```
> mrsvctl -m -a USER=john system.1 --flags=unset
successfully changed ACL for rsv system.1
```

### Change reservation group

```
> mrsvctl -m RSVGROUP=network ops.4
successfully changed RSVGROUP for rsv ops.4
```

[mschedctl -q](#) mschedctl -q pactions --xml

[mschedctl -p](#)

[mschedctl -r](#) [*resumetime*]

[mschedctl -R](#)

[mschedctl -s](#) [*STOPITERATION*]

[mschedctl -S](#) [*STEPITERATION*]

## Overview

The `mschedctl` command controls various aspects of scheduling behavior. It is used to manage scheduling activity, shutdown the scheduler, and create resource trace files. It can also evaluate, modify, and create parameters, triggers, and messages.

**i** With many flags, the `--msg=<MSG>` option can be specified to annotate the action in the [event log](#).

## Format

-A - ANNOTATE	
<b>Format</b>	<STRING>
<b>Description</b>	Report the specified parameter modification to the event log and annotate it with the specified message. The <b>RECORDEVENTLIST</b> parameter must be set in order for this to work.
<b>Example</b>	<pre>mschedctl -A 'increase logging' -m 'LOGLEVEL 6'</pre> <p><i>Adjust the <b>LOGLEVEL</b> parameter and record an associated message.</i></p>
-c - CREATE	
<b>Format</b>	One of: <ul style="list-style-type: none"> <li>• <b>message</b> &lt;STRING&gt; [-o &lt;TYPE&gt;:&lt;VAL&gt;]</li> <li>• <b>trigger</b> &lt;TRIGSPEC&gt; -o &lt;OBJECTTYPE&gt;:&lt;OBJECTID&gt;</li> <li>• <b>gevent</b> -n &lt;NAME&gt; [-m &lt;message&gt;]</li> </ul> <p>where &lt;ATTR&gt; is one of account, duration, ID, messages, profile, reqresources, resources, rsvprofile, starttime, user, or variables</p>
<b>Description</b>	Create a message, trigger, or gevent and attach it to the specified object. To create a trigger on a default object, use the Moab configuration file ( <code>moab.cfg</code> ) rather than the <code>mschedctl</code> command.

**-c - CREATE**

**Example**

```
mschedctl -c message tell the admin to be nice
```

*Create a message on the system table.*

```
mschedctl -c trigger EType=start,AType=exec,Action="/tmp/email $OWNER $TIME" -o rsv:system.1
```

*Create a trigger linked to system.1.*

Creating triggers on default objects via `mschedctl -c trigger` does not propagate the triggers to individual objects. To propagate triggers to all objects, the triggers must be created within the `moab.cfg` file; for example: `NODECFG[DEFAULT] TRIGGER`.

```
mschedctl -c gevent -n diskfailure -m "node=n4"
```

*Create a gevent indicating a disk failure on the node labeled n4.*

**-d - DESTROY**

**Format**

One of:

- **trigger:**<TRIGID>
- **message:**<INDEX>

**Description**

Delete a trigger or message.

**Example**

```
mschedctl -d trigger:3
```

*Delete trigger 3.*

```
mschedctl -d message:5
```

*Delete message with index 5.*

-f - FLUSH	
<b>Format</b>	{all fairshare usage}
<b>Description</b>	Reset all internally-stored Moab Scheduler statistics to the initial start-up state as of the time the command was executed.
<b>Example</b>	<pre>mschedctl -f usage</pre> <p><i>Flush usage statistics.</i></p>

-k - KILL	
<b>Description</b>	Stop scheduling and exit the scheduler
<b>Example</b>	<pre>mschedctl -k</pre> <p><i>Kill the scheduler.</i></p>

-l - LIST	
<b>Format</b>	{config   gmetric   gres   message opsys   trans   trigger} [--flags=verbose] [--xml] <div style="border: 1px solid #000; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p><b>i</b> Using the <code>--xml</code> argument with the <code>trans</code> option returns XML that states if the queried TID is valid or not.</p> </div>
<b>Default</b>	config
<b>Description</b>	List the generic metrics, generic resources, scheduler configuration, system messages, operating systems, triggers, or transactions.

### -l - LIST

**Example**

```
mschedctl -l config
```

*List system parameters.*

```
mschedctl -l gmetric
```

*List all configured generic metrics.*

```
mschedctl -l gres
```

*List all configured generic resources.*

```
mschedctl -l message
```

*List all system messages.*

```
mschedctl -l opsys
```

*List all recognized operating systems*

```
mschedctl -l trans 1
```

*List transaction id 1.*

```
mschedctl -l trigger
```

*List triggers.*

### -L - LOG

**Format**

<INTEGER>

**Default**

7

**Description**

Create a temporary log file with the specified loglevel.

**Example**

```
mschedctl -L 7
```

*Create temporary log file with naming convention  
<logfile>.YYYYMMDDHHMMSS.*

-m - MODIFY	
<b>Format</b>	<p>One of:</p> <ul style="list-style-type: none"> <li>• <b>config</b> [&lt;STRING&gt;] <ul style="list-style-type: none"> <li>[-e]</li> <li>[--flags=pers]</li> </ul>           &lt;STRING&gt; is any string which would be acceptable in moab.cfg <ul style="list-style-type: none"> <li>◦ If no string is specified, &lt;STRING&gt; is read from STDIN.</li> <li>◦ If -e is specified, the configuration string will be evaluated for correctness but no configuration changes will take place. Any issues with the provided string will be reported to STDERR.</li> <li>◦ If --flags=persistent is specified, the Moab configuration files (moab.cfg and moab.dat) are modified.</li> </ul> </li> <li>• <b>trigger</b>:&lt;TRIGID&gt; &lt;ATTR&gt;=&lt;VAL&gt;</li> </ul> <p>where &lt;ATTR&gt; is one of action, atype, etype, iscomplete, oid, otype, offset, or threshold</p>
<b>Description</b>	Modify a system parameter or trigger.
<b>Example</b>	<pre>mschedctl -m config LOGLEVEL 9</pre> <p><i>Change the system loglevel to 9.</i></p> <pre>mschedctl -m trigger:2 AType=exec,Offset=200,OID=system.1</pre> <p><i>Change aspects of trigger 2.</i></p>
-p - PAUSE	
<b>Description</b>	Disable scheduling but allow the scheduler to update its cluster and workload state information.
<b>Example</b>	<pre>mschedctl -p</pre>
-q QUERY PENDING ACTIONS	
<b>Default</b>	mschedctl -q pactions --xml
<b>Description</b>	A way to view pending actions. Only an XML request is valid. Pending actions can be VMs or system jobs.

### -q QUERY PENDING ACTIONS

<b>Example</b>	<code>mschedctl -q pactions --xml</code>
----------------	------------------------------------------

### -R - RECYCLE

<b>Description</b>	Recycle scheduler immediately (shut it down and restart it using the original execution environment and command line arguments).
<b>Example</b>	<pre>mschedctl -R</pre> <p><i>Recycle scheduler immediately.</i></p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> To restart Moab with its last known scheduler state, use: <code>mschedctl -R savestate</code></p> </div>

### -r - RESUME

<b>Format</b>	<code>mschedctl -r [[HH:[MM:]]SS]</code>
<b>Default</b>	0
<b>Description</b>	Resume scheduling in the specified amount of time (or immediately if none is specified).
<b>Example</b>	<pre>mschedctl -r</pre> <p><i>Resume scheduling immediately.</i></p>

### -s - STOP

<b>Format</b>	<code>&lt;INTEGER&gt;</code>
<b>Default</b>	0
<b>Description</b>	Suspend/stop scheduling at specified iteration (or at the end of the current iteration if none is specified). If the letter I follows <code>&lt;ITERATION&gt;</code> , Moab will not process client requests until this iteration is reached.

-s - STOP	
<b>Example</b>	<pre>mschedctl -s 100I</pre> <p><i>Stop scheduling at iteration 100 and ignore all client requests until then.</i></p>
-S - STEP	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Step the specified number of iterations (or to the next iteration if none is specified) and suspend scheduling. If the letter I follows <ITERATION>, Moab will not process client requests until this iteration is reached.
<b>Example</b>	<pre>mschedctl -S</pre> <p><i>Step to the next iteration and stop scheduling.</i></p>

## Examples

*Example 3-43: Shutting down the Scheduler*

```
mschedctl -k
scheduler will be shutdown immediately
```

## mshow

### Synopsis

```
mshow [-a] [-q jobqueue=active]
```

### Overview

The `mshow` command displays various diagnostic messages about the system and job queues.

## Arguments

Flag	Description
<a href="#">-a</a>	<a href="#">AVAILABLE RESOURCES</a>
<b>-q</b> [<QUEUENAME>]	Displays the job queues.

## Format

AVAILABLE RESOURCES	
<b>Format</b>	Can be combined with <code>--flags=[tid verbose future]</code> <code>--format=xml</code> and/or <code>-w</code>
<b>Description</b>	Display available resources.
<b>Example</b>	<pre>&gt; mshow -a -w user=john --flags=tid --format=xml</pre> <p><i>Show resources available to john in XML format with a transaction id. See <a href="#">mshow -a</a> for details.</i></p>

JOB QUEUE	
<b>Format</b>	<QUEUENAME>, where the queue name is one of: active, eligible, or blocked. Job queue names can be delimited by a comma to display multiple queues. If no job queue name is specified, mshow displays all job queues.
<b>Description</b>	Displays the job queues. If a job queue name is specified, mshow shows only that job queue.
<b>Example</b>	<pre>&gt; mshow -q active,blocked [Displays all jobs in the active and blocked queues] ...</pre>

### mshow -a

## Synopsis

`mshow -a [-i] [-o] [-T] [-w where] [-x] [--xml]`

## Overview

The `mshow -a` command allows for querying of available system resources.

## Arguments

<code>[-i]</code>	INTERSECTION
<code>[-o]</code>	NO AGGREGATE
<code>[-T]</code>	TIMELOCK
<code>[-w]</code>	WHERE
<code>[-x]</code>	EXCLUSIVE

Table 3-4: Argument Format

--flags	
<b>Name</b>	Flags
<b>Format</b>	<code>--flags=[ future   policy   tid   summary   verbose ]</code>
<b>Description</b>	<p><b>future</b> will return resources available immediately and available in the future.</p> <p><b>policy (Deprecated. May be removed in a future release.)</b> will apply charging policies to determine the total cost of each reported solution (only enabled for XML responses).</p> <p><b>summary</b> will assign all jointly allocated transactions as dependencies of the first transaction reported.</p> <p><b>tid</b> will associate a transaction id with the reported results.</p> <p><b>verbose</b> will return diagnostic information.</p>
<b>Example</b>	<pre>&gt; mshow -a -w user=john --flags=tid --xml</pre> <p><i>Show resources available to john in XML format with a transaction ID.</i></p>

--xml	
<b>Name</b>	XML
<b>Format</b>	--xml
<b>Description</b>	Report results in XML format.
<b>Example</b>	<pre>&gt; mshow -a -w user=john --flags=tid --xml</pre> <p><i>Show resources available to john in XML format with a transaction ID.</i></p>

-i	
<b>Name</b>	INTERSECTION
<b>Description</b>	Specifies that an intersection should be performed during an <code>mshow -a</code> command with multiple requirements.

-o	
<b>Name</b>	NO AGGREGATE
<b>Description</b>	Specifies that the results of the command <code>mshow -a</code> with multiple requirements should not be aggregated together.

-T	
<b>Name</b>	TIMELock
<b>Description</b>	Specifies that the multiple requirements of an <code>mshow -a</code> command should be timelocked.
<b>Example</b>	<pre>&gt; mshow -a -w minprocs=1,os=linux,duration=1:00:00 \ -w minprocs=1,os=aix,duration=10:00 \ --flags=tid,future -x -T</pre>

-w	
<b>Name</b>	WHERE
<b>Format</b>	Comma delimited list of <ATTR>=<VAL> pairs: <ATTR>=<VAL> [,<ATTR>=<VAL>]... <div style="border: 1px solid #004a7c; border-radius: 10px; padding: 10px; margin: 10px 0;"> <p><b>i</b> If any of the &lt;ATTR&gt;=&lt;VAL&gt; pairs contains a sub-list that is also comma delimited, the entire -w string must be wrapped in single quotations with the sub-list expression wrapped in double quotations. See the example below.</p> </div> Attributes are listed below in <a href="#">table 2</a> .
<b>Description</b>	Add a Where clause to the current command (currently supports up to six co-allocation clauses).
<b>Example</b>	<pre>&gt; mshow -a -w minprocs=2,duration=1:00:00 -w nodemem=512,duration=1:00:00</pre> <p><i>Moab returns a list of all nodes with at least 2 processors and one hour duration or with a memory of 512 and a duration of one hour.</i></p> <pre>&gt; mshow -a -w nodefeature=!vmware:gpfs --flags=future</pre> <p><i>Moab returns a list of all nodes that do not contain the vmware feature but that do contain the gpfs feature.</i></p> <pre>&gt; mshow -a -w 'duration=INFINITY,"excludehostlist=n01,n12,n23"'</pre> <p><i>Moab returns a list of all nodes with a duration of INFINITY, except for nodes named n01, n12, and n23.</i>  <i>Note the use of single quotations containing the entire -w string and the use of double quotations containing the excludehostlist attribute.</i></p>

-x	
<b>Name</b>	EXCLUSIVE
<b>Description</b>	Specifies that the multiple requirements of an mshow -a command should be exclusive (i.e. each node may only be allocated to a single requirement)
<b>Example</b>	<pre>&gt; mshow -a -w minprocs=1,os=linux -w minprocs=1,os=aix --flags=tid -x</pre>

Table 3-5: Request Attributes

Name	Description
<b>account</b>	The account credential of the requestor
<b>acl</b>	ACL to attach to the reservation  This ACL must be enclosed in quotation marks. For example: <code>\$ mshow -a ... -w acl=\"user=john\" ...</code>
<b>arch</b>	Select only nodes with the specified architecture
<b>cal</b>	Select resources subject to the constraints of the specified global calendar
<b>class</b>	The class credential of the requestor
<b>coalloc</b>	The co-allocation group of the specific Where request (can be any string but must match co-allocation group of at least one other Where request)  <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF;"> <span style="font-size: 1.2em; font-weight: bold; color: #0070C0;">i</span> The number of tasks requested in each Where request must be equal whether this taskcount is specified via <code>minprocs</code>, <code>mintasks</code>, or <code>gres</code>.                     </div>
<b>count</b>	The number of profiles to apply to the resource request
<b>displaymode</b>	Possible value is <code>future</code> . (Example: <code>displaymode=future</code> ). Constrains how results are presented; setting <code>future</code> evaluates which resources are available now and which resources will be available in the future that match the requested attributes.
<b>duration</b>	The duration for which the resources will be required in format <code>[ [DD:]HH:]MM:]SS</code>
<b>excludehostlist</b>	Do not select any nodes from the given list. The list must be comma delimited.  <div style="border: 1px dashed #ccc; padding: 10px;"> <pre>&gt; mshow -a -w 'duration=INFINITY,"excludehostlist=n01,n12,n23"'</pre> <p><i>Moab returns a list of all nodes with a duration of <b>INFINITY</b>, except for nodes named <b>n01</b>, <b>n12</b>, and <b>n23</b>.</i></p> <p><i>Note the use of single quotations to contain the entire <code>-w</code> string, and the use of double quotations containing the <b>excludehostlist</b> attribute.</i></p> </div>
<b>gres</b>	Select only nodes which possess the specified generic resource
<b>group</b>	The group credential of the requestor

Name	Description
<b>hostlist</b>	<p>Select only the specified resources. The list must be comma delimited.</p> <pre>&gt; mshow -a -w 'duration=INFINITY,"hostlist=n01,n12,n23"'</pre> <p><i>Moab returns a list of nodes from the selected hostlist that have a duration of <b>INFINITY</b>.</i></p> <p><i>Note the use of single quotations to contain the entire <code>-w</code> string, and the use of double quotations containing the <b>hostlist</b> attribute.</i></p>
<b>job</b>	Use the resource, duration, and credential information for the job specified as a resource request template
<b>jobfeature</b>	Select only resources which would allow access to jobs with the specified job features
<b>jobflags</b>	Select only resources which would allow access to jobs with the specified job flags. The <code>job-flags</code> attribute accepts a colon delimited list of multiple flags.
<b>label</b>	Removed label 1/2013 for DOC-16 Associate the specified label with all results matching this request
<b>minnodes</b>	Return only results with at least the number of nodes specified. If used with TID's, return only solutions with exactly minnodes nodes available
<b>minprocs</b>	Return only results with at least the number of processors specified. If used with TID's, return only solutions with exactly minprocs processors available
<b>mintasks</b>	<b>FORMAT:</b> <code>&lt;TASKCOUNT&gt;[@&lt;RESTYPE&gt;:&lt;COUNT&gt;[+&lt;RESTYPE&gt;:&lt;COUNT&gt;]...]</code> where <code>&lt;RESTYPE&gt;</code> is one of <code>procs</code> , <code>mem</code> , <code>disk</code> , or <code>swap</code> . Return only results with at least the number of tasks specified. If used with TID's, return only solutions with exactly mintasks available
<b>nodedisk</b>	Select only nodes with at least <code>nodedisk</code> MB of local disk configured
<b>nodefeature</b>	Select only nodes with all specified features present and nodes without all \! specified features using format <code>[ \! ] &lt;feature&gt; [ : [ \! ] &lt;feature&gt; ] ...</code> . You must set the <a href="#">future</a> flag when specifying node features.
<b>nodemem</b>	Select only nodes with at least <code>nodemem</code> MB of memory configured
<b>offset</b>	Select only resources which can be co-allocated with the specified time offset where offset is specified in the format <code>[ [ DD : ] HH : ] MM : ] SS</code>

Name	Description
<b>os</b>	Select only nodes with have, or can be provisioned to have, the specified operating system
<b>partition</b>	The partition in which the resources must be located
<b>policylevel</b>	Enable policy enforcement at the specified policy constraint level
<b>qos</b>	The qos credential of the requestor
<b>rsvprofile</b>	Use the specified profile if committing a resulting transaction id directly to a reservation
<b>starttime</b>	<p>Constrain the timeframe for the returned results by specifying one or more ranges using the format <code>&lt;STIME&gt;[-&lt;ENDTIME&gt;];&lt;STIME&gt;[-&lt;ENDTIME&gt;]</code> where each time is specified in the format in absolute, relative, or epoch time format (<code>[HH[:MM[:SS]]][_MO[/DD[/YY]]]</code>) or <code>+ [[DD:]HH:]MM:]SS</code> or <code>&lt;EPOCHTIME&gt;</code>).</p> <div style="border: 1px solid #004a87; border-radius: 10px; padding: 5px; background-color: #e6f2ff;"> <p> The starttime specified is not the exact time at which the returned range must start, but is rather the earliest possible time the range may start.</p> </div>
<b>taskmem</b>	Require <code>taskmem</code> MB of memory per task located
<b>tpn</b>	Require exactly <code>tpn</code> tasks per node on all discovered resources
<b>user</b>	The user credential of the requestor
<b>var</b>	Use associated variables in generating per transaction charging quotes
<b>variables</b>	Takes a string of the format <code>variables='var[=attr]';'var[=attr]'</code> and passes the variables onto the reservation when used in conjunction with <code>--flags=tid</code> and <code>mrsvctl -c -R &lt;tid&gt;</code> .
<b>vmusage</b>	Possible value is <code>vmcreate</code> . Moab will find resources for the job assuming it is a <code>vmcreate</code> job, and if <code>os</code> is also specified, Moab will look for a hypervisor capable of running a VM with the requested OS.

## Usage Notes

The `mshow -a` command allows for querying of available system resources. When combined with the `--flags=tid` option these available resources can then be placed into a packaged reservation (using [mrsvctl -c -R](#)). This allows system administrators to grab and reserve available resources for whatever reason, without conflicting with jobs or reservations that may be holding certain resources.

There are a few restrictions on which *<ATTR>* from the *-w* command can be placed in the same req: *minprocs*, *minnodes*, and *gres* are all mutually exclusive, only one may be used per *-w* request.

The allocation of available nodes will follow the global [NODEALLOCATIONPOLICY](#).

When the *-o* flag is not used, multi-request results will be aggregated. This aggregation will negate the use of offsets and request-specific starttimes.

The config parameter [RESOURCEQUERYDEPTH](#) controls the maximum number of options that will be returned in response to a resource query.

## Examples

### Example 3-44: Basic Compute Node Query and Reservation

```
> mshow -a -w duration=10:00:00,minprocs=1,os=AIX53,jobfeature=shared --
flags=tid,future
```

Partition	Tasks	Nodes	Duration	StartOffset	StartDate		
ALL	1	1	10:00:00	00:00:00	13:28:09_04/27	TID=4	ReqID=0
ALL	1	1	10:00:00	10:00:00	17:14:48_04/28	TID=5	ReqID=0
ALL	1	1	10:00:00	20:00:00	21:01:27_04/29	TID=6	ReqID=0

```
> mrsvctl -c -R 4
Note: reservation system.2 created
```

### Example 3-45: Mixed Processor and License Query

Select one node with 4 processors and 1 matlab license where the matlab license is only available for the last hour of the reservation. Also, select 16 additional processors which are available during the same timeframe but which can be located anywhere in the cluster. Group the resulting transactions together using transaction dependencies so only the first transaction needs to be committed to reserve all associated resources.

```
> mshow -a -i -o -x -w mintasks=1@PROCS:4,duration=10:00:00,coalloc=a \
-w gres=matlab,offset=9:00:00,duration=1:00:00,coalloc=a \
-w minprocs=16,duration=10:00:00 --flags=tid,future,summary
```

Partition	Tasks	Nodes	Duration	StartOffset	StartDate		
ALL	1	1	10:00:00	00:00:00	13:28:09_04/27	TID=4	ReqID=0
ALL	1	1	10:00:00	10:00:00	17:14:48_04/28	TID=5	ReqID=0
ALL	1	1	10:00:00	20:00:00	21:01:27_04/29	TID=6	ReqID=0

```
> mrsvctl -c -R 4

Note: reservation system.2 created
Note: reservation system.3 created
Note: reservation system.4 created
```

### Example 3-46: Request for Generic Resources

Query for a generic resource on a specific host (no processors, only a generic resource).

```

> mshow -a -i -x -o -w gres=dvd,duration=10:00,hostlist=node03 --flags=tid,future
Partition      Tasks  Nodes  StartOffset  Duration  StartDate
-----
ALL            1      1      00:00:00     00:10:00  11:33:25_07/27  TID=16
ReqID=0
ALL            1      1      00:10:00     00:10:00  11:43:25_07/27  TID=17
ReqID=0
ALL            1      1      00:20:00     00:10:00  11:53:25_07/27  TID=18
ReqID=0
> mrvsvctl -c -R 16
Note: reservation system.6 created
> mdiag -r system.6
Diagnosing Reservations
RsvID          Type Par  StartTime  EndTime  Duration Node Task
Proc
-----

CL:   RSV==system.6
Accounting Creds: User:test
Task Resources: dvd: 1
Attributes (HostExp='^node03$')
Rsv-Group: system.6

```

#### Example 3-47: Allocation of Shared Resources

This example walks through a relatively complicated example in which a set of resources can be reserved to be allocated for shared requests. In the example below, the first `mshow` query looks for resources within an existing shared reservation. In the example, this first query fails because there is now existing reservation. The second query looks for resources within an existing shared reservation. In the example, this first query fails because there is now existing reservation. The second `mshow` request asks for resources outside of a shared reservation and finds the desired resources. These resources are then reserved as a shared pool. The third `mshow` request again asks for resources inside of a shared reservation and this time finds the desired resources.

```

> mshow -a -w duration=10:00:00,minprocs=1,os=AIX53,jobflags=ADVRES,jobfeature=shared
--flags=tid
Partition      Tasks  Nodes  Duration  StartOffset  StartDate
-----
> mshow -a -w duration=100:00:00,minprocs=1,os=AIX53,jobfeature=shared --flags=tid
Partition      Tasks  Nodes  Duration  StartOffset  StartDate
-----
ALL            1      1      100:00:00  00:00:00     13:20:23_04/27  TID=1  ReqID=0
> mrvsvctl -c -R 1
Note: reservation system.1 created
> mshow -a -w duration=10:00:00,minprocs=1,os=AIX53,jobflags=ADVRES,jobfeature=shared
--flags=tid
Partition      Tasks  Nodes  Duration  StartOffset  StartDate
-----
ALL            1      1      10:00:00   00:00:00     13:20:36_04/27  TID=2  ReqID=0
> mrvsvctl -c -R 2
Note: reservation system.2 created

```

*Example 3-48: Full Resource Query in XML Format*

The following command will report information on all available resources which meet at least the minimum specified processor and walltime constraints and which are available to the specified user. The results will be reported in XML to allow for easy system processing.

```

> mshow -a -w class=grid,minprocs=8,duration=20:00 --format=xml --flags=future,verbose

### mshow -a

## Basic Current and Future Requests

The `mshow` command can report information on many aspects of the scheduling environment. To request information on available resources, the `-a` flag should be used. By default, the `mshow` command resource availability query only reports resources that are immediately available. To request information on specific resources, the type of resources required can be specified using the `-w` flag as in the following example:

```
> mshow -a -w taskmem=1500,duration=600
...
```

To view current and future resource availability, the `future` flag should be set as in the following example:

```
> mshow -a -w taskmem=1500,duration=600 --flags=future
...
```

## Co-allocation Resources Queries

In many cases, a particular request will need simultaneous access to resources of different types. The `mshow` command supports a co-allocation request specified by using multiple `-w` arguments. For example, to request 16 nodes with feature `fastcpu` and 2 nodes with feature `fastio`, the following request might be used:

```
> mshow -a -w minprocs=16,duration=1:00:00,nodefeature=fastcpu -w
minprocs=2,nodefeature=fastio,duration=1:00:00 --flags=future
Partition      Procs   Nodes   StartOffset      Duration      StartDate      ReqID=0
-----
ALL            16      8       00:00:00         1:00:00      13:00:18_08/25
ALL             2       1       00:00:00         1:00:00      13:00:18_08/25      ReqID=1
```

The [mshow -a](#) documentation contains a list of the different resources that may be queried as well as examples on using `mshow`.

## Using Transaction IDs

By default, the `mshow` command reports simply when and where the requested resources are available. However, when the `tid` flag is specified, the `mshow` command returns both resource availability information and a handle to these resources called a Transaction ID as in the following example:

```
> mshow -a -w minprocs=16,nodefeature=fastcpu,duration=2:00:00 --flags=future,tid
Partition      Procs  Nodes  StartOffset      Duration      StartDate
-----
ALL            16    16      00:00:00        2:00:00      13:00:18_08/25  TID=26 ReqID=0
```

In the preceding example, the returned transaction id (TID) may then be used to reserve the available resources using the [mrsvctl -c -R](#) command:

```
> mrsvctl -c -R 26
reservation system.1 successfully created
```

Any TID can be printed out using the [mschedctl -l trans](#) command:

```
Code example (replace with your own content)
> mschedctl -l trans 26 TID[26] A1='node01' A2='600' A3='1093465728' A4='ADVRES' A5='fastio'
```

Where A1 is the hostlist, A2 is the duration, A3 is the starttime, A4 are any flags, and A5 are any features.

## Using Reservation Profiles

Reservation profiles ([RSVPROFILE](#)) stand as templates against which reservations can be created. They can contain a hostlist, starttime, endtime, duration, access-control list, flags, triggers, variables, and most other attributes of an Administrative Reservation. The following example illustrates how to create a reservation with the exact same trigger-set.

```

-----
# moab.cfg
-----
RSVPROFILE[test1] TRIGGER=Sets=$Var1.$Var2.$Var3.!Net,EType=start,AType=exec,
    Action=/tmp/host/triggers/Net.sh,
    Timeout=1:00:00
RSVPROFILE[test1]                                TRIGGER=Requires=$Var1.$Var2.$Var3,
    Sets=$Var4.$Var5,EType=start,
    AType=exec,Action=/tmp/host/triggers/
    FS.sh+$Var1:$Var2:$Var3,Timeout=20:00
RSVPROFILE[test1]
TRIGGER=Requires=$Var1.$Var2.$Var3.$Var4.$Var5,
    Sets=!NOOSinit.OSinit,EType=start,
    AType=exec,
    Action=/tmp/host/triggers/
    OS.sh+$Var1:$Var2:$Var3:$Var4:$Var5
RSVPROFILE[test1]
TRIGGER=Requires=NOOSini,AType=cancel,EType=start
RSVPROFILE[test1]
TRIGGER=EType=start,Requires=OSinit,AType=exec,
    Action=/tmp/host/triggers/success.sh
...
-----

```

To create a reservation with this profile the `mrsvctl -c -P` command is used:

```

> mrsvctl -c -P test1
reservation system.1 successfully created

```

## Using Reservation Groups

Reservation groups are a way for Moab to tie reservations together. When a reservation is created using multiple Transaction IDs, these transactions and their resulting reservations are tied together into one group.

```

> mrsvctl -c -R 34,35,36
reservation system.99 successfully created
reservation system.100 successfully created
reservation system.101 successfully created

```

In the preceding example, these three reservations would be tied together into a single group. The `mdiag -r` command can be used to see which group a reservation belongs to. The `mrsvctl -q diag -g` command can also be used to print out a specific group of reservations. The `mrsvctl -c -g` command can also be used to release a group of reservations.

- [mshow](#)

# msub

## Synopsis

```
msub [-a datetime][-A account][-c interval][-C directive_prefix][-d path] [-e path][-E][-F][-h][-l][-j join][-k keep][-K][-l resourcelist][-m mailoptions] [-M user_list][-N name][-o path][-p priority][-q destination][-r] [-S pathlist][-t jobarrays][-u userlist][-v variablelist][-V] [-W additionalattributes][-x][-z][--stagein][--stageout][--stageinfile][--stageoutfile][--stageinsize][--stageoutsize][--workflowjobsids][script]
```

## Overview

msub allows users to submit jobs directly to Moab. When a job is submitted directly to a resource manager (such as TORQUE), it is constrained to run on only those nodes that the resource manager is directly monitoring. In many instances, a site may be controlling multiple resource managers. When a job is submitted to Moab rather than to a specific resource manager, it is not constrained as to what nodes it is executed on. msub can accept command line arguments (with the same syntax as qsub), job scripts (in either PBS or LoadLeveler syntax), or the SSS Job XML specification.

**i** Moab must run as a root user in order for msub submissions to work. Workload submitted via msub when Moab is running as a non-root user fail immediately.

Submitted jobs can then be viewed and controlled via the [mjobctl](#) command.

**i** Flags specified in the following table are not necessarily supported by all resource managers.

## Access

When Moab is configured to run as root, any user may submit jobs via msub.

## Flags

-a	
<b>Name</b>	Eligible Date
<b>Format</b>	[[[[[CC]YY]MM]DD]hhmm[.SS]
<b>Description</b>	Declares the time after which the job is eligible for execution.
<b>Example</b>	<pre>&gt; msub -a 12041300 cmd.pbs</pre> <p><i>Moab will not schedule the job until 1:00 pm on December 4, of the current year.</i></p>

-A	
<b>Name</b>	Account
<b>Format</b>	<ACCOUNT NAME>
<b>Description</b>	Defines the account associated with the job.
<b>Example</b>	<pre>&gt; msub -A research cmd.pbs</pre> <p><i>Moab will associate this job with account research.</i></p>

-c	
<b>Name</b>	Checkpoint Interval
<b>Format</b>	[n s c c=<minutes>]
<b>Description</b>	<p>Checkpoint of the will occur at the specified interval.</p> <p><b>n</b> — No Checkpoint is to be performed.  <b>s</b> — Checkpointing is to be performed only when the server executing the job is shut down.  <b>c</b> — Checkpoint is to be performed at the default minimum time for the server executing the job.  <b>c=&lt;minutes&gt;</b> — Checkpoint is to be performed at an interval of minutes.</p>
<b>Example</b>	<pre>&gt; msub -c c=12 cmd.pbs</pre> <p><i>The job will be checkpointed every 12 minutes.</i></p>

-C	
<b>Name</b>	Directive Prefix
<b>Format</b>	'<PREFIX NAME>'
<b>Default</b>	First known prefix (#PBS, #@, #BSUB, #!, #MOAB, #MSUB)

-C	
<b>Description</b>	<p>Specifies which directive prefix should be used from a job script.</p> <ul style="list-style-type: none"> <li>• It is best to submit with single quotes. '#PBS'</li> <li>• An empty prefix will cause Moab to not search for any prefix. -C ''</li> <li>• Command line arguments have precedence over script arguments.</li> <li>• Custom prefixes can be used with the -C flag. -C '#MYPREFIX'</li> <li>• Custom directive prefixes must use PBS syntax.</li> <li>• If the -C flag is not given, Moab will take the first default prefix found. Once a directive is found, others are ignored.</li> </ul>
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; msub -C '#MYPREFIX' cmd.pbs #MYPREFIX -l walltime=5:00:00 (in cmd.pbs)</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Moab will use the #MYPREFIX directive specified in cmd.pbs, setting the wallclock limit to five hours.</i></p>

-d	
<b>Name</b>	Execution Directory
<b>Format</b>	<path>
<b>Default</b>	Depends on the RM being used. If using TORQUE, the default is \$HOME. If using SLURM, the default is the submission directory.
<b>Description</b>	Specifies which directory the job should execute in.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; msub -d /home/test/job12 cmd.pbs</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>The job will begin execution in the /home/test/job12 directory.</i></p>

-e	
<b>Name</b>	Error Path
<b>Format</b>	[<hostname>:]<path>
<b>Default</b>	\$SUBMISSIONDIR/\$JOBNAME.e\$JOBID

-e	
<b>Description</b>	Defines the path to be used for the standard error stream of the batch job.
<b>Example</b>	<pre>&gt; msub -e test12/stderr.txt</pre> <p><i>The STDERR stream of the job will be placed in the relative (to execution) directory specified.</i></p>

-E	
<b>Name</b>	Environment Variables
<b>Description</b>	<p>Moab adds the following variables, if populated, to the job's environment:</p> <ul style="list-style-type: none"> <li>• MOAB_ACCOUNT — Account name.</li> <li>• MOAB_BATCH — Set if a batch job (non-interactive).</li> <li>• MOAB_CLASS — Class name.</li> <li>• MOAB_DEPEND — Job dependency string.</li> <li>• MOAB_GROUP — Group name.</li> <li>• MOAB_JOBARRAYINDEX — For a job in an array, the index of the job.</li> <li>• MOAB_JOBARRAYRANGE — For a system with job arrays, the range of all job arrays.</li> <li>• MOAB_JOBID — Job ID. If submitted from the grid, grid jobid.</li> <li>• MOAB_JOBNAME — Job name.</li> <li>• MOAB_MACHINE — Name of the machine (i.e. Destination RM) that the job is running on.</li> <li>• MOAB_NODECOUNT — Number of nodes allocated to job.</li> <li>• MOAB_NODELIST — Comma-separated list of nodes (listed singly with no ppn info).</li> <li>• MOAB_PARTITION — Partition name the job is running in. If grid job, cluster scheduler's name.</li> <li>• MOAB_PROCCOUNT — Number of processors allocated to job.</li> <li>• MOAB_QOS — QOS name.</li> <li>• MOAB_TASKMAP — Node list with procs per node listed. &lt;nodename&gt;.&lt;procs&gt;</li> <li>• MOAB_USER — User name.</li> </ul> <p>In SLURM environments, not all variables will be populated since the variables are added at submission (such as NODELIST). With TORQUE/PBS, the variables are added just before the job is started.</p> <p>This feature only works with SLURM and TORQUE/PBS.</p>
<b>Example:</b>	<pre>&gt; msub -E mySim.cmd</pre> <p><i>The job mySim will be submitted with extra environment variables.</i></p>

-F	
<b>Name</b>	Script Flags
<b>Format</b>	"\"<STRING>\""
<b>Description</b>	<p>Specifies the flags TORQUE will pass to the job script at execution time.</p> <div style="border: 1px solid #4a6982; border-radius: 10px; padding: 5px; background-color: #d9e1f2;"> <p> The <code>-F</code> flag is only compatible with TORQUE resource managers.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; border-radius: 10px; padding: 10px; background-color: #f0f0f0;"> <pre>&gt; msub -F "\"arg1 arg2\"" -l nodes=1,walltime=60 files/job.sh</pre> <p><i>TORQUE will pass parameters <code>arg1</code> and <code>arg2</code> to the <code>job.sh</code> script when the job executes.</i></p> </div>

-h	
<b>Name</b>	Hold
<b>Description</b>	Specifies that a user hold be applied to the job at submission time.
<b>Example</b>	<div style="border: 1px dashed #ccc; border-radius: 10px; padding: 10px; background-color: #f0f0f0;"> <pre>&gt; msub -h cmd.ll</pre> <p><i>The job will be submitted with a user hold on it.</i></p> </div>

-I	
<b>Name</b>	Interactive
<b>Description</b>	<p>Declares the job is to be run interactively.</p> <div style="border: 1px solid #4a6982; border-radius: 10px; padding: 5px; background-color: #d9e1f2;"> <p> <code>qsub</code> must exist on the same host as <code>msub</code> if the interactive job is destined for a TORQUE cluster, because the interactive <code>msub</code> request will be converted to a <code>qsub -l</code> request.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; border-radius: 10px; padding: 10px; background-color: #f0f0f0;"> <pre>&gt; msub -I job117.sh</pre> <p><i>The job will be submitted in interactive mode.</i></p> </div>

-j	
<b>Name</b>	Join
<b>Format</b>	[eo oe n]
<b>Default</b>	n (not merged)
<b>Description</b>	<p>If <code>eo</code> is specified, the error and output streams are merged into the <i>error</i> stream. If <code>oe</code> is specified, the error and output streams will be merged into the <i>output</i> stream.</p> <div style="border: 1px solid #004a7c; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p><b>i</b> If using either the <code>-e</code> or the <code>-o</code> option and the <code>-j eo oe</code> option, the <code>-j</code> option takes precedence and all standard error and output messages go to the chosen output file.</p> </div>
<b>Example</b>	<pre>&gt; msub -j oe cmd.sh</pre> <p><i>STDOUT and STDERR will be merged into one file.</i></p>

-k	
<b>Name</b>	Keep
<b>Format</b>	[e o eo oe n]
<b>Default</b>	n (not retained)
<b>Description</b>	Defines which (if either) of output and error streams will be retained on the execution host (overrides path for stream).
<b>Example</b>	<pre>&gt; msub -k oe myjob.sh</pre> <p><i>STDOUT and STDERR for the job will be retained on the execution host.</i></p>

-K	
<b>Name</b>	Continue Running
<b>Format</b>	N/A

-K	
<b>Description</b>	<p>Tells the client to continue running until the submitted job is completed. The client will query the status of the job every 5 seconds. The time interval between queries can be specified or disabled via <a href="#">MSUBQUERYINTERVAL</a>.</p> <div style="border: 1px solid #4a7c9c; background-color: #e6f2ff; padding: 5px; margin-top: 10px;"> <p><b>i</b> Use the <code>-K</code> option sparingly (if at all) as it slows down the Moab scheduler with frequent queries. Running ten jobs with the <code>-K</code> option creates an additional fifty queries per minute for the scheduler.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 10px;">&gt; msub -K newjob.sh 3 Job 3 completed*</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"><i>*Only shows up after job completion.</i></p>

-l	
<b>Name</b>	Resource List
<b>Format</b>	<p>&lt;STRING&gt;                      -l [BANDWIDTH DDISK DEADLINE DEPEND DMEM EXCLUDENODES FEATURE...[]                      Additional options can be referenced on the <a href="#">resource manager extensions</a> page.</p>
<b>Description</b>	<p>Defines the resources that are required by the job and establishes a limit to the amount of resource that can be consumed. Resources native to the resource manager, scheduler <a href="#">resource manager extensions</a>, or <a href="#">job flags</a> may be specified. Note that resource lists are dependent on the resource manager in use.</p> <p>For information on specifying multiple types of resources for allocation, see <a href="#">Multi-Req Support</a>.</p>

**-l****Example**

```
> msub -l nodes=32:ppn=2,pmem=1800mb,walltime=3600,VAR=testvar:myvalue cmd.sh
> msub -l nodes=32:ppn=2,pmem=1800mb,walltime=3600,VAR=testvar:
myvalue cmd.sh
```

*The job requires 32 nodes with 2 processors each, 1800 MB per task, a walltime of 3600 seconds, and a variable named `testvar` with a value of `myvalue`.*

**i** If `JOBNODEMATCHPOLICY` is not set, Moab does not reserve the requested number of processors on the requested number of nodes. It reserves the total number of requested processors (`nodes x ppn`) on any number of nodes. Rather than setting `nodes=<value>:ppn=<value>`, set `procs=<value>`, replacing `<value>` with the total number of processors the job requires. Note that `JOBNODEMATCHPOLICY` is not set by default.

```
> msub -l nodes=32:ppn=2 -l advres=!<resvid>
```

*This entry would tell Moab to only consider resources outside of the specified `<reservation id>`.*

**-m****Name**

Mail Options

**Format**<STRING> (either `n` or one or more of the characters `a`, `b`, and `e`)**Description**Defines the set of conditions (`abort`,`begin`,`end`) when the server will send a mail message about the job to the user.**Example**

```
> msub -m be cmd.sh
```

*Mail notifications will be sent when the job begins and ends.*

**-M****Name**

Mail List

**Format**

&lt;user&gt;[@&lt;host&gt;][,&lt;user&gt;[@&lt;host&gt;],...]

**Default**

\${JOBOWNER}

-M	
<b>Description</b>	Specifies the list of users to whom mail is sent by the execution server. Overrides the <b>EMAILADDRESS</b> specified on the <a href="#">USERCFG</a> credential.
<b>Example</b>	<pre>&gt; msub -M jon@node01,bill@node01,jill@node02 cmd.sh</pre> <p><i>Mail will be sent to the specified users if the job is aborted.</i></p>

-N	
<b>Name</b>	Name
<b>Format</b>	<STRING>
<b>Default</b>	STDIN or name of job script
<b>Description</b>	Specifies the user-specified job name attribute.
<b>Example</b>	<pre>&gt; msub -N chemjob3 cmd.sh</pre> <p><i>Job will be associated with the name chemjob3.</i></p>

-O	
<b>Name</b>	Output Path
<b>Format</b>	[<hostname>:]<path> - %J and %I are acceptable variables. %J is the master array name and %I is the array member index in the array.
<b>Default</b>	\$SUBMISSIONDIR/\$JOBNAME. o\$JOBID

-o	
<b>Description:</b>	<p>Defines the path to be used for the standard output stream of the batch job.</p> <p>More variables are allowed when they are used in the job script instead of <code>msub -o</code>. In the job script, specify a <code>#PBS -o</code> line and input your desired variables. The allowable variables are:</p> <ul style="list-style-type: none"> <li>• OID</li> <li>• OTYPE</li> <li>• USER</li> <li>• OWNER</li> <li>• JOBID</li> <li>• JOBNAME</li> </ul> <p>Submitting a job script that has the line <code>#PBS -o \$(USER)_\$(JOBID)_\$(JOBNAME).txt</code> results in a file called <code>&lt;username&gt;_&lt;jobID&gt;_&lt;jobName&gt;.txt</code>.</p> <p>Do not use <code>msub -o</code> when submitting a job script that has a <code>#PBS -o</code> line defined.</p>
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; msub -o test12/stdout.txt</pre> <p style="text-align: center;"><i>The STDOUT stream of the job will be placed in the relative (to execution) directory specified.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px;"> <pre>&gt; msub -t 1-2 -o /home/jsmith/simulations/%J-%I.out ~/sim5.sh</pre> <p style="text-align: center;"><i>A job array is submitted and the name of the output files includes the master array index and the array member index.</i></p> </div>

-p	
<b>Name</b>	Priority
<b>Format</b>	<code>&lt;INTEGER&gt;</code> (between -1024 and 0)
<b>Default</b>	0
<b>Description</b>	<p>Defines the priority of the job.</p> <p>To enable priority range from -1024 to +1023, see <a href="#">ENABLEPOSUSERPRIORITY</a>.</p>
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; msub -p 25 cmd.sh</pre> <p style="text-align: center;"><i>The job will have a user priority of 25.</i></p> </div>

-q	
<b>Name</b>	Destination Queue (Class)
<b>Format</b>	[<queue>][@<server>]
<b>Default</b>	[<DEFAULT>]
<b>Description</b>	Defines the destination of the job.
<b>Example</b>	<pre>&gt; msub -q priority cmd.sh</pre> <p><i>The job will be submitted to the priority queue.</i></p>

-r	
<b>Name</b>	Rerunable
<b>Format</b>	[y n]
<b>Default</b>	n
<b>Description:</b>	Declares whether the job is rerunable.
<b>Example</b>	<pre>&gt; msub -r n cmd.sh</pre> <p><i>The job cannot be rerun.</i></p>

-S	
<b>Name</b>	Shell
<b>Format</b>	<path>[@<host>][,<path>[@<host>],...]
<b>Default</b>	\$SHELL
<b>Description</b>	Declares the shell that interprets the job script.

**-S**

<b>Example</b>	<pre>&gt; msub -S /bin/bash</pre> <p><i>The job script will be interpreted by the /bin/bash shell.</i></p>
----------------	------------------------------------------------------------------------------------------------------------

**-t**

<b>Name</b>	Job Arrays
<b>Format</b>	<name>.[<indexlist>]%<limit>
<b>Description</b>	Starts a job array with the jobs in the index list. The limit variable specifies how many jobs may run at a time. For more information, see <a href="#">Submitting Job Arrays</a> .
	<div style="border: 1px solid #004a80; padding: 5px;"> <p><b>i</b> Moab enforces an internal limit of 100,000 sub-jobs that a single array job submission can specify.</p> </div>
<b>Example</b>	<pre>&gt; msub -t myarray.[1-1000]%4</pre>

**-u**

<b>Name</b>	User List
<b>Format</b>	<user>[@<host>[,<user>[@<host>],...]]
<b>Default</b>	UID of msub command
<b>Description</b>	Defines the user name under which the job is to run on the execution system.
<b>Example</b>	<pre>&gt; msub -u bill@node01 cmd.sh</pre> <p><i>On node01 the job will run under Bill's UID, if permitted.</i></p>

**-v**

<b>Name</b>	Variable List
-------------	---------------

-v	
<b>Format</b>	<string>[,<string>,...]
<b>Description</b>	Expands the list the environment variables that are exported to the job (taken from the msub command environment).
<b>Example</b>	<pre>&gt; msub -v DEBUG cmd.sh</pre> <p><i>The DEBUG environment variable will be defined for the job.</i></p>

-V	
<b>Name</b>	All Variables
<b>Description</b>	Declares that all environment variables in the msub environment are exported to the batch job
<b>Example</b>	<pre>&gt; msub -V cmd.sh</pre> <p><i>All environment variables will be exported to the job.</i></p>

-W	
<b>Name</b>	Additional Attributes
<b>Format</b>	<string>
<b>Description</b>	Allows for specification of additional job attributes (See <a href="#">Resource Manager Extension</a> )
<b>Example</b>	<pre>&gt; msub -W x=GRES:matlab:1 cmd.sh</pre> <p><i>The job requires one resource of matlab.</i></p> <p>This flag can be used to set a filter for what namespaces will be passed from a job to a trigger using a comma-delimited list. This limits the trigger's action to objects contained in certain workflows. For more information, see <a href="#">Requesting name space variables on page 778</a>.</p> <pre>&gt; msub -W x="trigns=vc1,vc2"</pre> <p><i>The job passes namespaces vc1 and vc2 to triggers.</i></p>

-x	
<b>Format</b>	<script> or <command>
<b>Description</b>	<p>When running an interactive job, the <code>-x</code> flag makes it so that the corresponding script won't be parsed for PBS directives, but is instead a command that is launched once the interactive job has started. The job terminates at the completion of this command. This option works only when using TORQUE.</p> <div style="border: 1px solid #4a7c9c; padding: 5px; background-color: #e6f2ff;"> <p><b>i</b> The <code>-x</code> option for <code>msub</code> differs from <code>qsub</code> in that <code>qsub</code> does not require the script name to come directly after the flag. The <code>msub</code> command requires a script or command immediately after the <code>-x</code> declaration.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">&gt; msub -I -x ./script.pl &gt; msub -I -x /tmp/command</pre>

-z	
<b>Name</b>	Silent Mode
<b>Description</b>	The job's identifier will not be printed to stdout upon submission.
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">&gt; msub -z cmd.sh</pre> <div style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"> <p><i>No job identifier will be printout the stdout upon successful submission.</i></p> </div>

## Staging data

Data staging, or the ability to copy data required for a job from one location to another or to copy resulting data to a new location (See [About data staging on page 901](#) for more information), must be specified at job submission. To stage data in, you would use the `msub --stagein` and/or `--stageinfile` option, optionally with `--stageinsize`. You would use similar options the same way for staging out: `--stageout`, `--stageoutfile`, and `--stageoutsize`. `--stagein` and `--stageout`, which you can use multiple times in the same `msub` command, allow you to specify a single file or directory to stage in or out. `--stageinfile` and `--stageoutfile` allow you to specify a text file that lists the files to stage in or out. The `--stageinsize` and `[--stageoutsize]` options allow you to estimate the total size of the files and directories that you want to stage in or out, which can help Moab make an intelligent guess about how long it will take to stage the data in or out, thus ensuring that the job can start as soon as possible after the staging has occurred.

### Staging a file or directory

The `--stagein` and `--stageout` options use the same format.

```
--<stagein|stageout><=| ><source>%<destination>
```

Where *<source>* and *<destination>* take on the following format:

```
[<user>@] <host>: / <path> [ / <fileName> ]
```

Specifying a user and file name are optional. If you do not specify a file name, Moab will assume a directory.

```
> msub ... --stagein=student@biology:/stats/file001%admin@moab:/tmp/staging
<jobScript>
```

*This msub command tells Moab that the job requires file001 from student's stats directory on the biology server to be staged to admin's staging directory on the moab server prior to the job's starting.*

You can specify the option multiple times for the same `msub` command; however, staging large number of files is easier with `--stageinfile` or `--stageoutfile`.

You can also use `#MSUB` or `#PBS` within a job script to specify data staging options. For example:

```
#MSUB --stageinsize=1gb
#MSUB --stagein=...
```

See [Sample user job script on page 922](#) for more information. Note that the data staging options are not compatible with `qsub`.

### Staging multiple files or directories

The `--stageinfile` and `--stageoutfile` options use the same format. You must include the path to a text file that lists each file to stage in or out on its own line. Each file specification follows the same format as a `--stagein` or `--stageout` specification as described above. The format of the command options looks like this:

```
--<stageinfile|stageoutfile><=| ><path>/<fileName>
```

The file contains multiple lines with the following format:

```
[<user>@] <host>: / <path> [ / <fileName> ] % [ <user>@ ] <host>: / <path> [ / <fileName> ]
...
```

Moab ignores blank lines in the file. You can comment out lines by preceding them with a pound sign (`#`). The following examples demonstrate what the `--stageinfile` option looks like on the command line and what the file it specifies might look like.

```
> msub ... --stageinfile=/tmp/myStagingFile <jobScript>
```

```
/tmp/myStagingFile:
```

```
student@biology:/stats/file001%moab:/tmp/staging
student@biology:/stats/file002%moab:/tmp/staging
student@biology:/stats/file003%moab:/tmp/staging
#student@biology:/stats/file004%moab:/tmp/staging
student@biology:/stats/file005%moab:/tmp/staging

student@biology:/stats/file006%moab:/tmp/staging
student@biology:/stats/file007%moab:/tmp/staging
student@biology:/stats/file008%moab:/tmp/staging
student@biology:/stats/file009%moab:/tmp/staging
student@biology:/stats/file010%moab:/tmp/staging
```

*Moab stages in each file listed in `myStagingFile` to the `/tmp/staging` directory. Each file resides on the biology host as the student user. Moab ignores the blank line and the line specifying `file004`.*

### Stage in or out file size

The optional `--stageinsize` and `--stageoutsize` options give you the opportunity to estimate the size of the file(s) or directory(-ies) being staged to aid Moab in choosing an appropriate start time. Both options use the same format:

```
--<stageinsize|stageoutsize>=<integer>[unit]
```

The integer indicates the size of the file(s) and directory(-ies) in megabytes unless you specify a different unit. Moab accepts the follow case-insensitive suffixes: KB, MB, GB, or TB.

```
> msub --stageinfile=/stats/file003 --stageinsize=100 <jobScript>
```

*Moab copies the `/davidharris/research/recordlist` file, which is approximately 100 megabytes, from the biology node to the host where the job will run prior to job start.*

```
> msub --stageinfile=/stats/file002 --stageinsize=1gb <jobScript>
```

*Moab copies all files specified in the `/davidharris/research/recordlist` file, which add up to approximately 1 gigabyte, to the host where the job will run prior to job start.*

### Return all the job IDs in the workflow at submission time

By default, `msub` will print the job ID to stdout at the time of submission. If you want `msub` to print all of the jobs that are created as part of the workflow template, you can use the `msub --workflowjobids` option to show all the job IDs at submission time:

```
$ echo sleep 60 | msub -l walltime=15 --workflowjobids
```

```
MoabA.3.dsin MoabA.3 MoabA.3.dsout
```

### Job Script

The `msub` command supports job scripts written in any one of the following languages:

Language	Notes
<a href="#">PBS/TORQUE Job Submission Language</a>	---

Language	Notes
<a href="#">LoadLeveler Job Submission Language</a>	Use the <a href="#">INSTANTSTAGE</a> parameter as only a subset of the command file keywords are interpreted by Moab.
<a href="#">SSS XML Job Object Specification</a>	---
<b>LSF Job Submission Language</b>	enabled in Moab 4.2.4 and higher

## /etc/msubrc

Sites that wish to automatically add parameters to every job submission can populate the file `/etc/msubrc` with global parameters that every job submission will inherit.

For example, if a site wished every job to request a particular generic resource they could use the following `/etc/msubrc`:

```
-W x=GRES:matlab:2
```

## Usage Notes

`msub` is designed to be as flexible as possible, allowing users accustomed to PBS, LSF, or LoadLeveler syntax, to continue submitting jobs as they normally would. It is not recommended that different styles be mixed together in the same `msub` command.

When only one resource manager is configured inside of Moab, all jobs are immediately staged to the only resource manager available. However, when multiple resource managers are configured Moab will determine which resource manager can run the job soonest. Once this has been determined, Moab will stage the job to the resource manager.

It is possible to have Moab take a best effort approach at submission time using the `forward` flag. When this flag is specified, Moab will do a quick check and make an intelligent guess as to which resource manager can run the job soonest and then immediately stage the job.

Moab can be configured to instantly stage a job to the underlying resource manager (like TORQUE/LOADLEVELER) through the parameter [INSTANTSTAGE](#). When set inside `moab.cfg`, Moab will migrate the job instantly to an appropriate resource manager. Once migrated, Moab will destroy all knowledge of the job and refresh itself based on the information given to it from the underlying resource manager.

In most instances Moab can determine what syntax style the job belongs to (PBS or LoadLeveler); if Moab is unable to make a guess, it will default the style to whatever resource manager was configured at compile time. If LoadLeveler and PBS were both compiled then LoadLeveler takes precedence.

Moab can translate a subset of job attributes from one syntax to another. It is therefore possible to submit a PBS style job to a LoadLeveler resource manager, and vice versa, though not all job attributes will be translated.

## Examples

### Example 3-49:

```
> msub -l nodes=3:ppn=2,walltime=1:00:00,pmem=100kb script2.pbs.cmd
4364.orion
```

### Example 3-50:

This example is the XML-formatted version of the above example. See [Submitting Jobs via msub in XML](#) for more information.

```
<job>
  <InitialWorkingDirectory>/home/user/test/perlAPI
</InitialWorkingDirectory>
  <Executable>/home/user/test/perlAPI/script2.pbs.cmd
</Executable>
  <SubmitLanguage>PBS</SubmitLanguage>
  <Requested>
    <Feature>ppn2</Feature>
    <Processors>3</Processors>
    <WallclockDuration>3600</WallclockDuration>
  </Requested>
</job>
```

### Applying the msub submit filter

When you use [msub](#) to submit a job, `msub` processes the input, converts it to XML, and sends the job specification XML to the Moab scheduler. You can create a submission filter to modify the job XML based on the criteria you set before Moab receives and processes it.

Image 3-1: Job submission process

The filter gives you the ability to customize the submission process, which is helpful if jobs should have certain defaults assigned to them, if you want to keep detailed submission statistics, or if you want to change job requests based on custom needs.

The submit filter, is a simple executable or script that receives XML via its standard input and returns the modified XML in its standard output. It modifies the attributes of the job specification XML based on policies you specify. It can perform various other actions at your request, too; for instance, logging. Once the submit filter has modified the job XML based on your criteria, it writes the XML representing the actual job submission to stdout. The new XML could potentially match the original XML, depending on whether the job met the criteria for modification set in the job submit filter script. Job submissions you want to proceed will leave the filter with an exit code of 0 and continue to Moab for scheduling. If the job meets the filter's specified criteria for rejection, it exits with a non-zero value, aborting the job submission process. You can configure the filter script to write a descriptive rejection message to stderr.

Job submit filters follow these rejection rules: 1) `msub` will reject job XML with an exit code of anything other than zero, 2) the `msub` command displays filter's error output on the command line, 3) `msub` will reject the job if the filter outputs invalid job XML, and 4) `msub` will reject the job if it violates any policies in your general Moab configuration; you cannot use a submit filter to bypass other policies.

To see the schema for job submission XML, please refer to [Submitting Jobs via msub in XML](#).

## Submit filter types

You can implement submit filters on either the client or server side of a job submission. The primary differences between the two submit filter types are the location from which the filter runs, the powers and privileges of the user running the filter, and whether a user can bypass the filter. Client-based submit filters run from the `msub` client as the user who submits the job and can be bypassed, and server-based submit filters run from the Moab server as the user as which the server is running and cannot be bypassed.

### Client-based submit filter

Client-based filters run from the `msub` client as the user who is submitting the job. Because they do not have elevated privileges, the risk of client-based submit filters' being abused is low; however, it is

possible for the client to specify its own configuration file and bypass the filter or substitute its own filter. Job submissions do not even reach the server if a client-based submit filter rejects it.

To configure `msub` to use the submit filter, give each submission host access to the submit filter script and add a `SUBMITFILTER` parameter to the Moab configuration file (`moab.cfg`) on each submission host. The following example demonstrates how you might modify the `moab.cfg` file:

```
SUBMITFILTER /home/submitfilter/filter.pl
```

If you experience problems with your submit filter and want to debug its interaction with `msub`, enter `msub --loglevel=9`. This will cause `msub` to print verbose log messages to the terminal.

### Server-based submit filter

Server-based submit filters run from the Moab server as the user as which the server is running. Because it runs as a privileged user, you must evaluate the script closely for security implications. A client configuration cannot bypass the filter.

To configure Moab to automatically apply a filter to all job submissions, use the `SERVERSUBMITFILTER` on page 1041 parameter. `SERVERSUBMITFILTER` specifies the path to a global job submit filter script, which Moab will run on the head node and apply to every job submitted.

```
SERVERSUBMITFILTER /opt/moab/scripts/jobFilter.pl
```

*Moab runs `jobFilter.pl`, located in the `/opt/moab/scripts` directory, on the head node, applying the filter to all jobs submitted.*

### Sample submit filter script

The following example is a trivial implementation that will not affect whether a job is submitted. Use it as reference to verify that you are writing your filter properly.

```
#!/usr/bin/perl
use strict;

## Simple filter example that re-directs the output to a file.

my $file = "xmllog.out";

open FILE, ">>$file" or die "Couldn't open $file: $!";
while (<>)
{
    print FILE;
    print;
}
close FILE;
```

### Submitting Jobs via `msub` in XML

The following describes the XML format used with the `msub` command to submit a job to a Moab server. This information can be used to implement a filter and modify the XML normally generated by the `msub` command. The XML format described in what follows is based on a variant of the [Scalable Systems Software Job Object Specification](#).

## Overall XML Format

The overall format of an XML request to submit a job can be shown through the following example:

```
<job>
**job attribute children**
</job>
```

An example of a simple job element with all the required children for a job submission is as follows:

```
<job>
  <Owner>user</Owner>
  <UserId>user</UserId>
  <GroupId>group</GroupId>
  <InitialWorkingDirectory>/home/user/directory</InitialWorkingDirectory>
  <UMask>18</UMask>
  <Executable>/full/path/to/script/or/first/line/of/stdin</Executable>
  <SubmitLanguage>Resource Manager Type</SubmitLanguage>
  <SubmitString>\START\23!/usr/bin/ruby\0contents\20of\20script</SubmitString>
</job>
```

The section that follows entitled Job Element Format describes the possible attributes and their meanings in detail. In actuality, all that is needed to run a job in Moab is something similar to the following:

```
<job>
  <SubmitString>\START\23!/bin/sh\0asleep\201000</SubmitString>
</job>
```

*This piece of XML requests Moab to submit a job using the contents of the SubmitString tag as a script, which is in this case a simple sh script to sleep for 1000 seconds. The msub command will create default values for all other needed attributes.*

## Job Element Format

The job element of the submission request contains a list of children and string values inside the children that represent the attribute/value pairs for the job. The earlier section, Overall XML Format, gives an example of this format. This section explains these attributes in detail.

**Arguments** — The arguments to be passed to the program are normally specified as arguments after the first argument specifying the script to be executed.

**EligibleTime** — The minimum time after which the job is eligible. This is the equivalent of the `-a` option in `msub`. Format: [ [ [ [CC] YY] MM] DD] hhmm [ . SS]

**Environment** — The semi-colon list of environment variables that are exported to the job (taken from the `msub` command environment). The `-v msub` flag, for example, adds all the environment variables present at the time `msub` is invoked. Environment variables are delimited by the `~rs;` characters. Following is an example of the results of the `msub -v arg1=1, arg2=2` command:

```
<Environment>arg1=1~rs;arg2=2~rs;</Environment>
```

**ErrorFile** — Defines the path to be used for the standard error stream of the batch job. This is equivalent to the `-e` flag in `msub`.

**Executable** — This is normally either the name of the script to be executed, or the first line of the script if it is passed to `msub` through standard input.

**Extension** — The resource manager extension string. This can be specified via the command line in a number of ways, including the `-W x=` directive. Some other requests, such as some extensions used in the `-l` flag, are also converted to an extension string. The element has the following format:

```
<Extension>x=extension</Extension>
```

See [Using the Extension Element to Submit Triggers](#) for additional information on the extension element.

**GroupId** — The string name of the group of the user submitting the job. This will correspond to the user's primary group on the operating system.

**Hold** — Specifies that a user hold be applied to the job at submission time. This is the equivalent to the `msub` flag `-h`. It will have the form:

```
<Hold>User</Hold>
```

**InitialWorkingDirectory** — Specifies in which directory the job should begin executing. This is equivalent to the `-d` flag in the `msub` command.

```
<InitialWorkingDirectory>/home/user/directory</InitialWorkingDirectory>
```

**Interactive** — Specifies that the job is to be interactive. This is the equivalent of the `-I` flag in `msub`.

```
<Interactive>TRUE</Interactive>
```

**JobName** — Specifies the user-specified job name attribute. This is equivalent to the `-N` flag in `msub`.

**NotificationList** — Specifies the job states after which an email should be sent and also specifies the users to be emailed. This is the equivalent of the `-m` and `-M` options in `msub`.

```
<NotificationList URI=user1:user2>JobFail,JobStart,JobEnd</NotificationList>
```

*In this example, the command `msub -m abc -M user1:user2` ran indicating that emails should be sent when a job fails, starts, or ends, and that they should be sent to `user1` and `user2`.*

**OutputFile** — Defines the path to be used for the standard output stream of the batch job. This is the equivalent of the `-o` flag in `msub`.

**Priority** — A user-requested priority value. This is the equivalent to the `msub -p` flag.

**ProjectId** — Defines the account associated with the job. This is equivalent to the `-A` `msub` flag.

**QueueName** — The requested class of the job. This is the equivalent of the `msub -q` flag.

**Requested** — Specifies resources and attributes the job specifically requests and has the following form:

```
<Requested>
  <... requested attributes>
</Requested>
```

See the section dedicated to requestable attributes in this element.

**RMFlags** — Flags that will get passed directly to the resource manager on job submission. This is equivalent to any arguments listed after the `-l msub` flag.

```
<RMFlags>arg1 arg2 arg3</RMFlags>
```

**ShellName** — Declares the shell that interprets the job script. This is equivalent to the `msub` flag `-S`.

**SubmitLanguage** — Resource manager whose language the job is using. Use TORQUE to specify a TORQUE resource manager.

**SubmitString** — Contains the contents of the script to be run, retrieved either from an actual script or from standard input. This also includes all resource manager specific directives that may have been in the script already or added as a result of other command line arguments.

**TaskGroup** — Groups a set of requested resources together. It does so by encapsulating a Requested element. For example, the command `msub -l nodes=2+nodes=3:ppn=2` generates the following XML:

```
<TaskGroup>
  <Requested>
    <Processors>2</Processors>
    <TPN>2</TPN>
  </Requested>
</TaskGroup>
<TaskGroup>
  <Requested>
    <Processors>2</Processors>
  </Requested>
</TaskGroup>
```

**UserId** — The string value of the user ID of the job owner. This will correspond to the user's name on the operating system.

## Using the Extension Element to Submit Triggers

Use the Extension element to submit triggers. With the exception of certain characters, the syntax for [trigger creation](#) is the same for non-XML trigger submission. See [About object triggers on page 745](#) for detailed information on triggers. The ampersand (&) and less than sign (<) characters must be replaced for the XML to be valid. The following example shows how the Extension element is used to submit multiple triggers (separated by a semi-colon). Note that ampersand characters are replaced with `&amp;` in the example:

```
<Job>
  <UserId>user1</UserId>
  <GroupId>user1</GroupId>
  <Arguments>60</Arguments>
  <Executable>/bin/sleep</Executable>

  <Extension>x=trig:AType=exec&amp;Action="env"&amp;EType=start;trig:AType=exec&amp;Action="trig2.sh"&amp;EType=end</Extension>
  <Processors>3</Processors>
  <Disk>500</Disk>
  <Memory>1024</Memory>
  <Swap>600</Swap>
  <WallclockDuration>300</WallclockDuration>
  <Environment>PERL5LIB=/perl5:</Environment>
</Job>
```

## Elements Found in Requested Element

The following describes the tags that can be found in the Requested sub-element of the job element in a job submission request.

**Nodes** — A list of nodes that the job requests to be run on. This is the equivalent of the `-l hosts=<host-list> msub` directive.

```
<Requested>
  <Nodes>
    <Node>n1:n2</Node>
  </Nodes>
</Requested>
```

*In this example, the users requested the hosts n1 and n2 with the command `msub -l host=n1:n2`.*

**Processors** — The number of processors requested by the job. The following example was generated with the command `msub -l nodes=5`:

```
<Requested>
  <Processors>5</Processors>
</Requested>
```

**TPN** — Tasks per node. This is generated using the ppn resource manager extensions. For example, from `msub -l nodes=3:ppn=2`, the following results:

```
<Requested>
  <Processors>6</Processors>
  <TPN>2</TPN>
</Requested>
```

**WallclockDuration** — The requested wallclock duration of the job. This attribute is specified in the Requested element.

```
<Requested>
  <WallclockDuration>3600</WallclockDuration>
</Requested>
```

## mvctl (Moab Virtual Container Control)

### Synopsis

- `mvctl -a <OType>:<OName>[,<OType>:<OName>] <name>`
- `mvctl -c [<description>]`
- `mvctl -d <name>`
- `mvctl -m <ATTR>=VAL[,<ATTR>=VAL] <name>`

- `mvctl -q` [*<name>*|ALL] [--xml][--blocking][--flags=fullxml]
- `mvctl -r` *<OType>*:*<OName>*[,*<OType>*:*<OName>*] *<name>*
- `mvctl -x` *<action>**<name>*

## Overview

A virtual container (VC) is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, jobs, reservations, and nodes. Containers can also be nested inside other containers.

A VC can be owned by a user, group, or account. Users can only view VCs to which they have access. Level 1 administrators (Admin1) can view and modify all VCs. The owner can also be changed. When modifying the owner, you must also specify the owner type:

```
mvctl -m OWNER=acct:bob myvc
```

Adding objects to VCs at submission: You associate jobs, VMs, and reservations with a specified VC upon submission. For example,

- `mrsvctl -c ... -H <VC>`
- `msub ... -W x="vc=<VC>"`
- `mvmctl -c ...,vc=<VC>`

The user who submits objects must have access to the VC or the command is rejected.

## FullXML flag

The FullXML flag will cause the `mvctl -q` command to show VCs in a hierarchical manner. If doing a non-XML (plaintext) query, sub-VCs will be listed inside their parent VCs. Each VC will be indented more than its parent.

```
VC[vc2] (vc2)
  Owner: user:jason
  VCs:
  VC[vc1] (vc1)
    Owner: user:jason
    Jobs: Moab.1
    Rsvs: system.1
    VCs:
    VC[vc3] (vc3)
      Owner: user:jason
  VC[vc4] (vc4)
    Owner: user:jason
```

If doing an XML query, the XML for all sub-objects (VCs, but also reservations, jobs, etc.) will also be included in the VC.

```

<Data>
  <vc DESCRIPTION="vc2" NAME="vc2" OWNER="user:jason">
    <vc DESCRIPTION="vc1" NAME="vc1" OWNER="user:jason">
      <job CmdFile="sleep 7200" Flags="GLOBALQUEUE,NORMSTART"
        Group="jason" JobID="Moab.1" PAL="[base]" RM="internal"
        ReqAWDDuration="2:00:00" User="jason">
        <req Index="0"></req>
      </job>
      <rsv ACL="RSV=%=system.1=;" AUser="jason"
        AllocNodeList="n0,n1,n2,n3,n4,n5,n6,n7,n8,n9" HostExp="ALL"
        HostExpIsSpecified="TRUE" Name="system.1" Partition="base"
        ReqNodeList="n0:1,n1:1,n2:1,n3:1,n4:1,n5:1,n6:1,n7:1,n8:1,n9:1"
        Resources="PROCS=[ALL]" StatCIPS="5964.00" SubType="Other"
        Type="User" ctime="1299953557" duration="3600"
        endtime="1299957157"
        flags="ISCLOSED,ISGLOBAL,ISACTIVE,REQFULL"
        starttime="1299953557">
        <ACL aff="neutral" cmp="%" name="system.1" type="RSV">

        </History>
      </rsv>
    </vc DESCRIPTION="vc3" NAME="vc3" OWNER="user:jason"></vc>
  </vc>
  <vc DESCRIPTION="vc4" NAME="vc4" OWNER="user:jason"></vc>
</vc>
</Data>

```

*Note that the XML from the blocking and non-blocking commands may differ.*

## Virtual Container Flags

The following table indicates available virtual container (VC) flags and associated descriptions. Note that the `Deleting`, `HasStarted`, and `Workflow` flags cannot be set by a user but are helpful indicators of status.

VC Flags	
<b>DestroyObjects</b>	When the VC is destroyed, any reservations, jobs, and VMs in the VC are also destroyed. This is recursive, so any objects in sub-VCs are also destroyed. Nodes are not removed.
<b>DestroyWhenEmpty</b>	When the VC is empty, it is destroyed.
<b>Deleting</b>	Set by the scheduler when the VC has been instructed to be removed.

 Internal flag. Administrators cannot set or clear this flag.

VC Flags	
<b>HasStarted</b>	<p>This flag is set on a VC workflow where at least one job has started.</p> <div style="border: 1px solid #004a87; border-radius: 5px; padding: 5px; background-color: #e6f2ff;"> <span style="font-size: 1.2em; font-weight: bold; color: #004a87;">i</span> Internal flag. Administrators cannot set or clear this flag.                 </div>
<b>HoldJobs</b>	<p>This flag will place a hold on any job that is submitted to the VC while this flag is set. It is not applied for already existing jobs that are added into the VC. If a job with a workflow is submitted to the VC, all jobs within the workflow are placed on hold.</p>
<b>NoReleaseWhenScheduled</b>	<p>Prevents Moab from lifting the UserHold on the workflow when it is scheduled. This enables an approval method in which an administrator must release the hold manually before the service is allowed to start as scheduled.</p>
<b>Workflow</b>	<p>Designates this VC as a VC that is for workflows. This flag is set when generated by a job template workflow. Workflow jobs can only be attached to one workflow VC.</p> <div style="border: 1px solid #004a87; border-radius: 5px; padding: 5px; background-color: #e6f2ff;"> <span style="font-size: 1.2em; font-weight: bold; color: #004a87;">i</span> Internal flag. Administrators cannot set or clear this flag.                 </div>

## Format

-a	
<b>Format</b>	<pre>mvctl -a&lt;OType&gt;:&lt;OName&gt;[,&lt;OType&gt;:&lt;OName&gt;] &lt;name&gt;</pre> <p>Where &lt;OType&gt; is one of JOB, RSV, NODE, VC, or VM.</p>
<b>Description</b>	Add the given object(s).
<b>Example</b>	<pre>mvctl -a JOB:Moab.45 vc13 &gt;&gt;job 'Moab.45' added to VC 'vc13'</pre>

-c	
<b>Format</b>	<pre>mvctl -c [&lt;description&gt;]</pre>
<b>Description</b>	Create a virtual container (VC). The VC name is auto-generated. It is recommended that you supply a description; otherwise the description is the same as the auto-generated name.
<b>Example</b>	<pre>mvctl -c "Linux testing machine" &gt;&gt;VC 'vc13' created</pre>

-d	
<b>Format</b>	<code>mvccctl -d&lt;lab01&gt;</code>
<b>Description</b>	Destroy the VC.
<b>Example</b>	<pre>mvccctl -d vc13 &gt;&gt;VC 'vc13' destroyed</pre>

-m	
<b>Format</b>	<code>mvccctl -m&lt;ATTR&gt;=VAL[,&lt;ATTR&gt;=&lt;VAL&gt;] &lt;name&gt;</code>
<b>Description</b>	Modify the VC. Attributes are flags, owner, reqstarttime, reqnodeset, variables, and owner; note that only the owner can modify owner. Use reqstarttime when implementing guaranteed start time to specify when jobs should start. The reqnodeset attribute indicates the node set that jobs should run in that are submitted to a virtual container.
<b>Example</b>	<pre>mvccctl -m variables+=HV=node8 vc13 &gt;&gt;VC 'vc13' successfully modified  mvccctl -m flags+=DESTROYWHENEMPTY vc1 &gt;&gt;VC 'vc1' successfully modified</pre>

-q	
<b>Format</b>	<code>mvccctl -q [&lt;name&gt; ALL] [--xml][--blocking][--flags=fullxml]</code>
<b>Description</b>	Query VCs
<b>Example</b>	<pre>mvccctl -q ALL VC[vc13] (Linux testing machine) Create Time: 1311027343   Creator: jdoe Owner: user:jdoe ACL:  USER=%=jdoe+; Jobs: Moab.45 Vars: HV=node88 Flags: DESTROYWHENEMPTY</pre>

-r	
<b>Format</b>	<code>mvccctl -r&lt;OType&gt;:&lt;OName&gt;[,&lt;OType&gt;:&lt;OName&gt;] &lt;name&gt;</code> Where <OType> is one of JOB, RSV, NODE, VC, or VM.
<b>Description</b>	Remove the given object(s) from the VC.
<b>Example</b>	<pre>mvccctl -r JOB:Moab.45 vc13 &gt;&gt;job 'Moab.45' removed from VC 'vc13'</pre>

-x	
<b>Format</b>	<code>mvccctl -x&lt;action&gt;&lt;name&gt;</code>
<b>Description</b>	Executes the given action on the virtual container (VC).
<b>Example</b>	<pre>mvccctl -x schedulevc vc1</pre>

## mvmctl

### Synopsis

[mvmctl -d](#) [--flags=force] <vmid>

[mvmctl -f](#) <migrationPolicy> [--flags=eval [--xml]]

[mvmctl -m](#) [<options>] <vmid>

[mvmctl -M](#) dsthost=<newhost><vmid>

[mvmctl -q](#) <vmid> [--blocking] [--xml]

[mvmctl -w](#) state=drained

### Overview

mvmctl controls the modification, querying, migration, and destruction of virtual machines (VMs).

## Format

-d	
<b>Name</b>	Destroy
<b>Format</b>	<code>mvmctl -d [--flags=force] &lt;vmid&gt;</code>
<b>Description</b>	Destroys the specified VM. When you add the force flag, Moab forces the deletion of the VM if and only if it does not have a VM-tracking job.
<b>Example</b>	<pre>&gt; mvmctl -d oldVM</pre> <pre>&gt; mvmctl -d --flags=force oldVM</pre> <p><i>Because oldVM does not have a VM-tracking job associated with it and you set the force flag, Moab forces the deletion of oldVM.</i></p>

-f	
<b>Name</b>	Force Migrate
<b>Format</b>	<code>mvmctl -f consolidation overcommit [--flags=eval [--xml]]</code>
<b>Description</b>	Forces the migration policy on the system. The <code>eval</code> flag causes Moab to run through migration routines and report the results without actually migrating the VMs.
<b>Example</b>	<pre>&gt; mvmctl -f consolidation --flags=eval</pre> <p>Moab returns a report like the following:</p> <pre>1: VM 'vm1' from 'h0' to 'h3' 2: VM 'vm2' from 'h0' to 'h5'</pre>

-m	
<b>Name</b>	Modify
<b>Format</b>	<p><code>[&lt;options&gt;] &lt;vmid&gt;</code></p> <p>The <code>&lt;options&gt;</code> variable is a comma-separated list of <code>&lt;attr&gt;=&lt;value&gt;</code> pairs.</p>

-m	
<b>Description</b>	Modifies the VM.
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m gevent=hitemp:'mymessage' myNewVM</pre> <p><i>Gevents can be set using gevent.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m gmetric=bob:5.6 myNewVM</pre> <p><i>Gmetrics can be set using gmetric.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m os=compute myNewVM</pre> <p><i>Reprovisioning is done by changing os.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m powerstate=off myNewVM</pre> <p><i>Power management is done by modifying powerstate.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m variable=user:bob+purpose:myVM myNewVM</pre> <p><i>The modify variable uses the same syntax as Create.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>&gt; mvmctl -m flags=cannotmigrate myNewVM</pre> <p><i>Allow a VM to migrate by setting the canmigrate flag.</i></p> </div> <div style="border: 1px dashed gray; padding: 5px;"> <pre>&gt; mvmctl -m flags=canmigrate myNewVM</pre> <p><i>Allows a VM to migrate by setting the canmigrate flag.</i></p> </div>
<b>Notes</b>	<ul style="list-style-type: none"> <li>The variable option is a set-only operation. Previous variables will be overwritten.</li> </ul>

-M	
<b>Name</b>	Migrate
<b>Format</b>	dsthost=<newhost><vmid>

-M	
<b>Description</b>	<p>Migrate the given VM to the destination host.</p> <p>When you set the <i>vmid</i> to ANY, Moab migrates the VM to any available eligible hypervisor. For this to work, the following conditions must be met:</p> <ul style="list-style-type: none"> <li>• The VM reports a <b>CPULOAD</b>, and it is greater than 0.</li> <li>• The VM's <b>AMEMORY</b> is less than its <b>CMEMORY</b>. This indicates that some memory is currently in use and tells Moab that the RM is reporting memory correctly.</li> <li>• The VM's state is not "Unknown."</li> <li>• All hypervisors report a <b>CPULOAD</b>, and it is greater than 0.</li> <li>• All hypervisors report an <b>AMEMORY</b>, and it is less than its <b>CMEMORY</b>.</li> <li>• All hypervisors report a hypervisor type.</li> </ul>
<b>Example</b>	<pre>&gt; mvmctl -M dsthost=node05 myNewVM</pre> <p><i>myNewVM migrates to node05.</i></p> <pre>&gt; mvmctl -M dsthost=ANY vm42</pre> <p><i>Moab migrates vm42 to a node based on policy destination limitations (such as the <a href="#">NoVMMigrations</a> flag).</i></p>

-q	
<b>Name</b>	Query
<b>Format</b>	<vmid> [--blocking] [--xml]
<b>Description</b>	<p>Queries the specified VM; that is, it returns detailed information about the given VM. May be used with or without the <code>--xml</code> flag. ALL may also be used to display information about all VMs. This option gathers information from the Moab cache which prevents it from waiting for the scheduler, but the <code>--blocking</code> option can be used to bypass the cache and allow waiting for the scheduler.</p>
<b>Example</b>	<pre>&gt; mvmctl -q myNewVM</pre> <pre>&gt; mvmctl -q ALL --blocking</pre> <pre>&gt; mvmctl -q ALL --xml</pre>

-w	
<b>Name</b>	Constraint
<b>Format</b>	state=drained
<b>Description</b>	Overrides the HIDE DRAINED <a href="#">DISPLAYFLAGS</a> attribute allowing display of VMs in a <a href="#">DRAINED</a> state.
<b>Example</b>	<pre>&gt; mvmctl -q -w state=drained</pre>

## showbf

### Synopsis

`showbf [-A] [-a account] [-c class] [-d duration] [-D] [-f features] [-g group] [-L] [-m [=|>|>=|<|<=] memory] [-n nodecount] [-p partition] [-q qos] [-u user] [-v] [--blocking]`

### Overview

Shows what resources are available for immediate use.

**i** The results Moab returns do not include resources that may be freed due to preemption.

This command can be used by any user to find out how many processors are available for immediate use on the system. It is anticipated that users will use this information to submit jobs that meet these criteria and thus obtain quick job turnaround times. This command incorporates down time, reservations, and node state information in determining the available backfill window.

**i** If specific information is not specified, `showbf` will return information for the user and group running but with global access for other credentials. For example, if `-q qos` is not specified, Moab will return resource availability information for a job as if it were entitled to access all QOS based resources (i.e., resources covered by reservations with a QOS based ACL), if `-c class` is not specified, the command will return information for resources accessible by any class.

**i** The `showbf` command incorporates node configuration, node utilization, node state, and node reservation information into the results it reports. This command does not incorporate constraints imposed by credential based fairness policies on the results it reports.

### Access

By default, this command can be used by any user or administrator.

## Parameters

Parameter	Description
<b>ACCOUNT</b>	Account name.
<b>CLASS</b>	Class/queue required.
<b>DURATION</b>	Time duration specified as the number of seconds or in [DD:]HH:MM:SS notation.
<b>FEATURELIST</b>	Colon separated list of node features required.
<b>GROUP</b>	Specify particular group.
<b>MEMCMP</b>	Memory comparison used with the <code>-m</code> flag. Valid signs are <code>&gt;</code> , <code>&gt;=</code> , <code>==</code> , <code>&lt;=</code> , and <code>&lt;</code> .
<b>MEMORY</b>	Specifies the amount of required real memory configured on the node, (in MB), used with the <code>-m</code> flag.
<b>NODECOUNT</b>	Specify number of nodes for inquiry with <code>-n</code> flag.
<b>PARTITION</b>	Specify partition to check with <code>-p</code> flag.
<b>QOS</b>	Specify QOS to check with <code>-q</code> flag.
<b>USER</b>	Specify particular user to check with <code>-u</code> flag.

## Flags

Flag	Description
<b>-A</b>	Show resource availability information for all users, groups, and accounts. By default, <code>showbf</code> uses the default user, group, and account ID of the user issuing the command.
<b>-a</b>	Show resource availability information only for specified account.
<b>--blocking</b>	Do not use cache information in the output. The <code>--blocking</code> flag retrieves results exclusively from the scheduler.
<b>-d</b>	Show resource availability information for specified duration.

Flag	Description
<b>-D</b>	Display current and future resource availability notation.
<b>-g</b>	Show resource availability information only for specified group.
<b>-h</b>	Help for this command.
<b>-L</b>	Enforce Hard limits when showing available resources.
<b>-m</b>	Allows user to specify the memory requirements for the backfill nodes of interest. It is important to note that if the optional MEMCMP and MEMORY parameters are used, they must be enclosed in single ticks (') to avoid interpretation by the shell. For example, enter <code>showbf -m '==256'</code> to request nodes with 256 MB memory.
<b>-n</b>	Show resource availability information for a specified number of nodes. That is, this flag can be used to force <code>showbf</code> to display only blocks of resources with at least this many nodes available.
<b>-p</b>	Show resource availability information for the specified partition.
<b>-q</b>	Show information for the specified QOS.
<b>-r</b>	Show resource availability for the specified processor count.
<b>-u</b>	Show resource availability information only for specified user.

## Examples

### Example 3-51:

In this example, a job requiring up to 2 processors could be submitted for immediate execution in partition `ClusterA` for any duration. Additionally, a job requiring 1 processor could be submitted for immediate execution in partition `ClusterB`. Note that by default, each task is tracked and reported as a request for a single processor.

```
> showbf
Partition      Tasks  Nodes  StartOffset  Duration  StartDate
-----
ALL            3      3      00:00:00     INFINITY  11:32:38_08/19
ReqID=0
ClusterA      1      1      00:00:00     INFINITY  11:32:38_08/19
ReqID=0
ClusterB      2      2      00:00:00     INFINITY  11:32:38_08/19
ReqID=0
```

 StartOffset is the amount of time remaining before resources will be available.

**Example 3-52:**

In this example, the output verifies that a backfill window exists for jobs requiring a 3 hour runtime and at least 16 processors. Specifying job duration is of value when time based access is assigned to reservations (i.e., using the **SRCFG TIMELIMIT ACL**)

```
> showbf -r 16 -d 3:00:00
Partition    Tasks    Nodes    Duration    StartOffset    StartDate
-----
ALL          20       20       INFINITY    00:00:00       09:22:25_07/19
```

**Example 3-53:**

In this example, a resource availability window is requested for processors located only on nodes with at least 512 MB of memory.

```
> showbf -m '=512'
Partition    Tasks    Nodes    Duration    StartOffset    StartDate
-----
ALL          20       20       INFINITY    00:00:00       09:23:23_07/19
ClusterA     10       10       INFINITY    00:00:00       09:23:23_07/19
ClusterB     10       10       INFINITY    00:00:00       09:23:23_07/19
```

## showq

### Synopsis

```
showq [-b] [-g] [-l] [-c|-i|-r] [-n] [-o] [-p partition] [-R rsvid] [-u] [-v] [-w <CONSTRAINT>] [--blocking] [--noblock]
```

### Overview

Displays information about active, eligible, blocked, and/or recently completed jobs. Since the resource manager is not actually scheduling jobs, the job ordering it displays is not valid. The `showq` command displays the actual job ordering under the Moab Workload Manager. When used without flags, this command displays all jobs in active, idle, and non-queued states.

### Access

By default, this command can be run by any user. However, the `-c`, `-i`, and `-r` flags can only be used by level 1, 2, or 3 Moab administrators.

## Flags

Flag	Description
<b>-b</b>	Display blocked jobs only
<b>-c</b>	Display details about recently <a href="#">completed</a> jobs (see <a href="#">example</a> , <a href="#">JOBPURGETIME</a> ).
<b>-g</b>	Display grid job and system IDs for all jobs.
<b>-i</b>	Display extended details about idle jobs. (see <a href="#">example</a> )
<b>-l</b>	Display local/remote view. For use in a <a href="#">Grid</a> environment, displays job usage of both local and remote compute resources.
<b>-n</b>	Displays normal showq output, but lists job names under JOBID
<b>-o</b>	Displays jobs in the active queue in the order specified (uses format <code>showq -o &lt;specifiedOrder&gt;</code> ). Valid options include REMAINING, REVERSEORDER, JOB, USER, STATE, and STARTTIME. The default is REMAINING.
<b>-p</b>	Display only jobs assigned to the specified partition.
<b>-r</b>	Display extended details about active (running) jobs. (see <a href="#">example</a> )
<b>-R</b>	Display only jobs which overlap the specified reservation.
<b>-u</b>	Display all running jobs for a particular user.
<b>-v</b>	Display local and full resource manager job IDs as well as partitions. If specified with the <code>-i</code> option, will display job reservation time. The <code>-v</code> option displays all array subjobs. All <code>showq</code> commands without the <code>-v</code> option show just the master jobs in an array.
<b>-w</b>	Display only jobs associated with the specified constraint. Valid constraints include user, group, acct, class, and qos (see <a href="#">showq -w</a> example.).
<b>--blocking</b>	Do not use cache information in the output. The <code>--blocking</code> flag retrieves results exclusively from the scheduler.
<b>--noblock</b>	Use cache information for a faster response.

## Details

Beyond job information, the `showq` command will also report if the scheduler is stopped or paused or if a system reservation is in place. Further, the `showq` command will also report public system messages.

## Examples

- [Default Report on page 323](#)
  - [Detailed Active/Running Job Report on page 326](#)
  - [Eligible Jobs on page 325](#)
  - [Detailed Completed Job Report on page 329](#)
- [Filtered Job Report on page 330](#)

*Example 3-54: Default Report*

The output of this command is divided into three parts, [Active](#) Jobs, [Eligible](#) Jobs, and [Blocked](#) Jobs.

```

> showq

14 eligible jobs

blocked jobs-----
JOBID      USERNAME      STATE  PROCS    WCLIMIT          QUEUE TIME

0 blocked jobs

Total jobs: 18

```

The fields are as follows:

Column	Description
<b>JOBID</b>	Job identifier.
<b>USERNAME</b>	<a href="#">User</a> owning job.
<b>STATE</b>	<a href="#">Job State</a> . Current batch state of the job.
<b>PROCS</b>	Number of processors being used by the job.

Column	Description
<b>REMAINING/WCLIMIT</b>	For active jobs, the time the job has until it has reached its wallclock limit or for idle/blocked jobs, the amount of time requested by the job. Time specified in [DD:]HH:MM:SS notation.
<b>STARTTIME</b>	Time job started running.

### Active Jobs

Active jobs are those that are [Running](#) or [Starting](#) and consuming resources. Displayed are the job id\*, the job's owner, and the job state. Also displayed are the number of processors allocated to the job, the amount of time remaining until the job completes (given in HH:MM:SS notation), and the time the job started. All active jobs are sorted in "Earliest Completion Time First" order.

**i** \*Job IDs may be marked with a single character to specify the following conditions:

Character	Description
<b>_ (underbar)</b>	job violates usage limit
<b>* (asterisk)</b>	job is backfilled AND is preemptible
<b>+ (plus)</b>	job is backfilled AND is NOT preemptible
<b>- (hyphen)</b>	job is NOT backfilled AND is preemptible

**i** Detailed active job information can be obtained using the `-r` flag.

### Eligible Jobs

Eligible Jobs are those that are queued and eligible to be scheduled. They are all in the Idle job state and do not violate any fairness policies or have any job holds in place. The jobs in the Idle section display the same information as the Active Jobs section except that the wallclock CPULIMIT is specified rather than job time REMAINING, and job QUEUE TIME is displayed rather than job STARTTIME. The jobs in this section are ordered by job priority. Jobs in this queue are considered eligible for both scheduling and backfilling.

**i** Detailed eligible job information can be obtained using the `-i` flag.

### Blocked Jobs

Blocked jobs are those that are ineligible to be run or queued. Jobs listed here could be in a number of states for the following reasons:

State	Description
<b>Idle</b>	Job violates a fairness policy. Use <code>diagnose -q</code> for more information.
<b>UserHold</b>	A user hold is in place.
<b>SystemHold</b>	An administrative or system hold is in place.
<b>BatchHold</b>	A scheduler batch hold is in place (used when the job cannot be run because the requested resources are not available in the system or because the resource manager has repeatedly failed in attempts to start the job).
<b>Deferred</b>	A scheduler defer hold is in place (a temporary hold used when a job has been unable to start after a specified number of attempts. This hold is automatically removed after a short period of time).
<b>NotQueued</b>	Job is in the resource manager state NQ (indicating the job's controlling scheduling daemon is unavailable).

A summary of the job queue's status is provided at the end of the output.

*Example 3-55: Detailed Active/Running Job Report*

Total jobs: 4
    
```

The fields are as follows:

Column	Description
<b>JOBID</b>	Name of active job.

Column	Description
<b>S</b>	<a href="#">Job State</a> . Either R for Running or S for Starting.
<b>PAR</b>	Partition in which job is running.
<b>EFFIC</b>	CPU efficiency of job.
<b>XFACTOR</b>	Current expansion factor of job, where $XFactor = (QueueTime + WallClockLimit) / WallClockLimit$
<b>Q</b>	Quality Of Service specified for job.
<b>USERNAME</b>	User owning job.
<b>GROUP</b>	Primary group of job owner.
<b>MHOST</b>	Master Host running primary task of job.
<b>PROCS</b>	Number of processors being used by the job.
<b>REMAINING</b>	Time the job has until it has reached its wallclock limit. Time specified in HH:MM:SS notation.
<b>STARTTIME</b>	Time job started running.

After displaying the running jobs, a summary is provided indicating the number of jobs, the number of allocated processors, and the system utilization.

Column	Description
<b>JobName</b>	Name of active job.
<b>S</b>	Job State. Either R for Running or S for Starting.
<b>CCode</b>	Completion Code. The return/completion code given when a job completes. (Only applicable to completed jobs.)
<b>Par</b>	Partition in which job is running.
<b>Effic</b>	CPU efficiency of job.
<b>XFactor</b>	Current expansion factor of job, where $XFactor = (QueueTime + WallClockLimit) / WallClockLimit$

Column	Description
<b>Q</b>	Quality Of Service specified for job.
<b>User</b>	User owning job.
<b>Group</b>	Primary group of job owner.
<b>Nodes</b>	Number of processors being used by the job.
<b>Remaining</b>	Time the job has until it has reached its wallclock limit. Time specified in HH:MM:SS notation.
<b>StartTime</b>	Time job started running.

14 eligible jobs
Total jobs: 14
    
```

The fields are as follows:

Column	Description
<b>JOBID</b>	Name of job.
<b>PRIORITY</b>	Calculated job priority.
<b>XFACTOR</b>	Current expansion factor of job, where XFactor = (QueueTime + WallClockLimit) / WallClockLimit
<b>Q</b>	Quality Of Service specified for job.
<b>USER</b>	<a href="#">User</a> owning job.
<b>GROUP</b>	Primary <a href="#">group</a> of job owner.
<b>PROCS</b>	Minimum number of processors required to run job.
<b>WCLIMIT</b>	Wallclock limit specified for job. Time specified in HH:MM:SS notation.
<b>CLASS</b>	<a href="#">Class</a> requested by job.
<b>SYSTEMQUEUE TIME</b>	Time job was admitted into the system queue.

**i** An asterisk at the end of a job (job 12956\* in this example) indicates that the job has a [job reservation](#) created for it. The details of this reservation can be displayed using the [checkjob](#) command.

**Example 3-56: Detailed Completed Job Report**

```

> showq -c
completed jobs-----
JOBID      PROC      WALLTIME  SCCODE  PAR  EFFIC  XFACTOR  Q  USERNAME  GROUP  MHOST
13098     25      2:43:31  Thu Sep 1 15:02:50  C    0  bas  93.17    1.0  -   sartois  Arches  G5-014

3 completed jobs
    
```

The fields are as follows:

Column	Description
<b>JOBID</b>	job id for completed job.
<b>S</b>	<a href="#">Job State</a> . Either C for <a href="#">Completed</a> or V for <a href="#">Vacated</a> .
<b>CCODE</b>	Completion code reported by the job.
<b>PAR</b>	Partition in which job ran.
<b>EFFIC</b>	CPU efficiency of job.
<b>XFACTOR</b>	Expansion factor of job, where $XFactor = (QueueTime + WallClockLimit) / WallClockLimit$
<b>Q</b>	<a href="#">Quality of Service</a> specified for job.
<b>USERNAME</b>	<a href="#">User</a> owning job.
<b>GROUP</b>	Primary <a href="#">group</a> of job owner.
<b>MHOST</b>	Master Host which ran the primary task of job.
<b>PROCS</b>	Number of processors being used by the job.
<b>WALLTIME</b>	Wallclock time used by the job. Time specified in [DD:]HH:MM:SS notation.
<b>STARTTIME</b>	Time job started running.

After displaying the active jobs, a summary is provided indicating the number of jobs, the number of allocated processors, and the system utilization.

**i** If the [DISPLAYFLAGS](#) parameter is set to *ACCOUNTCENTRIC*, job group information will be replaced with job account information.

#### Example 3-57: Filtered Job Report

Show only jobs associated with user john and class benchmark.

```
> showq -w class=benchmark -w user=john
...
```

## Job Array

Job arrays show the name of the job array and then in parenthesis, the number of sub-jobs in the job array that are in the specified state.

```
> showq

active jobs-----
JOBID            USERNAME        STATE  PROCS   REMAINING        STARTTIME
Moab.1(14)       aesplin         Running  14     00:59:41  Fri May 27 14:58:57

## showhist.moab.pl

### Synopsis

```
showhist.moab.pl [-a accountname]
                 [-c classname] [-e enddate]
                 [-g groupname] [-j jobid] [-n days]
                 [-q qosname] [-s startdate]
                 [-u username]
```

## Overview

The `showhist.moab.pl` script displays historical job information. Its purpose is similar to the [checkjob](#) command's, but `showhist.moab.pl` displays information about jobs that have already completed.

## Access

By default, this script's use is limited to administrators on the head node; however, end users can also be given power to run the script. To grant access to the script to end users, move `showhist.moab.pl` from the `tools` directory to the `bin` directory.

## Arguments

<b>-a (Account)</b>	
<b>Format</b>	<ACCOUNTNAME>
<b>Description</b>	Displays job records matching the specified account.
<b>Example</b>	<pre>&gt; showhist.moab.pl -a myAccount</pre> <p><i>Information about jobs related to the account myAccount is displayed.</i></p>

<b>-c (Class)</b>	
<b>Format</b>	<CLASSNAME>
<b>Description</b>	Displays job records matching the specified class (queue).
<b>Example</b>	<pre>&gt; showhist.moab.pl -c newClass</pre> <p><i>Information about jobs related to the class newClass is displayed.</i></p>

<b>-e (End Date)</b>	
<b>Format</b>	YYYY-MM-DD
<b>Description</b>	Displays the records of jobs recorded before or on the specified date.

-e (End Date)	
<b>Example</b>	<pre>&gt; showhist.moab.pl -e 2001-01-03</pre> <p><i>Information about all jobs recorded on or before January 3, 2001 is displayed.</i></p> <pre>&gt; showhist.moab.pl -s 2011-01-01 -e 2011-01-31</pre> <p><i>Information is displayed about all jobs recorded in January 2011.</i></p>

-g (Group)	
<b>Format</b>	<GROUPNAME>
<b>Description</b>	Displays job records matching the specified group.
<b>Example</b>	<pre>&gt; showhist.moab.pl -g admins</pre> <p><i>Information about jobs related to the group admins is displayed.</i></p>

-j (Job ID)	
<b>Format</b>	<JOBID>
<b>Description</b>	Displays job records matching the specified job id.
<b>Example</b>	<pre>&gt; showhist.moab.pl -j moab01</pre> <p><i>Information about job moab01 is displayed.</i></p>

-n (Number of Days)	
<b>Format</b>	<INTEGER>

-n (Number of Days)	
<b>Description</b>	Restricts the number of past jobs to search by a specified number of days relative to today.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; showhist.moab.pl -n 90 -j moab924</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Displays job information for job moab924. The search is restricted to the last 90 days.</i></p>

-q (QoS)	
<b>Format</b>	<QOSNAME>
<b>Description</b>	Displays job records matching the specified quality of service.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; showhist.moab.pl -q myQoS</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Information about jobs related to the QoS myQoS is displayed.</i></p>

-s (Start Date)	
<b>Format</b>	YYYY-MM-DD
<b>Description</b>	Displays the records of jobs that recorded on the specified date and later.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; showhist.moab.pl -s 1776-07-04</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Information about all jobs recorded on July 4, 1776 and later is displayed.</i></p> <pre style="border: 1px dashed gray; padding: 5px; margin-top: 10px;">&gt; showhist.moab.pl -s 2001-07-05 -e 2002-07-05</pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 5px;"><i>Information is displayed about all jobs recorded between July 5, 2001 and July 5, 2002.</i></p>

<b>-u (User)</b>	
<b>Format</b>	<USERNAME>
<b>Description</b>	Displays job records matching the specified user.
<b>Example</b>	<pre>&gt; showhist.moab.pl -u bob</pre> <p><i>Information about user bob's jobs is displayed.</i></p>

### Sample Output

```
> showhist.moab.pl
Job Id           : Moab.4
User Name        : user1
Group Name       : company
Queue Name       : NONE
Processor Count  : 4
Wallclock Duration: 00:00:00
Submit Time      : Mon Nov 21 10:48:32 2011
Start Time       : Mon Nov 21 10:49:37 2011
End Time         : Mon Nov 21 10:49:37 2011
Exit Code        : 0
Allocated Nodelist: 10.10.10.3

Job Id           : Moab.1
Executable       : 4
User Name        : user1
Group Name       : company
Account Name     : 1321897709
Queue Name       : NONE
Quality Of Service: 0M
Processor Count  : -0
Wallclock Duration: 00:01:05
Submit Time      : Mon Nov 21 10:48:29 2011
Start Time       : Mon Nov 21 10:48:32 2011
End Time         : Mon Nov 21 10:49:37 2011
Exit Code        : 0
Allocated Nodelist: 512M
```

Information is displayed for all completed jobs.

When a job's Start Time and End Time are the same, the job is infinite and still running.

## showres

### Synopsis

```
showres [-f] [-n [-g]] [-o] [-r] [reservationid]
```

### Overview

This command displays all reservations currently in place within Moab. The default behavior is to display reservations on a reservation-by-reservation basis.

### Access

By default, this command can be run by any Moab administrator.

Flag	Description
<b>-f</b>	Show free (unreserved) resources rather than reserved resources. The <code>-f</code> flag cannot be used in conjunction with the any other flag
<b>-g</b>	When used with the <code>-n</code> flag, shows <code>grep</code> -able output with nodename on every line
<b>-n</b>	Display information regarding all nodes reserved by <code>&lt;RSVID&gt;</code>
<b>-o</b>	Display all reservations which overlap <code>&lt;RSVID&gt;</code> (in time and space) <div style="border: 1px solid #ccc; border-radius: 5px; padding: 5px; margin-top: 5px;">  Not supported with <code>-n</code> flag         </div>
<b>-r</b>	Display reservation timeframes in relative time mode
<b>-v</b>	Show verbose output. If used with the <code>-n</code> flag, the command will display all reservations found on nodes contained in <code>&lt;RSVID&gt;</code> . Otherwise, it will show long reservation start dates including the reservation year.

Parameter	Description
<b>RSVID</b>	ID of reservation of interest — optional

## Examples

Example 3-58:

```

> showres

15:02:50
12946              Job R      -00:05:01  1:05:54:59  1:06:00:00  1/2      Thu Sep 1
15:02:50
12954              Job R      -00:04:59  2:55:01  3:00:00  2/4      Thu Sep 1
15:02:52
12956              Job I      1:05:54:59  1:12:34:59  6:40:00  16/32    Fri Sep 2
21:02:50
12969              Job I      6:34:59    13:14:59  6:40:00  4/4      Thu Sep 1
21:42:50

6 reservations located
    
```

*The above example shows all reservations on the system.*

The fields are as follows:

Column	Description
<b>Type</b>	Reservation Type. This will be one of the following: Job or User.
<b>ReservationID</b>	This is the name of the reservation. Job reservation names are identical to the job name. User, Group, or Account reservations are the user, group, or account name followed by a number. System reservations are given the name SYSTEM followed by a number.
<b>S</b>	State. This field is valid only for job reservations. It indicates whether the job is (S)tarting, (R)unning, or (I)dle.
<b>Start</b>	Relative start time of the reservation. Time is displayed in HH:MM:SS notation and is relative to the present time.
<b>End</b>	Relative end time of the reservation. Time is displayed in HH:MM:SS notation and is relative to the present time. Reservations that will not complete in 1,000 hours are marked with the keyword INFINITY.
<b>Duration</b>	Duration of the reservation in HH:MM:SS notation. Reservations lasting more than 1,000 hours are marked with the keyword INFINITY.
<b>Nodes</b>	Number of nodes involved in reservation.

Column	Description
<b>StartTime</b>	Time Reservation became active.

*Example 3-59:*

52 nodes reserved							

*This example shows reservations for nodes.*

The fields are as follows:

Column	Description
<b>NodeName</b>	Node on which reservation is placed.

Column	Description
<b>Type</b>	Reservation Type. This will be one of the following: Job or User.
<b>ReservationID</b>	This is the name of the reservation. Job reservation names are identical to the job name. User, Group, or Account reservations are the user, group, or account name followed by a number. System reservations are given the name SYSTEM followed by a number.
<b>JobState</b>	This field is valid only for job reservations. It indicates the state of the job associated with the reservation.
<b>Start</b>	Relative start time of the reservation. Time is displayed in HH:MM:SS notation and is relative to the present time.
<b>Duration</b>	Duration of the reservation in HH:MM:SS notation. Reservations lasting more than 1000 hours are marked with the keyword INFINITY.
<b>StartTime</b>	Time Reservation became active.

Example 3-60:

```
> showres 12956
ReservationID      Type S      Start      End      Duration  N/P      StartTime
12956              Job I    1:04:09:32 1:10:49:32 6:40:00   16/32    Fri Sep 2
21:02:50
1 reservation located
```

*In this example, information for a specific reservation (job) is displayed.*

## showstart

### Synopsis

```
showstart {jobid|proccount[@duration]|s3jobspec} [-e {all|hist|prio|rsv}] [-f] [-g [peer]] [-l qos=<QOS>] [--  
blocking] [--format=xml]
```

## Overview

This command displays the estimated start time of a job based a number of analysis types. This analysis may include information based on historical usage, earliest available reservable resources, and priority based backlog analysis. Each type of analysis will provide somewhat different estimates based on current cluster environmental conditions. By default, only reservation based analysis is performed.

**i** The start time estimate Moab returns does not account for resources that will become available due to preemption.

**Historical** analysis utilizes historical queue times for jobs which match a similar processor count and job duration profile. This information is updated on a sliding window which is configurable within `moab.cfg`

**Reservation** based start time estimation incorporates information regarding current administrative, user, and job reservations to determine the earliest time the specified job could allocate the needed resources and start running. In essence, this estimate will indicate the earliest time the job would start assuming this job was the highest priority job in the queue.

**Priority** based job start analysis determines when the queried job would fit in the queue and determines the estimated amount of time required to complete the jobs which are currently running or scheduled to run before this job can start.

In all cases, if the job is running, this command will return the time the job started. If the job already has a reservation, this command will return the start time of the reservation.

## Access

By default, this command can be run by any user.

## Parameters

Parameter	Description
<b>--blocking</b>	Do not use cache information in the output. The <code>--blocking</code> flag retrieves results exclusively from the scheduler.
<b>DURATION</b>	Duration of pseudo-job to be checked in format <code>[[[DD:]HH:]MM:]SS</code> (default duration is 1 second)
<b>-e</b>	Estimate method. By default, Moab will use the reservation based estimation method.
<b>-f</b>	Use feedback. If specified, Moab will apply historical accuracy information to Improve the quality of the estimate. See <a href="#">ENABLESTARTESTIMATESTATS</a> for more information.

Parameter	Description
<b>-g</b>	<p>Grid mode. Obtain showstart information from remote resource managers. If -g is not used and Moab determines that job is already migrated, Moab obtains showstart information from the remote Moab where the job was migrated to. All resource managers can be queried by using the keyword "all" which returns all information in a table.</p> <pre style="border: 1px dashed gray; padding: 5px;">\$ showstart -g all head.1 Estimated Start Times [ Remote RM ] [ Reservation ] [ Priority ] [ Historical ] [ c1 ] [ 00:15:35 ] [ ] [ ] [ c2 ] [ 3:15:38 ] [ ] [ ]</pre>
<b>-l qos- s=&lt;QOS&gt;</b>	Specifies what QOS the job must start under, using the same syntax as the <a href="#">msub</a> command. Currently, no other resource manager extensions are supported. This flag only applies to hypothetical jobs by using the <code>proccount[@duration]</code> syntax.
<b>JOBID</b>	Job to be checked
<b>PROCCOUNT</b>	Number of processors in pseudo-job to be checked
<b>S3JOBSPEC</b>	XML describing the job according to the Dept. of Energy <a href="#">Scalable Systems Software/S3</a> job specification.

## Examples

### Example 3-61:

```
> showstart orion.13762
job orion.13762 requires 2 procs for 0:33:20
Estimated Rsv based start in          1:04:55 on Fri Jul 15 12:53:40
Estimated Rsv based completion in     2:44:55 on Fri Jul 15 14:33:40
Estimated Priority based start in      5:14:55 on Fri Jul 15 17:03:40
Estimated Priority based completion in  6:54:55 on Fri Jul 15 18:43:40
Estimated Historical based start in    00:00:00 on Fri Jul 15 11:48:45
Estimated Historical based completion in 1:40:00 on Fri Jul 15 13:28:45
Best Partition: fast
```

### Example 3-62:

```
> showstart 12@3600
job 12@3600 requires 12 procs for 1:00:00
Earliest start in          00:01:39 on Wed Aug 31 16:30:45
Earliest completion in    1:01:39 on Wed Aug 31 17:30:45
Best Partition: 32Bit
```

**i** You cannot specify job flags when running `showstart`, and since a job by default can only run on one partition, `showstart` fails when querying for a job requiring more nodes than the largest partition available.

## Additional Information

For reservation based estimates, the information provided by this command is more highly accurate if the job is highest priority, if the job has a reservation, or if the majority of the jobs which are of higher priority have reservations. Consequently, sites wishing to make decisions based on this information may want to consider using the [RESERVATIONDEPTH](#) parameter to increase the number of priority based reservations. This can be set so that most or even all idle jobs receive priority reservations and make the results of this command generally useful. The only caution of this approach is that increasing the **RESERVATIONDEPTH** parameter more tightly constrains the decisions of the scheduler and may resulting in slightly lower system utilization (typically less than 8% reduction).

## showstate

### Synopsis

`showstate`

### Overview

This command provides a summary of the state of the system. It displays a list of all active jobs and a text-based map of the status of all nodes and the jobs they are servicing. Basic diagnostic tests are also performed and any problems found are reported.

### Access

By default, this command can be run by any Moab Administrator.

## Examples

Example 3-63:

```
> showstate
cluster state summary for Wed Nov 23 12:00:21

Key:  XXX:Unknown [*]:Down w/Job [#]:Down [']:Idle w/Job [ ]:Idle [@]:Busy w/No Job
      [!]:Drained
Key:  [a]:(Any lower case letter indicates an idle node that is assigned to a job)

Check Memory on Node fr3n07
Check Memory on Node fr4n06
Check Memory on Node fr4n09
```

*In this example, nine active jobs are running on the system. Each job listed in the top of the output is associated with a letter. For example, job fr17n11.942.0 is associated with the letter A. This letter can now be used to determine where the job is currently running. By looking at the system map, it can be found that job fr17n11.942.0 (job A) is running on nodes fr2n10, fr2n13, fr2n16, fr3n07...*

*The key at the bottom of the system map can be used to determine unusual node states. For example, fr7n15 is currently in the state down.*

*After the key, a series of warning messages may be displayed indicating possible system problems. In this case, warning messages indicate that there are memory problems on three nodes, fr3n07, fr4n06, and fr4n09. Also, warning messages indicate that job fr15n09.1097.0 is having difficulty starting. Node fr11n08 is in state BUSY but has no job assigned to it (it possibly has a runaway job running on it).*

[showstats -u](#) [*userid*] [-v] [-t <TIMESPEC>]

### Overview

This command shows various accounting and resource usage statistics for the system. Historical statistics cover the timeframe from the most recent execution of the [mschedctl -f](#) command.

### Access

By default, this command can be run by any Moab level 1, 2, or 3 Administrator.

### Parameters

Flag	Description
<b>-a</b> <ACCOUNTID>	Display account statistics. See <a href="#">Account statistics on page 349</a> for an example.
<b>-c</b> <CLASSID>	Display class statistics
<b>-f</b> <statistictype>	Display full matrix statistics (see <a href="#">showstats -f</a> for full details)

Flag	Description
<b>-g</b> [<GROUPID>]	Display group statistics. See <a href="#">Group statistics on page 351</a> for an example.
<b>-j</b> [<JOBTEMPLATE>]	Display template statistics
<b>-n</b> [<NODEID>]	Display node statistics ( <a href="#">ENABLEPROFILING</a> must be set). See <a href="#">Node statistics on page 353</a> for an example.
<b>-q</b> [<QOSID>]	Display QoS statistics
<b>-s</b>	display general scheduler statistics
<b>-t</b>	<p>Display statistical information from the specified timeframe:</p> <pre style="border: 1px dashed gray; padding: 5px;"> &lt;START_TIME&gt;[,&lt;END_TIME&gt;]   (ABSTIME: [HH[:MM[:SS]]][_MO[/DD[/YY]]] ie 14:30_06/20)   (RELTIME: -[[[DD:]HH:]MM:]SS) </pre> <p>See <a href="#">Statistics from an absolute time frame on page 359</a> and <a href="#">Statistics from a relative time frame on page 359</a> for examples.</p> <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;"> <p><b>i</b> Profiling must be enabled for the credential type you want statistics for. See <a href="#">Credential Statistics</a> for information on how to enable profiling. Also, <b>-t</b> is not a stand-alone option. It must be used in conjunction with the <b>-a</b>, <b>-c</b>, <b>-g</b>, <b>-n</b>, <b>-q</b>, or <b>-u</b> flag.</p> </div>
<b>-T</b>	Display fairshare tree statistics. See <a href="#">Fairshare tree statistics on page 358</a> for an example.
<b>-u</b> [<USERID>]	Display user statistics. See <a href="#">User statistics on page 355</a> for an example.
<b>-v</b>	Display verbose information. See <a href="#">Verbose statistics on page 353</a> for an example.

```

*This example shows a statistical listing of all active accounts. The top line (Account Statistics Initialized...) of the output indicates the beginning of the timeframe covered by the displayed statistics.*

*The statistical output is divided into two categories, Running and Completed. Running statistics include information about jobs that are currently running. Completed statistics are compiled using historical information from both running and completed jobs.*

The fields are as follows:

Column	Description
<b>Account</b>	Account Number
<b>Jobs</b>	Number of running jobs
<b>Procs</b>	Number of processors allocated to running jobs
<b>ProcHours</b>	Number of proc-hours required to complete running jobs
<b>Jobs*</b>	Number of jobs completed
<b>%</b>	Percentage of total jobs that were completed by account
<b>PHReq*</b>	Total proc-hours requested by completed jobs
<b>%</b>	Percentage of total proc-hours requested by completed jobs that were requested by account

Column	Description
<b>PHDed</b>	Total proc-hours dedicated to active and completed jobs. The proc-hours dedicated to a job are calculated by multiplying the number of allocated procs by the length of time the procs were allocated, regardless of the job's CPU usage.
<b>%</b>	Percentage of total proc-hours dedicated that were dedicated by account
<b>FSTgt</b>	Fairshare target. An account's fairshare target is specified in the <code>fs.cfg</code> file. This value should be compared to the account's node-hour dedicated percentage to determine if the target is being met.
<b>AvgXF*</b>	Average expansion factor for jobs completed. A job's XFactor (expansion factor) is calculated by the following formula: $(\text{QueuedTime} + \text{RunTime}) / \text{WallClockLimit}$ .
<b>MaxXF*</b>	Highest expansion factor received by jobs completed
<b>AvgQH*</b>	Average queue time (in hours) of jobs
<b>Effic</b>	Average job efficiency. Job efficiency is calculated by dividing the actual node-hours of CPU time used by the job by the node-hours allocated to the job.
<b>WCAcc*</b>	Average wallclock accuracy for jobs completed. Wallclock accuracy is calculated by dividing a job's actual run time by its specified wallclock limit. <div style="border: 1px solid black; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p> A job's wallclock accuracy is capped at 100% so even if a job exceeds its requested walltime it will report an accuracy of 100%.</p> </div>

\* These fields are empty until an account has completed at least one job.

*This example shows a statistical listing of all active groups. The top line (Group Statistics Initialized...) of the output indicates the beginning of the timeframe covered by the displayed statistics.*

*The statistical output is divided into two categories, Running and Completed. Running statistics include information about jobs that are currently running. Completed statistics are compiled using historical information from both running and completed jobs.*

The fields are as follows:

Column	Description
<b>GroupName</b>	Name of group.
<b>GID</b>	Group ID of group.
<b>Jobs</b>	Number of running jobs.
<b>Procs</b>	Number of procs allocated to running jobs.
<b>ProcHours</b>	Number of proc hours required to complete running jobs.
<b>Jobs*</b>	Number of jobs completed.

Column	Description
%	Percentage of total jobs that were completed by group.
<b>PHReq*</b>	Total proc-hours requested by completed jobs.
%	Percentage of total proc-hours requested by completed jobs that were requested by group.
<b>PHDed</b>	Total proc-hours dedicated to active and completed jobs. The proc-hours dedicated to a job are calculated by multiplying the number of allocated procs by the length of time the procs were allocated, regardless of the job's CPU usage.
%	Percentage of total proc-hours dedicated that were dedicated by group.
<b>FSTgt</b>	Fairshare target. A group's fairshare target is specified in the <code>fs.cfg</code> file. This value should be compared to the group's node-hour dedicated percentage to determine if the target is being met.
<b>AvgXF*</b>	Average expansion factor for jobs completed. A job's XFactor (expansion factor) is calculated by the following formula: $(\text{QueuedTime} + \text{RunTime}) / \text{WallClockLimit}$ .
<b>MaxXF*</b>	Highest expansion factor received by jobs completed.
<b>AvgQH*</b>	Average queue time (in hours) of jobs.
<b>Effic</b>	Average job efficiency. Job efficiency is calculated by dividing the actual node-hours of CPU time used by the job by the node-hours allocated to the job.
<b>WCAcc*</b>	Average wallclock accuracy for jobs completed. Wallclock accuracy is calculated by dividing a job's actual run time by its specified wallclock limit. <div style="border: 1px solid black; border-radius: 10px; padding: 5px; margin-top: 10px;">  A job's wallclock accuracy is capped at 100% so even if a job exceeds its requested walltime it will report an accuracy of 100%. </div>

\* These fields are empty until a group has completed at least one job.

**Example 3-66: Node statistics**

```
> showstats -n

**Example 3-67: Verbose statistics**

```
> showstats -v
current scheduler time: Sat Aug 18 18:23:02 2007
moab active for      00:00:01  started on Wed Dec 31 17:00:00
statistics for iteration      0  initialized on Sat Aug 11 23:55:25
Eligible/Idle Jobs:          6/8   (75.000%)
Active Jobs:                  13
Successful/Completed Jobs:   167/167 (100.000%)
Preempt Jobs:                 0
Avg/Max QTime (Hours):       0.34/2.07
Avg/Max XFactor:             1.165/3.26
Avg/Max Bypass:              0.40/8.00
Dedicated/Total ProcHours:   4.46K/4.47K (99.789%)
Preempt/Dedicated ProcHours: 0.00/4.46K (0.000%)
Current Active/Total Procs:  32/32  (100.0%)
Current Active/Total Nodes:  16/16  (100.0%)
Avg WallClock Accuracy:     64.919%
Avg Job Proc Efficiency:     99.683%
Min System Utilization:     87.323% (on iteration 46)
Est/Avg Backlog:            02:14:06/03:02:567
```

*This example shows a concise summary of the system scheduling state. Note that `showstats` and `showstats-s` are equivalent.*

*The first line of output indicates the number of scheduling iterations performed by the current scheduling process, followed by the time the scheduler started. The second line indicates the amount of time the Moab Scheduler has been scheduling in HH:MM:SS notation followed by the statistics initialization time.*

The fields are as follows:

Column	Description
<b>Active Jobs</b>	Number of jobs currently active (Running or Starting).
<b>Eligible Jobs</b>	Number of jobs in the system queue (jobs that are considered when scheduling).
<b>Idle Jobs</b>	Number of jobs both in and out of the system queue that are in the LoadLeveler Idle state.
<b>Completed Jobs</b>	Number of jobs completed since statistics were initialized.
<b>Successful Jobs</b>	Jobs that completed successfully without abnormal termination.
<b>XFactor</b>	Average expansion factor of all completed jobs.
<b>Max XFactor</b>	Maximum expansion factor of completed jobs.
<b>Max Bypass</b>	Maximum bypass of completed jobs.
<b>Available ProcHours</b>	Total proc-hours available to the scheduler.
<b>Dedicated ProcHours</b>	Total proc-hours made available to jobs.
<b>Effic</b>	Scheduling efficiency (DedicatedProcHours / Available ProcHours).
<b>Min Efficiency</b>	Minimum scheduling efficiency obtained since scheduler was started.
<b>Iteration</b>	Iteration on which the minimum scheduling efficiency occurred.
<b>Available Procs</b>	Number of procs currently available.
<b>Busy Procs</b>	Number of procs currently busy.
<b>Effic</b>	Current system efficiency (BusyProcs/AvailableProcs).
<b>WallClock Accuracy</b>	Average wallclock accuracy of completed jobs (job-weighted average).
<b>Job Efficiency</b>	Average job efficiency (UtilizedTime / DedicatedTime).

Column	Description
<b>Est Backlog</b>	Estimated backlog of queued work in hours.
<b>Avg Backlog</b>	Average backlog of queued work in hours.

**showstats -f**

**Synopsis**

`showstats -f <statistictype>`

**Overview**

Shows table of various scheduler statistics.

This command displays a table of the selected Moab Scheduler statistics, such as expansion factor, bypass count, jobs, proc-hours, wallclock accuracy, and backfill information.

**i** Statistics are aggregated over time. This means statistical information is not available for time frames and the `-t` option is not supported with `showstats -f`.

## Access

This command can be run by any Moab Scheduler Administrator.

## Parameters

Parameter	Description
<b>AVGBYPASS</b>	Average bypass count. Includes summary of job-weighted expansion bypass and total samples.
<b>AVGQTIME</b>	Average queue time. Includes summary of job-weighted queue time and total samples.
<b>AVGXFACTOR</b>	Average expansion factor. Includes summary of job-weighted expansion factor, processor-weighted expansion factor, processor-hour-weighted expansion factor, and total number of samples.
<b>BFCOUNT</b>	Number of jobs backfilled. Includes summary of job-weighted backfill job percent and total samples.
<b>BFPHRUN</b>	Number of proc-hours backfilled. Includes summary of job-weighted backfill proc-hour percentage and total samples.
<b>ESTSTARTTIME</b>	Job start time estimate for jobs meeting specified processor/duration criteria. This estimate is based on the <a href="#">reservation start time analysis</a> algorithm.
<b>JOB COUNT</b>	Number of jobs. Includes summary of total jobs and total samples.
<b>MAXBYPASS</b>	Maximum bypass count. Includes summary of overall maximum bypass and total samples.
<b>MAXXFACTOR</b>	Maximum expansion factor. Includes summary of overall maximum expansion factor and total samples.
<b>PHREQUEST</b>	proc-hours requested. Includes summary of total proc-hours requested and total samples.
<b>PHRUN</b>	proc-hours run. Includes summary of total proc-hours run and total samples.
<b>QOSDELIVERED</b>	Quality of service delivered. Includes summary of job-weighted quality of service success rate and total samples.
<b>WCACCURACY</b>	Wallclock accuracy. Includes summary of overall wall clock accuracy and total samples.

Job Weighted X Factor: 1.0888
Node Weighted X Factor: 1.1147
NS Weighted X Factor: 1.1900
Total Samples: 9

```

The `showstats -f` command returns a table with data for the specified `STATISTICTYPE` parameter. The left-most column shows the maximum number of processors required by the jobs shown in the other columns. The column headers indicate the maximum wallclock time (in HH:MM:SS notation) requested by the jobs shown in the columns. The data returned in the table varies by the `STATISTICTYPE` requested. For table entries with one number, it is of the data requested. For table entries with two numbers, the left number is the data requested and the right number is the number of jobs used to calculate the average. Table entries that contain only dashes (-----) indicate no job has completed that matches the profile associated for this inquiry. The bottom row shows the totals for each column. Following each table is a summary, which varies by the `STATISTICTYPE` requested.

 The column and row break down can be adjusted using the `STATPROC*` and `STATTIME*` parameters respectively.

This particular example shows the average expansion factor grid. Each table entry indicates two pieces of information — the average expansion factor for all jobs that meet this slot's profile and the number of jobs that were used to calculate this average. For example, the XFactors of two jobs were averaged to obtain an average XFactor of 1.24 for jobs requiring over 2 hours 8 minutes, but not more than 4 hours 16 minutes and between 5 and 8 processors. Totals along the bottom provide overall XFactor averages weighted by job, processors, and processor-hours.

## TIMESPEC

### Relative Time Format

The relative time format specifies a time by using the current time as a reference and specifying a time offset.

#### Format

+[[[DD:]HH:]MM:]SS

#### Examples

2 days, 3 hours and 57 seconds in the future:

```
+02:03:0:57
```

21 days (3 weeks) in the future:

```
+21:0:0:0
```

30 seconds in the future:

```
+30
```

### Absolute Time Format

The absolute time format specifies a specific time in the future.

#### Format

[HH[:MM[:SS]]][\_MO[/DD[/YY]]] i.e. 14:30\_06/20

#### Examples

1 PM, March 1 (this year)

```
13:00_03/01
```

### Deprecated commands

#### canceljob

This command is deprecated. Use [mjobctl -c](#) instead.

### Synopsis

canceljob *jobid* [*jobid*]...

## Overview

The `canceljob` command is used to selectively cancel the specified job(s) (active, idle, or non-queued) from the queue.

## Access

This command can be run by any Moab Administrator and by the owner of the job (see [ADMINCFG](#)).

Flag	Name	Format	Default	Description	Example
<b>-h</b>	HELP		N/A	Display usage information	<pre>&gt; canceljob -h</pre>
	JOB ID	<STRING>	---	a jobid, a job expression, or the keyword ALL	<pre>&gt; canceljob 13001 13003</pre>

## Examples

*Example 3-73: Cancel job 6397*

```
> canceljob 6397
```

### changeparam

This command is deprecated. Use [mschedctl -m](#) instead.

## Synopsis

`changeparam` [parametervalue](#)

## Overview

The `changeparam` command is used to dynamically change the value of any parameter which can be specified in the `moab.cfg` file. The changes take effect at the beginning of the next scheduling iteration. They are not persistent, only lasting until Moab is shut down.

`changeparam` is a compact command of [mschedctl -m](#).

## Access

This command can be run by a level 1 Moab administrator.

### diagnose

This command is deprecated. Use [mdiag](#) instead.

## Synopsis

[diagnose -a](#) [*accountid*]  
[diagnose -b](#) [-l *policylevel*] [-t *partition*]  
[diagnose -c](#) [*classid*]  
[diagnose -C](#) [*configfile*]  
[diagnose -f](#) [-o user|group|account|qos|class]  
[diagnose -g](#) [*groupid*]  
[diagnose -j](#) [*jobid*]  
[diagnose -L](#)  
[diagnose -m](#) [*rackid*]  
[diagnose -n](#) [-t *partition*] [*nodeid*]  
[diagnose -p](#) [-t *partition*]  
[diagnose -q](#) [*qosid*]  
[diagnose -r](#) [*reservationid*]  
[diagnose -R](#) [*resourcemanagername*]  
[diagnose -s](#) [*standingreservationid*]  
[diagnose -S](#) [diagnose -u](#) [*userid*]  
[diagnose -v](#)  
[diagnose -x](#)

## Overview

The `diagnose` command is used to display information about various aspects of scheduling and the results of internal diagnostic tests.

### releasehold

This command is deprecated. Use [mjobctl -u](#) instead.

## Synopsis

`releasehold` [-a|-b] [jobexp](#)

## Overview

Release hold on specified job(s).

This command allows you to release batch holds or all holds (system, user, and batch) on specified jobs. Any number of jobs may be released with this command.

## Access

By default, this command can be run by any Moab Scheduler Administrator.

## Parameters

JOBEXP	Job expression of job(s) to release.
--------	--------------------------------------

## Flags

-a	Release all types of holds (user, system, batch) for specified job(s).
-b	Release batch hold from specified job(s).
-h	Help for this command.

## Examples

### Example 3-74: `releasehold -b`

```
> releasehold -b 6443
batch hold released for job 6443
```

*In this example, a batch hold was released from this one job.*

### Example 3-75: `releasehold -a`

```
> releasehold -a "81[1-6]"
holds modified for job 811
holds modified for job 812
holds modified for job 813
holds modified for job 814
holds modified for job 815
holds modified for job 816
```

*In this example, all holds were released from the specified jobs.*

- [mjobctl](#)

**releaseres**

 This command is deprecated. Use [mrsvctl -r](#) instead.

**Synopsis**

releaseres [*arguments*] *reservationid* [*reservationid...*]

**Overview**

Release existing reservation.

This command allows Moab Scheduler Administrators to release any user, group, account, job, or system reservation. Users are allowed to release reservations on jobs they own. Note that releasing a reservation on an active job has no effect since the reservation will be automatically recreated.

**Access**

Users can use this command to release any reservation they own. Level 1 and level 2 Moab administrators may use this command to release any reservation.

**Parameters**

RESERVATION ID	Name of reservation to release.
----------------	---------------------------------

**Examples**

*Example 3-76: Release two existing reservations*

```
> releaseres system.1 bob.2
released User reservation 'system.1'
released User reservation 'bob.2'
```

**resetstats**

 This command is deprecated. Use [mschedctl -f](#) instead.

**Synopsis**

resetstats

**Overview**

This command resets all internally-stored Moab Scheduler statistics to the initial start-up state as of the time the command was executed.

## Access

By default, this command can be run by level 1 scheduler administrators.

## Examples

Example 3-77:

```
> resetstats Statistics Reset at time Wed Feb 25 23:24:55 2011
```

Related topics

- Moab Client Installation - explains how to distribute this command to client nodes

### runjob

This command is deprecated. Use [mjobctl -x](#) instead.

## Synopsis

```
runjob [-c|-f|-n nodelist|-p partition|-s|-x] jobid
```

## Overview

This command will attempt to immediately start the specified job.

`runjob` is a deprecated command, replaced by [mjobctl](#).

## Access

By default, this command can be run by any Moab administrator.

## Parameters

JOBID	Name of the job to run.
-------	-------------------------

Args	Description
<b>-c</b>	Clear job parameters from previous runs (used to clear PBS neednodes attribute after PBS job launch failure)
<b>-f</b>	Attempt to <i>force</i> the job to run, ignoring throttling policies
<b>-n</b> <b>&lt;NODELIST&gt;</b>	Attempt to start the job using the specified <i>nodelist</i> where nodenames are comma or colon delimited

Args	Description
<b>-p</b> <b>&lt;PARTITION&gt;</b>	Attempt to start the job in the specified <i>partition</i>
<b>-s</b>	Attempt to <i>suspend</i> the job
<b>-x</b>	Attempt to force the job to run, ignoring throttling policies, QoS constraints, and reservations

## Examples

Example 3-78: Run job *cluster.231*

```
> runjob cluster.231
job cluster.231 successfully started
```

## See Also

- [mjobctl](#)
- [canceljob](#) - cancel a job.
- [checkjob](#) - show detailed status of a job.
- [showq](#) - list queued jobs.

### sethold

This command is deprecated. Use [mjobctl -h](#) instead.

## Synopsis

```
sethold [-b] jobid [jobid...]
```

## Overview

Set hold on specified job(s).

## Permissions

This command can be run by any Moab Scheduler Administrator.

## Parameters

JOB	Job number of job to hold.
-----	----------------------------

## Flags

<b>-b</b>	Set a batch hold. Typically, only the scheduler places batch holds. This flag allows an administrator to manually set a batch hold.
<b>-h</b>	Help for this command.

## Examples

Example 3-79:

```
> sethold -b fr17n02.1072.0 fr15n03.1017.0
Batch Hold Placed on All Specified Jobs
```

*In this example, a batch hold is placed on job fr17n02.1072.0 and job fr15n03.1017.0.*

### setqos

This command is deprecated. Use [mjobctl -m](#) instead.

## Synopsis

```
setqos qosid jobid
```

## Overview

Set Quality Of Service for a specified job.

This command allows users to change the QOS of their own jobs.

## Access

This command can be run by any user.

## Parameters

JOBID	Job name.
QOSID	QOS name.

## Examples

Example 3-80:

```
> setqos high_priority moab.3
```

```
Job QOS Adjusted
```

*This example sets the Quality Of Service to a value of `high_priority` for job `moab.3`.*

### setres

This command is deprecated. Use [mrsvctl -c](#) instead.

## Synopsis

setres [*arguments*] *resourceexpression*

```
[ -a <ACCOUNT_LIST> ]
[ -b <SUBTYPE> ]
[ -c <CHARGE_SPEC> ]
[ -d <DURATION> ]
[ -e <ENDTIME> ]
[ -E ] // EXCLUSIVE
[ -f <FEATURE_LIST> ]
[ -g <GROUP_LIST> ]
[ -n <NAME> ]
[ -o <OWNER> ]
[ -p <PARTITION> ]
[ -q <QUEUE_LIST> ] // (i.e. CLASS_LIST)
[ -Q <QOSLIST> ]
[ -r <RESOURCE_DESCRIPTION> ]
[ -R <RESERVATION_PROFILE> ]
[ -s <STARTTIME> ]
[ -T <TRIGGER> ]
[ -u <USER_LIST> ]
[ -x <FLAGS> ]
```

## Overview

Reserve resources for use by jobs with particular credentials or attributes.

## Access

This command can be run by level 1 and level 2 Moab administrators.

## Parameters

Name	Format	Default	Description
<b>ACCOUNT_LIST</b>	<STRING> [:<STRING>]...	---	List of accounts that will be allowed access to the reserved resources
<b>SUBTYPE</b>	<STRING>	---	Specify the subtype for a reservation
<b>CHARGE_SPEC</b>	<ACCOUNT> [,<GROUP> [,<USER>]]	---	Specifies which credentials will be accountable for unused resources dedicated to the reservation
<b>CLASS_LIST</b>	<STRING> [:<STRING>]...	---	List of classes that will be allowed access to the reserved resource
<b>DURATION</b>	[[[DD:]HH:]MM:]SS	INFINITY	Duration of the reservation (not needed if ENDTIME is specified)
<b>ENDTIME</b>	[HH[:MM[:SS]]][_MO[/DD[/YY]]] or +[[[DD:]HH:]MM:]SS	INFINITY	Absolute or relative time reservation will end (not required if Duration specified)
<b>EXCLUSIVE</b>	N/A	N/A	Requests exclusive access to resources
<b>FEATURE_LIST</b>	<STRING> [:<STRING>]...	---	List of node features which must be possessed by the reserved resources
<b>FLAGS</b>	<STRING> [:<STRING>]...	---	List of reservation flags (See <a href="#">Managing Reservations</a> for details)
<b>GROUP_LIST</b>	<STRING> [:<STRING>]...	---	List of groups that will be allowed access to the reserved resources
<b>NAME</b>	<STRING>	Name set to first name listed in ACL or SYSTEM if no ACL specified	Name for new reservation

Name	Format	Default	Description
<b>OWNER</b>	<CREDTYPE> :<CREDID> where CREDTYPE is one of user, group, acct, class, or qos	N/A	Specifies which credential is granted reservation ownership privileges
<b>PARTITION</b>	<STRING>	[ANY]	Partition in which resources must be located
<b>QOS_LIST</b>	<STRING> [:<STRING>]...	---	List of QOS's that will be allowed access to the reserved resource
<b>RESERVATION_ PROFILE</b>	Existing reservation profile ID	N/A	Requests that default reservation attributes be loaded from the specified reservation profile (see <a href="#">RSVPROFILE</a> )
<b>RESOURCE_ DESCRIPTION</b>	Colon delimited list of zero or more of the following <ATTR>=<VALUE> pairs PROCS=<INTEGER> MEM=<INTEGER> DISK=<INTEGER> SWAP=<INTEGER> GRES=<STRING>	PROCS=-1	Specifies the resources to be reserved per task. (-1 indicates all resources on node)
<b>RESOURCE_ EXPRESSION</b>	ALL or TASKS{== >=} <TASKCOUNT> or <HOST_REGEX>	Required Field. No Default	Specifies the tasks to reserve. ALL indicates all resources available should be reserved. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"><b>i</b> If ALL or a host expression is specified, Moab will apply the reservation regardless of existing reservations and exclusive issues. If TASKS is used, Moab will only allocate accessible resources.</div>
<b>STARTTIME</b>	[HH[:MM[:SS]]]_ MO[/DD[/YY]]] or +[[[DD:]HH:]MM:] SS	NOW	Absolute or relative time reservation will start

Name	Format	Default	Description
<b>TRIGGER</b>	<STRING>	N/A	Comma delimited reservation trigger list following format described in the <a href="#">trigger format</a> section of the reservation configuration overview.
<b>USER_LIST</b>	<STRING> [:<STRING>]...	---	List of users that will be allowed access to the reserved resources

## Description

The `setres` command allows an arbitrary block of resources to be reserved for use by jobs which meet the specified access constraints. The timeframe covered by the reservation can be specified on either an absolute or relative basis. Only jobs with credentials listed in the reservation ACL (i.e., **USERLIST**, **GROUPLIST**,...) can utilize the reserved resources. However, these jobs still have the freedom to utilize resources outside of the reservation. The reservation will be assigned a name derived from the ACL specified. If no reservation ACL is specified, the reservation is created as a system reservation and no jobs will be allowed access to the resources during the specified timeframe (valuable for system maintenance, etc.). See the [Reservation Overview](#) for more information.

Reservations can be viewed using the [showres](#) command and can be released using the [releaseres](#) command.

## Examples

### Example 3-81:

```
> setres -u john:mary -s +24:00:00 -d 8:00:00 TASKS==2
reservation 'john.1' created on 2 nodes (2 tasks)
node001:1
node005:1
```

*Reserve two nodes for use by users john and mary for a period of 8 hours starting in 24 hours.*

### Example 3-82:

```
> setres -s 8:00:00_06/20 -e 17:00:00_06/22 ALL
reservation 'system.1' created on 8 nodes (8 tasks)
node001:1
node002:1
node003:1
node004:1
node005:1
node006:1
node007:1
node008:1
```

*Schedule a system wide reservation to allow system maintenance on Jun 20, 8:00 AM until Jun 22, 5:00 PM.*

**Example 3-83:**

```
> setres -r PROCS=1:MEM=512 -g staff -l interactive 'node00[3-6] '
reservation 'staff.1' created on 4 nodes (4 tasks)
node003:1
node004:1
node005:1
node006:1
```

*Reserve one processor and 512 MB of memory on nodes node003 through node node006 for members of the group staff and jobs in the interactive class.*

**setspri**

 This command is deprecated. Use [mjobctl -p](#) instead.

**Synopsis**

setspri [-r] priorityjobid

**Overview**

(This command is deprecated by the [mjobctl command](#))

Set or remove absolute or relative system priorities for a specified job.

This command allows you to set or remove a system priority level for a specified job. Any job with a system priority level set is guaranteed a higher priority than jobs without a system priority. Jobs with higher system priority settings have priority over jobs with lower system priority settings.

**Access**

This command can be run by any Moab Scheduler Administrator.

**Parameters**

JOB	Name of job.
PRIORITY	System priority level. By default, this priority is an absolute priority overriding the policy generated priority value. Range is 0 to clear, 1 for lowest, 1000 for highest. The given value is added onto the system priority (see 32-bit and 64-bit values below), except for a given value of zero. If the '-r' flag is specified, the system priority is relative, adding or subtracting the specified value from the policy generated priority.  If a relative priority is specified, any value in the range +/- 1,000,000,000 is acceptable.

**Flags**

-r	Set relative system priority on job.
----	--------------------------------------

## Examples

### Example 3-84:

```
> setspri 10 orion.4752
job system priority adjusted
```

*In this example, a system priority of 10 is set for job orion.4752.*

### Example 3-85:

```
> setspri 0 clusterB.1102
job system priority adjusted
```

*In this example, system priority is cleared for job clusterB.1102.*

### Example 3-86:

```
> setspri -r 100000 job.00001
job system priority adjusted
```

*In this example, the job's priority will be increased by 100000 over the value determine by configured priority policy.*

 This command is deprecated. Use [mjobctl](#) instead.

### showconfig

 This command is deprecated. Use [mschedctl -l](#) instead.

## Synopsis

```
showconfig [-v]
```

## Overview

View the current configurable parameters of the Moab Scheduler.

The `showconfig` command shows the current scheduler version and the settings of all "in memory" parameters. These parameters are set via internal defaults, command line arguments, environment variable settings, parameters in the `moab.cfg` file, and via the [mschedctl -m](#) command. Because of the many sources of configuration settings, the output may differ from the contents of the `moab.cfg` file. The output is such that it can be saved and used as the contents of the `moab.cfg` file if desired.

## Access

This command can be run by a level 1, 2, or 3 Moab administrator.

## Flags

- <b>h</b>	Help for this command.
- <b>v</b>	This optional flag turns on verbose mode, which shows all possible Moab Scheduler parameters and their current settings. If this flag is not used, this command operates in context-sensitive terse mode, which shows only relevant parameter settings.

## Examples

### Example 3-87: showconfig

```
> showconfig
# moab scheduler version 4.2.4 (PID: 11080)
BACKFILLPOLICY          FIRSTFIT
BACKFILLMETRIC          NODES
ALLOCATIONPOLICY         MINRESOURCE
RESERVATIONPOLICY      CURRENTHIGHEST
...
```

**i** The `showconfig` command without the `-v` flag does not show the settings of all parameters. It does show all major parameters and all parameters which are in effect and have been set to non-default values. However, it hides other rarely used parameters and those which currently have no effect or are set to default values. To show the settings of all parameters, use the `-v` (verbose) flag. This will provide an extended output. This output is often best used in conjunction with the `grep` command as the output can be voluminous.

## Job Prioritization

In general, prioritization is the process of determining which of many options best fulfills overall goals. In the case of scheduling, a site will often have multiple, independent goals that may include maximizing system utilization, giving preference to users in specific projects, or making certain that no job sits in the queue for more than a given period of time. The approach used by Moab in representing a multi-faceted set of site goals is to assign weights to the various objectives so an overall value or priority can be associated with each potential scheduling decision. With the jobs prioritized, the scheduler can roughly fulfill site objectives by starting the jobs in priority order.

## Priority Overview

Moab's prioritization mechanism allows component and subcomponent weights to be associated with many aspects of a job to enable fine-grained control over this aspect of scheduling. To allow this level of control, Moab uses a simple priority-weighting hierarchy where the contribution of each priority subcomponent is calculated as follows:

$$\langle \text{COMPONENT WEIGHT} \rangle * \langle \text{SUBCOMPONENT WEIGHT} \rangle * \langle \text{PRIORITY SUBCOMPONENT VALUE} \rangle$$

Each priority component contains one or more subcomponents as described in the section titled [Job Priority Factors on page 378](#). For example, the Resource component consists of Node, Processor, Memory, Swap, Disk, Walltime, and PE subcomponents. While there are numerous priority components and many more subcomponents, a site need only focus on and configure the subset of components related to their particular priority needs. In actual usage, few sites use more than a small fraction (usually 5 or fewer) of the available priority subcomponents. This results in fairly straightforward priority configurations and tuning. By mixing and matching priority weights, sites may generally obtain the desired job-start behavior. At any time, you can issue the [mdiag -p](#) command to determine the impact of the current priority-weight settings on idle jobs. Likewise, the command [showstats -f](#) can assist the administrator in evaluating priority effectiveness on historical system usage metrics such as queue time or expansion factor.

As mentioned above, a job's priority is the weighted sum of its activated subcomponents. By default, the value of all component and subcomponent weights is set to 1 and 0 respectively. The one exception is the "QUEUE TIME" subcomponent weight that is set to 1. This results in a total job priority equal to the period of time the job has been queued, causing Moab to act as a simple FIFO. Once the summed component weight is determined, this value is then bounded resulting in a priority ranging between 0

and `MAX_PRIO_VAL` which is currently defined as 1000000000 (one billion). In no case will a job obtain a priority in excess of `MAX_PRIO_VAL` through its priority subcomponent values.

 Negative priority jobs may be allowed if desired; see [ENABLENEGJOBPRIORITY](#) and [REJECTNEGPRIOJOBS](#) for more information.

Using the `mjobctl -p` command, site administrators may adjust the base calculated job priority by either assigning a relative priority adjustment or an absolute system priority. A relative priority adjustment causes the base priority to be increased or decreased by a specified value. Setting an absolute system priority, `SPRIO`, causes the job to receive a priority equal to `MAX_PRIO_VAL + SPRIO`, and thus guaranteed to be of higher value than any naturally occurring job priority.

## Job Priority Factors

- [Credential \(CRED\) Component](#)
- [Fairshare \(FS\) Component](#)
- [Resource \(RES\) Component](#)
- [Service \(SERVICE\) Component](#)
- [Target Service \(TARG\) Component](#)
- [Usage \(USAGE\) Component](#)
- [Job Attribute \(ATTR\) Component](#)

Moab allows jobs to be prioritized based on a range of job related factors. These factors are broken down into a two-tier hierarchy of priority factors and subfactors, each of which can be independently assigned a weight. This approach provides the administrator with detailed yet straightforward control of the job selection process.

Each factor and subfactor can be configured with independent priority weight and priority [cap](#) values (described later). In addition, per credential and per QoS priority weight adjustments may be specified for a subset of the priority factors. For example, QoS credentials can adjust the queuetime subfactor weight and group credentials can adjust fairshare subfactor weight.

The following table highlights the factors and subfactors that make up a job's total priority.

Factor	SubFactor	Metric
<b><u>CRED</u></b> <b>(job credentials)</b>	USER	user-specific priority (See <a href="#">USERCFG</a> )
	GROUP	group-specific priority (See <a href="#">GROUPCFG</a> )
	ACCOUNT	account-specific priority (See <a href="#">ACCOUNTCFG</a> )
	QOS	QoS-specific priority (See <a href="#">QOSCFG</a> )
	CLASS	class/queue-specific priority (See <a href="#">CLASSCFG</a> )

Factor	SubFactor	Metric
<b>FS</b> <b>(fairshare usage)</b>	FSUSER	user-based historical usage (See <a href="#">Fairshare Overview</a> )
	FSGROUP	group-based historical usage (See <a href="#">Fairshare Overview</a> )
	FSACCOUNT	account-based historical usage (See <a href="#">Fairshare Overview</a> )
	FSQOS	QoS-based historical usage (See <a href="#">Fairshare Overview</a> )
	FSCCLASS	class/queue-based historical usage (See <a href="#">Fairshare Overview</a> )
	FSGUSER	imported global user-based historical usage (See <a href="#">ID Manager</a> and <a href="#">Fairshare Overview</a> )
	FSGGROUP	imported global group-based historical usage (See <a href="#">ID Manager</a> and <a href="#">Fairshare Overview</a> )
	FSGACCOUNT	imported global account-based historical usage (See <a href="#">ID Manager</a> and <a href="#">Fairshare Overview</a> )
	FSJPU	current active jobs associated with job user
	FSPPU	current number of processors allocated to active jobs associated with job user
	FSPSPU	current number of processor-seconds allocated to active jobs associated with job user
	WCACCURACY	user's current historical job wallclock accuracy calculated as total processor-seconds dedicated / total processor-seconds requested

 Factor values are in the range of 0.0 to 1.0.

Factor	SubFactor	Metric
<b><u>RES</u></b> <b>(requested job resources)</b>	NODE	number of nodes requested
	PROC	number of processors requested
	MEM	total real memory requested (in MB)
	SWAP	total virtual memory requested (in MB)
	DISK	total local disk requested (in MB)
	PS	total processor-seconds requested
	PE	total processor-equivalent requested
	WALLTIME	total walltime requested (in seconds)
<b><u>SERV</u></b> <b>(current service levels)</b>	<u>QUEUETIME</u>	time job has been queued (in minutes)
	<u>XFACTOR</u>	minimum job expansion factor
	<u>BYPASS</u>	number of times job has been bypassed by backfill
	<u>STARTCOUNT</u>	number of times job has been restarted
	<u>DEADLINE</u>	proximity to job deadline
	<u>SPVIOLATION</u>	Boolean indicating whether the active job violates a <u>soft</u> usage limit
	<u>USERPRIO</u>	user-specified job priority
<b><u>TARGET</u></b> <b>(target service levels)</b>	TARGETQUEUETIME	time until queuetime target is reached (exponential)
	TARGETXFACTOR	distance to target expansion factor (exponential)

Factor	SubFactor	Metric
<b>USAGE</b> (consumed resources -- active jobs only)	CONSUMED	processor-seconds dedicated to date
	REMAINING	processor-seconds outstanding
	PERCENT	percent of required walltime consumed
	EXECUTIONTIME	seconds since job started
<b>ATTR</b> (job attribute-based prioritization)	ATTRATTR	<a href="#">Attribute priority</a> if specified job attribute is set (attributes may be user-defined or one of <b>preemptor</b> , or <b>preemptee</b> ). Default is 0.
	ATTRSTATE	<a href="#">Attribute priority</a> if job is in specified state (see <a href="#">Job States</a> ). Default is 0.
	ATTRGRES	<a href="#">Attribute priority</a> if a <a href="#">generic resource</a> is requested. Default is 0.

**i** \*CAP parameters (**FSCAP**, for example) are available to limit the maximum absolute value of each priority component and subcomponent. If set to a positive value, a priority cap will bound priority component values in both the positive and negative directions.

**i** All \*CAP and \*WEIGHT parameters are specified as positive or negative integers. Non-integer values are not supported.

## Credential (CRED) Component

The credential component allows a site to prioritize jobs based on political issues such as the relative importance of certain groups or accounts. This allows direct political priorities to be applied to jobs.

The priority calculation for the credential component is as follows:

$$\text{Priority} += \text{CREDWEIGHT} * ( \text{USERWEIGHT} * \text{Job.User.Priority} + \text{GROUPWEIGHT} * \text{Job.Group.Priority} + \text{ACCOUNTWEIGHT} * \text{Job.Account.Priority} + \text{QOSWEIGHT} * \text{Job.Qos.Priority} + \text{CLASSWEIGHT} * \text{Job.Class.Priority} )$$

All user, group, account, QoS, and class weights are specified by setting the **PRIORITY** attribute of using the respective \*CFG parameter (namely, **USERCFG**, **GROUPCFG**, **ACCOUNTCFG**, **QOSCFG**, and **CLASSCFG**).

For example, to set user and group priorities, you might use the following:

```

CREDWEIGHT      1
USERWEIGHT      1
GROUPWEIGHT     1
USERCFG[john]   PRIORITY=2000
USERCFG[paul]   PRIORITY=-1000
GROUPCFG[staff] PRIORITY=10000

```

**i** Class (or queue) priority may also be specified via the resource manager where supported (as in PBS queue priorities). However, if Moab class priority values are also specified, the resource manager priority values will be overwritten.

All priorities may be positive or negative.

## Fairshare (FS) Component

Fairshare components allow a site to favor jobs based on short-term historical usage. The [Fairshare Overview](#) describes the configuration and use of fairshare in detail.

The fairshare factor is used to adjust a job's priority based on current and historical percentage system utilization of the job's user, group, account, class, or QoS. This allows sites to steer workload toward a particular usage mix across user, group, account, class, and QoS dimensions.

The fairshare priority factor calculation is as follows:

```

Priority += FSWEIGHT * MIN(FSCAP, (
  FSUSERWEIGHT * DeltaUserFSUsage +
  FSGROUPWEIGHT * DeltaGroupFSUsage +
  FSACCOUNTWEIGHT * DeltaAccountFSUsage +
  FSQOSWEIGHT * DeltaQOSFSUsage +
  FSCLASSWEIGHT * DeltaClassFSUsage +
  FSJPUWEIGHT * ActiveUserJobs +
  FSPPUWEIGHT * ActiveUserProcs +
  FSPSPUWEIGHT * ActiveUserPS +
  WCACCURACYWEIGHT * UserWCAccuracy ))

```

All **\*WEIGHT** parameters just listed are specified on a per partition basis in the `moab.cfg` file. The `Delta*Usage` components represent the difference in actual fairshare usage from the corresponding fairshare usage target. Actual fairshare usage is determined based on historical usage over the time frame specified in the fairshare configuration. The target usage can be a target, floor, or ceiling value as specified in the fairshare configuration file. See the [Fairshare Overview](#) for further information on configuring and tuning fairshare. Additional insight may be available in the [fairshare usage example](#). The `ActiveUser*` components represent current usage by the job's user credential.

How violated ceilings and floors affect fairshare-based priority

Moab determines `FSUsageWeight` in the previous section. In order to account for violated ceilings and floors, Moab multiplies that number by the `FSUsagePriority` as demonstrated in the following formula:

$$FSPriority = FSUsagePriority * FSUsageWeight$$

When a ceiling or floor is violated, `FSUsagePriority = 0`, so `FSPriority = 0`. This means the job will gain no priority because of fairshare. If fairshare is the only component of priority, then violation

takes the priority to 0. For more information, see [Priority-Based Fairshare on page 439](#) and [Fairshare Targets on page 436](#).

## Resource (RES) Component

Weighting jobs by the amount of resources requested allows a site to favor particular types of jobs. Such prioritization may allow a site to better meet site mission objectives, improve fairness, or even improve overall system utilization.

Resource based prioritization is valuable when you want to favor jobs based on the resources requested. This is good in three main scenarios: (1) when you need to favor large resource jobs because it's part of your site's mission statement, (2) when you want to level the response time distribution across large and small jobs (small jobs are more easily backfilled and thus generally have better turnaround time), and (3) when you want to improve system utilization. While this may be surprising, system utilization actually increases as large resource jobs are pushed to the front of the queue. This keeps the smaller jobs in the back where they can be selected for backfill and thus increase overall system utilization. The situation is like the story about filling a cup with golf balls and sand. If you put the sand in first, it gets in the way and you are unable to put in as many golf balls. However, if you put in the golf balls first, the sand can easily be poured in around them completely filling the cup.

The calculation for determining the total resource priority factor is as follows:

$$\text{Priority} += \text{RESWEIGHT} * \text{MIN}(\text{RESCAP}, ($$

$$\text{NODEWEIGHT} * \text{TotalNodesRequested} +$$

$$\text{PROCWEIGHT} * \text{TotalProcessorsRequested} +$$

$$\text{MEMWEIGHT} * \text{TotalMemoryRequested} +$$

$$\text{SWAPWEIGHT} * \text{TotalSwapRequested} +$$

$$\text{DISKWEIGHT} * \text{TotalDiskRequested} +$$

$$\text{WALLTIMEWEIGHT} * \text{TotalWalltimeRequested} +$$

$$\text{PEWEIGHT} * \text{TotalPERequested}))$$

The sum of all weighted resources components is then multiplied by the **RESWEIGHT** parameter and capped by the **RESCAP** parameter. Memory, Swap, and Disk are all measured in megabytes (MB). The final resource component, PE, represents [Processor Equivalents](#). This component can be viewed as a processor-weighted maximum *percentage of total resources* factor.

For example, if a job requested 25% of the processors and 50% of the total memory on a 128-processor system, it would have a PE value of  $\text{MAX}(25,50) * 128$ , or 64. The concept of PEs is a highly effective metric in shared resource systems.

Ideal values for requested job processor count and walltime can be specified using [PRIORITYTARGETPROCCOUNT](#) and [PRIORITYTARGETDURATION](#).

## Service (SERVICE) Component

The Service component specifies which service metrics are of greatest value to the site. Favoring one service subcomponent over another generally improves that service metric.

The priority calculation for the service priority factor is as follows:

$$\text{Priority} += \text{SERVICEWEIGHT} * ($$

$$\text{QUEUETIMEWEIGHT} * \langle \text{QUEUETIME} \rangle +$$

[XFACTORWEIGHT](#) \* <XFACTOR> +  
[BYPASSWEIGHT](#) \* <BYPASSCOUNT> +  
[STARTCOUNTWEIGHT](#) \* <STARTCOUNT> +  
[DEADLINEWEIGHT](#) \* <DEADLINE> +  
[SPVIOLATIONWEIGHT](#) \* <SPBOOLEAN> +  
[USERPRIOWEIGHT](#) \* <USERPRIO> )

## QueueTime (QUEUE TIME) Subcomponent

In the priority calculation, a job's queue time is a duration measured in minutes. Using this subcomponent tends to prioritize jobs in a FIFO order. Favoring queue time improves queue time based fairness metrics and is probably the most widely used single job priority metric. In fact, under the initial default configuration, this is the only priority subcomponent enabled within Moab. It is important to note that within Moab, a job's queue time is not necessarily the amount of time since the job was submitted. The parameter [JOBPRIOACCRUALPOLICY](#) allows a site to select how a job will accrue queue time based on meeting various [throttling policies](#). Regardless of the policy used to determine a job's queue time, this effective queue time is used in the calculation of the [QUEUE TIME](#), [XFACTOR](#), [TARGET QUEUE TIME](#), and [TARGET XFACTOR](#) priority subcomponent values.

The need for a distinct effective queue time is necessitated by the fact that many sites have users who like to work the system, whatever system it happens to be. A common practice at some long existing sites is for some users to submit a large number of jobs and then place them on hold. These jobs remain with a hold in place for an extended period of time and when the user is ready to run a job, the needed executable and data files are linked into place and the hold released on one of these pre-submitted jobs. The extended hold time guarantees that this job is now the highest priority job and will be the next to run. The use of the [JOBPRIOACCRUALPOLICY](#) parameter can prevent this practice and prevent "queue stuffers" from doing similar things on a shorter time scale. These "queue stuffer" users submit hundreds of jobs at once to swamp the machine and consume use of the available compute resources. This parameter prevents the user from gaining any advantage from stuffing the queue by not allowing these jobs to accumulate any queue time based priority until they meet certain idle and active Moab fairness policies (such as max job per user and max idle job per user).

As a final note, you can adjust the [QUEUE TIME WEIGHT](#) parameter on a per QoS basis using the [QOSCFG](#) parameter and the [QTWEIGHT](#) attribute. For example, the line [QOSCFG\[\*special\*\] QTWEIGHT=5000](#) causes jobs using the QoS *special* to have their queue time subcomponent weight increased by 5000.

## Expansion Factor (XFACTOR) Subcomponent

The expansion factor subcomponent has an effect similar to the queue time factor but favors shorter jobs based on their requested wallclock run time. In its traditional form, the expansion factor (XFactor) metric is calculated as follows:

$$\text{XFACTOR} = 1 + \frac{\langle \text{QUEUE TIME} \rangle}{\langle \text{EXECUTION TIME} \rangle}$$

However, a couple of aspects of this calculation make its use more difficult. First, the length of time the job will actually run—[EXECUTION TIME](#)—is not actually known until the job completes. All that is known is how much time the job requests. Secondly, as described in the [Queue Time Subcomponent](#) section, Moab does not necessarily use the raw time since job submission to determine [QUEUE TIME](#) to prevent various scheduler abuses. Consequently, Moab uses the following modified equation:

$$\text{XFACTOR} = 1 + \frac{\langle \text{EFF QUEUE TIME} \rangle}{\langle \text{WALLCLOCK LIMIT} \rangle}$$

In the equation Moab uses, <EFFQUEUEETIME> is the effective queue time subject to the [JOBPRIOACCRUALPOLICY](#) parameter and <WALLCLOCKLIMIT> is the user—or system—specified job wallclock limit.

Using this equation, it can be seen that short running jobs will have an XFactor that will grow much faster over time than the xfactor associated with long running jobs. The following table demonstrates this favoring of short running jobs:

Job Queue Time	1 hour	2 hours	4 hours	8 hours	16 hours
<b>XFactor for 1 hour job</b>	$1 + (1 / 1) = 2.00$	$1 + (2 / 1) = 3.00$	$1 + (4 / 1) = 5.00$	$1 + (8 / 1) = 9.00$	$1 + (16 / 1) = 17.0$
<b>XFactor for 4 hour job</b>	$1 + (1 / 4) = 1.25$	$1 + (2 / 4) = 1.50$	$1 + (4 / 4) = 2.00$	$1 + (8 / 4) = 3.00$	$1 + (16 / 4) = 5.0$

Since XFactor is calculated as a ratio of two values, it is possible for this subcomponent to be almost arbitrarily large, potentially swamping the value of other priority subcomponents. This can be addressed either by using the subcomponent cap [XFACTORCAP](#), or by using the [XFMINWCLIMIT](#) parameter. If the latter is used, the calculation for the XFactor subcomponent value becomes:

$$XFACTOR = 1 + \text{<EFFQUEUEETIME>} / \text{MAX(}<XFMINWCLIMIT>, \text{<WALLCLOCKLIMIT>)}$$

Using the [XFMINWCLIMIT](#) parameter allows a site to prevent very short jobs from causing the XFactor subcomponent to grow inordinately.

Some sites consider XFactor to be a more fair scheduling performance metric than queue time. At these sites, job XFactor is given far more weight than job queue time when calculating job priority and job XFactor distribution consequently tends to be fairly level across a wide range of job durations. (That is, a flat XFactor distribution of 1.0 would result in a one-minute job being queued on average one minute, while a 24-hour job would be queued an average of 24 hours.)

Like queue time, the effective XFactor subcomponent weight is the sum of two weights, the [XFACTORWEIGHT](#) parameter and the QoS-specific XFWEIGHT setting. For example, the line [QOSCFG \[special\] XFWEIGHT=5000](#) causes jobs using the QoS *special* to increase their expansion factor subcomponent weight by 5000.

### Bypass (BYPASS) Subcomponent

The bypass factor is based on the bypass count of a job where the bypass count is increased by one every time the job is bypassed by a lower priority job via backfill. Backfill starvation has never been reported, but if encountered, use the BYPASS subcomponent.

### StartCount (STARTCOUNT) Subcomponent

Apply the startcount factor to sites with trouble starting or completing due to policies or failures. The primary causes of an idle job having a startcount greater than zero are resource manager level job start failure, administrator based requeue, or requeue based preemption.

## Deadline (DEADLINE) Subcomponent

The deadline factor allows sites to take into consideration the proximity of a job to its [DEADLINE](#). As a jobs moves closer to its deadline its priority increases linearly. This is an alternative to the strict deadline discussed in [QOS SERVICE](#).

## Soft Policy Violation (SPVIOLATION) Subcomponent

The soft policy violation factor allows sites to favor jobs which do not violate their associated [soft resource limit policies](#).

## User Priority (USERPRIO) Subcomponent

The user priority subcomponent allows sites to consider end-user specified job priority in making the overall job priority calculation. Under Moab, end-user specified priorities may only be negative and are bounded in the range 0 to -1024. See [Manual Priority Usage](#) and [Enabling End-user Priorities](#) for more information.

User priorities can be positive, ranging from -1024 to 1023, if [ENABLEPOSUSERPRIORITY](#) TRUE is specified in `moab.cfg`.

## Target Service (TARG) Component

The target factor component of priority takes into account job scheduling performance targets. Currently, this is limited to target expansion factor and target queue time. Unlike the expansion factor and queue time factors described earlier which increase gradually over time, the target factor component is designed to grow exponentially as the target metric is approached. This behavior causes the scheduler to do essentially all in its power to make certain the scheduling targets are met.

The priority calculation for the target factor is as follows:

$$\text{Priority} += \frac{\text{TARGETWEIGHT}}{\text{TARGETQUEUE TIMEWEIGHT}} * \text{QueueTimeComponent} + \frac{\text{TARGETXFACTORWEIGHT}}{\text{TARGETXFACTORWEIGHT}} * \text{XFactorComponent}$$

The queue time and expansion factor target are specified on a per QoS basis using the **XFTARGET** and **QTTARGET** attributes with the [QOSCFG](#) parameter. The QueueTime and XFactor component calculations are designed to produce small values until the target value begins to approach, at which point these components grow very rapidly. If the target is missed, this component remains high and continues to grow, but it does not grow exponentially.

## Usage (USAGE) Component

The Usage component applies to active jobs only. The priority calculation for the usage priority factor is as follows:

$$\text{Priority} += \frac{\text{USAGEWEIGHT}}{\text{USAGECONSUMEDWEIGHT}} * \text{ProcSecondsConsumed} + \frac{\text{USAGEHUNGERWEIGHT}}{\text{USAGEHUNGERWEIGHT}} * \text{ProcNeededToBalanceDynamicJob} + \frac{\text{USAGEREMAININGWEIGHT}}{\text{USAGEREMAININGWEIGHT}} * \text{ProcSecRemaining} +$$

[USAGEEXECUTIONTIMEWEIGHT](#) \* SecondsSinceStart +  
[USAGEPERCENTWEIGHT](#) \* WalltimePercent )

## Job Attribute (ATTR) Component

The Attribute component allows the incorporation of job attributes into a job's priority. The most common usage for this capability is to do one of the following:

- adjust priority based on a job's state (favor suspended jobs)
- adjust priority based on a job's requested node features (favor jobs that request attribute **pvfs**)
- adjust priority based on internal job attributes (disfavor **backfill** or **preemptee** jobs)
- adjust priority based on a job's requested licenses, network consumption, or generic resource requirements

To use job attribute based prioritization, the [JOBPRIOF](#) parameter must be specified to set corresponding attribute priorities. To favor jobs based on node feature requirements, the parameter [NODETOJOBATTRMAP](#) must be set to map node feature requests to job attributes.

The priority calculation for the attribute priority factor is as follows:

Priority += [ATTRWEIGHT](#) \* (  
[ATTRATTRWEIGHT](#) \* <ATTRPRIORITY> +  
[ATTRSTATEWEIGHT](#) \* <STATEPRIORITY> +  
[ATTRGRESWEIGHT](#) \* <GRESPRIORITY>  
[JOBIDWEIGHT](#) \* <JOBID> +  
[JOBNAMEWEIGHT](#) \* <JOBNAME\_INTEGER> )

Example 3-88:

```
ATTRWEIGHT      100
ATTRATTRWEIGHT  1
ATTRSTATEWEIGHT 1
ATTRGRESWEIGHT  5
# favor suspended jobs
# disfavor preemptible jobs
# favor jobs requesting 'matlab'

JOBPRIOF STATE[Running]=100 STATE[Suspended]=1000 ATTR[PREEMPTEE]=-200 ATTR[gpfs]
=30 GRES[matlab]=400
# map node features to job features

NODETOJOBATTRMAP gpfs,pvfs
...
```

## Fairshare Job Priority Example

Consider the following information associated with calculating the fairshare factor for job X.

Job X

User A  
 Group B  
 Account C  
 QOS D  
 Class E

User A

Fairshare Target: 50.0  
 Current Fairshare Usage: 45.0

Group B

Fairshare Target: [NONE]  
 Current Fairshare Usage: 65.0

Account C

Fairshare Target: 25.0  
 Current Fairshare Usage: 35.0

QOS D

Fairshare Target: 10.0+  
 Current Fairshare Usage: 25.0

Class E

Fairshare Target: [NONE]  
 Current Fairshare Usage: 20.0

Priority Weights:

FSWEIGHT 100  
 FSUSERWEIGHT 10  
 FSGROUPWEIGHT 20  
 FSACCOUNTWEIGHT 30  
 FSQOSWEIGHT 40  
 FSCLASSWEIGHT 0

In this example, the Fairshare component calculation would be as follows:

$$\text{Priority} += 100 * ( 10 * 5 + 20 * 0 + 30 * (-10) + 40 * 0 + 0 * 0 )$$

User A is 5% below his target so fairshare increases the total fairshare factor accordingly. Group B has no target so group fairshare usage is ignored. Account C is 10% above its fairshare usage target so this component decreases the job's total fairshare factor. QOS D is 15% over its target but the '+' in the target specification indicates that this is a 'floor' target, only influencing priority when fairshare usage drops below the target value. Thus, the QOS D fairshare usage delta does not influence the fairshare factor.

Fairshare is a great mechanism for influencing job turnaround time via priority to favor a particular distribution of jobs. However, it is important to realize that fairshare can only favor a particular

distribution of jobs, it cannot force it. If user X has a fairshare target of 50% of the machine but does not submit enough jobs, no amount of priority favoring will get user X's usage up to 50%.

See the [Fairshare Overview](#) for more information.

## Common Priority Usage

- [Credential Priority Factors](#)
- [Service Level Priority Factors](#)
- [Priority Factor Caps](#)
- [User Selectable Prioritization](#)

Site administrators vary widely in their preferred manner of prioritizing jobs. Moab's scheduling hierarchy allows sites to meet job control needs without requiring adjustments to dozens of parameters. Some choose to use numerous subcomponents, others a few, and still others are content with the default FIFO behavior. Any subcomponent that is not of interest may be safely ignored.

## Credential Priority Factors

To help clarify the use of priority weights, a brief example may help. Suppose a site wished to maintain the FIFO behavior but also incorporate some credential based prioritization to favor a special user. Particularly, the site would like the user *john* to receive a higher initial priority than all other users. Configuring this behavior requires two steps. First, the user credential subcomponent must be enabled and second, *john* must have his relative priority specified. Take a look at the sample `moab.cfg` file:

```
USERWEIGHT      1
USERCFG[john]   PRIORITY=300
```

**i** The "USER" priority subcomponent was enabled by setting the [USERWEIGHT](#) parameter. In fact, the parameters used to specify the weights of all components and subcomponents follow this same "\*WEIGHT" naming convention (as in [RESWEIGHT](#) and [TARGETQUEUEWEIGHT](#)).

The second part of the example involves specifying the actual user priority for the user *john*. This is accomplished using the [USERCFG](#) parameter. Why was the priority 300 selected and not some other value? Is this value arbitrary? As in any priority system, actual priority values are meaningless, only relative values are important. In this case, we are required to balance user priorities with the default queue time based priorities. Since queue time priority is measured in minutes queued, the user priority of 300 places a job by user *john* on par with a job submitted 5 minutes earlier by another user.

Is this what the site wants? Maybe, maybe not. At the onset, most sites are uncertain what they want in prioritization. Often, an estimate initiates prioritization and adjustments occur over time. Cluster resources evolve, the workload evolves, and even site policies evolve, resulting in changing priority needs over time. Anecdotal evidence indicates that most sites establish a relatively stable priority policy within a few iterations and make only occasional adjustments to priority weights from that point.

## Service Level Priority Factors

In another example, suppose a site administrator wants to do the following:

- favor jobs in the low, medium, and high QoSs so they will run in QoS order
- balance job expansion factor
- use job queue time to prevent jobs from starving

Under such conditions, the sample `moab.cfg` file might appear as follows:

```

QOSWEIGHT          1
XFACTORWEIGHT      1
QUEUEUETIMEWEIGHT 10
TARGETQUEUEUETIMEWEIGHT 1
QOSCFG [low]        PRIORITY=1000
QOSCFG [medium]     PRIORITY=10000
QOSCFG [high]       PRIORITY=100000
QOSCFG [DEFAULT]   QTTARGET=4:00:00

```

This example is a bit more complicated but is more typical of the needs of many sites. The desired QoS weightings are established by enabling the QoS subfactor using the `QOSWEIGHT` parameter while the various QoS priorities are specified using `QOSCFG`. `XFACTORWEIGHT` is then set as this subcomponent tends to establish a balanced distribution of expansion factors across all jobs. Next, the queue time component is used to gradually raise the priority of all jobs based on the length of time they have been queued. Note that in this case, `QUEUEUETIMEWEIGHT` was explicitly set to 10, overriding its default value of 1. Finally, the `TARGETQUEUEUETIMEWEIGHT` parameter is used in conjunction with the `USERCFG` line to specify a queue time target of 4 hours.

## Priority Factor Caps

Assume now that the site administrator is content with this priority mix but has a problem with users submitting large numbers of very short jobs. Very short jobs would tend to have rapidly growing XFactor values and would consequently quickly jump to the head of the queue. In this case, a factor cap would be appropriate. Such caps allow a site to limit the contribution of a job's priority factor to be within a defined range. This prevents certain priority factors from swamping others. Caps can be applied to either priority components or subcomponents and are specified using the `<COMPONENTNAME>CAP` parameter (such as `QUEUEUETIMECAP`, `RESCAP`, and `SERVCAP`). Note that both component and subcomponent caps apply to the pre-weighted value, as in the following equation:

```

Priority =
  C1WEIGHT * MIN(C1CAP, SUM(
    S11WEIGHT * MIN(S11CAP, S11S) +
    S12WEIGHT * MIN(S12CAP, S12S) +
    ...)) +
  C2WEIGHT * MIN(C2CAP, SUM(
    S21WEIGHT * MIN(S21CAP, S21S) +
    S22WEIGHT * MIN(S22CAP, S22S) +
    ...)) +
  ...

```

*Example 3-89: Priority cap*

```

QOSWEIGHT      1
QOSCAP         10000
XFACTORWEIGHT  1
XFACTORCAP     1000
QUEUE TIMEWEIGHT 10
QUEUE TIMECAP  1000

```

## User Selectable Prioritization

Moab allows users to specify a job priority to jobs they own or manage. This priority may be set at job submission time or it may be dynamically modified (using [setspri](#) or [mjobctl](#)) after submitting the job. For fairness reasons, users may only apply a negative priority to their job and thus slide it further back in the queue. This enables users to allow their more important jobs to run before their less important ones without gaining unfair advantage over other users.

**i** User priorities can be positive if [ENABLEPOSUSERPRIORITY](#) TRUE is specified in `moab.cfg`. In order to set **ENABLEPOSUSERPRIORITY**, you must change the [USERPRIOWEIGHT](#) from its default value of 0. For example:

```
USERPRIOWEIGHT 100
```

```
> setspri -r 100 332411
successfully modified job priority
```

**i** Specifying a user priority at job submission time is resource manager specific. See the associated resource manager documentation for more information.

## User Selectable Priority w/QoS

Using the [QoS](#) facility, organizations can set up an environment in which users can more freely select the desired priority of a given job. Organizations may enable access to a number of QoSs each with its own charging rate, priority, and target service levels. Users can then assign job importance by selecting the appropriate QoS. If desired, this can allow a user to jump ahead of other users in the queue if they are willing to pay the associated costs.

### Related topics

- [User Selectable Priority](#)

## Prioritization Strategies

Each component or subcomponent may be used to accomplish different objectives. **WALLTIME** can be used to favor (or disfavor) jobs based on their duration. Likewise, **ACCOUNT** can be used to favor jobs associated with a particular project while **QUEUE TIME** can be used to favor those jobs waiting the longest.

- Queue Time
- Expansion Factor
- Resource
- Fairshare
- Credential
- Target Metrics

Each priority factor group may contain one or more subfactors. For example, the Resource factor consists of Node, Processor, Memory, Swap, Disk, and PE components. From the table in [Job Priority Factors](#) section, it is apparent that the prioritization problem is fairly complex since every site needs to prioritize a bit differently. When calculating a priority, the various priority factors are summed and then bounded between 0 and MAX\_PRIO\_VAL, which is currently defined as 100000000 (one billion).

The [mdiag -p](#) command assists with visualizing the priority distribution resulting from the current job priority configuration. Also, the [showstats -f](#) command helps indicate the impact of the current priority settings on scheduler service distributions.

## Manual Job Priority Adjustment

Batch administrator's regularly find a need to adjust the calculated priority of a job to meet current needs. Current needs often are broken into two categories:

1. The need to run an administrator test job as soon as possible.
2. The need to pacify a disserved user.

You can use the [setspri](#) command to handle these issues in one of two ways; this command allows the specification of either a relative priority adjustment or the specification of an absolute priority. Using absolute priority specification, administrators can set a job priority guaranteed to be higher than any calculated value. Where Moab-calculated job priorities are in the range of 0 to 1 billion, system administrator assigned absolute priorities start at 1 billion and go up. Issuing the `setspri <PRIO> <JOBID>` command, for example, assigns a priority of 1 billion + <PRIO> to the job. Thus, `setspri 5 job.1294` sets the priority of "job.1294" to 1000000005.

For more information, see [Common Priority Usage - End-user Adjustment](#).

## Node Allocation Policies

While job prioritization allows a site to determine which job to run, node allocation policies allow a site to specify how available resources should be allocated to each job. The algorithm used is specified by the parameter [NODEALLOCATIONPOLICY](#). There are multiple node allocation policies to choose from allowing selection based on reservation constraints, node configuration, resource usage, preferred other factors. You can specify these policies with a system-wide default value, on a per-partition basis, or on a per-job basis. Please note that **LASTAVAILABLE** is the default policy.

Available algorithms are described in detail in the following sections and include [FIRSTAVAILABLE](#), [LASTAVAILABLE](#), [PRIORITY](#), [CPULOAD](#), [MINRESOURCE](#), [CONTIGUOUS](#), [MAXBALANCE](#), [PLUGIN](#).

  - [Specifying Resource Preferences](#)
  - [Selecting Preferred Resources](#)

## Node Allocation Overview

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Making this decision intelligently is important in an environment that possesses one or more of the following attributes:

- heterogeneous resources (resources which vary from node to node in terms of quantity or quality)
- shared nodes (nodes may be utilized by more than one job)
- reservations or service guarantees
- non-flat network (a network in which a perceptible performance degradation may potentially exist depending on workload placement)

## Heterogeneous Resources

Moab analyzes job processing requirements and assigns resources to maximize hardware utility.

For example, suppose two nodes are available in a system, A and B. Node A has 768 MB of RAM and node B has 512 MB. The next two jobs in the queue are X and Y. Job X requests 256 MB and job Y requests 640

MB. Job X is next in the queue and can fit on either node, but Moab recognizes that job Y (640 MB) can only fit on node A (768 MB). Instead of putting job X on node A and blocking job Y, Moab can put job X on node B and job Y on node A.

## Shared Nodes

### *Symmetric Multiprocessing (SMP)*

When sharing SMP-based compute resources amongst tasks from more than one job, resource contention and fragmentation issues arise. In SMP environments, the general goal is to deliver maximum system utilization for a combination of compute-intensive and memory-intensive jobs while preventing overcommitment of resources.

By default, most current systems do not do a good job of logically partitioning the resources (such as CPU, memory, and network bandwidth) available on a given node. Consequently contention often arises between tasks of independent jobs on the node. This can result in a slowdown for all jobs involved, which can have significant ramifications if large-way parallel jobs are involved. Virtualization, CPU sets, and other techniques are maturing quickly as methods to provide logical partitioning within shared resources.

On large-way SMP systems (> 32 processors/node), job packing can result in intra-node fragmentation. For example, take two nodes, A and B, each with 64 processors. Assume they are currently loaded with various jobs and A has 24 and B has 12 processors free. Two jobs are submitted; job X requests 10 processors and job Y requests 20 processors. Job X can start on either node but starting it on node A prevents job Y from running. An algorithm to handle intra-node fragmentation is straightforward for a single resource case, but the algorithm becomes more involved when jobs request a combination of processors, memory, and local disk. These workload factors should be considered when selecting a site's node allocation policy as well as identifying appropriate policies for handling resource utilization limit violations.

### *Interactive Nodes*

In many cases, sites are interested in allowing multiple users to simultaneously use one or more nodes for interactive purposes. Workload is commonly not compute intensive consisting of intermittent tasks including coding, compiling, and testing. Because these jobs are highly variant in terms of resource usage over time, sites are able to pack a larger number of these jobs onto the same node. Consequently, a common practice is to restrict job scheduling based on utilized, rather than dedicated resources.

### *Interactive Node Example*

The example configuration files that follow show one method by which node sharing can be accomplished within a [TORQUE](#) + Moab environment. This example is based on a hypothetical cluster composed of 4 nodes each with 4 cores. For the compute nodes, job tasks are limited to actual cores preventing overcommitment of resources. For the interactive nodes, up to 32 job tasks are allowed, but the node also stops allowing additional tasks if either memory is fully utilized or if the CPU load exceeds 4.0. Thus, Moab continues packing the interactive nodes with jobs until carrying capacity is reached.

*Example 3-90: /opt/moab/etc/moab.cfg*

```
# constrain interactive jobs to interactive nodes
# constrain interactive jobs to 900 proc-seconds
CLASSCFG[interactive]  HOSTLIST=interactive01,interactive02
CLASSCFG[interactive]  MAX.CPUTIME=900
RESOURCELIMITPOLICY    CPUTIME:ALWAYS:CANCEL
# base interactive node allocation on load and jobs
NODEALLOCATIONPOLICY    PRIORITY
NODECFG[interactive01] PRIORITYF='-20*LOAD - JOBCOUNT'
NODECFG[interactive02] PRIORITYF='-20*LOAD - JOBCOUNT'
```

*Example 3-91: /var/spool/torque/server\_priv/nodes*

```
interactive01 np=32
interactive02 np=32
compute01    np=4
compute02    np=4
```

*Example 3-92: /var/spool/torque/mom\_priv/config on "interactive01"*

```
# interactive01
$max_load 4.0
```

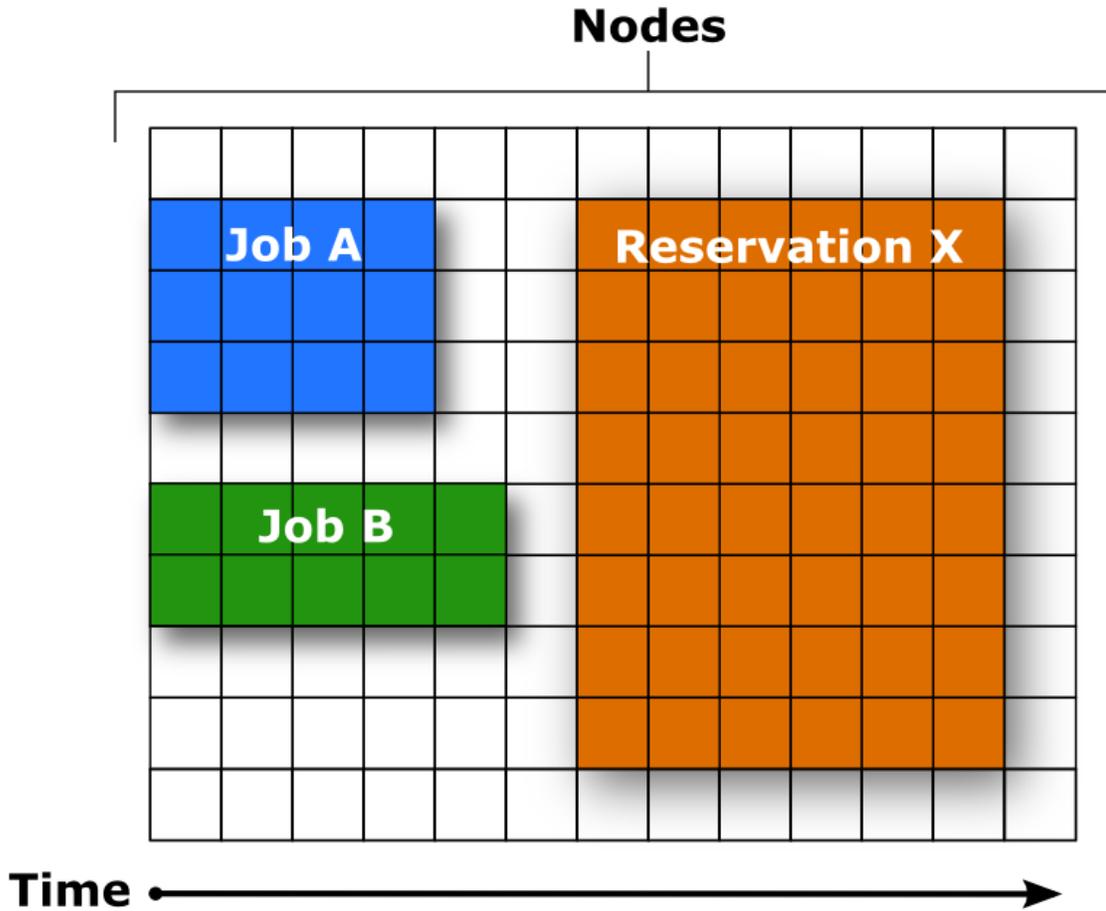

*Example 3-93: /var/spool/torque/mom\_priv/config on "interactive02"*

```
# interactive02
$max_load 4.0
```

**Reservations or Service Guarantees**

A reservation-based system adds the time dimension into the node allocation decision. With reservations, node resources must be viewed in a type of two dimension node-time space. Allocating nodes to jobs fragments this node-time space and makes it more difficult to schedule jobs in the remaining, more constrained node-time slots. Allocation decisions should be made in such a way as to minimize this fragmentation and maximize the scheduler's ability to continue to start jobs in existing slots. The following figure shows that job A and job B are running. A reservation, X, is created some time in the future. Assume that job A is 2 hours long and job B is 3 hours long. Again, two new single-processor jobs are submitted, C and D; job C requires 3 hours of compute time while job D requires 5 hours. Either job will just fit in the free space located above job A or in the free space located below job B. If job C is placed above job A, job D, requiring 5 hours of time will be prevented from running by the presence of reservation X. However, if job C is placed below job B, job D can still start immediately above job A.

Image 3-2: Job A, Job B, and Reservation X scheduled on nodes

The preceding example demonstrates the importance of time based reservation information in making node allocation decisions, both at the time of starting jobs and at the time of creating reservations. The impact of time based issues grows significantly with the number of reservations in place on a given system. The **LASTAVAILABLE** algorithm works on this premise, locating resources that have the smallest space between the end of a job under consideration and the start of a future reservation.

### Non-flat Network

On systems where network connections do not resemble a flat all-to-all topology, task placement may impact performance of communication intensive parallel jobs. If latencies and network bandwidth between any two nodes vary significantly, the node allocation algorithm should attempt to pack tasks of a given job as close to each other as possible to minimize impact of bandwidth and latency differences.

## Node selection factors

While the node allocation policy determines which nodes a job will use, other factors narrow the options before the policy makes the final decision. The following process demonstrates how Moab executes its node allocation process and how other policies affect the decision:

1. Moab eliminates nodes that do not meet the hard resource requirements set by the job.
2. Moab gathers affinity information, first from workload proximity rules and then from reservation affinity rules (See [Affinity on page 485](#) for more information.). Reservation affinity rules trump workload proximity rules.
3. Moab allocates nodes using the allocation policy.
  - If more than enough nodes with Required affinity exist, only they are passed down for the final sort by the node allocation policy.
  - If the number of nodes with Required affinity matches the number of nodes requested exactly, then the node allocation policy is skipped entirely and all of those nodes are assigned to the job.
  - If too few nodes have Required affinity, all of them are assigned to the job, then the node allocation policy is applied to the remaining eligible nodes (after Required, Moab will use Positive, then Neutral, then Negative.).

## Resource-Based Algorithms

Moab contains a number of allocation algorithms that address some of the needs described earlier. You can also create allocation algorithms and interface them with the Moab scheduling system. Each of these policies has a name and descriptive alias. They can be configured using either one, but Moab will only report their names.

**i** If [ENABLEHIGHTHROUGHPUT on page 950](#) is *TRUE*, you must set [NODEALLOCATIONPOLICY on page 999](#) to *FIRSTAVAILABLE*.

The current suite of algorithms is described in what follows:

Allocation algorithm name	Alias	Description
<b>CPULOAD</b>	ProcessorLoad	Nodes are selected that have the maximum amount of available, unused CPU power (<#of CPU's> - <CPU load>). CPULOAD is a good algorithm for timesharing node systems and applies to jobs starting immediately. For the purpose of future reservations, the MINRESOURCE algorithm is used.
<b>FIRSTAVAILABLE</b>	InReportedOrder	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, and very fast algorithm.

Allocation algorithm name	Alias	Description
<b>LASTAVAILABLE</b>	InReserveReportedOrder	Nodes are allocated in descending order that they are presented by the resource manager, or the reverse of FIRSTAVAILABLE.

Allocation algorithm name	Alias	Description
<b>PRIORITY</b>	CustomPriority	<p>Allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity. Using node allocation priority, you can specify the following priority components:</p> <ul style="list-style-type: none"> <li>• <b>ADISK</b> - Local disk currently available to batch jobs in MB.</li> <li>• <b>AMEM</b> - Real memory currently available to batch jobs in MB.</li> <li>• <b>APROCS</b> - Processors currently available to batch jobs on node (configured procs - dedicated procs).</li> <li>• <b>ARCH[&lt;ARCH&gt;]</b> - Processor architecture.</li> <li>• <b>ASWAP</b> - Virtual memory currently available to batch jobs in MB.</li> <li>• <b>CDISK</b> - Total local disk allocated for use by batch jobs in MB.</li> <li>• <b>CMEM</b> - Total real memory on node in MB.</li> <li>• <b>COST</b> - Based on node <b>CHARGERATE</b>.</li> <li>• <b>CPROCS</b> - Total processors on node.</li> <li>• <b>CSWAP</b> - Total virtual memory configured on node in MB.</li> <li>• <b>FEATURE[&lt;FNAME&gt;]</b> - Boolean; specified feature is present on node.</li> <li>• <b>FREETIME</b> - FREETIME is calculated as the time during which there is no reservation on the machine. It uses either the job wallclock limit (if there is a job), or 2 months. The more free time a node has within either the job wallclock limit or 2 months, the higher this value will be.</li> <li>• <b>GMETRIC[&lt;GMNAME&gt;]</b> - Current value of specified generic metric on node.</li> <li>• <b>JOB COUNT</b> - Number of jobs currently running on node.</li> <li>• <b>JOB FREETIME</b> - The number of seconds that the node is idle between now and when the job is scheduled to start.</li> <li>• <b>LOAD</b> - Current 1 minute load average.</li> <li>• <b>MTBF</b> - Mean time between failures (in seconds).</li> <li>• <b>NODEINDEX</b> - Node's nodeindex as specified by the resource manager.</li> <li>• <b>OS</b> - True if job compute requirements match node operating system.</li> <li>• <b>PARAPROCS</b> - Processors currently available to batch jobs within partition (configured procs - dedicated procs).</li> <li>• <b>POWER</b> - TRUE if node is ON.</li> <li>• <b>PREF</b> - Boolean; node meets job specific resource preferences.</li> <li>• <b>PRIORITY</b> - Administrator specified node priority.</li> <li>• <b>RANDOM</b> - Per iteration random value between 0 and 1. (Allows introduction of random allocation factor.)</li> </ul>

Allocation algorithm name	Alias	Description
		<p><i>Example 5:</i> Pack tasks onto nodes with the most processors available and the lowest CPU temperature.</p> <pre> RMCFG[torque] TYPE=pbs RMCFG[temp] TYPE=NATIVE CLUSTERQUERYURL=exec://\$TOOLS DIR/hwmon.pl NODEALLOCATIONPOLICY PRIORITY NODECFG[DEFAULT] PRIORITYF='100*APROCS - GMETRIC[temp] ... </pre>
<b>MINRESOURCE</b>	Min-imumCon-figuredResources	Prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources that still meet the job's resource constraints are selected.
<b>CONTIGUOUS</b>	Contiguous	Allocates nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	ProcessorSpeedBalance	Attempts to allocate the most balanced set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node procspeed. Thus, if possible, nodes with identical procspeeds are allocated to the job. If identical procspeed nodes cannot be found, the algorithm allocates the set of nodes with the minimum node procspeed span or range.

## User-Defined Algorithms

User-defined algorithms allow administrators to define their own algorithms based on factors such as their system's network topology. When node allocation is based on topology, jobs finish faster, administrators see better cluster productivity and users pay less for resources.

### PLUGIN

This algorithm allows administrators to define their own node allocation policy and create a plug-in that allocates nodes based on factors such as a cluster's network topology. This has the following advantages:

- plug-ins keep the source code of the cluster's interconnect network for node allocation separate from Moab's source code (customers can implement plug-ins independent of Moab's release schedule)
- plug-ins can be independently created and tailored to specific hardware and network topology
- plug-ins can be modified without assistance from Adaptive Computing, Inc.

## Specifying *Per Job* Resource Preferences

While the resource based node allocation algorithms can make a good guess at what compute resources would best satisfy a job, sites often possess a subset of jobs that benefit from more explicit resource allocation specification. For example one job may perform best on a particular subset of nodes due to direct access to a tape drive, another may be very memory intensive. Resource preferences are distinct from node requirements. While the former describes what a job needs to run at all, the latter describes what the job needs to run well. In general, a scheduler must satisfy a job's node requirement specification and then satisfy the job's resource preferences as well as possible.

### Specifying Resource Preferences

A number of resource managers natively support the concept of resource preferences (such as Loadleveler). When using these systems, the language specific preferences keywords may be used. For systems that do not support resource preferences natively, Moab provides a [resource manager extension](#) keyword, "[PREF](#)," which you can use to specify desired resources. This extension allows specification of node features, memory, swap, and disk space conditions that define whether the node is considered preferred.

 Moab 5.2 (and earlier) only supports feature-based preferences.

### Selecting Preferred Resources

Enforcing resource preferences is not completely straightforward. A site may have a number of potentially conflicting requirements that the scheduler is asked to simultaneously satisfy. For example, a scheduler may be asked to maximize the proximity of the allocated nodes at the same time it is supposed to satisfy resource preferences and minimize node overcommitment. To allow site specific weighting of these varying requirements, Moab allows resource preferences to be enabled through the [PRIORITY](#) node allocation algorithm. For example, to use resource preferences together with node load, the following configuration might be used:

```
NODEALLOCATIONPOLICY PRIORITY
NODECFG[DEFAULT]    PRIORITYF='5 * PREF - LOAD'
...
```

To request specific resource preferences, a user could then submit a job indicating those preferences. In the case of a PBS job, the following can be used:

```
> qsub -l nodes=4,walltime=1:00:00,pref=feature:fast
```

## Node Access Policies

Moab allocates resources to jobs on the basis of a job task—an atomic collection of resources that must be co-located on a single compute node. A given job may request 20 tasks where each task is defined as one processor and 128 MB of RAM. Compute nodes with multiple processors often possess enough resources to support more than one task simultaneously. When it is possible for more than one task to run on a node, node access policies determine which tasks may share the compute node's resources.

Moab supports a distinct number of node access policies that are listed in the following table:

Policy	Description
<b>SHARED</b>	Tasks from any combination of jobs may use available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may use available resources.
<b>SINGLEACCOUNT</b>	Tasks from any jobs owned by the same account may use available resources.
<b>SINGLEGROUP</b>	Tasks from any jobs owned by the same group may use available resources.
<b>SINGLEJOB</b>	Only tasks from a single job may use the node's resources.
<b>SINGLETASK</b>	Only a single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may use available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node. <b>UNIQUEUSER</b> limits the number of jobs a single user can run on a node, allowing other users to run jobs with the remaining resources.

 This policy is useful in environments where job epilog/prologs scripts are used to clean up processes based on userid.

## Configuring Node Access Policies

The global node access policies may be specified via the parameter [NODEACCESSPOLICY](#). This global default may be overridden on a per node basis with the [ACCESS](#) attribute of the [NODECFG](#) parameter or on a per job basis using the resource manager extension [NACCESSPOLICY](#). Finally, a per queue node access policy may also be specified by setting either the [NODEACCESSPOLICY](#) or [FORCENODEACCESSPOLICY](#) attributes of the [CLASSCFG](#) parameter. **FORCENODEACCESSPOLICY** overrides any per job specification in all cases, whereas **NODEACCESSPOLICY** is overridden by per job specification.

By default, nodes are accessible using the setting of the system wide **NODEACCESSPOLICY** parameter unless a specific **ACCESS** policy is specified on a per node basis using the **NODECFG** parameter. Jobs may override this policy and subsequent jobs are bound to conform to the access policies of all jobs currently

running on a given node. For example, if the **NODEACCESSPOLICY** parameter is set to **SHARED**, a new job may be launched on an idle node with a job specific access policy of **SINGLEUSER**. While this job runs, the effective node access policy changes to **SINGLEUSER** and subsequent job tasks may only be launched on this node provided they are submitted by the same user. When all single user jobs have completed on that node, the effective node access policy reverts back to **SHARED** and the node can again be used in **SHARED** mode.

For example, to set a global policy of **SINGLETASK** on all nodes except nodes 13 and 14, use the following:

```
# by default, enforce dedicated node access on all nodes
NODEACCESSPOLICY SINGLETASK
# allow nodes 13 and 14 to be shared
NODECFG[node13] ACCESS=SHARED
NODECFG[node14] ACCESS=SHARED
```

## Node Availability Policies

- [Node Resource Availability Policies](#)
- [Node Categorization](#)
- [Node Failure/Performance Based Notification](#)
- [Node Failure/Performance Based Triggers](#)
- [Handling Transient Node Failures](#)
- [Allocated Resource Failure Policy for Jobs on page 409](#)

Moab enables several features relating to node availability. These include policies that determine how per node resource availability should be reported, how node failures are detected, and what should be done in the event of a node failure.

### Node Resource Availability Policies

Moab allows a job to be launched on a given compute node as long as the node is not full or busy. The [NODEAVAILABILITYPOLICY](#) parameter allows a site to determine what criteria constitute a node being busy. The legal settings are listed in the following table:

Availability Policy	Description
<b>DEDICATED</b>	The node is considered busy if dedicated resources equal or exceed configured resources.

Availability Policy	Description
<b>UTILIZED</b>	The node is considered busy if utilized resources equal or exceed configured resources.
<b>COMBINED</b>	The node is considered busy if either dedicated or utilized resources equal or exceed configured resources.

The default setting for all nodes is **COMBINED**, indicating that a node can accept workload so long as the jobs that the node was allocated to do not request or use more resources than the node has available. In a load balancing environment, this may not be the desired behavior. Setting the **NODEAVAILABILITYPOLICY** parameter to **UTILIZED** allows jobs to be packed onto a node even if the aggregate resources requested exceed the resources configured. For example, assume a scenario with a 4-processor compute node and 8 jobs requesting 1 processor each. If the resource availability policy was set to **COMBINED**, this node would only allow 4 jobs to start on this node even if the jobs induced a load of less than 1.0 each. With the resource availability policy set to **UTILIZED**, the scheduler continues allowing jobs to start on the node until the node's load average exceeds a per processor load value of 1.0 (in this case, a total load of 4.0). To prevent a node from being over populated within a single scheduling iteration, Moab artificially raises the node's load for one scheduling iteration when starting a new job. On subsequent iterations, the actual measured node load information is used.

### Per Resource Availability Policies

By default, the **NODEAVAILABILITYPOLICY** sets a global per node resource availability policy. This policy applies to all resource types on each node such as processors, memory, swap, and local disk. However, the syntax of this parameter is as follows:

```
<POLICY> [ :<RESOURCETYPE> ] . . .
```

This syntax allows per resource availability specification. For example, consider the following:

```
NODEAVAILABILITYPOLICY DEDICATED:PROC COMBINED:MEM COMBINED:DISK
. . .
```

This configuration causes Moab to only consider the quantity of processing resources actually dedicated to active jobs running on each node and ignore utilized processor information (such as CPU load). For memory and disk, both utilized resource information and dedicated resource information should be combined to determine what resources are actually available for new jobs.

### Node Categorization

Moab allows organizations to detect and use far richer information regarding node status than the standard batch "idle," "busy," "down states" commonly found. Using node categorization, organizations can record, track, and report on per node and cluster level status including the following categories:

Category	Description
<b>Active</b>	Node is healthy and currently executing batch workload.
<b>BatchFailure</b>	Node is unavailable due to a failure in the underlying batch system (such as a resource manager server or resource manager node daemon).
<b>Benchmark</b>	Node is reserved for benchmarking.
<b>EmergencyMaintenance</b>	Node is reserved for unscheduled system maintenance.
<b>GridReservation</b>	Node is reserved for grid use.
<b>HardwareFailure</b>	Node is unavailable due to a failure in one or more aspects of its hardware configuration (such as a power failure, excessive temperature, memory, processor, or swap failure).
<b>HardwareMaintenance</b>	Node is reserved for scheduled system maintenance.
<b>Idle</b>	Node is healthy and is currently not executing batch workload.
<b>JobReservation</b>	Node is reserved for job use.
<b>NetworkFailure</b>	Node is unavailable due to a failure in its network adapter or in the switch.
<b>Other</b>	Node is in an uncategorized state.
<b>OtherFailure</b>	Node is unavailable due to a general failure.
<b>PersonalReservation</b>	Node is reserved for dedicated use by a personal reservation.
<b>Site[1-8]</b>	Site specified usage categorization.
<b>SoftwareFailure</b>	Node is unavailable due to a failure in a local software service (such as automounter, security or information service such as NIS, local databases, or other required software services).
<b>SoftwareMaintenance</b>	Node is reserved for software maintenance.
<b>StandingReservation</b>	Node is reserved by a standing reservation.

Category	Description
<b>StorageFailure</b>	Node is unavailable due to a failure in the cluster storage system or local storage infrastructure (such as failures in Lustre, GPFS, PVFS, or SAN).
<b>UserReservation</b>	Node is reserved for dedicated use by a particular user or group and may or may not be actively executing jobs.

Node categories can be explicitly assigned by cluster administrators using the [mrsvctl -c](#) command to create a reservation and associate a category with that node for a specified timeframe. Further, outside of this explicit specification, Moab automatically mines all configured interfaces to learn about its environment and the health of the resources it is managing. Consequently, Moab can identify many hardware failures, software failures, and batch failures without any additional configuration. However, it is often desirable to make additional information available to Moab to allow it to integrate this information into reports; automatically notify managers, users, and administrators; adjust internal policies to steer workload around failures; and launch various custom [triggers](#) to rectify or mitigate the problem.

**i** You can specify the [FORCERSVSUBTYPE](#) parameter to require all administrative reservations be associated with a node category at reservation creation time. For example:

```
NODECFG [DEFAULT] ENABLEPROFILING=TRUE
FORCERSVSUBTYPE TRUE
```

Node health and performance information from external systems can be imported into Moab using the [native resource manager interface](#). This is commonly done using [generic metrics](#) or [consumable generic resources](#) for performance and node categories or node variables for status information. Combined with arbitrary node messaging information, Moab can combine detailed information from remote services and report this to other external services.

**i** Use the [NODECATCREDLIST](#) parameter to generate extended node category based statistics.

## Node Failure/Performance Based Notification

Moab can be configured to cause node failures and node performance levels that cross specified thresholds to trigger notification events. This is accomplished using the [GEVENTCFG](#) parameter as described in the [Generic Event Overview](#) section. For example, the following configuration can be used to trigger an email to administrators each time a node is marked down.

```
GEVENTCFG [nodedown] ACTION=notify REARM=00:20:00
...
```

## Node Failure/Performance Based Triggers

Moab supports per node triggers that can be configured to fire when specific events are fired or specific thresholds are met. These triggers can be used to modify internal policies or take external actions. A few

examples follow:

- decrease node allocation priority if node throughput drops below threshold X
- launch local diagnostic/recovery script if parallel file system mounts become stale
- reset high performance network adapters if high speed network connectivity fails
- create general system reservation on node if processor or memory failure occurs

As mentioned, Moab triggers can be used to initiate almost any action, from sending mail to updating a database, to publishing data for an SNMP trap, to driving a web service.

## Handling Transient Node Failures

Since Moab actively schedules both current and future actions of the cluster, it is often important for it to have a reasonable estimate of when failed nodes will be again available for use. This knowledge is particularly useful for proper scheduling of new jobs and management of resources in regard to [backfill](#). With backfill, Moab determines which resources are available for priority jobs and when the highest priority idle jobs can run. If a node experiences a failure, Moab should have a concept of when this node will be restored.

When Moab analyzes [down](#) nodes for allocation, one of two issues may occur with the highest priority jobs. If Moab believes that down nodes will not be recovered for an extended period of time, a transient node failure within a reservation for a priority job may cause the reservation to slide far into the future allowing other lower priority jobs to allocate and launch on nodes previously reserved for it. Moments later, when the transient node failures are resolved, Moab may be unable to restore the early reservation start time as other jobs may already have been launched on previously available nodes.

In the reverse scenario, if Moab recognizes a likelihood that down nodes will be restored too quickly, it may make reservations for top priority jobs that allocate those nodes. Over time, Moab slides those reservations further into the future as it determines that the reserved nodes are not being recovered. While this does not delay the start of the top priority jobs, these unfulfilled reservations can end up blocking other jobs that should have properly been backfilled and executed.

## Creating Automatic Reservations

If a node experiences occasional transient failures (often not associated with a node state of down), Moab can automatically create a temporary reservation over the node to allow the transient failure time to clear and prevent Moab from attempting to re-use the node while the failure is active. This reservation behavior is controlled using the [NODEFAILURERESERVETIME](#) parameter as in the following example:

```
# reserve nodes for 1 minute if transient failures are detected
NODEFAILURERESERVETIME 00:01:00
```

## Blocking Out Down Nodes

If one or more resource managers identify failures and mark nodes as down, Moab can be configured to associate a default *unavailability* time with this failure and the node state *down*. This is accomplished using the [NODEDOWNSTATEDELAYTIME](#) parameter. This delay time floats and is measured as a fixed time into the future from the time "NOW"; it is not associated with the time the node was originally

marked down. For example, if the delay time was set to 10 minutes, and a node was marked down 20 minutes ago, Moab would still consider the node unavailable until 10 minutes into the future.

While it is difficult to select a good default value that works for all clusters, the following is a general rule of thumb:

- Increase **NODEDOWNSTATEDELAYTIME** if jobs are getting blocked due to priority reservations sliding as down nodes are not recovered.
- Decrease **NODEDOWNSTATEDELAYTIME** if high priority job reservations are getting regularly delayed due to transient node failures.

```
# assume down nodes will not be recovered for one hour
NODEDOWNSTATEDELAYTIME 01:00:00
```

## Allocated Resource Failure Policy for Jobs

If a failure occurs within a collection of nodes allocated to a job, Moab can automatically re-allocate replacement resources. This can be configured with [JOBACTIONONNODEFAILURE](#).

How an active job behaves when one or more of its allocated resources fail depends on the allocated resource failure policy. Depending on the type of job, type of resources, and type of middleware infrastructure, a site may choose to have different responses based on the job, the resource, and the type of failure.

### Failure Responses

By default, Moab cancels a job when an allocated resource failure is detected. However, you can specify the following actions:

Option	Policy action
<b>CANCEL</b>	Cancels the job
<b>FAIL</b>	Terminates the job as a failed job
<b>HOLD</b>	Places a hold on the job. This option is only applicable if you are using checkpointing
<b>IGNORE</b>	Ignores the failed node, allowing the job to proceed
<b>NOTIFY</b>	Notifies the administrator and user of failure but takes no further action
<b>REQUEUE</b>	Requeues job and allows it to run when alternate resources become available

### Policy Precedence

For a given job, the applied policy can be set at various levels with policy precedence applied in the job, class/queue, partition, and then system level. The following table indicates the available methods for

setting this policy:

Object	Parameter	Example
Job	<a href="#">RESFAILPOLICY</a> resource manager extension	<pre>&gt; qsub -l resfailpolicy=requeue</pre>
Class/Queue	<a href="#">RESFAILPOLICY</a> attribute of <a href="#">CLASSCFG</a> parameter	<pre>CLASSCFG[batch] RESFAILPOLICY=CANCEL</pre>
Partition	<a href="#">JOBACTIONNONNODEFAILURE</a> attribute of <a href="#">PARCFG</a> parameter	<pre>PARCFG[web3] JOBACTIONNONNODEFAILURE=NOTIFY</pre>
System	<a href="#">NODEALLOCRESFAILUREPOLICY</a> parameter	<pre>NODEALLOCRESFAILUREPOLICY=MIGRATE</pre>

## Failure Definition

Any allocated node going down constitutes a failure. However, for certain types of workload, responses to failures may be different depending on whether it is the master task (task 0) or a slave task that fails. To indicate that the associated policy should only take effect if the master task fails, the allocated resource failure policy should be specified with a trailing asterisk (\*), as in the following example:

```
CLASSCFG[virtual_services] RESFAILPOLICY=requeue*
```

## TORQUE Failure Details

When a node fails becoming unresponsive, the resource manager central daemon identifies this failure within a configurable time frame (default: 60 seconds). Detection of this failure triggers an event that causes Moab to immediately respond. Based on the specified policy, Moab notifies administrators, holds the job, requeues the job, allocates replacement resources to the job, or cancels the job. If the job is canceled or requeued, Moab sends the request to TORQUE, which immediately frees all non-failed resources making them available for use by other jobs. Once the failed node is recovered, it contacts the resource manager central daemon, determines that the associated job has been canceled/requeued, cleans up, and makes itself available for new workload.

## Managing Fairness - Throttling Policies, Fairshare, and Allocation Management

- [Fairness Overview on page 411](#)
- [Usage Limits/Throttling Policies on page 414](#)
- [Fairshare on page 432](#)
- [Charging a Workflow on page 446](#)

## Fairness Overview

The concept of cluster fairness varies widely from person to person and site to site. While some interpret it as giving all users equal access to compute resources, more complicated concepts incorporating historical resource usage, political issues, and job value are equally valid. While no scheduler can address all possible definitions of fair, Moab provides one of the industry's most comprehensive and flexible set of tools allowing most sites the ability to address their many and varied fairness management needs.

Under Moab, most fairness policies are addressed by a combination of the facilities described in the following table:

Job Prioritization	
Description:	Specifies what is most important to the scheduler. Using service based priority factors allows a site to balance job turnaround time, expansion factor, or other scheduling performance metrics.

### Job Prioritization

Example:

```
SERVICEWEIGHT 1
QUEUETIMEWEIGHT 10
```

*Causes jobs to increase in priority by 10 points for every minute they remain in the queue.*

### Usage Limits (Throttling Policies)

Description:

Specifies limits on exactly what resources can be used at any given instant.

Example:

```
USERCFG[john] MAXJOB=3
GROUPCFG[DEFAULT] MAXPROC=64
GROUPCFG[staff] MAXPROC=128
```

*Allows john to only run 3 jobs at a time. Allows the group staff to use up to 128 total processors and all other groups to use up to 64 processors.*

### Fairshare

Description:

Specifies usage targets to limit resource access or adjust priority based on historical cluster and grid level resource usage.

Example:

```
USERCFG[steve] FSTARGET=25.0+
FSWEIGHT 1
FSUSERWEIGHT 10
```

*Enables priority based fairshare and specifies a fairshare target for user steve such that his jobs are favored in an attempt to keep his jobs using at least 25.0% of delivered compute cycles.*

### Allocation Management

Description:

Specifies long term, credential-based resource usage limits.

Example:

```
AMCFG[mam] TYPE=MAM HOST=server.sys.net
```

*Enables the Moab Accounting Manager allocation management interface. Within the allocation manager, project or account based allocations may be configured. These allocations may, for example, do such things as allow project X to use up to 100,000 processor-hours per quarter, provide various QoS sensitive charge rates, and share allocation access.*

Quality of Service	
Description:	Specifies additional resource and service access for particular users, groups, and accounts. QoS facilities can provide special priorities, policy exemptions, reservation access, and other benefits (as well as special charge rates).
Example:	<pre>QOSCFG[orion] PRIORITY=1000 XFTARGET=1.2 QOSCFG[orion] QFLAGS=PREEMPTOR,IGNSYSTEM,RESERVEALWAYS</pre> <p><i>Enables jobs requesting the orion QoS a priority increase, an expansion factor target to improve response time, the ability to preempt other jobs, an exemption from system level job size policies, and the ability to always reserve needed resources if it cannot start immediately.</i></p>

Standing Reservations	
Description:	Reserves blocks of resources within the cluster for specific, periodic time frames under the constraints of a flexible access control list.
Example:	<pre>SRCFG[jupiter] HOSTLIST=node01[1-4] SRCFG[jupiter] STARTTIME=9:00:00 ENDTIME=17:00:00 SRCFG[jupiter] USERLIST=john,steve ACCOUNTLIST=jupiter</pre> <p><i>Reserve nodes <b>node011</b> through <b>node014</b> from 9:00 AM until 5:00 PM for use by jobs from user john or steve or from the project jupiter.</i></p>

Class/Queue Constraints	
Description:	Associates users, resources, priorities, and limits with cluster classes or cluster queues that can be assigned to or selected by end-users.
Example:	<pre>CLASSCFG[long] MIN.WCLIMIT=24:00:00 SRCFG[jupiter] PRIORITY=10000 SRCFG[jupiter] HOSTLIST=acn[1-4][0-9]</pre> <p><i>Assigns long jobs a high priority but only allow them to run on certain nodes.</i></p>

## Selecting the Correct Policy Approach

Moab supports a rich set of policy controls in some cases allowing a particular policy to be enforced in more than one way. For example, cycle distribution can be controlled using usage limits, fairshare, or even queue definitions. Selecting the most correct policy depends on site objectives and needs; consider the following when making such a decision:

- Minimal end-user training
  - Does the solution use an approach familiar to or easily learned by existing users?
- End-user transparency
  - Can the configuration be enabled or disabled without impacting user behavior or job submission?
- Impact on system utilization and system responsiveness
- Solution complexity
  - Is the impact of the configuration readily intuitive, and is it easy to identify possible side effects?
- Solution extensibility and flexibility
  - Will the proposed approach allow the solution to be easily tuned and extended as cluster needs evolve?

## Usage Limits/Throttling Policies

A number of Moab policies allow an administrator to control job flow through the system. These throttling policies work as filters allowing or disallowing a job to be considered for scheduling by specifying limits regarding system usage for any given moment. These policies may be specified as global or specific constraints specified on a per user, group, account, QoS, or class basis.

## Fairness via Throttling Policies

Moab allows significant flexibility with usage limits, or throttling policies. At a high level, Moab allows resource usage limits to be specified in three primary workload categories: (1) active, (2) idle, and (3) system job limits.

### Basic Fairness Policies

Workload category	Description
<b>Active job limits</b>	Constrain the total cumulative resources available to active jobs at a given time.
<a href="#">Idle job limits</a>	Constrain the total cumulative resources available to idle jobs at a given time.
<b>System job limits</b>	Constrain the maximum resource requirements of any single job.

These limits can be applied to any job credential (user, group, account, QoS, and class), or on a system-wide basis. Using the keyword *DEFAULT*, a site may also specify the default setting for the desired user, group, account, QoS, and class. Additionally, you may configure QoS to allow limit overrides to any particular policy.

To run, a job must meet all policy limits. Limits are applied using the **\*CFG** set of parameters, particularly [USERCFG](#), [GROUPCFG](#), [ACCOUNTCFG](#), [QOSCFG](#), [CLASSCFG](#), and [SYSCFG](#). Limits are specified by associating the desired limit to the individual or default object. The usage limits currently supported are listed in the following table.

MAXARRAYJOB	
<b>Units</b>	Number of simultaneous active array job sub-jobs.
<b>Description</b>	Limits the number of simultaneously active (starting or running) array sub-jobs a credential can have.
<b>Example</b>	<pre>USERCFG[gertrude] MAXARRAYJOB=10</pre> <p><i>Gertrude can have a maximum of 10 active job array sub-jobs.</i></p>

MAXGRES	
<b>Units</b>	# of concurrent uses of a generic resource
<b>Description</b>	Limits the concurrent usage of a generic resource to a specific quantity or quantity range.
<b>Example</b>	<pre>USERCFG[joe] MAXGRES[matlab]=2 USERCFG[jim] MAXGRES[matlab]=2,4</pre>

MAXJOB	
<b>Units</b>	# of jobs
<b>Description</b>	<p>Limits the number of jobs a credential may have active (starting or running) at any given time. Moab places a hold on all new jobs submitted by that credential once it has reached its maximum number of allowable jobs.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin: 5px 0;"> <p><b>i</b> MAXJOB=0 is not supported. You can, however, achieve similar results by using the <a href="#">HOLD</a> attribute of the <a href="#">USERCFG</a> parameter:</p> <pre>USERCFG[john] HOLD=yes</pre> </div>
<b>Example</b>	<pre>USERCFG[DEFAULT] MAXJOB=8 GROUPCFG[staff] MAXJOB=2,4</pre>

MAXMEM	
<b>Units</b>	total memory in MB
<b>Description</b>	Limits the total amount of dedicated memory (in MB) that can be allocated by a credential's active jobs at any given time.
<b>Example</b>	<pre>ACCOUNTCFG[jasper] MAXMEM=2048</pre>

MAXNODE	
<b>Units</b>	# of nodes

MAXNODE	
<b>Description</b>	Limits the total number of compute nodes that can be in use by active jobs at any given time. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> On some systems (including TORQUE/PBS), nodes have been softly defined rather than strictly defined; that is, a job may request 2 nodes but TORQUE will translate this request into 1 node with 2 processors. This can prevent Moab from enforcing a <b>MAXNODE</b> policy correctly for a single job. Correct behavior can be achieved using <b>MAXPROC</b>.</p> </div>
<b>Example</b>	<code>CLASSCFG[batch] MAXNODE=64</code>

MAXPE	
<b>Units</b>	# of <a href="#">processor equivalents</a>
<b>Description</b>	Limits the total number of dedicated processor-equivalents that can be allocated by active jobs at any given time.
<b>Example</b>	<code>QOSCFG[base] MAXPE=128</code>

MAXPROC	
<b>Units</b>	# of processors
<b>Description</b>	Limits the total number of dedicated processors that can be allocated by active jobs at any given time per credential. To set <b>MAXPROC</b> per job, use <a href="#">msub -W</a> .
<b>Example</b>	<code>CLASSCFG[debug] MAXPROC=32</code>

MAXPS	
<b>Units</b>	<# of processors> * <walltime>
<b>Description</b>	Limits the number of outstanding processor-seconds a credential may have allocated at any given time. For example, if a user has a 4-processor job that will complete in 1 hour and a 2-processor job that will complete in 6 hours, they have $4 * 1 * 3600 + 2 * 6 * 3600 = 16 * 3600$ outstanding processor-seconds. The outstanding processor-second usage of each credential is updated each scheduling iteration, decreasing as jobs approach their completion time.

MAXPS	
<b>Example</b>	<code>USERCFG[DEFAULT] MAXPS=720000</code>
MAXSUBMITJOBS	
<b>Units</b>	# of jobs
<b>Description</b>	Limits the number of jobs a credential may submit and have in the system at once. Moab will reject any job submitted beyond this limit. If you use a TORQUE resource manager, you should also set <code>max_user_queueable</code> in case the user submits jobs via <code>qsub</code> instead of <code>msub</code> . See " <a href="#">Queue attributes on page 2626</a> " in the <i>TORQUE Administrator Guide</i> for more information.
<b>Example</b>	<code>USERCFG[DEFAULT] MAXSUBMITJOBS=5</code>
MAXWC	
<b>Units</b>	job duration [[[DD:]HH:]MM:]SS
<b>Description</b>	Limits the cumulative remaining walltime a credential may have associated with active jobs. It behaves identically to the <a href="#">MAXPS on page 417</a> limit (listed earlier) only lacking the processor weighting. Like MAXPS, the cumulative remaining walltime of each credential is also updated each scheduling iteration.  <div style="border: 1px solid #0056b3; padding: 5px; background-color: #e6f2ff;"><b>i</b> MAXWC does not limit the maximum wallclock limit per job. For this capability, use <a href="#">MAX.WCLIMIT on page 137</a>.</div>
<b>Example</b>	<code>USERCFG[ops] MAXWC=72:00:00</code>

The following example demonstrates a simple limit specification:

<code>USERCFG[DEFAULT] MAXJOB=4</code>
<code>USERCFG[john] MAXJOB=8</code>
<i>This example allows user john to run up to 8 jobs while all other users may only run up to 4.</i>

Simultaneous limits of different types may be applied per credential and multiple types of credentials may have limits specified. The next example demonstrates this mixing of limits and is a bit more complicated.

```

USERCFG[steve]      MAXJOB=2  MAXNODE=30
GROUPCFG[staff]    MAXJOB=5
CLASSCFG[DEFAULT]  MAXNODE=16
CLASSCFG[batch]    MAXNODE=32

```

This configuration may potentially apply multiple limits to a single job. As discussed previously, a job may only run if it satisfies all applicable limits. Thus, in this example, the scheduler will be constrained to allow at most **2** simultaneous user *steve* jobs with an aggregate node consumption of no more than **30** nodes. However, if the job is submitted to a class other than *batch*, it may be limited further. Here, only **16** total nodes may be used simultaneously by jobs running in any given class with the exception of the class *batch*. If *steve* submitted a job to run in the class *interactive*, for example, and there were jobs already running in this class using a total of 14 nodes, his job would be blocked unless it requested 2 or fewer nodes by the default limit of **16** nodes per class.

## Multi-Dimension Fairness Policies and Per Credential Overrides

Multi-dimensional fairness policies allow a site to specify policies based on combinations of job credentials. A common example might be setting a maximum number of jobs allowed per queue per user or a total number of processors per group per QoS. As with basic fairness policies, multi-dimension policies are specified using the **\*CFG** parameters or through the [identity manager interface](#). Moab supports the most commonly used multi-dimensional fairness policies (listed in the table below) using the following format:

```
*CFG [X] <LIMITTYPE>[<CRED>]=<LIMITVALUE>
```

**\*CFG** is one of **USERCFG**, **GROUPCFG**, **ACCOUNTCFG**, **QOSCFG**, or **CLASSCFG**, the **<LIMITTYPE>** policy is one of the policies listed in the table in section [6.2.1.1](#), and **<CRED>** is of the format **<CREDTYPE>[:<VALUE>]** with **CREDTYPE** being one of **USER**, **GROUP**, **ACCT**, **QoS**, or **CLASS**. The optional **<VALUE>** setting can be used to specify that the policy only applies to a specific credential value. For example, the following configuration sets limits on the class *fast*, controlling the maximum number of jobs any group can have active at any given time and the number of processors in use at any given time for user *steve*.

```

CLASSCFG[fast] MAXJOB[GROUP]=12
CLASSCFG[fast] MAXPROC[USER:steve]=50
CLASSCFG[fast] MAXIJOB[USER]=10

```

The following example configuration may clarify further:

```

# allow class batch to run up the 3 simultaneous jobs
# allow any user to use up to 8 total nodes within class
CLASSCFG[batch] MAXJOB=3 MAXNODE[USER]=8
# allow users steve and bob to use up to 3 and 4 total processors respectively within
class
CLASSCFG[fast] MAXPROC[USER:steve]=3 MAXPROC[USER:bob]=4

```

Multi-dimensional policies cannot be applied on **DEFAULT** credentials.

The table below lists the currently implemented, multi-dimensional usage limit permutations. The "slmt" stands for "Soft Limit" and "hlmt" stands for "Hard Limit."

	MAXWC[GROUP]=slmt,hlmt MAXWC[GROUP:groupname]=slmt,hlmt

## Override Limits

Like all job credentials, the QoS object may be associated with resource usage limits. However, this credential can also be given special override limits that supersede the limits of other credentials, effectively causing all other limits of the same type to be ignored. See [QoS Usage Limits and Overrides](#) for a complete list of policies that can be overridden. The following configuration provides an example of this in the last line:

```
USERCFG[steve]    MAXJOB=2    MAXNODE=30
GROUPCFG[staff]  MAXJOB=5
CLASSCFG[DEFAULT] MAXNODE=16
CLASSCFG[batch]  MAXNODE=32
QOSCFG[hiprio]   OMAXJOB=3   OMAXNODE=64
```

*Only 3 hiprio QoS jobs may run simultaneously and hiprio QoS jobs may run with up to 64 nodes per credential ignoring other credential **MAXNODE** limits.*

Given the preceding configuration, assume a job is submitted with the credentials, user *steve*, group *staff*, class *batch*, and QoS *hiprio*.

Such a job will start so long as running it does not lead to any of the following conditions:

- Total nodes used by user *steve* does not exceed **64**.
- Total active jobs associated with user *steve* does not exceed **2**.
- Total active jobs associated with group *staff* does not exceed **5**.
- Total nodes dedicated to class *batch* does not exceed **64**.
- Total active jobs associated with QoS *hiprio* does not exceed **3**.

While the preceding example is a bit complicated for most sites, similar combinations may be required to enforce policies found on many systems.

## Idle Job Limits

Idle (or queued) job limits control which jobs are eligible for scheduling. To be eligible for scheduling, a job must meet the following conditions:

- Be idle as far as the resource manager is concerned (no holds).
- Have all job prerequisites satisfied (no outstanding job or data dependencies).
- Meet all idle job throttling policies.

If a job fails to meet any of these conditions, it will not be considered for scheduling and will not accrue service based job prioritization. (See [service component](#) and [JOBPRIOACCRUALPOLICY](#).) The primary purpose of idle job limits is to ensure fairness among competing users by preventing queue stuffing and other similar abuses. Queue stuffing occurs when a single entity submits large numbers of jobs, perhaps thousands, all at once so they begin accruing queue time based priority and remain first to run despite subsequent submissions by other users.

Idle limits are specified in a manner almost identical to active job limits with the insertion of the capital letter *I* into the middle of the limit name. Below are examples of the **MAXIJOB** and **MAXINODE** limits, which are idle limit equivalents to the [MAXJOB on page 416](#) and [MAXNODE on page 416](#) limits:

MAXIJOB	
<b>Units</b>	# of jobs
<b>Description</b>	Limits the number of idle (eligible) jobs a credential may have at any given time.
<b>Example</b>	<pre>USERCFG[DEFAULT]  MAXIJOB=8 GROUPCFG[staff]  MAXIJOB=2,4</pre>

MAXINODE	
<b>Units</b>	# of nodes

MAXINODE	
<b>Description</b>	Limits the total number of compute nodes that can be requested by jobs in the eligible/idle queue at any time. Once the limit is exceeded, the remaining jobs will be placed in the blocked queue. The number of nodes is determined by <code>&lt;tasks&gt; / &lt;maximumProcsOnOneNode&gt;</code> or, if using <a href="#">JOBNODEMATCHPOLICY on page 981</a> <code>EXACTNODE</code> , by the number of nodes requested.
<b>Example</b>	<code>USERCFG[DEFAULT] MAXINODE=2</code>

Idle limits can constrain the total number of jobs considered to be eligible on a per credential basis. Further, like active job limits, idle job limits can also constrain eligible jobs based on aggregate requested resources. This could, for example, allow a site to indicate that for a given user, only jobs requesting up to a total of 64 processors, or 3200 processor-seconds would be considered at any given time. Which jobs to select is accomplished by prioritizing all idle jobs and then adding jobs to the eligible list one at a time in priority order until jobs can no longer be added. This eligible job selection is done only once per scheduling iteration, so, consequently, idle job limits only support a single hard limit specification. Any specified soft limit is ignored.

All single dimensional job limit types supported as active job limits are also supported as idle job limits. In addition, Moab also supports [MAXIJOB\[USER\]](#) and [MAXIPROC\[USER\]](#) policies on a per class basis. (See [Basic Fairness Policies](#).)

**Example:**

<code>USERCFG[steve]</code>	<code>MAXIJOB=2</code>
<code>GROUPCFG[staff]</code>	<code>MAXIJOB=5</code>
<code>CLASSCFG[batch]</code>	<code>MAXIJOB[USER]=2 MAXIJOB[USER:john]=6</code>
<code>QOSCFG[hiprio]</code>	<code>MAXIJOB=3</code>

## Hard and Soft Limits

Hard and soft limit specification allows a site to balance both fairness and utilization on a given system. Typically, throttling limits are used to constrain the quantity of resources a given credential (such as user or group) is allowed to consume. These limits can be very effective in enforcing fair usage among a group of users. However, in a lightly loaded system, or one in which there are significant swings in usage from project to project, these limits can reduce system utilization by blocking jobs even when no competing jobs are queued.

Soft limits help address this problem by providing additional scheduling flexibility. They allow sites to specify two tiers of limits; the more constraining limits soft limits are in effect in heavily loaded situations and reflect tight fairness constraints. The more flexible hard limits specify how flexible the scheduler can be in selecting jobs when there are idle resources available after all jobs meeting the tighter soft limits have started. Soft and hard limits are specified in the format `[<SOFTLIMIT>, ] <HARDLIMIT>`. For example, a given site may want to use the following configuration:

```
USERCFG[DEFAULT] MAXJOB=2, 8
```

*With this configuration, the scheduler would select all jobs that meet the per user **MAXJOB** limit of 2. It would then attempt to start and reserve resources for all of these selected jobs. If after doing so there still remain available resources, the scheduler would then select all jobs that meet the less constraining hard per user **MAXJOB** limit of 8 jobs. These jobs would then be scheduled and reserved as available resources allow.*

*If no soft limit is specified or the soft limit is less constraining than the hard limit, the soft limit is set equal to the hard limit.*

### Example:

```
USERCFG[steve] MAXJOB=2, 4 MAXNODE=15, 30
GROUPCFG[staff] MAXJOB=2, 5
CLASSCFG[DEFAULT] MAXNODE=16, 32
CLASSCFG[batch] MAXNODE=12, 32
QOSCFG[hiprio] MAXJOB=3, 5 MAXNODE=32, 64
```

**i** Job [preemption](#) status can be adjusted based on whether the job violates a soft policy using the [ENABLESPVIOLATIONPREEMPTION](#) parameter.

## Per-partition Limits

Per-partition scheduling can set limits and enforce credentials and policies on a per-partition basis. Configuration for per-partition scheduling is done on the grid head. In a grid, each Moab cluster is considered a partition. Per-partition scheduling is typically used in a Master/Slave grid.

To enable per-partition scheduling, add the following to `moab.cfg`:

```
PERPARTITIONSCHEDULING TRUE
JOBMIGRATEPOLICY JUSTINTIME
```

**i** With per-partition scheduling, it is recommended that limits go on the specific partitions and not on the global level. If limits are specified on both levels, Moab will take the more constricting of the limits. Also, please note that a `DEFAULT` policy on the global partition is not overridden by any policy on a specific partition.

## Per-partition Limits

You can configure per-job limits and credential usage limits on a per-partition basis in the `moab.cfg` file. Here is a sample configuration for partitions `g02` and `g03` in `moab.cfg`.

```
PARCFG[g02] CONFIGFILE=/opt/moab/parg02.cfg
PARCFG[g03] CONFIGFILE=/opt/moab/parg03.cfg
```

You can then add per-partition limits in each partition configuration file:

```
# /opt/moab/parg02.cfg
CLASSCFG[pbatch] MAXJOB=5
```

```
# /opt/moab/parg03.cfg
CLASSCFG[pbatch] MAXJOB=10
```

You can configure Moab so that jobs submitted to any partition besides *g02* and *g03* get the default limits in `moab.cfg`:

```
st1
CLASSCFG[pbatch] MAXJOB=2
```

## Supported Credentials and Limits

The user, group, account, QoS, and class credentials are supported in per-partition scheduling.

The following per-job limits are supported:

- [MAX.NODE](#)
- [MAX.WCLIMIT](#)
- [MAX.PROC](#)

The following credential usage limits are supported:

- [MAXJOB](#)
- [MAXNODE](#)
- [MAXPROC](#)
- [MAXWC](#)
- [MAXSUBMITJOBS](#)

[Multi-dimensional limits](#) are supported for the listed credentials and per-job limits. For example:

```
CLASSCFG[pbatch] MAXJOB[user:frank]=10
```

## Usage-based limits

Resource usage limits constrain the amount of resources a given job may consume. These limits are generally proportional to the resources requested and may include walltime, any standard resource, or any specified generic resource. The parameter [RESOURCELIMITPOLICY](#) controls which resources are limited, what limit policy is enforced per resource, and what actions the scheduler should take in the event of a policy violation.

## Configuring Actions

The [RESOURCELIMITPOLICY](#) parameter accepts a number of policies, resources, and actions using the format and values defined below.

**i** If walltime is the resource to be limited, be sure that the resource manager is configured to not interfere if a job surpasses its given walltime. For TORQUE, this is done by using [\\$ignwalltime](#) in the configuration on each MOM node.

## Format

RESOURCELIMITPOLICY<RESOURCE>: [ <SPOLICY>, ] <HPOLICY>: [ <SACTION>, ] <HACTION> [ : [ <SVIOLATIONTIME>, ] <HVIOLATIONTIME> ] . . .

Resource	Description
<b>CPUTIME</b>	Maximum total job proc-seconds used by any single job (allows scheduler enforcement of cpulimit).
<b>DISK</b>	Local disk space (in MB) used by any single job task.
<b>JOBMEM</b>	Maximum real memory/RAM (in MB) used by any single job. <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 5px;">  JOBMEM will only work with the <a href="#">MAXMEM</a> flag.         </div>
<b>JOBPROC</b>	Maximum processor load associated with any single job. You must set <a href="#">MAXPROC on page 417</a> to use <b>JOBPROC</b> .
<b>MEM</b>	Maximum real memory/RAM (in MB) used by any single job task.
<b>MINJOBPROC</b>	Minimum processor load associated with any single job (action taken if job is using 5% or less of potential CPU usage).
<b>NETWORK</b>	Maximum network load associated with any single job task.
<b>PROC</b>	Maximum processor load associated with any single job task.
<b>SWAP</b>	Maximum virtual memory/SWAP (in MB) used by any single job task.
<b>WALLTIME</b>	Requested job walltime.

Policy	Description
<b>ALWAYS</b>	take action whenever a violation is detected
<b>EXTENDEDVIOLATION</b>	take action only if a violation is detected and persists for greater than the specified time limit
<b>BLOCKEDWORKLOADONLY</b>	take action only if a violation is detected and the constrained resource is required by another job

Action	Description
<b>CANCEL</b>	terminate the job
<b>CHECKPOINT</b>	<a href="#">checkpoint</a> and terminate job
<b>MIGRATE</b>	requeue the job and require a different set of hosts for execution
<b>NOTIFY</b>	notify admins and job owner regarding violation
<b>REQUEUE</b>	terminate and requeue the job
<b>SUSPEND</b>	suspend the job and leave it suspended for an amount of time defined by the <a href="#">MINADMINSTIME</a> parameter

*Example 3-94: Notify and then cancel job if requested memory is exceeded*

```
# if job exceeds memory usage, immediately notify owner
# if job exceeds memory usage for more than 5 minutes, cancel the job
RESOURCELIMITPOLICY MEM:ALWAYS,EXTENDEDVIOLATION:NOTIFY,CANCEL:00:05:00
```

*Example 3-95: Checkpoint job on walltime violations*

```
# if job exceeds requested walltime, checkpoint job
RESOURCELIMITPOLICY WALLTIME:ALWAYS:CHECKPOINT
# when checkpointing, send term signal, followed by kill 1 minute later
RMCFG[base] TYPE=PBS CHECKPOINTTIMEOUT=00:01:00 CHECKPOINTSIG=SIGTERM
```

*Example 3-96: Cancel jobs that use 5% or less of potential CPU usage for more than 5 minutes*

```
RESOURCELIMITPOLICY MINJOBPROC:EXTENDEDVIOLATION:CANCEL:5:00
```

*Example 3-97: Migrating a job when it blocks other workload*

```
RESOURCELIMITPOLICY JOBPROC:BLOCKEDWORKLOADONLY:MIGRATE
```

## Specifying Hard and Soft Policy Violations

Moab is able to perform different actions for both hard and soft policy violations. In most resource management systems, a mechanism does not exist to allow the user to specify both hard and soft limits. To address this, Moab provides the [RESOURCELIMITMULTIPLIER](#) parameter that allows per partition and per resource multiplier factors to be specified to generate the actual hard and soft limits to be used. If the factor is less than one, the soft limit will be lower than the specified value and a Moab action will be taken before the specified limit is reached. If the factor is greater than one, the hard limit will be set higher than the specified limit allowing a buffer space before the hard limit action is taken.

In the following example, job owners will be notified by email when their memory reaches 100% of the target, and the job will be canceled if it reaches 125% of the target. For wallclock usage, the job will be

requeued when it reaches 90% of the specified limit if another job is waiting for its resources, and it will be checkpointed when it reaches the full limit.

```
RESOURCELIMITPOLICY      MEM:ALWAYS, ALWAYS:NOTIFY, CANCEL
RESOURCELIMITPOLICY      WALLTIME:BLOCKEDWORKLOADONLY, ALWAYS:REQUEUE, CHECKPOINT
RESOURCELIMITMULTIPLIER  MEM:1.25, WALLTIME:0.9
```

## Constraining Walltime Usage

While Moab constrains walltime using the parameter [RESOURCELIMITPOLICY](#) like other resources, it also allows walltime exception policies which are not available with other resources. In particular, Moab allows jobs to exceed the requested wallclock limit by an amount specified on a global basis using the [JOBMAXOVERRUN](#) parameter or on a per credential basis using the **OVERRUN** attribute of the [CLASSCFG](#) parameter.

```
JOBMAXOVERRUN      00:10:00
CLASSCFG [debug]   overrun=00:00:30
```

## Fairshare

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect.

## Fairshare Parameters

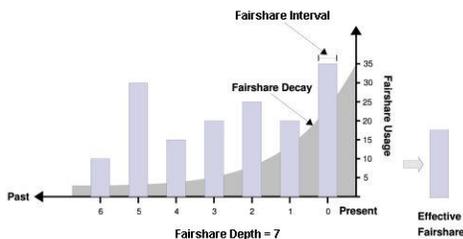

Fairshare is configured at two levels. First, at a system level, configuration is required to determine how fairshare usage information is to be collected and processed. Second, some configuration is required at the credential level to determine how this fairshare information affects particular jobs. The following are system level parameters:

Parameter	Description
<a href="#">FSINTERVAL</a>	Duration of each fairshare window.
<a href="#">FSDEPTH</a>	Number of fairshare windows factored into current fairshare utilization.
<a href="#">FSDECAY</a>	Decay factor applied to weighting the contribution of each fairshare window.
<a href="#">FSPOLICY</a>	Metric to use when tracking fairshare usage.

Credential level configuration consists of specifying fairshare utilization targets using the **\*CFG** suite of parameters, including [ACCOUNTCFG](#), [CLASSCFG](#), [GROUPCFG](#), [QOSCFG](#), and [USERCFG](#).

If global (multi-cluster) fairshare is used, Moab must be configured to synchronize this information with an [identity manager](#).

Image 3-3: Effective fairshare over 7 days

## FSPOLICY - Specifying the Metric of Consumption

As Moab runs, it records how available resources are used. Each iteration (**RMPOLLINTERVAL** seconds) it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the **FSPOLICY** parameter allowing various aspects of resource consumption information to be measured. This parameter allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

Metric	Description
<b>DEDICATEDPES</b>	Usage tracked by <a href="#">processor-equivalent</a> seconds dedicated to each job. This is based on the total number of dedicated processor-equivalent seconds delivered in the system. Useful in dedicated and shared nodes environments.
<b>DEDICATEDPS</b>	Usage tracked by processor seconds dedicated to each job. This is based on the total number of dedicated processor seconds delivered in the system. Useful in dedicated node environments.
<b>DEDICATEDPS%</b>	Usage tracked by processor seconds dedicated to each job. This is based on the total number of dedicated processor seconds <i>available</i> in the system.
<b>UTILIZEDPS</b>	Usage tracked by processor seconds used by each job. This is based on the total number of utilized processor seconds delivered in the system. Useful in shared node/SMP environments.

Example 3-98:

An example may clarify the use of the **FSPOLICY** parameter. Assume a 4-processor job is running a parallel `/bin/sleep` for 15 minutes. It will have a dedicated fairshare usage of 1 processor-hour but a consumed fairshare usage of essentially nothing since it did not consume anything. Most often, dedicated fairshare usage is used on dedicated resource platforms while consumed tracking is used in shared SMP environments.

```
FSPOLICY      DEDICATEDPS%
FSINTERVAL    24:00:00
FSDEPTH       28
FSDECAY       0.75
```

## Specifying Fairshare Timeframe

When configuring fairshare, it is important to determine the proper timeframe that should be considered. Many sites choose to incorporate historical usage information from the last one to two weeks while others are only concerned about the events of the last few hours. The correct setting is very site dependent and usually incorporates both average job turnaround time and site mission policies.

With Moab's fairshare system, time is broken into a number of distinct fairshare windows. Sites configure the amount of time they want to consider by specifying two parameters, **FSINTERVAL** and **FSDEPTH**. The **FSINTERVAL** parameter specifies the duration of each window while the **FSDEPTH**

parameter indicates the number of windows to consider. Thus, the total time evaluated by fairshare is simply **FSINTERVAL \* FSDEPTH**.

Many sites want to limit the impact of fairshare data according to its age. The **FSDECAY** parameter allows this, causing the most recent fairshare data to contribute more to a credential's total fairshare usage than older data. This parameter is specified as a standard decay factor, which is applied to the fairshare data. Generally, decay factors are specified as a value between 1 and 0 where a value of 1 (the default) indicates no decay should be specified. The smaller the number, the more rapid the decay using the calculation  $\text{WeightedValue} = \text{Value} * \langle \text{DECAY} \rangle ^ \langle N \rangle$  where  $\langle N \rangle$  is the window number. The following table shows the impact of a number of commonly used decay factors on the percentage contribution of each fairshare window.

Decay Factor	Wino	Win1	Win2	Win3	Win4	Win5	Win6	Win7
1.00	100%	100%	100%	100%	100%	100%	100%	100%
0.80	100%	80%	64%	51%	41%	33%	26%	21%
0.75	100%	75%	56%	42%	31%	23%	17%	12%
0.50	100%	50%	25%	13%	6%	3%	2%	1%

While selecting how the total fairshare time frame is broken up between the number and length of windows is a matter of preference, it is important to note that more windows will cause the decay factor to degrade the contribution of aged data more quickly.

## Managing Fairshare Data

Using the selected fairshare usage metric, Moab continues to update the current fairshare window until it reaches a fairshare window boundary, at which point it rolls the fairshare window and begins updating the new window. The information for each window is stored in its own file located in the Moab statistics directory. Each file is named `FS.<EPOCHTIME>[.<PNAME>]` where `<EPOCHTIME>` is the time the new fairshare window became active (see [sample data file](#)) and `<PNAME>` is only used if per-partition [share trees](#) are configured. Each window contains utilization information for each entity as well as for total usage.

**i** Historical fairshare data is recorded in the fairshare file using the metric specified by the **FSPOLICY** parameter. By default, this metric is processor-seconds.

**i** Historical fairshare data can be directly analyzed and reported using the `midag -f -v` command.

When Moab needs to determine current fairshare usage for a particular credential, it calculates a decay-weighted average of the usage information for that credential using the most recent fairshare intervals where the number of windows evaluated is controlled by the **FSDEPTH** parameter. For example, assume the credential of interest is user *john* and the following parameters are set:

```

FSINTERVAL 12:00:00
FSDEPTH    4
FSDECAY    0.5
    
```

Further assume that the fairshare usage intervals have the following usage amounts:

Fairshare interval	Total user <i>john</i> usage	Total cluster usage
0	60	110
1	0	125
2	10	100
3	50	150

Based on this information, the current fairshare usage for user *john* would be calculated as follows:

$$Usage = (60 * 1 + .5^1 * 0 + .5^2 * 10 + .5^3 * 50) / (110 + .5^1*125 + .5^2*100 + .5^3*150)$$

**i** The current fairshare usage is relative to the actual resources delivered by the system over the timeframe evaluated, not the resources available or configured during that time.

**i** Historical fairshare data is organized into a number of data files, each file containing the information for a length of time as specified by the `FSINTERVAL` parameter. Although `FSDEPTH`, `FSINTERVAL`, and `FSDECAY` can be freely and dynamically modified, such changes may result in unexpected fairshare status for a period of time as the fairshare data files with the old `FSINTERVAL` setting are rolled out.

## Using Fairshare Information

### Fairshare Targets

Once the global fairshare policies have been configured, the next step involves applying resulting fairshare usage information to affect scheduling behavior. As mentioned in the Fairshare Overview, by specifying fairshare targets, site administrators can configure how fairshare information impacts scheduling behavior. The targets can be applied to user, group, account, QoS, or class credentials using the `FSTARGET` attribute of `*CFG` credential parameters. These targets allow fairshare information to affect job priority and each target can be independently selected to be one of the types documented in the following table:

Target type - Ceiling	
Target modifier	-

Target type - Ceiling	
<b>Job impact</b>	Priority
<b>Format</b>	Percentage Usage
<b>Description</b>	Adjusts job priority down when usage exceeds target. See <a href="#">How violated ceilings and floors affect fairshare-based priority on page 383</a> for more information on how ceilings affect job priority.

Target type - Floor	
<b>Target modifier</b>	+
<b>Job impact</b>	Priority
<b>Format</b>	Percentage Usage
<b>Description</b>	Adjusts job priority up when usage falls below target. See <a href="#">How violated ceilings and floors affect fairshare-based priority on page 383</a> for more information on how floors affect job priority.

Target type - Target	
<b>Target modifier</b>	N/A
<b>Job impact</b>	Priority
<b>Format</b>	Percentage Usage
<b>Description</b>	Adjusts job priority when usage does not meet target.

**i** Setting a fairshare target value of *0* indicates that there is no target and that the priority of jobs associated with that credential should not be affected by the credential's previous fairshare target. If you want a credential's cluster usage near 0%, set the target to a very small value, such as *0.001*.

**Example**

The following example increases the priority of jobs belonging to user *john* until he reaches 16.5% of total cluster usage. All other users have priority adjusted both up and down to bring them to their target usage of 10%:

```

FSPOLICY          DEDICATEDPS
FSWEIGHT          1
FSUSERWEIGHT     100
USERCFG[john]    FSTARGET=16.5+
USERCFG[DEFAULT] FSTARGET=10
...
    
```

### Fairshare Caps

Where fairshare targets affect a job's priority and position in the eligible queue, fairshare caps affect a job's eligibility. Caps can be applied to users, accounts, groups, classes, and QoSs using the **FSCAP** attribute of **\*CFG** credential parameters and can be configured to modify scheduling behavior. Unlike fairshare targets, if a credential reaches its fairshare cap, its jobs can no longer run and are thus removed from the eligible queue and placed in the blocked queue. In this respect, fairshare targets behave like soft limits and fairshare caps behave like hard limits. Fairshare caps can be absolute or relative as described in the following table. If no modifier is specified, the cap is interpreted as relative.

Absolute Cap	
<b>Cap Modifier:</b>	^
<b>Job Impact:</b>	Feasibility
<b>Format:</b>	Absolute Usage
<b>Description:</b>	Constrains job eligibility as an absolute quantity measured according to the scheduler charge metric as defined by the <a href="#">FSPOLICY</a> parameter

Relative Cap	
<b>Cap Modifier:</b>	%
<b>Job Impact:</b>	Feasibility
<b>Format:</b>	Percentage Usage
<b>Description:</b>	Constrains job eligibility as a percentage of total delivered cycles measured according to the scheduler charge metric as defined by the <a href="#">FSPOLICY</a> parameter.

### Example

The following example constrains the *marketing* account to use no more than **16,500** processor seconds during any given floating one week window. At the same time, all other accounts are constrained to use no more than **10%** of the total delivered processor seconds during any given one week window.

```
FSPOLICY          DEDICATEDPS
FSINTERVAL        12:00:00
FSDEPTH           14
ACCOUNTCFG[marketing] FSCAP=16500^
ACCOUNTCFG[DEFAULT]  FSCAP=10
...
```

## Priority-Based Fairshare

The most commonly used type of fairshare is priority based fairshare. In this mode, fairshare information does not affect whether a job can run, but rather only the job's priority relative to other jobs. In most cases, this is the desired behavior. Using the standard fairshare target, the priority of jobs of a particular user who has used too many resources over the specified fairshare window is lowered. Also, the standard fairshare target increases the priority of jobs that have not received enough resources.

While the standard fairshare target is the most commonly used, Moab can also specify fairshare ceilings and floors. These targets are like the default target; however, ceilings only adjust priority down when usage is too high and floors only adjust priority up when usage is too low.

Since fairshare usage information must be integrated with Moab's overall priority mechanism, it is critical that the corresponding fairshare priority weights be set. Specifically, the [FSWEIGHT](#) component weight parameter and the target type subcomponent weight (such as [FSACCOUNTWEIGHT](#), [FSCCLASSWEIGHT](#), [FSGROUPWEIGHT](#), [FSQOSWEIGHT](#), and [FSUSERWEIGHT](#)) be specified.

If these weights are not set, the fairshare mechanism will be enabled but have no effect on scheduling behavior. See the [Job Priority Factor Overview](#) for more information on setting priority weights.

## Example

```
# set relative component weighting
FSWEIGHT          1
FSUSERWEIGHT      10
FSGROUPWEIGHT     50

FSINTERVAL        12:00:00
FSDEPTH           4
FSDECAY           0.5
FSPOLICY          DEDICATEDPS
# all users should have a FS target of 10%
USERCFG[DEFAULT]  FSTARGET=10.0
# user john gets extra cycles
USERCFG[john]     FSTARGET=20.0
# reduce staff priority if group usage exceed 15%
GROUPCFG[staff]   FSTARGET=15.0-
# give group orion additional priority if usage drops below 25.7%
GROUPCFG[orion]   FSTARGET=25.7+
```

**i** Job preemption status can be adjusted based on whether the job violates a fairshare target using the `ENABLEFSVIOLATIONPREEMPTION` parameter.

## Credential-Specific Fairshare Weights

Credential-specific fairshare weights can be set using the **FSWEIGHT** attribute of the `ACCOUNT`, `GROUP`, and `QOS` credentials as in the following example:

```
FSWEIGHT 1000
ACCOUNTCFG[orion1] FSWEIGHT=100
ACCOUNTCFG[orion2] FSWEIGHT=200
ACCOUNTCFG[orion3] FSWEIGHT=-100
GROUPCFG[staff] FSWEIGHT=10
```

If specified, a per-credential fairshare weight is added to the global component fairshare weight.

**i** The **FSWEIGHT** attribute is only enabled for `ACCOUNT`, `GROUP`, and `QOS` credentials.

## Extended Fairshare Examples

### Example 3-99: Multi-Cred Cycle Distribution

Example 1 represents a university setting where different schools have access to a cluster. The Engineering department has put the most money into the cluster and therefore has greater access to the cluster. The Math, Computer Science, and Physics departments have also pooled their money into the cluster and have reduced relative access. A support group also has access to the cluster, but since they only require minimal compute time and shouldn't block the higher-paying departments, they are constrained to five percent of the cluster. At this time, users Tom and John have specific high-priority projects that need increased cycles.

```

#global general usage limits - negative priority jobs are considered in scheduling
ENABLENEGJOBPRIORITY TRUE
# site policy - no job can last longer than 8 hours
USERCFG[DEFAULT] MAX.WCLIMIT=8:00:00
# Note: default user FS target only specified to apply default user-to-user balance
USERCFG[DEFAULT] FSTARGET=1
# high-level fairshare config
FSPOLICY DEDICATEDPS
FSINTERVAL 12:00:00
FSDEPTH 32 #recycle FS every 16 days
FSDECAY 0.8 #favor more recent usage info
# qos config
QOSCFG[inst] FSTARGET=25
QOSCFG[supp] FSTARGET=5
QOSCFG[premium] FSTARGET=70
# account config (QoS access and fstargets)
# Note: user-to-account mapping handled via allocation manager
# Note: FS targets are percentage of total cluster, not percentage of QOS
ACCOUNTCFG[cs] QLIST=inst FSTARGET=10
ACCOUNTCFG[math] QLIST=inst FSTARGET=15

ACCOUNTCFG[phys] QLIST=supp FSTARGET=5
ACCOUNTCFG[eng] QLIST=premium FSTARGET=70
# handle per-user priority exceptions
USERCFG[tom] PRIORITY=100
USERCFG[john] PRIORITY=35
# define overall job priority
USERWEIGHT 10 # user exceptions
# relative FS weights (Note: QOS overrides ACCOUNT which overrides USER)
FSUSERWEIGHT 1
FSACCOUNTWEIGHT 10
FSQOSWEIGHT 100
# apply XFactor to balance cycle delivery by job size fairly
# Note: queuetime factor also on by default (use QUEUETIMEWEIGHT to adjust)
XFACTORWEIGHT 100
# enable preemption
PREEMPTPOLICY QUEUEUE
# temporarily allow phys to preempt math
ACCOUNTCFG[phys] JOBFLAGS=PREEMPTOR PRIORITY=1000
ACCOUNTCFG[math] JOBFLAGS=PREEMPTTEE

```

## Hierarchical Fairshare/Share Trees

Moab supports arbitrary depth hierarchical fairshare based on a share tree. In this model, users, groups, classes, and accounts can be arbitrarily organized and their usage tracked and limited. Moab extends common share tree concepts to allow mixing of credential types, enforcement of ceiling and floor style usage targets, and mixing of hierarchical fairshare state with other priority components.

### Defining the Tree

The `FSTREE` parameter can be used to define and configure the share tree used in fairshare configuration. This parameter supports the following attributes:

SHARES	
<b>Format:</b>	<COUNT>[@<PARTITION>][,<COUNT>[@<PARTITION>]]... where <COUNT> is a double and <PARTITION> is a specified partition name.
<b>Description:</b>	Specifies the node target usage or share.
<b>Example:</b>	<pre>FSTREE [Eng]    SHARES=1500.5 FSTREE [Sales] SHARES=2800</pre>

MEMBERLIST	
<b>Format:</b>	Comma delimited list of child nodes of the format [<OBJECT_TYPE>]:<OBJECT_ID> where object types are only specified for <i>leaf nodes</i> associated with <b>user</b> , <b>group</b> , <b>class</b> , <b>qos</b> , or <b>acct</b> credentials.
<b>Description:</b>	Specifies the tree objects associated with this node.
<b>Example:</b>	<pre>FSTREE [root]    SHARES=100    MEMBERLIST=Eng, Sales FSTREE [Eng]    SHARES=1500.5  MEMBERLIST=user:john,user:steve,user:bob FSTREE [Sales]  SHARES=2800    MEMBERLIST=Sales1, Sales2, Sales3 FSTREE [Sales1] SHARES=30      MEMBERLIST=user:kellyp,user:sam FSTREE [Sales2] SHARES=10      MEMBERLIST=user:ux43,user:ux44,user:ux45 FSTREE [Sales3] SHARES=60      MEMBERLIST=user:robert,user:tjackson</pre>

Current tree configuration and monitored usage distribution is available using the [mdiag -f -v](#) commands.

### Controlling Tree Evaluation

Moab provides multiple policies to customize how the share tree is evaluated.

Policy	Description
<b>FSTREETIERMULTIPLIER</b>	Decreases the value of sub-level usage discrepancies. It can be a positive or negative value. When positive, the parent's usage in the tree takes precedence; when negative, the child's usage takes precedence. The usage amount is not changed, only the coefficient used when calculating the value of fstree usage in priority. When using this parameter, it is recommended that you research how it changes the values in <code>mdiag -p</code> to determine the appropriate use.
<b>FSTREECAP</b>	Caps lower level usage factors to prevent them from exceeding upper tier discrepancies.

### Using FS Floors and Ceilings with Hierarchical Fairshare

All standard fairshare facilities including target floors, target ceilings, and target caps are supported when using hierarchical fairshare.

### Multi-Partition Fairshare

Moab supports independent, per-partition hierarchical fairshare targets allowing each partition to possess independent prioritization and usage constraint settings. This is accomplished by setting the **PERPARTITIONSCHEDULING** attribute of the **FSTREE** parameter to **TRUE** in `moab.cfg` and setting `partition="name"` in your `<fstree>` leaf.

```
FSTREE [tree]
<fstree>
  <tnode partition="slave1" name="root" type="acct" share="100" limits="MAXJOB=6">
    <tnode name="accta" type="acct" share="50" limits="MAXSUBMITJOBS=2 MAXJOB=1">
      <tnode name="fred" type="user" share="1" limits="MAXWC=1:00:00">
      </tnode>
    </tnode>
    <tnode name="acctb" type="acct" share="50" limits="MAXSUBMITJOBS=4 MAXJOB=3">
      <tnode name="george" type="user" share="1" >
      </tnode>
    </tnode>
  </tnode>
  <tnode partition="slave2" name="root" type="acct" share="100"
limits="MAXSUBMITJOBS=6 MAXJOB=5">
    <tnode name="accta" type="acct" share="50">
      <tnode name="paul" type="user" share="1">
      </tnode>
    </tnode>
    <tnode name="acctb" type="acct" share="50">
      <tnode name="ringo" type="user" share="1">
      </tnode>
    </tnode>
  </tnode>
</fstree>
```

**i** If no partition is specified for a given share value, then this value is assigned to the global partition. If a partition exists for which there are no explicitly specified shares for any node, this partition will use the share distribution assigned to the global partition.

### Dynamically Importing Share Tree Data

Share trees can be centrally defined within a database, flat file, information service, or other system and this information can be dynamically imported and used within Moab by setting the **FSTREE** parameter within the [Identity Managers on page 786](#). This interface can be used to load current information at startup and periodically synchronize this information with the master source.

### To create a fairshare tree in a separate XML file and import it into Moab

1. Create a file to store your fair share tree specification. Give it a descriptive name and store it in your Moab home directory (`$MOABHOMEDIR` or `$MOABHOMEDIR/etc`). In this example, the file is called `fstree.dat`.
2. In the first line of `fstree.dat`, set **FSTREE**[myTree] to indicate that this is a fairshare file.
3. Build a tree in XML to match your needs. For example:

```
FSTREE [myTree]
<fstree>
<tnode name="root" share="100">
<tnode name="john" type="user" share="50" limits="MAXJOB=8 MAXPROC=24
MAXWC=01:00:00"></tnode>
<tnode name="jane" type="user" share="50" limits="MAXJOB=5"></tnode>
</tnode>
</fstree>
```

*This configuration creates a fairshare tree in which users share a value of 100. Users john and jane share the value equally, because each has been given 50.*

Because 100 is an arbitrary number, users john and jane could be assigned 10000 and 10000 respectively and still have a 50% share under the parent leaf. To keep the example simple, however, it is recommended that you use 100 as your arbitrary share value and distribute the share as percentages. In this case, john and jane each have 50%.

If the users' numbers do not add up to at least the fairshare value of 100, the remaining value is shared among all users under the tree. For instance, if the tree had a value of 100, user john had a value of 50, and user jane had a value of 25, then 25% of the fairshare tree value would belong to all other users associated with the tree. By default, tree leaves do not limit who can run under them.

**i** Each value specified in the `tnode` elements must be contained in quotation marks.

- Optional: Share trees defined within a flat file can be cumbersome; consider running `tidy` for xml to improve readability. Sample usage:

```
> tidy -i -xml goldy.cfg <filename> <output file>

# Sample output

FSTREE [myTree]
<fstree>
  <tnode name="root" share="100">
    <tnode name="john" type="user" share="50" limits="MAXJOB=8
MAXPROC=24 MAXWC=01:00:00">
    </tnode>
    <tnode name="jane" type="user" share="50" limits="MAXJOB=5">
    </tnode>
  </tnode>
</fstree>
```

- Link the new file to Moab using the `IDCFG` parameter in your Moab configuration file.

```
IDCFG [myTree] server="FILE:/// $MOABH OMEDIR/etc/fstree.dat" REFRESHPERIOD=INFINITY
```

*Moab imports the myTree fairshare tree from the fstree.dat file. Setting `REFRESHPERIOD` to `INFINITY` causes Moab to read the file each time it starts or restarts, but other settings (hour, day, month) cause Moab to read the file more often (See [Refreshing Identity Manager Data](#) for more information).*

- To view your fairshare tree configuration, run `mdiag -f`. If it is configured correctly, the tree information will appear beneath all the information about your fairshare settings configured in `moab.cfg`.

```

> mdiag -f
Share Tree Overview for partition 'ALL'
Name          Usage      Target      (FSFACTOR)
-----
root          100.00    100.00    of  100.00 (node: 1171.81) (0.00)
- john        16.44     50.00    of  100.00 (user: 192.65) (302.04) MAXJOB=8
MAXPROC=24 MAXWC=3600
- jane        83.56     50.00    of  100.00 (user: 979.16) (-302.04) MAXJOB=5

```

*The settings you configured in `fstree.dat` appear in the output. The tree of 100 is shared equally between users `john` and `jane`.*

### Specifying Share Tree Based Limits

Limits can be specified on internal nodes of the share tree using standard [credential limit semantics](#). The following credential usage limits are valid:

- **MAXJOB** (Maximum number of idle jobs allowed for the credential)
- [MAXJOB on page 416](#)
- [MAXMEM on page 416](#)
- [MAXNODE on page 416](#)
- [MAXPROC on page 417](#)
- [MAXSUBMITJOBS on page 418](#)
- [MAXWC on page 418](#)

#### Example 3-100: FSTREE limits example

```

FSTREE [myTree]
<fstree>
  <tnode name="root" share="100">
    <tnode name="john" type="user" share="50" limits="MAXJOB=8
      MAXPROC=24 MAXWC=01:00:00">
    </tnode>
    <tnode name="jane" type="user" share="50" limits="MAXJOB=5">
    </tnode>
  </tnode>
</fstree>

```

### Other Uses of Share Trees

If a share tree is defined, it can be used for purposes beyond fairshare, including organizing general usage and performance statistics for reporting purposes (see [showstats -T](#)), enforcement of tree node based usage limits, and specification of resource access policies.

#### Related topics

- [mdiag -f](#) command (provides diagnosis and monitoring of the fairshare facility)

- [FSTARGETISABSOLUTE](#) parameter

## Sample FairShare Data File

```
FS.<EPOCHTIME>
```

```
# FS Data File (Duration: 43200 seconds) Starting: Sat Jul 8 06:00:20
user          jvella      134087.910
user          reynolds    98283.840
user          gastor      18751.770
user          uannan      145551.260
user          mwillis     149279.140
...
group         DEFAULT     411628.980
group         RedRock     3121560.280
group         Summit      500327.640
group         Arches      3047918.940
acct          Administration 653559.290
acct          Engineering 4746858.620
acct          Shared      75033.020
acct          Research    1605984.910
qos           Deadline    2727971.100
qos           HighPriority 4278431.720
qos           STANDARD    75033.020
class         batch       7081435.840
sched         iCluster    7081435.840
```

*The total usage consumed in this time interval is 7081435.840 processor-seconds. Since every job in this example scenario had a user, group, account, and QOS assigned to it, the sum of the usage of all members of each category should equal the total usage value:  $USERA + USERB + USERC + USERD = GROUPA + GROUPB = ACCTA + ACCTB + ACCTC = QOSO + QOS1 + QOS2 = SCHED$ .*

## Charging a Workflow

The first thing you need to do is install Moab Accounting Manager. You can do this through the [Adaptive Computing](#) website. After Moab Accounting Manager is installed you can look at the `createExampleGoldState.pl` script to see examples of how to define users, projects, accounts, and charge rates in Moab Accounting Manager. You can also run the script to set up a few test users, accounts, and charge rates in Moab Accounting Manager. If ever you want to clear the sqlite database in Moab Accounting Manager, run `./resetdb` as root with the first parameter being the accounting admin user and it will restore the accounting state the same as a fresh install.

## Add NAMI URLs to moab.cfg

The out-of-the-box-solution doesn't use the create or modify NAMI URL. Moab uses the reserve URL to reserve funds and charge for setup costs, the charge URL to reserve funds and charge for reoccurring costs, and the delete URL to unreserve the funds. *These three URLs must be defined in `moab.cfg` in order to charge a workflow.* You should set a Reserve Failure Action in `moab.cfg` (the bottom line in the example) in case the customer doesn't have enough funds to proceed. Therefore a sample `moab.cfg` might look like this in the NAMI section:

```
AMCFG[nami] TYPE=NATIVE
AMCFG[nami] StartURL=exec:///opt/moab/tools/mam/usage.start.mam.pl
AMCFG[nami] UpdateURL=exec:///opt/moab/tools/mam/usage.update.mam.pl
AMCFG[nami] PauseURL=exec:///opt/moab/tools/mam/usage.pause.mam.pl
AMCFG[nami] EndURL=exec:///opt/moab/tools/mam/usage.end.mam.pl
AMCFG[nami] DeleteURL=exec:///opt/moab/tools/mam/usage.delete.mam.pl
AMCFG[nami] FLUSHINTERVAL=hour
AMCFG[nami] StartFailureAction=HOLD
```

## How Workflows Are Expressed in nami.cfg

The `nami.cfg` file was designed to be similar to the `moab.cfg`. Each line is parsed as either **Predicate** [`constant`] **Attribute=***value* or **key** *value*. Each constant in the **JobTemplate** predicate identifies specific job templates in `moab.cfg`. In respect to the workflow, `nami.cfg` needs to know about:

- (required) What job template in the workflow is the infinite job that you will charge based on a recurring bill cycle. In order to specify this you must set the **Recurring** attribute to *True*. For example:

```
JobTemplate[newvm]                Recurring=True
```

- (required) What job template starts off the workflow where you will reserve funds for the eventual infinite job's first recurring bill as well as any setup costs that might occur. For example:

```
JobTemplate[newvm]                StartJob=newvmprovision
```

- (required) What job templates follow the infinite job. This is important to register these template names with NAMI in case of a job failure; otherwise, NAMI will simply ignore them.

```
JobTemplate[newvm]                TemplateDepend=newvmprovision
JobTemplate[newvm]                TemplateDepend=vmstoragehookup
```

- (optional) Moab Accounting Manager VBF charge rate associated with provision jobs. These charge rates will be fixed setup costs per provision job that will be summed up and reserved with the first recurring bill at the run time of the start job. They will be charged at run time of the infinite job to ensure that all provision jobs ran successfully. It is important to note that the run time of the infinite job is also when the bill cycle starts. The first recurring bill is not charged with the setup costs at the beginning of the first bill cycle but rather at the end of each bill cycle after the resources are used. The following is an example of configuring multiple set up costs:

```
JobTemplate[newvmprovision]       GoldChargeRateName=VmSetUpCost
JobTemplate[vmstoragehookup]     GoldChargeRateName=V
```

- (optional) In case you want to toggle billing on and off for a workflow, you can use the **TrackUsage** attribute. The attribute only needs to be set on the recurring job for each workflow. Since having billing on is the default behavior, here is an example of turning billing off:

```
JobTemplate[newvm]                TrackUsage=False
```

## Workflow from moab.cfg to nami.cfg Example

### moab.cfg

```

JOBCFG[newvmprovision]    GENERICSYSJOB=AType=exec,Action="$TOOLSDIR/newvmprovision.pl
$*.SM",EType=start,Timeout=2:00,Flags=objectxmlstdin
JOBCFG[newvmprovision]    INHERITRES=TRUE
JOBCFG[newvmprovision]    FLAGS=NORMSTART

JOBCFG[vmstoragehookup]
GENERICSYSJOB=AType=exec,Action="$TOOLSDIR/vmstoragehookup.pl $.SM
$.SMMAP",EType=start,Timeout=2:00,Flags=objectxmlstdin
JOBCFG[vmstoragehookup]  INHERITRES=TRUE
JOBCFG[vmstoragehookup]  FLAGS=NORMSTART
JOBCFG[vmstoragehookup]  TEMPLATEDEPEND=AFTEROK:newvmprovision

JOBCFG[newvm]             FLAGS=VMTRACKING    SELECT=true
JOBCFG[newvm]             TEMPLATEDEPEND=AFTEROK:vmstoragehookup
JOBCFG[newvm]             FLAGS=NORMSTART
JOBCFG[newvm]             DESTROYTEMPLATE=destroyvm
JOBCFG[newvm]             MIGRATETEMPLATE=migratevm

```

### nami.cfg

```

JobTemplate[newvm]        Recurring=True
JobTemplate[newvm]        StartJob=newvmprovision
JobTemplate[newvm]        TrackUsage=True
JobTemplate[newvm]        TemplateDepend=newvmprovision
JobTemplate[newvm]        TemplateDepend=vmstoragehookup
JobTemplate[newvmprovision] GoldChargeRateName=VmSetUpCost
JobTemplate[vmstoragehookup] GoldChargeRateName=VmStorageHookUpCost

```

## Understanding UsageAttributes in nami.cfg

Recurring jobs are represented in Moab Accounting Manager as usage records. A usage record helps constrain what account to charge, how much to charge, as well as keep record of additional information about the job. The `nami.cfg` file defines what the usage record will like for the recurring job. Each constant in the `UsageAttribute` can be an account constraint, charge rate name, usage record property name, or any combination of the three. Because the constant can be a usage record property (something that gets recorded and shown when you do a `glsusage`) and a charge rate name, most people make charge rate names match the usage record property. For example, *Processors* is something that you probably want to both record and charge for, so it is easier if the charge rate name and usage record attribute name are both called *Processors* and `nami.cfg` has the line:

```
UsageAttribute[Processors]    MoabXMLAttribute=Processors
```

The `nami.cfg` file interprets this to mean that the value in the *Processors* tag sent from Moab should be the same value passed in the *Processors* tag in the usage record sent to Moab Accounting Manager. Moab Accounting Manager will then recognize that it is the usage record property name, so it will record it and show it when you do a `glsusage` command and will also recognize that it is a charge rate so it will charge it accordingly. Other attributes like `user` and `project` help constrain which account gets charged. However, there is nothing preventing you from making additional charge rates in Moab Accounting Manager for them as well.

Currently, the NAMI scripts allow anything in the Moab job XML to be sent to Moab Accounting Manager, including gres and user-defined variables. Gres and variables are expressed with either a *gres:* or *var:* prepended to the name of what it is representing. For example you might see the following in `nami.cfg`:

```
UsageAttribute[Disk]           MoabXMLAttribute=GRes:Os
UsageAttribute[StorageHost]   MoabXMLAttribute=Var:SH
```

## Other Important nami.cfg Parameters

**SetupTime** - The amount of time (in seconds) beyond the bill cycle time that the reservation for the setup cost and first bill cycle should last before it destroys itself (defaults to 43200). Here is an example of how to define it in `nami.cfg`:

```
SetupTime                       3213 (Defaults to 43200)
```

**BillCycle** - The amount of time of the bill cycle. It helps determine how much funds to reserve for each bill cycle. Possible values are hour, day, week, month (the default is day). If you want to over- or under-reserve funds for the bill cycle, you can also configure the default values for hour (60), day (86400), week (604800), and month (2630000). Be careful to understand that if you use this with **RoundChargeDuration**, the charge duration will be rounded to the modified bill cycle which is probably not what you wanted to do. Configuring the bill cycle time is intended to increase or decrease the barrier of entry for your job and assumes that the charge duration is not rounded. Here is an example of setting the bill cycle and changing the time duration of *Month*.

```
BILLCYCLE                       Month      (Defaults to Day)
BILLCYCLE[Month]                 2640000 (Defaults to average seconds in a month)
```

**RoundChargeDuration** - If set to *True*, then the charge duration sent from Moab will be rounded up or down to match what was quoted within the default bounds of plus or minus 0 seconds. Otherwise, charge duration will not be rounded. The bound to round the charge duration is configurable with the **Bound** attribute. Here is an example of rounding the charge duration if it is within plus or minus a half a day:

```
RoundChargeDuration             True      (Defaults to False)
RoundChargeDuration[config]     Bound=43200 (Defaults to 0)
```

**Log** - If set to *True*, the `nami.log` will also include everything that is written to the `gold.log` in `/opt/mam/log/`. An example log configuration is:

```
LOG[config]      path=../log/nami.log      (Defaults to ../log/nami.log)
LOG[config]      loglevel=debug          (Possible values are fatal, error, warn, info,
debug and it defaults to info)
LOG[config]      includeGoldLog=false    (Defaults to true)
LOG[config]      permissions=640        (Defaults to 666)
LOG[config]      maxSize=10000000       (Defaults to 10000000)
LOG[config]      rolloverLimit=7        (Defaults to 7)
```

# Controlling Resource Access - Reservations, Partitions, and QoS Facilities

- [Advance Reservations](#) on page 450
- [Partitions](#) on page 494
- [Quality of Service \(QoS\) Facilities](#) on page 498

## Advance Reservations

An advance reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday. Advance reservation technology enables many features including [backfill](#), [deadline](#) based scheduling, [grid scheduling](#), and [QOS](#) support.

The [mrsvctl](#) command is used to [create](#), [modify](#), [query](#), and [release](#) reservations.

- [Reservation Overview](#)
- [Administrative Reservations](#)
- [Standing Reservations](#)
- [Reservation Policies](#)
- [Configuring and Managing Reservations](#)
- [Enabling Reservations for End-users](#)

## Reservation Overview

- [Resources](#)
- [TimeFrame](#)
- [Access Control List](#)
- [Job to Reservation Binding](#)
- [Reservation Specification](#)
- [Reservation Behavior](#)
- [Reservation Group](#)

Every reservation consists of 3 major components: (1) a set of resources, (2) a time frame, and (3) an access control list. Additionally, a reservation may also have a number of optional attributes controlling its behavior and interaction with other aspects of scheduling. Reservation attribute descriptions follow.

## Resources

Under Moab, the resources specified for a reservation are specified by way of a [task](#) description. Conceptually, a task can be thought of as an atomic, or indivisible, collection of resources. If reservation resources are unspecified, a task is a node by default. To define a task, specify resources. The resources may include processors, memory, swap, local disk, and so forth. For example, a single task may consist of one processor, 2 GB of memory, and 10 GB of local disk.

A reservation consists of one or more tasks. In attempting to locate the resources required for a particular reservation, Moab examines all feasible resources and locates the needed resources in groups specified by the task description. An example may help clarify this concept:

Reservation A requires four tasks. Each task is defined as 1 processor and 1 GB of memory.

Node X has 2 processors and 3 GB of memory available

Node Y has 2 processors and 1 GB of memory available

Node Z has 2 processors and 2 GB of memory available

When collecting the resources needed for the reservation, Moab examines each node in turn. Moab finds that Node X can support 2 of the 4 tasks needed by reserving 2 processors and 2 GB of memory, leaving 1 GB of memory unreserved. Analysis of Node Y shows that it can only support 1 task reserving 1 processor and 1 GB of memory, leaving 1 processor unreserved. Note that the unreserved memory on Node X cannot be combined with the unreserved processor on Node Y to satisfy the needs of another task because a task requires all resources to be located on the same node. Finally, analysis finds that node Z can support 2 tasks, fully reserving all of its resources.

Both reservations and jobs use the concept of a task description in specifying how resources should be allocated. It is important to note that although a task description is used to allocate resources to a reservation, this description does not in any way constrain the use of those resources by a job. In the above example, a job requesting resources simply sees 4 processors and 4 GB of memory available in reservation A. If the job has access to the reserved resources and the resources meet the other requirements of the job, the job could use these resources according to its own task description and needs.

Currently, the resources that can be associated with reservations include processors, memory, swap, local disk, initiator classes, and any number of arbitrary resources. Arbitrary resources may include peripherals such as tape drives, software licenses, or any other site specific resource.

## Time Frame

Associated with each reservation is a time frame. This specifies when the resources will be reserved or dedicated to jobs that meet the reservation's access control list (ACL). The time frame simply consists of a start time and an end time. When configuring a reservation, this information may be specified as a start time together with either an end time or a duration.

## Access Control List

A reservation's access control list specifies which jobs can use a reservation. Only jobs that meet one or more of a reservation's access criteria are allowed to use the reserved resources during the reservation time frame. Currently, the reservation access criteria include the following: users, groups, accounts, classes, QOS, job attributes, job duration, and job templates.

## Job to Reservation Binding

While a reservation's ACL will allow particular jobs to use reserved resources, it does not force any job to use these resources. With each job, Moab attempts to locate the best possible combination of available resources whether these are reserved or unreserved. For example, in the following figure, note that job X, which meets access criteria for both reservation A and B, allocates a portion of its resources from each reservation and the remainder from resources outside of both reservations.

Image 3-4: Job X uses resources from reservations A and B

Although by default, reservations make resources available to jobs that meet particular criteria, Moab can be configured to constrain jobs to only run within accessible reservations. This can be requested by the user on a job by job basis using a resource manager extension flag, or it can be enabled administratively via a QoS flag. For example, assume two reservations were created as follows:

```
> mrsvctl -c -a GROUP==staff -d 8:00:00 -h 'node[1-4]'
reservation staff.1 created
```

```
> mrsvctl -c -a USER==john -t 2
reservation john.2 created
```

If the user "john," who happened to also be a member of the group "staff," wanted to force a job to run within a particular reservation, "john" could do so using the **FLAGS** [resource manager extension](#).

Specifically, in the case of a PBS job, the following submission would force the job to run within the "staff.1" reservation.

```
> msub -l nodes=1,walltime=1:00:00,flags=ADVRES:staff.1 testjob.cmd
```

Note that for this to work, PBS needs to have resource manager extensions enabled as described in the [PBS Resource Manager Extension Overview](#). ([TORQUE](#) has resource manager extensions enabled by default.) If the user wants the job to run on reserved resources but does not care which, the user could submit the job with the following:

```
> msub -l nodes=1,walltime=1:00:00,flags=ADVRES testjob.cmd
```

To enable job to reservation mapping via [QoS](#), the QoS flag [USERRESERVED](#) should be set in a similar manner.

**i** Use the reservation [BYNAME](#) flag to require explicit binding for reservation access.

To lock jobs linked to a particular QoS into a reservation or reservation group, use the [REQRID](#) attribute.

## Reservation Specification

There are two main types of reservations that sites typically deal with. The first, administrative reservations, are typically one-time reservations created for special purposes and projects. These reservations are created using the [mrsvctl](#) or [setres](#) commands. These reservations provide an integrated mechanism to allow graceful management of unexpected system maintenance, temporary projects, and time critical demonstrations. This command allows an administrator to select a particular set of resources or just specify the quantity of resources needed. For example an administrator could use a regular expression to request a reservation be created on the nodes "blue0[1-9]" or could simply request that the reservation locate the needed resources by specifying a quantity based request such as "TASKS==20."

The second type of reservation is called a [standing reservation](#). It is specified using the [SRCFG](#) parameter and is of use when there is a recurring need for a particular type of resource distribution. Standing reservations are a powerful, flexible, and efficient means for enabling persistent or periodic policies such as those often enabled using [classes](#) or queues. For example, a site could use a standing reservation to reserve a subset of its compute resources for quick turnaround jobs during business hours on Monday thru Friday. The [Standing Reservation Overview](#) provides more information about configuring and using these reservations.

## Reservation Behavior

As previously mentioned, a given reservation may have one or more access criteria. A job can use the reserved resources if it meets at least one of these access criteria. It is possible to stack multiple reservations on the same node. In such a situation, a job can only use the given node if it has access to each active reservation on the node.

## Reservation Group

Reservations groups are ways of associating multiple reservations. This association is useful for [variable namespace](#) and [reservation requests](#). The reservations in a group inherit the variables from the reservation group head, but if the same variable is set locally on a reservation in the group, the local variable overrides the inherited variable. Variable inheritance is useful for [triggers](#) as it provides greater flexibility with automating certain tasks and system behaviors.

Jobs may be bound to a reservation group (instead of a single reservation) by using the resource manager extension [ADVRES](#).

## Infinite Jobs and Reservations

To allow infinite walltime jobs, you must have the following scheduler flag set:

```
SCHEDCFG[Moab] FLAGS=allowinfinitejobs
```

You can submit an infinite job by completing:

```
msub -l walltime=INFINITY
```

Or an infinite reservation by completing:

```
mrsvctl -c -d INFINITY
```

Infinite jobs can run in infinite reservations. Infinite walltime also works with job templates and advres.

Output XML for infinite jobs will print "INFINITY" in the ReqAWDDuration, and XML for infinite rsvs will print "INFINITY" in duration and endtime.

```

## Administrative Reservations

- [Annotating Administrative Reservations](#)
- [Using Reservation Profiles](#)
- [Optimizing Maintenance Reservations](#)

Administrative reservations behave much like standing reservations but are generally created to address non-periodic, one-time issues. All administrative reservations are created using the `mrsvctl -c` (or `setres`) command and are persistent until they expire or are removed using the `mrsvctl -r` (or `releaseres`) command.

## Annotating Administrative Reservations

Reservations can be labeled and annotated using comments allowing other administrators, local users, portals and other services to obtain more detailed information regarding the reservations. Naming and annotations are configured using the `-n` and `-D` options of the `mrsvctl` command respectively, as in the following example:

```
> mrsvctl -c -D 'testing infiniband performance' -n nettest -h 'r:agt[15-245]'
```

## Using Reservation Profiles

You can set up reservation profiles to avoid manually and repetitively inputting standard reservation attributes. Profiles can specify reservation names, descriptions, ACLs, durations, hostlists, triggers, flags, and other aspects that are commonly used. With a reservation profile defined, a new administrative reservation can be created that uses this profile by specifying the `-P` flag as in the following example.

*Example 3-101:*

```
RSVPROFILE [mtn1] TRIGGER=Atype=exec,Action="/tmp/trigger1.sh",EType=start
RSVPROFILE [mtn1] USERLIST=steve,marym
RSVPROFILE [mtn1] HOSTEXP="r:50-250"
```

```
> mrsvctl -c -P mtn1 -s 12:00:00_10/03 -d 2:00:00
```

*Example 3-102: Non-Blocking System Reservations with Scheduler Pause*

```
RSVPROFILE [pause] TRIGGER=atype=exec,etype=start,action="/opt/moab/bin/mschedctl -p"
RSVPROFILE [pause] TRIGGER=atype=exec,etype=cancel,action="/opt/moab/bin/mschedctl -r"
RSVPROFILE [pause] TRIGGER=atype=exec,etype=end,action="/opt/moab/bin/mschedctl -r"
```

```
> mrsvctl -c -P pause -s 12:00:00_10/03 -d 2:00:00
```

## Optimizing Maintenance Reservations

Any reservation causes some negative impact on cluster performance as it further limits the scheduler's ability to optimize scheduling decisions. You can mitigate this impact by using flexible ACLs and triggers.

In particular, a maintenance reservation can be configured to reduce its effective reservation shadow by allowing overlap with checkpointable/preemptible jobs until the time the reservation becomes active. This can be done using a series of triggers that perform the following actions:

- Modify the reservation to disable preemption access.
- Preempt jobs that may overlap the reservation.
- Cancel any jobs that failed to properly checkpoint and exit.

The following example highlights one possible configuration:

```
RSVPROFILE[adm1] JOBATTRLIST=PREEMPTEE
RSVPROFILE[adm1] DESCRIPTION="regular system maintenance"
RSVPROFILE[adm1] TRIGGER=EType=start,Offset=-
300,AType=internal,Action="rsv:-:modify:acl:jattr-=PREEMPTEE"
RSVPROFILE[adm1] TRIGGER=EType=start,Offset=-240,AType=jobpreempt,Action="checkpoint"
RSVPROFILE[adm1] TRIGGER=EType=start,Offset=-60,AType=jobpreempt,Action="cancel"
```

```
> mrsvctl -c -P adm1 -s 12:00:00_10/03 -d 8:00:00 -h ALL
```

This reservation reserves all nodes in the cluster for a period of eight hours. Five minutes before the reservation starts, the reservation is modified to remove access to new preemptible jobs. Four minutes before the reservation starts, preemptible jobs that overlap the reservation are checkpointed. One minute before the reservation, all remaining jobs that overlap the reservation are canceled.

Reservations can also be used to evacuate virtual machines from a nodelist. To do this, you can configure a reservation profile in the `moab.cfg` file that calls an internal trigger to enable the evacuate VM logic. For example:

```
RSVPROFILE[evacvms]
TRIGGER=EType=start,AType=internal,action=node:$(HOSTLIST):evacvms
```

```
> mrsvctl -c -P evacvms -s 12:00:00_10/03 -d 8:00:00 -h ALL
```

Please note that Moab gives its best effort in evacuating VMs; however, if other reservations and policies prevent Moab from locating an alternate location for the VMs to be migrated to, then no action will occur. Administrators can attach additional triggers to the reservation profile to add evacuation logic where needed.

 You can also manually create a reservation that evacuates VMs from a nodelist by using the [EVACVMS](#) reservation flag. For example:

```
> mrsvctl -c -F EVACVMS -s 12:00:00_10/03 -d 8:00:00 -h ALL
```

## Standing Reservations

Standing reservations build upon the capabilities of advance reservations to enable a site to enforce advanced usage policies in an efficient manner. Standing reservations provide a superset of the capabilities typically found in a batch queuing system's class or queue architecture. For example, queues can be used to allow only particular types of jobs access to certain compute resources. Also, some batch systems allow these queues to be configured so that they only allow this access during certain times of the day or week. Standing reservations allow these same capabilities but with greater flexibility and efficiency than is typically found in a normal queue management system.

Standing reservations provide a mechanism by which a site can dedicate a particular block of resources for a special use on a regular daily or weekly basis. For example, node X could be dedicated to running jobs only from users in the accounting group every Friday from 4 to 10 p.m. See the [Reservation Overview](#) for more information about the use of reservations. The [Managing Reservations](#) section provides a detailed explanation of the concepts and steps involved in the creation and configuration of standing reservations.

A standing reservation is a powerful means of doing the following:

- Controlling local credential based access to resources.
- Controlling external peer and grid based access to resources.
- Controlling job responsiveness and turnaround.

## Reservation Policies

- [Controlling Priority Reservation Creation](#)
- [Managing Resource Failures](#)
- [Resource Allocation Policy](#)
- [Resource Re-Allocation Policy](#)

## Controlling Priority Reservation Creation

In addition to standing and administrative reservations, Moab can also create priority reservations. These reservations are used to allow the benefits of out-of-order execution (such as is available with [backfill](#)) without the side effect of job starvation. Starvation can occur in any system where the potential exists for a job to be overlooked by the scheduler for an indefinite period. In the case of backfill, small jobs may continue to run on available resources as they become available while a large job sits in the queue, never able to find enough nodes available simultaneously on which to run.

To avoid such situations, priority reservations are created for high priority jobs that cannot run immediately. When making these reservations, the scheduler determines the earliest time the job could start and then reserves these resources for use by this job at that future time.

## Priority Reservation Creation Policy

Organizations have the ability to control how priority reservations are created and maintained. It is possible that one job can be at the top of the priority queue for a time and then get bypassed by another job submitted later. The parameter [RESERVATIONPOLICY](#) allows a site to determine how existing reservations should be handled when new reservations are made.

Value	Description
<b>HIGHEST</b>	<p>All jobs that have ever received a priority reservation up to the <b>RESERVATIONDEPTH</b> number will maintain that reservation until they run, even if other jobs later bypass them in priority value.</p> <p>For example, if there are four jobs with priorities of 8, 10,12, and 20.</p> <div style="border: 1px dashed gray; padding: 5px; margin: 10px 0;"> <pre>RESERVATIONPOLICY HIGHEST RESERVATIONDEPTH 3</pre> </div> <p>Only jobs 20, 12, and 10 get priority reservations. Later, if a job with priority higher than 20 is submitted into the queue, it will also get a priority reservation along with the jobs listed previously. If four jobs higher than 20 were to be submitted into the queue, only three would get priority reservations, in accordance with the condition set in the <b>RESERVATIONDEPTH</b> policy.</p> <p>With <b>HIGHEST</b>, Moab may appear to exceed the <b>RESERVATIONDEPTH</b> if it has already scheduled the maximum number of priority reservations and then users submit jobs with higher priority than those already given a priority reservation. Moab keeps all of the previously-created priority reservations and creates new ones for jobs with higher priority (again up to the quantity specified with <b>RESERVATIONDEPTH</b>). This means that, if your <b>RESERVATIONDEPTH</b> is set to 3, Moab can potentially schedule up to 3 new priority reservations each scheduling iteration, as long as new higher-priority jobs are continually submitted. This behavior ensures that the highest-priority jobs receive attention while the former highest-priority jobs do not lose their priority reservation.</p>
<b>CURRENTHIGHEST</b>	<p>Only the current top &lt;<b>RESERVATIONDEPTH</b>&gt; priority jobs receive reservations. Under this policy, all job reservations are destroyed each iteration when the queue is re-prioritized. The top jobs in the queue are then given new reservations.</p>
<b>NEVER</b>	<p>No priority reservations are made.</p>

## Priority Reservation Depth

By default, only the highest priority job receives a priority reservation. However, this behavior is configurable via the [RESERVATIONDEPTH](#) policy. Moab's default behavior of only reserving the highest priority job allows backfill to be used in a form known as liberal backfill. Liberal backfill tends to maximize system utilization and minimize overall average job turnaround time. However, it does lead to the potential of some lower priority jobs being indirectly delayed and may lead to greater variance in job turnaround time. The **RESERVATIONDEPTH** parameter can be set to a very large value, essentially enabling what is called conservative backfill where every job that cannot run is given a reservation. Most sites prefer the liberal backfill approach associated with the default **RESERVATIONDEPTH** of 1 or else select a slightly higher value. It is important to note that to prevent starvation in conjunction with

reservations, monotonically increasing priority factors such as queue time or job XFactor should be enabled. See the [Prioritization Overview](#) for more information on priority factors.

Another important consequence of backfill and reservation depth is how they affect job priority. In Moab, all jobs are prioritized. Backfill allows jobs to be run out of order and thus, to some extent, job priority to be ignored. This effect, known as priority dilution, can cause many site policies implemented via Moab prioritization policies to be ineffective. Setting the **RESERVATIONDEPTH** parameter to a higher value gives job priority more teeth at the cost of slightly lower system utilization. This lower utilization results from the constraints of these additional reservations, decreasing the scheduler's freedom and its ability to find additional optimizing schedules. Anecdotal evidence indicates that these utilization losses are fairly minor, rarely exceeding 8%.

It is difficult a priori to know the right setting for the **RESERVATIONDEPTH** parameter. Surveys indicate that the vast majority of sites use the default value of 1. Sites that do modify this value typically set it somewhere in the range of 2 to 10. The following guidelines may be useful in determining if and how to adjust this parameter:

### Reasons to Increase RESERVATIONDEPTH

- The estimated job start time information provided by the [showstart](#) command is heavily used and the accuracy needs to be increased.
- Priority dilution prevents certain key mission objectives from being fulfilled.
- Users are more interested in knowing when their job will run than in having it run sooner.

### Reasons to Decrease RESERVATIONDEPTH

- Scheduling efficiency and job throughput need to be increased.

### Assigning Per-QoS Reservation Creation Rules

QoS based reservation depths can be enabled via the [RESERVATIONQOSLIST](#) parameter. This parameter allows varying reservation depths to be associated with different sets of job QoSs. For example, the following configuration creates two reservation depth groupings:

```
RESERVATIONDEPTH[0]      8
RESERVATIONQOSLIST[0]   highprio, interactive, debug
RESERVATIONDEPTH[1]      2
RESERVATIONQOSLIST[1]   batch
```

*This example causes that the top 8 jobs belonging to the aggregate group of **highprio**, **interactive**, and **debug** QoS jobs will receive priority reservations. Additionally, the top two **batch** QoS jobs will also receive priority reservations. Use of this feature allows sites to maintain high throughput for important jobs by guaranteeing that a significant proportion of these jobs progress toward starting through use of the priority reservation.*

By default, the following parameters are set inside Moab:

```
RESERVATIONDEPTH[DEFAULT] 1
RESERVATIONQOSLIST[DEFAULT] ALL
```

*This allows one job with the highest priority to get a reservation. These values can be overwritten by modifying the **DEFAULT** policy.*

## Managing Resource Failures

Moab allows organizations to control how to best respond to a number of real-world issues. Occasionally when a reservation becomes active and a job attempts to start, various resource manager race conditions or corrupt state situations will prevent the job from starting. By default, Moab assumes the resource manager is corrupt, releases the reservation, and attempts to re-create the reservation after a short timeout. However, in the interval between the reservation release and the re-creation timeout, other priority reservations may allocate the newly available resources, reserving them before the original reservation gets an opportunity to reallocate them. Thus, when the original job reservation is re-established, its original resource may be unavailable and the resulting new reservation may be delayed several hours from the earlier start time. The parameter [RESERVATIONRETRYTIME](#) allows a site that is experiencing frequent resource manager race conditions and/or corruption situations to tell Moab to hold on to the reserved resource for a period of time in an attempt to allow the resource manager to correct its state.

## Resource Allocation Policy

By default, when a standing or administrative reservation is created, Moab allocates nodes in accordance with the specified taskcount, node expression, node constraints, and the [MINRESOURCE](#) node allocation policy.

  - [Specifying Reservation Resources](#)
  - [Enforcing Policies Via Multiple Reservations](#)
  - [Affinity](#)
  - [ACL Modifiers](#)
  - [Reservation Ownership](#)

- [Partitions](#)
- [Resource Allocation Behavior](#)
- [Rolling Reservations](#)
- [Modifying Resources with Standing Reservations](#)
- [Managing Administrative Reservations](#)

## Reservation Attributes

All reservations possess a time frame of activity, an access control list (ACL), and a list of resources to be reserved. Additionally, reservations may also possess a number of extension attributes including epilog/prolog specification, reservation ownership and accountability attributes, and special flags that modify the reservation's behavior.

### Start/End Time

All reservations possess a start and an end time that define the reservation's active time. During this active time, the resources within the reservation may only be used as specified by the reservation access control list (ACL). This active time may be specified as either a start/end pair or a start/duration pair. Reservations exist and are visible from the time they are created until the active time ends at which point they are automatically removed.

### Access Control List (ACL)

For a reservation to be useful, it must be able to limit who or what can access the resources it has reserved.

**i** By default a reservation may allocate resources that possess credentials that meet the submitter's ACL. In other words, a user's reservation won't necessarily allocate only free and idle nodes. If a reservation exists that coincides with the submitter's ACL, the nodes under that reservation are also considered for allocation. This is referred to as ACL overlap. To make new reservations allocate *only* free and idle nodes, you must use the [NOACLOVERLAP](#) flag.

This is handled by way of an ACL. With reservations, ACLs can be based on credentials, resources requested, or performance metrics. In particular, with a standing reservation, the attributes [USERLIST](#), [GROUPLIST](#), [ACCOUNTLIST](#), [CLASSLIST](#), [QOSLIST](#), [JOBATTRLIST](#), [PROCLIMIT](#), [MAXTIME](#), or [TIMELIMIT](#) may be specified. (See [Affinity](#) and [Modifiers](#).)

**i** Reservation access can be adjusted based on a job's requested node features by mapping node feature requests to job attributes as in the following example:

```
NODECFG[DEFAULT]  FEATURES=ia64
NODETOJOBATTRMAP  ia64, ia32
SRCFG[pgs]        JOBATTRLIST=ia32
```

```
> mrsvctl -c -a jattr=gpfs\! -h "r:13-500"
```

## Selecting Resources

When specifying which resources to reserve, the administrator has a number of options. These options allow control over how many resources are reserved and where they are reserved. The following reservation attributes allow the administrator to define resources.

### Task Description

Moab uses the task concept extensively for its job and reservation management. A task is simply an atomic collection of resources, such as processors, memory, or local disk, which must be found on the same node. For example, if a task requires 4 processors and 2 GB of memory, the scheduler must find all processors AND memory on the same node; it cannot allocate 3 processors and 1 GB on one node and 1 processor and 1 GB of memory on another node to satisfy this task. Tasks constrain how the scheduler must collect resources for use in a standing reservation; however, they do not constrain the way in which the scheduler makes these cumulative resources available to jobs. A job can use the resources covered by an accessible reservation in whatever way it needs. If reservation X allocates 6 tasks with 2 processors and 512 MB of memory each, it could support job Y which requires 10 tasks of 1 processor and 128 MB of memory or job Z which requires 2 tasks of 4 processors and 1 GB of memory each. The task constraints used to acquire a reservation's resources are transparent to a job requesting use of these resources.

Example 3-103:

```
SRCFG[test] RESOURCES=PROCS:2, MEM:1024
```

### Taskcount

Using the task description, the taskcount attribute defines how many tasks must be allocated to satisfy the reservation request. To create a reservation, a taskcount and/or a hostlist must be specified.

Example 3-104:

```
SRCFG[test] TASKCOUNT=256
```

### Hostlist

A hostlist constrains the set of resources available to a reservation. If no taskcount is specified, the reservation attempts to reserve one task on each of the listed resources. If a taskcount is specified that requests fewer resources than listed in the hostlist, the scheduler reserves only the number of tasks from the hostlist specified by the taskcount attribute. If a taskcount is specified that requests more resources than listed in the hostlist, the scheduler reserves the hostlist nodes first and then seeks additional resources outside of this list.

Example 3-105:

```
SRCFG[test] HOSTLIST=node01,node1[3-5]
```

### Node Features

Node features can be specified to constrain which resources are considered.

Example 3-106:

```
SRCFG[test] NODEFEATURES=fastos
```

### Partition

A partition may be specified to constrain which resources are considered.

Example 3-107:

```
SRCFG[test] PARTITION=core3
```

## Flags

Reservation flags allow specification of special reservation attributes or behaviors. Supported flags are listed in the following table:

Flag Name	Description
<b>ACLOVERLAP</b>	<b>Deprecated (this is now a default flag).</b> In addition to free or idle nodes, a reservation may also reserve resources that possess credentials that meet the reservation's ACL. To change this behavior, set the <a href="#">NOACLOVERLAP on page 465</a> flag.
<b>ADVRESJOBDESTROY</b>	All jobs that have an <a href="#">ADVRES</a> matching this reservation are canceled when the reservation is destroyed.
<b>ALLOWJOBOVERLAP</b>	A job is allowed to start in a reservation that may end before the job completes. When the reservation ends before the job completes, the job will not be canceled but will continue to run.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job <a href="#">ADVRES</a> flag. (See <a href="#">Job to Reservation Binding</a> .)

Flag Name	Description
<p><b>DEDICATEDRESOURCE</b> (aka <b>EXCLUSIVE</b>)</p>	<p>Reservation placed only on resources that are not reserved by any other reservation including job, system, and user reservation. There are two exception to this:</p> <ol style="list-style-type: none"> <li>1. Reserved resources could be allocated when <b>DEDICATEDRESOURCE</b> is combined with <a href="#">IGNJOBRSV*</a></li> <li>2. Reserved resources could be allocated when a reservation matches the submitter's ACL. In this case, to make <b>DEDICATEDRESOURCE</b> <i>truly</i> exclusive, use the <a href="#">NOACLOVERLAP</a> flag.</li> </ol> <div data-bbox="646 590 1409 779" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> The order that SRCFG reservations are listed in the configuration is important when using <b>DEDICATEDRESOURCE</b>, because reservations made afterwards can steal resources later. During configuration, list <b>DEDICATEDRESOURCE</b> reservations last to guarantee exclusiveness.</p> </div>
<p><b>EVACVMS</b></p>	<p>Reservation will automatically evacuate virtual machines from the reservation nodelist.</p> <div data-bbox="646 898 1409 1024" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> The same action can be accomplished by using reservation profiles. For more information, see <a href="#">Optimizing Maintenance Reservations</a> on page 455.</p> </div>
<p><b>IGNIDLEJOBS*</b></p>	<p>Reservation can be placed on top of idle job reservations.</p> <div data-bbox="646 1108 1409 1203" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> This flag is meant to be used in conjunction with <b>DEDICATEDRESOURCE</b>.</p> </div>
<p><b>IGNJOBRSV*</b></p>	<p>Ignores existing job reservations, allowing the reservation to be forced onto available resources even if it conflicts with existing job reservations. User and system reservation conflicts are still valid. It functions the same as <a href="#">IGNIDLEJOBS</a> plus allows a reservation to be placed on top of an existing running job's reservation.</p> <div data-bbox="646 1413 1409 1507" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> This flag is meant to be used in conjunction with <b>DEDICATEDRESOURCE</b>.</p> </div>
<p><b>IGNRSV*</b></p>	<p>Request ignores existing resource reservations allowing the reservation to be forced onto available resources even if this conflicts with other reservations. It functions the same as <a href="#">IGNJOBRSV</a> plus allows the reservation to be placed on top of the system reservations.</p> <div data-bbox="646 1686 1409 1780" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> This flag is meant to be used in conjunction with <b>DEDICATEDRESOURCE</b>.</p> </div>

Flag Name	Description
<b>IGNSTATE*</b>	Reservation ignores node state when assigning nodes. It functions the same as <a href="#">IGNRSV</a> plus allows the reservation to be placed on nodes that are not currently available. Also ignores resource availability on nodes.
<b>NOACLOVERLAP</b>	<p>All resources must be free or idle, with no existing reservations. Moab will not allocate in-use resources even if they match the reservation's ACL.</p> <pre>mrsvctl -c -t 12 -E -F noaclovelap -a user==john</pre> <p><i>Moab looks for resources that are exclusive (free). Without the flag, Moab would look for resources that are exclusive or that are already running john's jobs.</i></p> <p><b>i</b> This flag is meant to be used in conjunction with <a href="#">DEDICATEDRESOURCE</a>.</p>
<b>NOVMIGRATION</b>	If set on a reservation, this prevents VMs from being migrated away from the reservation. If there are multiple reservations on the hypervisor and at least one reservation does not have the <a href="#">NOVMIGRATION</a> flag, then VMs will be migrated.
<b>OWNERPREEMPT</b>	Jobs by the reservation <a href="#">owner</a> are allowed to preempt non-owner jobs using reservation resources.
<b>OWNERPREEMPTIGNOREMINTIME</b>	<p>Allows the <a href="#">OWNERPREEMPT</a> flag to "trump" the <a href="#">PREEMPTMINTIME</a> setting for jobs already running on a reservation when the owner of the reservation submits a job. For example: without the <a href="#">OWNERPREEMPTIGNOREMINTIME</a> flag set, a job submitted by the owner of a reservation will not preempt non-owner jobs already running on the reservation until the <a href="#">PREEMPTMINTIME</a> setting (if set) for those jobs is passed.</p> <p>With the <a href="#">OWNERPREEMPTIGNOREMINTIME</a> flag set, a job submitted by the owner of a reservation immediately preempts non-owner jobs already running on the reservation, regardless of whether <a href="#">PREEMPTMINTIME</a> is set for the non-owner jobs.</p>
<b>REQFULL</b>	Reservation is only created when all resources can be allocated.
<b>SINGLEUSE</b>	Reservation is automatically removed after completion of the first job to use the reserved resources.

Flag Name	Description
SPACEFLEX	<b>Deprecated (this is now a default flag).</b> Reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

**i** \* *IGNIDLEJOBS*, *IGNJOBRSV*, *IGNRSV*, and *IGNSTATE* flags are built on one another and form a hierarchy. *IGNJOBRSV* performs the function of *IGNIDLEJOBS* plus its own functions. *IGNRSV* performs the function of *IGNJOBRSV* and *IGNIDLEJOBS* plus its own functions. *IGNSTATE* performs the function of *IGNRSV*, *IGNJOBRSV*, and *IGNIDLEJOBS* plus its own functions. While you can use combinations of these flags, it is not necessary. If you set one flag, you do not need to set other flags that fall beneath it in the hierarchy.

Most flags can be associated with a reservation via the [mrsvctl -c -F](#) command or the [SRCFG](#) parameter.

## Configuring Standing Reservations

Standing reservations allow resources to be dedicated for particular uses. This dedication can be configured to be permanent or periodic, recurring at a regular time of day and/or time of week. There is extensive applicability of standing reservations for everything from daily dedicated job runs to improved use of resources on weekends. By default, standing reservations can overlap other reservations. Unless you set an ignore-type flag (*ACLOVERLAP*, *DEDICATEDRESOURCE*, *IGNIDLEJOBS*, or *IGNJOBRSV*), they are automatically given the *IGNRSV* flag. All standing reservation attributes are specified via the [SRCFG](#) parameter using the attributes listed in the table below.

### Standing Reservation Attributes

ACCESS	
<b>Format</b>	<i>DEDICATED</i> or <i>SHARED</i>
<b>Default</b>	---
<b>Description</b>	If set to <i>SHARED</i> , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
<b>Example</b>	<pre>SRCFG[test] ACCESS=SHARED</pre> <p><i>Standing reservation test may access resources allocated to existing standing and administrative reservations.</i></p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> The order that SRCFG reservations are listed in the configuration are important when using <i>DEDICATED</i>, because reservations made afterwards can steal resources later. During configuration, list <i>DEDICATED</i> reservations last to guarantee exclusiveness.</p> </div>

ACCOUNTLIST	
<b>Format</b>	List of valid, comma delimited account names (see <a href="#">ACL Modifiers</a> ).
<b>Default</b>	---
<b>Description</b>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
<b>Example</b>	<pre>SRCFG[test] ACCOUNTLIST=ops,staff</pre> <p><i>Jobs using the account <b>ops</b> or <b>staff</b> are granted access to the resources in standing reservation <b>test</b>.</i></p>

CHARGE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	Overrides the default charging behavior. If set to <i>True</i> , indicates that this reservation should be charged, even if no <b>ChargeAccount</b> or <b>ChargeUser</b> are specified (this assumes your Accounting Manager is set up to permit this). If set to <i>False</i> , indicates that this reservation should not be charged. It is not necessary to specify <b>CHARGE=True</b> if <b>CHARGEACCOUNT</b> or <b>CHARGEUSER</b> is specified.
<b>Example</b>	<pre>SRCFG[sr_gold1] CHARGE=False</pre> <p><i>Prevent charges to this reservation (might be used when <b>AMCFG[] ALWAYSCHARGERESERVATIONS=True</b>).</i></p>

CHARGEACCOUNT	
<b>Format</b>	Any valid account name.
<b>Default</b>	---
<b>Description</b>	Specifies that idle cycles for this reservation should be charged against the specified account (via the Accounting Manager).
	<div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; display: inline-block;">  <b>CHARGEACCOUNT</b> must be used in conjunction with <a href="#">CHARGEUSER</a>.         </div>

## CHARGEACCOUNT

<b>Example</b>	<pre>SRCFG[sr_gold1] CHARGEACCOUNT=math SRCFG[sr_gold1] CHARGEUSER=john</pre> <p><i>Moab charges all idle cycles within reservations supporting standing reservation <code>sr_gold1</code> to account <code>math</code>.</i></p>
----------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## CHARGEUSER

<b>Format</b>	Any valid username.
<b>Default</b>	---
<b>Description</b>	<p>Specifies that idle cycles for this reservation should be charged against the specified user (via the Accounting Manager).</p> <div style="border: 1px solid #0070c0; border-radius: 5px; padding: 5px; background-color: #e6f2ff;">  <b>CHARGEUSER</b> must be used in conjunction with <a href="#">CHARGEACCOUNT</a>.         </div>
<b>Example</b>	<pre>SRCFG[sr_gold1] CHARGEACCOUNT=math SRCFG[sr_gold1] CHARGEUSER=john</pre> <p><i>Moab charges all idle cycles within reservations supporting standing reservation <code>sr_gold1</code> to user <code>john</code>.</i></p>

## CLASSLIST

<b>Format</b>	List of valid, comma delimited classes/queues (see <a href="#">ACL Modifiers</a> ).
<b>Default</b>	---
<b>Description</b>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
<b>Example</b>	<pre>SRCFG[test] CLASSLIST=!interactive</pre> <p><i>Jobs not using the class <code>interactive</code> are granted access to the resources in standing reservation <code>test</code>.</i></p>

CLUSTERLIST	
<b>Format</b>	List of valid, comma-delimited peer clusters (see <a href="#">Moab Workload Manager for Grids</a> ).
<b>Default</b>	---
<b>Description</b>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
<b>Example</b>	<pre>SRCFG[test] CLUSTERLIST=orion2,orion7</pre> <p><i>Moab grants jobs from the listed peer clusters access to the reserved resources.</i></p>

COMMENT	
<b>Format</b>	<STRING>  If the string contains whitespace, it should be enclosed in single (') or double quotes (").
<b>Default</b>	---
<b>Description</b>	Specifies a descriptive message associated with the standing reservation and all child reservations.
<b>Example</b>	<pre>SRCFG[test] COMMENT='rsv for network testing'</pre> <p><i>Moab annotates the standing reservation <b>test</b> and all child reservations with the specified message. These messages show up within Moab client commands, Moab web tools, and graphical administrator tools.</i></p>

DAYS	
<b>Format</b>	One or more of the following (comma-delimited): <ul style="list-style-type: none"> <li>• <i>Mon</i></li> <li>• <i>Tue</i></li> <li>• <i>Wed</i></li> <li>• <i>Thu</i></li> <li>• <i>Fri</i></li> <li>• <i>Sat</i></li> <li>• <i>Sun</i></li> <li>• <i>[ALL]</i></li> </ul>

DAYS	
<b>Default</b>	<i>[ALL]</i>
<b>Description</b>	Specifies which days of the week the standing reservation is active.
<b>Example</b>	<pre>SRCFG[test] DAYS=Mon,Tue,Wed,Thu,Fri</pre> <p><i>Standing reservation <b>test</b> is active Monday through Friday.</i></p>

DEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	2
<b>Description</b>	<p>Specifies the depth of standing reservations to be created (one per <a href="#">period</a>).</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> To satisfy the <b>DEPTH</b>, Moab creates new reservations at the beginning of the specified <a href="#">PERIOD</a> on page 475. If your reservation ends at the same time that a new <b>PERIOD</b> begins, the number of reservations may not match the requested <b>DEPTH</b>. To prevent or resolve this issue, set the <a href="#">ENDTIME</a> on page 471 a couple minutes before the beginning of the next <b>PERIOD</b>. For example, set the <b>ENDTIME</b> to <i>23:58</i> instead of <i>00:00</i>.</p> </div>
<b>Example</b>	<pre>SRCFG[test] PERIOD=DAY DEPTH=6</pre> <p><i>Specifies that six reservations will be created for standing reservation <b>test</b>.</i></p>

DISABLE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies that the standing reservation should no longer spawn child reservations.
<b>Example</b>	<pre>SRCFG[test] PERIOD=DAY DEPTH=7 DISABLE=TRUE</pre> <p><i>Specifies that reservations are created for standing reservation <b>test</b> for today and the next six days.</i></p>

ENDTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	24:00:00
<b>Description</b>	Specifies the time of day the standing reservation period ends (end of day or end of week depending on <a href="#">PERIOD</a> ).
<b>Example</b>	<pre>SRCFG[test] STARTTIME=8:00:00 SRCFG[test] ENDTIME=17:00:00 SRCFG[test] PERIOD=DAY</pre> <p><i>Standing reservation <b>test</b> is active from 8:00 AM until 5:00 PM.</i></p>

FLAGS	
<b>Format</b>	Comma-delimited list of zero or more flags listed in the <a href="#">reservation flags overview</a> .
<b>Default</b>	---
<b>Description</b>	Specifies special reservation attributes. See <a href="#">Managing Reservations - Flags</a> for details.
<b>Example</b>	<pre>SRCFG[test] FLAGS=BYNAME, DEDICATEDRESOURCE</pre> <p><i>Jobs may only access the resources within this reservation if they explicitly request the reservation by name. Further, the reservation is created to not overlap with other reservations.</i></p>

GROUPLIST	
<b>Format</b>	One or more comma-delimited group names.
<b>Default</b>	[ALL]
<b>Description</b>	Specifies the groups allowed access to this standing reservation (see <a href="#">ACL Modifiers</a> ).
<b>Example</b>	<pre>SRCFG[test] GROUPLIST=staff, ops, special SRCFG[test] CLASSLIST=interactive</pre> <p><i>Moab allows jobs with the listed group IDs or which request the job class <b>interactive</b> to use the resources covered by the standing reservation.</i></p>

HOSTLIST	
<b>Format</b>	One or more comma delimited host names or <a href="#">host expressions</a> or the string "class:<classname>".
<b>Default</b>	---
<b>Description</b>	<p>Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the "class:X" format, Moab only selects hosts that support the specified class. If <b>TASKCOUNT</b> is also specified, only <b>TASKCOUNT</b> tasks are reserved. Otherwise, all matching hosts are reserved.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> The <b>HOSTLIST</b> attribute is treated as host regular expression so <code>foo10</code> will map to <code>foo10</code>, <code>foo101</code>, <code>foo1006</code>, and so forth. To request an exact host match, the expression can be bounded by the caret and dollar symbol expression markers as in <code>^foo10\$</code>.</p> </div>
<b>Example</b>	<pre>SRCFG[test] HOSTLIST=node001,node002,node003 SRCFG[test] RESOURCES=PROCS:2;MEM:512 SRCFG[test] TASKCOUNT=2</pre> <p><i>Moab reserves a total of two tasks with 2 processors and 512 MB each, using resources located on <b>node001</b>, <b>node002</b>, and/or <b>node003</b>.</i></p> <pre>SRCFG[test] HOSTLIST=node01,node1[3-5]</pre> <p><i>The reservation will consume all nodes that have "node01" somewhere in their names and all nodes that have both "node1" and either a "3," "4," or "5" in their names.</i></p> <pre>SRCFG[test] HOSTLIST=r:node[1-6]</pre> <p><i>The reservation will consume all nodes with names that begin with "node" and end with any number 1 through 6. In other words, it will reserve <b>node1</b>, <b>node2</b>, <b>node3</b>, <b>node4</b>, <b>node5</b>, and <b>node6</b>.</i></p>

JOBATTRLIST	
<b>Format</b>	Comma-delimited list of one or more of the following job attributes: <ul style="list-style-type: none"> <li>• <b>PREEMPTEE</b></li> <li>• <b>INTERACTIVE</b></li> <li>• any generic attribute configured through <b>NODECFG</b>.</li> </ul>
<b>Default</b>	---

JOBATTRLIST	
<b>Description</b>	<p>Specifies job attributes that grant a job access to the reservation.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-bottom: 5px;"> <p><b>i</b> Values can be specified with a "!=" assignment to only allow jobs NOT requesting a certain feature inside the reservation.</p> </div> <div style="border: 1px solid #0070C0; padding: 5px;"> <p><b>i</b> To enable/disable reservation access based on requested node features, use the parameter <a href="#">NODETOJOBATTRMAP</a>.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #000; padding: 5px; margin-bottom: 5px;"> <pre>SRCFG[test] JOBATTRLIST=PREEMPTEE</pre> </div> <div style="border: 1px dashed #000; padding: 5px;"> <p><i>Preemptible jobs can access the resources reserved within this reservation.</i></p> </div>

MAXJOB	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Specifies the maximum number of jobs that can run in the reservation.
<b>Example</b>	<div style="border: 1px dashed #000; padding: 5px; margin-bottom: 5px;"> <pre>SRCFG[test] MAXJOB=1</pre> </div> <div style="border: 1px dashed #000; padding: 5px;"> <p><i>Only one job will be allowed to run in this reservation.</i></p> </div>

MAXTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS[+]
<b>Default</b>	---
<b>Description</b>	Specifies the maximum time for jobs allowable. Can be used with Affinity to attract jobs with same <b>MAXTIME</b> .
<b>Example</b>	<div style="border: 1px dashed #000; padding: 5px; margin-bottom: 5px;"> <pre>SRCFG[test] MAXTIME=1:00:00+</pre> </div> <div style="border: 1px dashed #000; padding: 5px;"> <p><i>Jobs with a time of 1:00:00 are attracted to this reservation.</i></p> </div>

NODEFEATURES	
<b>Format</b>	Comma-delimited list of node features.
<b>Default</b>	---
<b>Description</b>	Specifies the required node features for nodes that are part of the standing reservation.
<b>Example</b>	<pre>SRCFG[test] NODEFEATURES=wide, fddi</pre> <p><i>All nodes allocated to the standing reservation must have both the <b>wide</b> and <b>fddi</b> node attributes.</i></p>

OWNER	
<b>Format</b>	<p>&lt;CREDTYPE&gt;:&lt;CREDID&gt;</p> <p>Where &lt;CREDTYPE&gt; is one of <b>USER</b>, <b>GROUP</b>, <b>ACCT</b>, <b>QoS</b>, <b>CLASS</b> or <b>CLUSTER</b> and &lt;CREDTYPE&gt; is a valid credential id of that type.</p>
<b>Default</b>	---
<b>Description</b>	<p>Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-bottom: 5px;"> <p><b>i</b> Setting a <b>USER</b> as the <b>OWNER</b> of a reservation gives that user privileges to query and release the reservation.</p> </div> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px;"> <p><b>i</b> For sandbox reservations, sandboxes are applied to a specific peer only if <b>OWNER</b> is set to <b>CLUSTER:&lt;PEERNAME&gt;</b>.</p> </div>
<b>Example</b>	<pre>SRCFG[test] OWNER=ACCT:jupiter</pre> <p><i>User <b>jupiter</b> owns the reservation and may be granted special privileges associated with that ownership.</i></p>

PARTITION	
<b>Format</b>	Valid partition name.
<b>Default</b>	<b>[ALL]</b>

PARTITION	
<b>Description</b>	Specifies the partition in which to create the standing reservation.
<b>Example</b>	<pre>SRCFG[test] PARTITION=OLD</pre> <p><i>The standing reservation will only select resources from partition <b>OLD</b>.</i></p>

PERIOD	
<b>Format</b>	One of <i>DAY</i> , <i>WEEK</i> , or <i>INFINITY</i> .
<b>Default</b>	<i>DAY</i>
<b>Description</b>	Specifies the period of the standing reservation.
<b>Example</b>	<pre>SRCFG[test] PERIOD=WEEK</pre> <p>Each standing reservation covers a one week period.</p>

PROCLIMIT	
<b>Format</b>	<p>&lt;QUALIFIER&gt;&lt;INTEGER&gt;          &lt;QUALIFIER&gt; may be one of the following &lt;, &lt;=, ==, &gt;=, &gt;</p>
<b>Default</b>	---
<b>Description</b>	Specifies the processor limit for jobs requesting access to this standing reservation.
<b>Example</b>	<pre>SRCFG[test] PROCLIMIT&lt;=4</pre> <p><i>Jobs requesting 4 or fewer processors are allowed to run.</i></p>

PSLIMIT	
<b>Format</b>	<p>&lt;QUALIFIER&gt;&lt;INTEGER&gt;          &lt;QUALIFIER&gt; may be one of the following &lt;, &lt;=, ==, &gt;=, &gt;</p>

PSLIMIT	
<b>Default</b>	---
<b>Description</b>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
<b>Example</b>	<pre>SRCFG[test] PSLIMIT&lt;=40000</pre> <p><i>Jobs requesting 40000 or fewer processor-seconds are allowed to run.</i></p>

QOSLIST	
<b>Format</b>	Zero or more valid, comma-delimited QoS names.
<b>Default</b>	---
<b>Description</b>	Specifies that jobs with the listed QoS names can access the reserved resources.
<b>Example</b>	<pre>SRCFG[test] QOSLIST=hi, low, special</pre> <p><i>Moab allows jobs using the listed QoS's access to the reserved resources.</i></p>

REQUIREDTPN	
<b>Format</b>	<p>&lt;QUALIFIER&gt;&lt;INTEGER&gt;</p> <p>&lt;QUALIFIER&gt; may be one of the following &lt;, &lt;=, ==, &gt;=, &gt;</p>
<b>Default</b>	---
<b>Description</b>	Restricts access to reservations based on the job's TPN (tasks per node).
<b>Example</b>	<pre>SRCFG[test] REQUIREDTPN==4</pre> <p><i>Jobs with tpn=4 or ppn=4 would be allowed within the reservation, but any other TPN value would not. (For more information, see <a href="#">TPN (Exact Tasks Per Node)</a> on page 479.)</i></p>

RESOURCES	
<b>Format</b>	Semicolon delimited <ATTR>:<VALUE> pairs where <ATTR> may be one of <i>PROCS</i> , <i>MEM</i> , <i>SWAP</i> , or <i>DISK</i> .
<b>Default</b>	<i>PROCS</i> :-1 (All processors available on node)
<b>Description</b>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.) Supported resources currently include the following:</p> <ul style="list-style-type: none"> <li>• <i>PROCS</i> (number of processors)</li> <li>• <i>MEM</i> (real memory in MB)</li> <li>• <i>DISK</i> (local disk in MB)</li> <li>• <i>SWAP</i> (virtual memory in MB)</li> </ul>
<b>Example</b>	<pre>SRCFG[test] RESOURCES=PROCS:1;MEM:512</pre> <p><i>Each standing reservation task reserves one processor and 512 MB of real memory.</i></p>

ROLLBACKOFFSET	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See <a href="#">QoS</a> for more info about quality of service and service level agreements; also see <a href="#">Rollback Reservation Overview</a>.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF;"> <p> Neither credlock nor advres is compatible on the jobs submitted for this reservation.</p> </div>
<b>Example</b>	<pre>SRCFG[ajax] ROLLBACKOFFSET=24:00:00 TASKCOUNT=32 SRCFG[ajax] PERIOD=INFINITY ACCOUNTLIST=ajax</pre> <p><i>The standing reservation guarantees access to up to 32 processors within 24 hours to jobs from the ajax account.</i></p> <p>Adding an asterisk to the <b>ROLLBACKOFFSET</b> value pins rollback reservation start times when an idle reservation is created in the rollback reservation. For example:</p> <pre>SRCFG[staff] ROLLBACKOFFSET=18:00:00* PERIOD=INFINITY</pre>

RSVACCESSLIST	
<b>Format</b>	<RESERVATION>[,...]
<b>Default</b>	---
<b>Description</b>	A list of reservations to which the specified reservation has access.
<b>Example</b>	<pre>SRCFG[test] RSVACCESSLIST=rsv1,rsv2,rsv3</pre>

RSVGROUP	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	See section <a href="#">Reservation Group</a> for a detailed description.
<b>Example</b>	<pre>SRCFG[test] RSVGROUP=rsvgrp1 SRCFG[ajax] RSVGROUP=rsvgrp1</pre>

STARTTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	00:00:00:00 (midnight)
<b>Description</b>	<p>Specifies the time of day/week the standing reservation becomes active. Whether this indicates a time of day or time of week depends on the setting of the <a href="#">PERIOD</a> attribute.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #D9E1F2;"> <p><b>i</b> If specified within a <a href="#">reservation profile</a>, a value of 0 indicates the reservation should start at the earliest opportunity.</p> </div>
<b>Example</b>	<pre>SRCFG[test] STARTTIME=08:00:00 SRCFG[test] ENDTIME=17:00:00 SRCFG[test] PERIOD=DAY</pre> <p><i>The standing reservation will be active from 8:00 a.m. until 5:00 p.m. each day.</i></p>

TASKCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (unlimited tasks)
<b>Description</b>	Specifies how many tasks should be reserved for the reservation.
<b>Example</b>	<pre>SRCFG[test] RESOURCES=PROCS:1;MEM:256 SRCFG[test] TASKCOUNT=16</pre> <p><i>Standing reservation <b>test</b> reserves 16 tasks worth of resources; in this case, 16 processors and 4 GB of real memory.</i></p>

TIMELIMIT	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	-1 (no time based access)
<b>Description</b>	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access.
<b>Example</b>	<pre>SRCFG[test] TIMELIMIT=1:00:00</pre> <p><i>Moab allows jobs to access up to one hour of resources in the standing reservation.</i></p>

TPN (Exact Tasks Per Node)	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (no TPN constraint)
<b>Description</b>	Specifies the exact number of tasks per node that must be available on eligible nodes.
<b>Example</b>	<pre>SRCFG[2] TPN=4 SRCFG[2] RESOURCES=PROCS:2;MEM:256</pre> <p><i>Moab must locate four tasks on each node that is to be part of the reservation. That is, each node included in standing reservation 2 must have 8 processors and 1 GB of memory available.</i></p>

TRIGGER	
<b>Format</b>	See <a href="#">Creating a trigger</a> on page 748 for syntax.
<b>Default</b>	N/A
<b>Description</b>	Specifies event triggers to be launched by the scheduler under the scheduler's ID. These triggers can be used to conditionally cancel reservations, <a href="#">modify resources</a> , or launch various actions at specified event offsets. See <a href="#">About object triggers</a> on page 745 for more detail.
<b>Example</b>	<pre>SRCFG[fast] TRIGGER=EType=start,Offset=5:00:00,AType=exec,Action="/usr/local/domail.pl"</pre> <p><i>Moab launches the domail.pl script 5 hours after any fast reservation starts.</i></p>

USERLIST	
<b>Format</b>	Comma-delimited list of users.
<b>Default</b>	---
<b>Description</b>	Specifies which users have access to the resources reserved by this reservation (see <a href="#">ACL Modifiers</a> ).
<b>Example</b>	<pre>SRCFG[test] USERLIST=bob,joe,mary</pre> <p><i>Users bob, joe and mary can all access the resources reserved within this reservation.</i></p>

### Standing Reservation Overview

A standing reservation is similar to a normal administrative reservation in that it also places an access control list on a specified set of resources. Resources are specified on a per-task basis and currently include processors, local disk, real memory, and swap. The access control list supported for standing reservations includes users, groups, accounts, job classes, and QoS levels. Standing reservations can be configured to be permanent or periodic on a daily or weekly basis and can accept a daily or weekly start and end time. Regardless of whether permanent or recurring on a daily or weekly basis, standing reservations are enforced using a series of reservations, extending a number of periods into the future as controlled by the **DEPTH** attribute of the [SRCFG](#) parameter.

The following examples demonstrate possible configurations specified with the **SRCFG** parameter.

**Example 3-108: Basic Business Hour Standing Reservation**

```

SRCFG[interactive] TASKCOUNT=6 RESOURCES=PROCS:1, MEM:512
SRCFG[interactive] PERIOD=DAY DAYS=MON, TUE, WED, THU, FRI
SRCFG[interactive] STARTTIME=9:00:00 ENDTIME=17:00:00
SRCFG[interactive] CLASSLIST=interactive

```

**i** When using the SRCFG parameter, attribute lists must be delimited using the comma (,), pipe (|), or colon (:) characters; they cannot be space delimited. For example, to specify a multi-class ACL, specify:

```
SRCFG[test] CLASSLIST=classA,classB
```

**i** Only one **STARTTIME** and one **ENDTIME** value can be specified per reservation. If varied start and end times are desired throughout the week, complementary standing reservations should be created. For example, to establish a reservation from 8:00 p.m. until 6:00 a.m. the next day during business days, two reservations should be created—one from 8:00 p.m. until midnight, and the other from midnight until 6:00 a.m. Jobs can run across reservation boundaries allowing these two reservations to function as a single reservation that spans the night. The following example demonstrates how to span a reservation across 2 days on the same nodes:

```

SRCFG[Sun] PERIOD=WEEK
SRCFG[Sun] STARTTIME=00:20:00:00 ENDTIME=01:00:00:00
SRCFG[Sun] HOSTLIST=node01,node02,node03

SRCFG[Mon] PERIOD=WEEK
SRCFG[Mon] STARTTIME=01:00:00:00 ENDTIME=01:06:00:00
SRCFG[Sun] HOSTLIST=node01,node02,node03

```

The preceding example fully specifies a reservation including the quantity of resources requested using the **TASKCOUNT** and **RESOURCES** attributes. In all cases, resources are allocated to a reservation in units called tasks where a task is a collection of resources that must be allocated together on a single node. The **TASKCOUNT** attribute specifies the number of these tasks that should be reserved by the reservation. In conjunction with this attribute, the **RESOURCES** attribute defines the reservation task by indicating what resources must be included in each task. In this case, the scheduler must locate and reserve 1 processor and 512 MB of memory together on the same node for each task requested.

As mentioned previously, a standing reservation reserves resources over a given time frame. The **PERIOD** attribute may be set to a value of **DAY**, **WEEK**, or **INFINITY** to indicate the period over which this reservation should recur. If not specified, a standing reservation recurs on a daily basis. If a standing reservation is configured to recur daily, the attribute **DAYS** may be specified to indicate which days of the week the reservation should exist. This attribute takes a comma-delimited list of days where each day is specified as the first three letters of the day in all capital letters: **MON** or **FRI**. The preceding example specifies that this reservation is periodic on a daily basis and should only exist on business days.

The time of day during which the requested tasks are to be reserved is specified using the **STARTTIME** and **ENDTIME** attributes. These attributes are specified in standard military time HH:MM:SS format and both **STARTTIME** and **ENDTIME** specification is optional defaulting to midnight at the beginning and end of

the day respectively. In the preceding example, resources are reserved from 9:00 a.m. until 5:00 p.m. on business days.

The final aspect of any reservation is the access control list indicating who or what can use the reserved resources. In the preceding example, the **CLASSLIST** attribute is used to indicate that jobs requesting the class "interactive" should be allowed to use this reservation.

## Specifying Reservation Resources

In most cases, only a small subset of standing reservation attributes must be specified in any given case. For example, by default, **RESOURCES** is set to `PROCS=-1` which indicates that each task should reserve all of the processors on the node on which it is located. This, in essence, creates a one task equals one node mapping. In many cases, particularly on uniprocessor systems, this default behavior may be easiest to work with. However, in SMP environments, the **RESOURCES** attribute provides a powerful means of specifying an exact, multi-dimensional resource set.

**i** An examination of the parameters documentation shows that the default value of **PERIOD** is *DAYS*. Thus, specifying this parameter in the preceding above was unnecessary. It was used only to introduce this parameter and indicate that other options exist beyond daily standing reservations.

### Example 3-109: Host Constrained Standing Reservation

Although the first example did specify a quantity of resources to reserve, it did not specify where the needed tasks were to be located. If this information is not specified, Moab attempts to locate the needed resources anywhere it can find them. The Example 1 reservation essentially discovers hosts where the needed resources can be found. If the **SPACEFLEX** reservation flag is set, then the reservation continues to float to the best hosts over the life of the reservation. Otherwise, it will be locked to the initial set of allocated hosts.

If a site wanted to constrain a reservation to a subset of available resources, this could be accomplished using the **HOSTLIST** attribute. The **HOSTLIST** attribute is specified as a comma-separated list of hostnames and constrains the scheduler to only select tasks from the specified list. This attribute can exactly specify hosts or specify them using host regular expressions. The following example demonstrates a possible use of the **HOSTLIST** attribute:

```
SRCFG[interactive] DAYS=MON,TUE,WED,THU,FRI
SRCFG[interactive] PERIOD=DAY
SRCFG[interactive] STARTTIME=10:00:00 ENDTIME=15:00:00
SRCFG[interactive] RESOURCES=PROCS:2, MEM:256
SRCFG[interactive] HOSTLIST=node001,node002,node005,node020
SRCFG[interactive] TASKCOUNT=6
SRCFG[interactive] CLASSLIST=interactive
```

*Note that the **HOSTLIST** attribute specifies a non-contiguous list of hosts. Any combination of hosts may be specified and hosts may be specified in any order. In this example, the **TASKCOUNT** attribute is also specified. These two attributes both apply constraints on the scheduler with **HOSTLIST** specifying where the tasks can be located and **TASKCOUNT** indicating how many total tasks may be allocated. In this example, six tasks are requested but only four hosts are specified. To handle this, if adequate resources are available, the scheduler may attempt to allocate more than one task per host. For example, assume that each host is a quad-processor system with 1 GB of memory. In such a case, the scheduler could allocate up to two tasks per host and even satisfy the **TASKCOUNT** constraint without using all of the hosts in the hostlist.*

**i** It is important to note that even if there is a one to one mapping between the value of **TASKCOUNT** and the number of hosts in **HOSTLIST**, the scheduler will not necessarily place one task on each host. If, for example, node001 and node002 were 8 processor SMP hosts with 1 GB of memory, the scheduler could locate up to four tasks on each of these hosts fully satisfying the reservation taskcount without even partially using the remaining hosts. (Moab will place tasks on hosts according to the policy specified with the [NODEALLOCATIONPOLICY](#) parameter.) If the hostlist provides more resources than what is required by the reservation as specified via **TASKCOUNT**, the scheduler will simply select the needed resources within the set of hosts listed.

## Enforcing Policies Via Multiple Reservations

Single reservations enable multiple capabilities. Combinations of reservations can further extend a site's capabilities to impose specific policies.

### Example 3-110: Reservation Stacking

If **HOSTLIST** is specified but **TASKCOUNT** is not, the scheduler will pack as many tasks as possible onto all of the listed hosts. For example, assume the site added a second standing reservation named *debug* to its configuration that reserved resources for use by certain members of its staff using the following configuration:

```

SRCFG[interactive] DAYS=MON, TUE, WED, THU, FRI
SRCFG[interactive] PERIOD=DAY
SRCFG[interactive] STARTTIME=10:00:00 ENDTIME=15:00:00
SRCFG[interactive] RESOURCES=PROCS:2, MEM:256
SRCFG[interactive] HOSTLIST=node001, node002, node005, node020
SRCFG[interactive] TASKCOUNT=6
SRCFG[interactive] CLASSLIST=interactive
SRCFG[debug] HOSTLIST=node001, node002, node003, node004
SRCFG[debug] USERLIST=helpdesk
SRCFG[debug] GROUPLIST=operations, sysadmin
SRCFG[debug] PERIOD=INFINITY

```

The new standing reservation is quite simple. Since **RESOURCES** is not specified, it will allocate all processors on each host that is allocated. Since **TASKCOUNT** is not specified, it will allocate every host listed in **HOSTLIST**. Since **PERIOD** is set to *INFINITY*, the reservation is always in force and there is no need to specify **STARTTIME**, **ENDTIME**, or **DAYS**.

The standing reservation has two access parameters set using the attributes **USERLIST** and **GROUPLIST**. This configuration indicates that the reservation can be accessed if any one of the access lists specified is satisfied by the job. In essence, reservation access is logically OR'd allowing access if the requester meets any of the access constraints specified. In this example, jobs submitted by either user *helpdesk* or any member of the groups *operations* or *sysadmin* can use the reserved resources (See [ACL Modifiers](#)).

Unless [ACL Modifiers](#) are specified, access is granted to the logical *OR* of access lists specified within a standing reservation and granted to the logical *AND* of access lists across different standing reservations. A comparison of the standing reservations *interactive* and *debug* in the preceding example indicates that they both can allocate hosts *node001* and *node002*. If *node001* had both of these reservations in place simultaneously and a job attempted to access this host during business hours when standing reservation *interactive* was active. The job could only use the *doubly* reserved resources if it requests the run class *interactive* and it meets the constraints of reservation *debug*—that is, that it is submitted by user *helpdesk* or by a member of the group *operations* or *sysadmin*.

As a rule, the scheduler does not stack reservations unless it must. If adequate resources exist, it can allocate reserved resources side by side in a single SMP host rather than on top of each other. In the case of a 16 processor SMP host with two 8 processor standing reservations, 8 of the processors on this host will be allocated to the first reservation, and 8 to the next. Any configuration is possible. The 16 processor hosts can also have 4 processors reserved for user "John," 10 processors reserved for group "Staff," with the remaining 2 processors available for use by any job.

Stacking reservations is not usually required but some site administrators choose to do it to enforce elaborate policies. There is no problem with doing so as long as you can keep things straight. It really is not too difficult a concept; it just takes a little getting used to. See the [Reservation Overview](#) section for a more detailed description of reservation use and constraints.

As mentioned earlier, by default the scheduler enforces standing reservations by creating a number of reservations where the number created is controlled by the **DEPTH** attribute. Each night at midnight, the scheduler updates its periodic non-floating standing reservations. By default, **DEPTH** is set to 2, meaning when the scheduler starts up, it will create two 24-hour reservations covering a total of two days' worth of time—a reservation for today and one for tomorrow. For daily reservations, at midnight, the reservations roll, meaning today's reservation expires and is removed, tomorrow's reservation becomes today's, and the scheduler creates a new reservation for the next day.

With this model, the scheduler continues creating new reservations in the future as time moves forward. Each day, the needed resources are always reserved. At first, all appears automatic but the standing reservation **DEPTH** attribute is in fact an important aspect of reservation rolling, which helps address certain site specific environmental factors. This attribute remedies a situation that might occur when a job is submitted and cannot run immediately because the system is backlogged with jobs. In such a case, available resources may not exist for several days out and the scheduler must reserve these future resources for this job. With the default **DEPTH** setting of two, when midnight arrives, the scheduler attempts to roll its standing reservations but a problem arises in that the job has now allocated the resources needed for the standing reservation two days out. Moab cannot reserve the resources for the standing reservation because they are already claimed by the job. The standing reservation reserves what it can but because all needed resources are not available, the resulting reservation is now smaller than it should be, or is possibly even empty.

If a standing reservation is smaller than it should be, the scheduler will attempt to add resources each iteration until it is fully populated. However, in the case of this job, the job is not going to release its reserved resources until it completes and the standing reservation cannot claim them until this time. The **DEPTH** attribute allows a site to specify how deep into the future a standing reservation should reserve its resources allowing it to claim the resources first and prevent this problem. If a partial standing reservation is detected on a system, it may be an indication that the reservation's **DEPTH** attribute should be increased.

In Example 3, the **PERIOD** attribute is set to *INFINITY*. With this setting, a single, permanent standing reservation is created and the issues of resource contention do not exist. While this eliminates the contention issue, infinite length standing reservations cannot be made periodic.

#### *Example 3-111: Multiple ACL Types*

In most cases, access lists within a reservation are logically OR'd together to determine reservation access. However, exceptions to this rule can be specified by using the required ACL marker—the asterisk (\*). Any ACL marked with this symbol is required and a job is only allowed to use a reservation if it meets all required ACLs and at least one non-required ACL (if specified). A common use for this facility is in conjunction with the **TIMELIMIT** attribute. This attribute controls the length of time a job may use the

resources within a standing reservation. This access mechanism can be AND'd or OR'd to the cumulative set of all other access lists as specified by the required ACL marker. Consider the following example configuration:

```

SRCFG[special] TASKCOUNT=32
SRCFG[special] PERIOD=WEEK
SRCFG[special] STARTTIME=1:08:00:00
SRCFG[special] ENDTIME=5:17:00:00
SRCFG[special] NODEFEATURES=largememory
SRCFG[special] TIMELIMIT=1:00:00*
SRCFG[special] QOSLIST=high,low,special-
SRCFG[special] ACCCOUNTLIST=!projectX,!projectY

```

The above configuration requests 32 tasks which translate to 32 nodes. The **PERIOD** attribute makes this reservation periodic on a weekly basis while the attributes **STARTTIME** and **ENDTIME** specify the week offsets when this reservation is to start and end (Note that the specification format has changed to DD:HH:MM:SS.). In this case, the reservation starts on Monday at 8:00 a.m. and runs until Friday at 5:00 p.m. The reservation is enforced as a series of weekly reservations that only cover the specified time frame. The **NODEFEATURES** attribute indicates that each of the reserved nodes must have the node feature "largememory" configured.

As described earlier, **TIMELIMIT** indicates that jobs using this reservation can only use it for one hour. This means the job and the reservation can only overlap for one hour. Clearly jobs requiring an hour or less of wallclock time meet this constraint. However, a four-hour job that starts on Monday at 5:00 a.m. or a 12-hour job that starts on Friday at 4:00 p.m. also satisfies this constraint. Also, note the **TIMELIMIT** required ACL marker, \*; it is set indicating that jobs must not only meet the **TIMELIMIT** access constraint but must also meet one or more of the other access constraints. In this example, the job can use this reservation if it can use the access specified via **QOSLIST** or **ACCOUNTLIST**; that is, it is assigned a QoS of *high*, *low*, or *special*, or the submitter of the job has an account that satisfies the *!projectX* and *!projectY* criteria. See the [QoS Overview](#) for more info about QoS configuration and usage.

## Affinity

Reservation ACLs allow or deny access to reserved resources but they may be configured to also impact a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort—using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity. Note the '-' (hyphen or negative sign) following the *special* in the **QOSLIST** values. This special mark indicates that QoS *special* should be granted access to this reservation but should be assigned negative affinity. Thus, the **QOSLIST** attribute specifies that QoS *high* and *low* should be granted access with positive affinity (use the reservation first where possible) and QoS *special* granted access with negative affinity (use the reservation only when no other resources are available).

Affinity status is granted on a per access object basis rather than a per access list basis and always defaults to positive affinity. In addition to negative affinity, neutral affinity can also be specified using the equal sign (=) as in QOSLIST[0] normal= high debug= low-.

When a job matches multiple ACLs for a reservation, the final node affinity for the node, job, and reservation combination is based on the last matching ACL entry found in the configuration file.

For example, given the following reservation ACLs, a job matching both will receive a negative affinity:

```
SRCFG[res1] USERLIST=joe+ MAXTIME<=4:00:00-
```

With the following reservation ACLs, a job matching both will receive a positive affinity:

```
SRCFG[res1] MAXTIME<=4:00:00- USERLIST=joe+
```

### ACL Modifiers

ACL modifiers allow a site to change the default behavior of ACL processing. By default, a reservation can be accessed if one or more of its ACLs can be met by the requestor. This behavior can be changed using the "deny" or "required" ACL modifier, as in the following tables:

Not	
<b>Symbol:</b>	! (exclamation point)
<b>Description</b>	If attribute is met, the requestor is denied access regardless of any other satisfied ACLs.
<b>Example</b>	<pre>SRCFG[test] GROUPLIST=staff USERLIST=!steve</pre> <p><i>Allow access to all staff members other than <b>steve</b>.</i></p>

Required	
<b>Symbol:</b>	* (asterisk)
<b>Description</b>	All required ACLs must be satisfied for requestor access to be granted.
<b>Example</b>	<pre>SRCFG[test] QOSLIST=*high MAXTIME=*2:00:00</pre> <p><i>Only jobs in QoS <b>high</b> that request less than 2 hours of walltime are granted access.</i></p>

XOR	
<b>Symbol:</b>	^ (carat)
<b>Description</b>	All attributes of the type specified other than the ones listed in the ACL satisfy the ACL.

XOR	
<b>Example</b>	<pre>SRCFG[test] QOSLIST=^high</pre> <p><i>All jobs other than those requesting QoS <b>high</b> are granted access.</i></p>

CredLock	
<b>Symbol:</b>	& (ampersand)
<b>Description</b>	Matching jobs will be required to run on the resources reserved by this reservation. You can use this modifier on accounts, classes, groups, qualities of service, and users.
<b>Example</b>	<pre>SRCFG[test] USERLIST=&amp;john</pre> <p><i>All of user <b>john</b>'s jobs must run in this reservation.</i></p>

HPEnable (hard policy enable)	
<b>Symbol:</b>	~ (tilde)
<b>Description</b>	ACLs marked with this modifier are ignored during soft policy scheduling and are only considered for hard policy scheduling once all eligible soft policy jobs start.
<b>Example</b>	<pre>SRCFG[johnspace] USERLIST=john CLASSLIST=~debug</pre> <p><i>All of user <b>john</b>'s jobs are allowed to run in the reservation at any time. <b>Debug</b> jobs are also allowed to run in this reservation but are only considered after all of John's jobs are given an opportunity to start. User <b>john</b>'s jobs are considered before debug jobs regardless of job priority.</i></p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> If HPEnable and <b>Not</b> markers are used in conjunction, then specified credentials are <i>blocked-out</i> of the reservation during soft-policy scheduling.</p> </div>

Note the **ACCOUNTLIST** values in [Example 3-111](#) are preceded with an exclamation point, or NOT symbol. This indicates that all jobs with accounts other than **projectX** and **projectY** meet the account ACL. Note that if a !<X> value (!projectX) appears in an ACL line, that ACL is satisfied by any object not explicitly listed by a NOT entry. Also, if an object matches a NOT entry, the associated job is excluded from the reservation even if it meets other ACL requirements. For example, a QoS 3 job requesting account **projectX** is denied access to the reservation even though the job QoS matches the QoS ACL.

*Example 3-112: Binding Users to Reservations at Reservation Creation*

```
# create a 4 node reservation for john and bind all of john's jobs to that reservation
> mrsvctl -c -a user=&john -t 4
```

## Reservation Ownership

Reservation ownership allows a site to control who owns the reserved resources during the reservation time frame. Depending on needs, this ownership may be identical to, a subset of, or completely distinct from the reservation ACL. By default, reservation ownership implies resource accountability and resources not consumed by jobs are accounted against the reservation owner. In addition, ownership can also be associated with special privileges within the reservation.

Ownership is specified using the **OWNER** attribute in the format `<CREDTYPE>:<CREDID>`, as in **OWNER=USER:john**. To enable *john's* jobs to preempt other jobs using resources within the reservation, the **SRCFG** attribute **FLAG** should be set to **OWNERPREEMPT**. In the example below, the *jupiter* project chooses to share resources with the *saturn* project but only when it does not currently need them.

*Example 3-113: Limited Shared Access*

```
ACCOUNTCFG[jupiter] PRIORITY=10000
SRCFG[jupiter] HOSTLIST=node0[1-9]
SRCFG[jupiter] PERIOD=INFINITY
SRCFG[jupiter] ACCOUNTLIST=jupiter, saturn-
SRCFG[jupiter] OWNER=ACCT:jupiter
SRCFG[jupiter] FLAGS=OWNERPREEMPT
```

## Partitions

A reservation can be used in conjunction with a partition. Configuring a standing reservation on a partition allows constraints to be (indirectly) applied to a partition.

*Example 3-114: Time Constraints by Partition*

The following example places a 3-day wall-clock limit on two partitions and a 64 processor-hour limit on jobs running on partition *small*.

```
SRCFG[smallrsv] PARTITION=small MAXTIME=3:00:00:00 PSLIMIT<=230400 HOSTLIST=ALL
SRCFG[bigrsv] PARTITION=big MAXTIME=3:00:00:00 HOSTLIST=ALL
```

## Resource Allocation Behavior

As mentioned, standing reservations can operate in one of two modes, floating, or non-floating (essentially node-locked). A floating reservation is created when the flag **SPACEFLEX** is specified. If a reservation is non-floating, the scheduler allocates all resources specified by the **HOSTLIST** parameter regardless of node state, job load, or even the presence of other standing reservations. Moab interprets the request for a non-floating reservation as, "I want a reservation on these exact nodes, no matter what!"

If a reservation is configured to be floating, the scheduler takes a more relaxed stand, searching through all possible nodes to find resources meeting standing reservation constraints. Only *Idle*, *Running*, or *Busy* nodes are considered and further, only considered if no reservation conflict is detected. The reservation

attribute **ACCESS** modifies this behavior slightly and allows the reservation to allocate resources even if reservation conflicts exist.

**i** If a **TASKCOUNT** is specified with or without a **HOSTEXPRESSION**, Moab will, by default, only consider "up" nodes for allocation. To change this behavior, the reservation flag **IGNSTATE** can be specified as in the following example:

```
SRCFG[nettest] GROUPLIST=sysadm
SRCFG[nettest] FLAGS=IGNSTATE
SRCFG[nettest] HOSTLIST=node1 [3-8]
SRCFG[nettest] STARTTIME=9:00:00
SRCFG[nettest] ENDTIME=17:00:00
```

**i** Access to existing reservations can be controlled using the reservation flag **IGNRSV**.

Other standing reservation attributes not covered here include **PARTITION** and **CHARGEACCOUNT**. These parameters are described in some detail in the [parameters](#) documentation.

#### Example 3-115: Using Reservations to Guarantee Turnover

In some cases, it is desirable to make certain a portion of a cluster's resources are available within a specific time frame. The following example creates a floating reservation belonging to the *jupiter* account that guarantees 16 tasks for use by jobs requesting up to one hour.

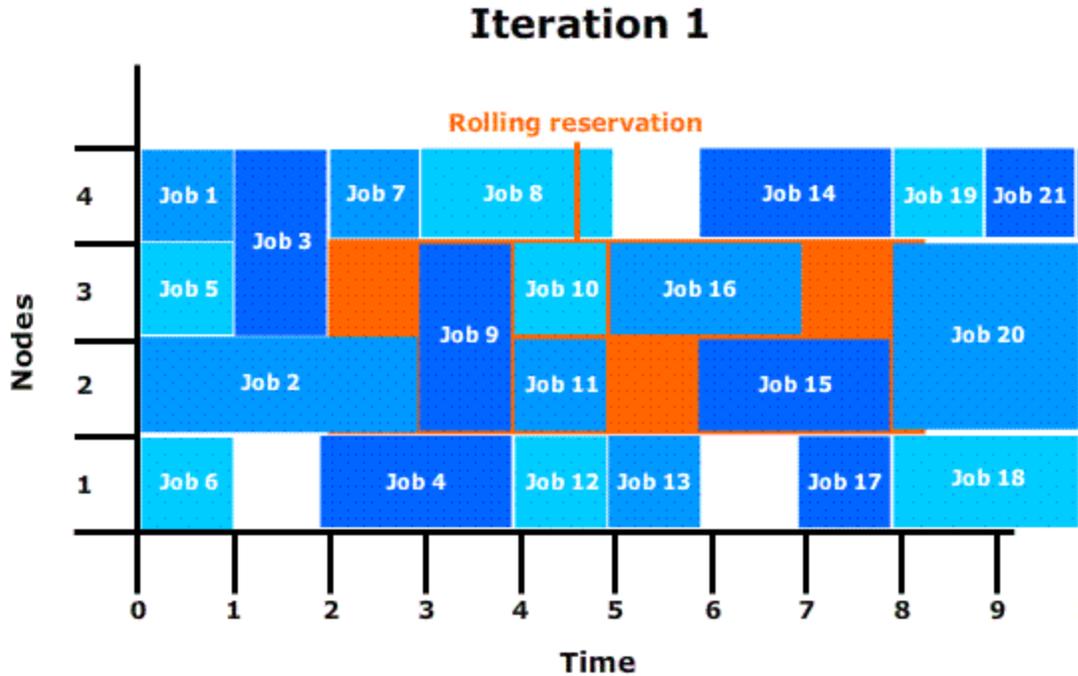

```
SRCFG[shortpool] OWNER=ACCT:jupiter
SRCFG[shortpool] FLAGS=SPACEFLEX
SRCFG[shortpool] MAXTIME=1:00:00
SRCFG[shortpool] TASKCOUNT=16
SRCFG[shortpool] STARTTIME=9:00:00
SRCFG[shortpool] ENDTIME=17:00:00
SRCFG[shortpool] DAYS=Mon,Tue,Wed,Thu,Fri
```

This reservation enables a capability similar to what was known in early Maui releases as "shortpool." The reservation covers every weekday from 9:00 a.m. to 5:00 p.m., reserving 16 tasks and allowing jobs to overlap the reservation for up to one hour. The **SPACEFLEX** flag indicates that the reservation may be dynamically modified--over time to re-locate to more optimal resources. In the case of a reservation with the **MAXTIME** ACL, this would include migrating to resources that are in use but that free up within the **MAXTIME** time frame. Additionally, because the **MAXTIME** ACL defaults to positive [affinity](#), any jobs that fit the ACL attempt to use available reserved resources first before looking elsewhere.

## Rolling Reservations

Rolling reservations are enabled using the [ROLLBACKOFFSET](#) attribute and can be used to allow users guaranteed access to resources, but the guaranteed access is limited to a time-window in the future. This functionality forces users to commit their resources in the future or lose access.

Image 3-5: Rolling reservation over 3 iterations

*Example 3-116: Rollback Reservations*

```

SRCFG[ajax] ROLLBACKOFFSET=24:00:00 TASKCOUNT=32
SRCFG[ajax] PERIOD=INFINITY ACCOUNTLIST=ajax
    
```

Adding an asterisk to the **ROLLBACKOFFSET** value pins rollback reservation start times when an idle reservation is created in the rollback reservation. For example: SRCFG[staff] ROLLBACKOFFSET=18:00:00\* PERIOD=INFINITY.

**Modifying Resources with Standing Reservations**

Moab can customize compute resources associated with a reservation during the life of the reservation. This can be done generally using the **TRIGGER** attribute, or it can be done for operating systems using the shortcut attribute **OS**. If set, Moab dynamically reprovisions allocated reservation nodes to the requested operating system as shown in the following example:

```

SRCFG[provision] PERIOD=DAY DAY=MON,WED,FRI STARTTIME=7:00:00 ENDTIME=10:00:00
SRCFG[provision] OS=rhel4 # provision nodes to use redhat during reservation, restore
when done
    
```

**Managing Administrative Reservations**

A default reservation with no ACL is termed an *administrative* reservation, but is occasionally referred to as a *system* reservation. It blocks access to all jobs because it possesses an empty access control list. It

is often useful when performing administrative tasks but cannot be used for enforcing resource usage policies.

Administrative reservations are created and managed using the [mrsvctl](#) command. With this command, all aspects of reservation time frame, resource selection, and access control can be dynamically modified. The [mdiag -r](#) command can be used to view configuration, state, allocated resource information as well as identify any potential problems with the reservation. The following table briefly summarizes commands used for common actions. More detailed information is available in the command summaries.

Action	Command
<b>create reservation</b>	<code>mrsvctl -c &lt;RSV_DESCRIPTION&gt;</code>
<b>list reservations</b>	<code>mrsvctl -l</code>
<b>release reservation</b>	<code>mrsvctl -r &lt;RSVID&gt;</code>
<b>modify reservation</b>	<code>mrsvctl -m &lt;ATTR&gt;=&lt;VAL&gt; &lt;RSVID&gt;</code>
<b>query reservation configuration</b>	<code>mdiag -r &lt;RSVID&gt;</code>
<b>display reservation hostlist</b>	<code>mrsvctl -q resources &lt;RSVID&gt;</code>

## Personal Reservations

- [Enabling Personal Reservation Management](#)
- [Reservation Accountability and Defaults](#)
  - [Reservation Allocation and Charging](#)
  - [Setting Reservation Default Attributes](#)
- [Reservation Limits](#)
- [Reservation and Job Binding](#)
  - [Constraining a job to only run in a particular reservation](#)
  - [Constraining a Reservation to Only Accept Certain Jobs](#)

By default, advance reservations are only available to scheduler administrators. While administrators may create and manage reservations to provide resource access to end-users, end-users cannot create, modify, or destroy these reservations. Moab extends the ability to manage reservations to end-users and

provides control facilities to keep these features manageable. Reservations created by end-users are called personal reservations or user reservations.

## Enabling Personal Reservation Management

User, or personal, reservations can be enabled on a per QoS basis by setting the [ENABLEUSERRSV](#) flag as in the following example:

```
QOSCFG[titan]    QFLAGS=ENABLEUSERRSV # allow 'titan' QoS jobs to create user
reservations
USERCFG[DEFAULT] QDEF=titan          # allow all users to access 'titan' QoS
...
```

If set, end-users are allowed to create, modify, cancel, and query reservations they own. As with jobs, users may associate a personal reservation with any QoS or account to which they have access. This is accomplished by specifying per reservation accountable credentials as in the following example:

```
> mrsvctl -c -S AQOS=titan -h node01 -d 1:00:00 -s 1:30:00
Note: reservation test.126 created
```

As in the preceding example, a non-administrator user who wants to create a reservation must *ALWAYS* specify an accountable QoS with the [mrsvctl -S](#) flag. This specified QoS must have the **ENABLEUSERRSV** flag. By default, a personal reservation is created with an ACL of only the user who created it.

*Example 3-117: Allow All Users in Engineering Group to Create Personal Reservations*

```
QOSCFG[rsv]      QFLAGS=ENABLEUSERRSV # allow 'rsv' QoS jobs to create user
reservations
GROUPCFG[sales] QDEF=rsv              # allow all users in group sales to access 'rsv'
QoS
...
```

*Example 3-118: Allow Specific Users to Create Personal Reservations*

```
# special qos has higher job priority and ability to create user reservations
QOSCFG[special] QFLAGS=ENABLEUSERRSV
QOSCFG[special] PRIORITY=1000
# allow betty and steve to use the special qos
USERCFG[betty]  QDEF=special
USERCFG[steve]  QLIST=fast,special,basic QDEF=rsv
...
```

## Reservation Accountability

Personal reservations must be configured with a set of accountable credentials. These credentials (user, group, account, and so forth) indicate who is responsible for the resources dedicated by the reservation. If resources are dedicated by a reservation but not consumed by a job, these resources can be charged against the specified accountable credentials. Administrators are allowed to create reservations and specify any accountable credentials for that reservation. While end-users can also be allowed to create and otherwise modify personal reservations, they are only allowed to create reservations with accountable credentials to which they have access. Further, while administrators may manage any reservation, end-users may only control reservations they own.

Like jobs, reservation accountable credentials specify which credentials are charged for reservation usage and what policies are enforced as far as usage limits and allocation management is concerned. (See the [mrsvctl](#) command documentation for more information on setting personal reservation credentials.) While similar to jobs, personal reservations do have a separate set of usage limits and different allocation charging policies.

## Setting Reservation Default Attributes

Organizations can use [reservation profiles](#) to set default attributes for personal reservations. These attributes can include reservation aspects such as management policies, charging credentials, ACLs, host constraints, and time frame settings.

## Reservation Limits

Allowing end-users the ability to create advance reservations can lead to potentially unfair and unproductive resource usage. This results from the fact that by default, there is nothing to prevent a user from reserving all resources in a given system or reserving resources during time slots that would greatly impede the scheduler's ability to schedule jobs efficiently. Because of this, it is highly advised that sites initially place either usage or allocation based constraints on the use of personal reservations. This can be achieved using Moab Accounting Manager (see the Moab Accounting Manager Administrator Guide).

## Reservation and Job Binding

Moab allows job-to-reservation binding to be configured at an administrator or end-user level. This binding constrains how job to reservation mapping is allowed.

### Constraining a job to only run in a particular reservation

Jobs may be bound to a particular reservation at submit time (using the RM extension [ADVRES](#)) or dynamically using the [mjobctl](#) command (See [Job to Reservation Mapping](#)). In either case, once bound to a reservation, a job may only run in that reservation even if other resources may be found outside of that reservation. The [mjobctl](#) command may also be used to dynamically release a job from reservation binding.

*Example 3-119: Bind job to reservation*

```
> mjobctl -m flags+=advres:grid.3 job1352
```

*Example 3-120: Release job from reservation binding*

```
> mjobctl -m flags-=advres job1352
```

### Constraining a Reservation to Only Accept Certain Jobs

Binding a job to a reservation is independent of binding a reservation to a job. For example, a reservation may be created for user "steve." User "steve" may then submit a number of jobs including one that is bound to that reservation using the **ADVRES** attribute. However, this binding simply forces that one job to use the reservation, it does not prevent the reservation from accepting other jobs

submitted by user "steve." To prevent these other jobs from using the reserved resources, reservation to job binding must occur. This binding is accomplished by specifying either general job binding or specific job binding.

General job binding is the most flexible form of binding. Using the [BYNAME](#) attribute, a reservation may be created that only accepts jobs specifically bound to it.

Specific job binding is more constraining. This form of binding causes the reservation to only accept specific jobs, regardless of other job attributes and is set using the **JOB** reservation ACL.

*Example 3-121: Configure a reservation to accept only jobs that are bound to it*

```
> mrsvctl -m flags+=byname grid.3
```

*Example 3-122: Remove general reservation to job binding*

```
> mrsvctl -m flags-=byname grid.3
```

*Example 3-123: Configure a reservation to accept a specific job*

```
> mrsvctl -m -a JOB=3456 grid.3
```

*Example 3-124: Remove a specific reservation to job binding*

```
> mrsvctl -m -a JOB=3456 grid.3 --flags=unset
```

## Partitions

- [Partition Overview](#)
- [Defining Partitions](#)
- [Managing Partition Access](#)
- [Requesting Partitions](#)
- [Per-Partition Settings](#)
- [Miscellaneous Partition Issues](#)

### Partition Overview

Partitions are a logical construct that divide available resources. Any single resource (compute node) may only belong to a single partition. Often, natural hardware or resource manager bounds delimit partitions such as in the case of disjoint networks and diverse processor configurations within a cluster. For example, a cluster may consist of 256 nodes containing four 64 port switches. This cluster may receive excellent interprocess communication speeds for parallel job tasks located within the same switch but sub-stellar performance for tasks that span switches. To handle this, the site may choose to create four partitions, allowing jobs to run within any of the four partitions but not span them.

While partitions do have value, it is important to note that within Moab, the [standing reservation](#) facility provides significantly improved flexibility and should be used in the vast majority of politically

motivated cases where partitions may be required under other resource management systems. Standing reservations provide time flexibility, improved access control features, and more extended resource specification options. Also, another Moab facility called [Node Sets](#) allows intelligent aggregation of resources to improve per job node allocation decisions. In cases where system partitioning is considered for such reasons, node sets may be able to provide a better solution.

Still, one key advantage of partitions over standing reservations and node sets is the ability to specify partition specific policies, limits, priorities, and scheduling algorithms although this feature is rarely required. An example of this need may be a cluster consisting of 48 nodes owned by the Astronomy Department and 16 nodes owned by the Mathematics Department. Each department may be willing to allow sharing of resources but wants to specify how their partition will be used. As mentioned, many of Moab's scheduling policies may be specified on a per partition basis allowing each department to control the scheduling goals within their partition.

The partition associated with each node should be specified as indicated in the [Node Location](#) section. With this done, partition access lists may be specified on a per job or per QoS basis to constrain which resources a job may have access to. (See the [QoS Overview](#) for more information.) By default, QoSs and jobs allow global partition access. Note that by default, a job may only use resources within a single partition.

If no partition is specified, Moab creates one partition per resource manager into which all resources corresponding to that resource manager are placed. (This partition is given the same name as the resource manager.)

**i** A partition may not span multiple resource managers. In addition to these resource manager partitions, a pseudo-partition named "[ALL]" is created that contains the aggregate resources of all partitions.

**i** While the resource manager partitions are real partitions containing resources not explicitly assigned to other partitions, the "[ALL]" partition is only a convenience object and is not a real partition; thus it cannot be requested by jobs or included in configuration ACLs.

## Defining Partitions

Node to partition mappings can be established directly using the [NODECFG](#) parameter or indirectly using the [FEATUREPARTITIONHEADER](#) parameter. If using direct mapping, this is accomplished as shown in the example that follows.

```
NODECFG[node001] PARTITION=astronomy
NODECFG[node002] PARTITION=astronomy
...
NODECFG[node049] PARTITION=math
...
```

**i** By default, Moab creates two partitions, "DEFAULT" and "[ALL]." These are used internally, and consume spots in the 31-partition maximum defined in the [MMAX\\_PAR](#) parameter. If more partitions are needed, you can adjust the maximum partition count. See [Adjusting Default Limits](#) for information on increasing the maximum number of partitions.

## Managing Partition Access

Partition access can be constrained by credential ACLs and by limits based on job resource requirements.

### Credential Based Access

Determining who can use which partition is specified using the **\*CFG** parameters ([USERCFG](#), [GROUPCFG](#), [ACCOUNTCFG](#), [QOSCFG](#), [CLASSCFG](#), and [SYSCFG](#)). These parameters allow you to select a partition access list on a credential or system wide basis using the **PLIST** attribute. By default, the access associated with any given job is the logical OR of all partition access lists assigned to the job's credentials.

For example, assume a site with two partitions, *general*, and *test*. The site management would like everybody to use the *general* partition by default. However, one user, Steve, needs to perform the majority of his work on the test partition. Two special groups, staff and management will also need access to use the test partition from time to time but will perform most of their work in the general partition. The following example configuration enables the needed user and group access and defaults for this site:

```
SYSCFG [base]      PLIST=general:test
USERCFG [DEFAULT] PLIST=general
USERCFG [steve]    PLIST=general:test
GROUPCFG [staff]   PLIST=general:test
GROUPCFG [mgmt]    PLIST=general:test
```

While using a logical OR approach allows sites to add access to certain jobs, some sites prefer to work the other way around. In these cases, access is granted by default and certain credentials are then restricted from accessing various partitions. To use this model, a system partition list must be specified as in the following example:

```
SYSCFG [base]      PLIST=general,test&
USERCFG [demo]     PLIST=test&
GROUPCFG [staff]   PLIST=general&
```

In the preceding example, note the ampersand (&). This character, which can be located anywhere in the **PLIST** line, indicates that the specified partition list should be logically AND'd with other partition access lists. In this case, the configuration limits jobs from user *demo* to running in partition *test* and jobs from group *staff* to running in partition *general*. All other jobs are allowed to run in either partition.

**i** When using AND-based partition access lists, the base system access list must be specified with **SYSCFG**.

### Per Job Resource Limits

Access to partitions can be constrained based on the resources requested on a per job basis with limits on both minimum and maximum resources requested. All limits are specified using [PARCFG](#). See [Usage Limits](#) for more information on the available limits.

```
PARCFG [amd]      MAX.PROC=16
PARCFG [pIII]     MAX.WCLIMIT=12:00:00 MIN.PROC=4
PARCFG [aix]      MIN.NODE=12
```

## Requesting Partitions

Users may request to use any partition they have access to on a per job basis. This is accomplished using the resource manager extensions since most native batch systems do not support the partition concept. For example, on a [TORQUE](#) system, a job submitted by a member of the group *staff* could request that the job run in the *test* partition by adding the line `-l partition=test` to the `qsub` command line. See the [resource manager extension overview](#) for more information on configuring and using resource manager extensions.

## Per-Partition Settings

The following settings can be specified on a per-partition basis using the [PARCFG](#) parameter:

Setting	Description
<b>GMETRIC</b>	<p>Specifies a <a href="#">generic metric</a> to apply to the partition. It is configured like a Moab parameter, with the <code>gmetric</code> name inside square brackets. Specify multiple gmetrics by separating each configuration with a space. For example:</p> <pre>PARCFG[par1] GMETRIC[GM1]=20 GMETRIC[GM2]=10</pre> <p><i>Partition par1 has a GM1 metric of 20 and a GM2 metric of 10.</i></p>
<b>JOBNODEMATCHPOLICY</b>	Specifies the <a href="#">JOBNODEMATCHPOLICY</a> to be applied to jobs that run in the specified partition.
<b>NODEACCESSPOLICY</b>	Specifies the <a href="#">NODEACCESSPOLICY</a> to be applied to jobs that run in the specified partition.
<b>NODEALLOCATIONPOLICY</b>	Specifies the <a href="#">NODEALLOCATIONPOLICY</a> to be applied to jobs that run in the specified partition.
<b>USETTC</b>	Specifies whether <a href="#">TTC</a> specified at submission should be used and displayed by the scheduler.
<b>VMCREATEDURATION</b>	Specifies the maximum amount of time VM creation can take before Moab considers it a failure (in [HH[:MM[:SS]]). If no value is set, there is no maximum limit.
<b>VMDELETEDURATION</b>	Specifies the maximum amount of time VM deletion can take before Moab considers it a failure (in [HH[:MM[:SS]]). If no value is set, there is no maximum limit.
<b>VMMIGRATEDURATION</b>	Specifies the maximum amount of time VM migration can take before Moab considers it a failure (in [HH[:MM[:SS]]). If no value is set, there is no maximum limit.

## Miscellaneous Partition Issues

A brief caution: Use of partitions has been quite limited in recent years as other, more effective approaches are selected for site scheduling policies. Consequently, some aspects of partitions have received only minor testing. Still, note that partitions are fully supported and any problem found will be rectified.

## Quality of Service (QoS) Facilities

This section describes how to do the following:

- Allow key projects access to special services (such as preemption, resource dedication, and advance reservations).
- Provide access to special resources by requested QoS.
- Enable special treatment within priority and fairshare facilities by requested QoS.
- Provide exemptions to usage limits and other policies by requested QoS.
- Specify delivered service and response time targets.
- Enable job deadline guarantees.
- Control the list of QoSs available to each user and job.
- Enable special charging rates based on requested or delivered QoS levels.
- Enable limits on the extent of use for each defined QoS.
- Monitor current and historical usage for each defined QoS.

It contains the following sub-sections:

- [QoS Overview](#)
- [QoS Enabled Privileges](#)
  - [Special Prioritization](#)
  - [Service Access and Constraints](#)
  - [Usage Limits and Overrides](#)
  - [Service Access Thresholds](#)
  - [Preemption Management](#)
- [Managing QoS Access](#)

- [Requesting QoS Services at Job Submission](#)
- [Restricting Access to Special Attributes](#)

## QoS Overview

Moab's QoS facility allows a site to give special treatment to various classes of jobs, users, groups, and so forth. Each QoS object can be thought of as a container of special privileges ranging from fairness policy exemptions, to special job prioritization, to special functionality access. Each QoS object also has an extensive access list of users, groups, and accounts that can access these privileges.

Sites can configure various QoSs each with its own set of priorities, policy exemptions, and special resource access settings. They can then configure user, group, account, and class access to these QoSs. A given job will have a default QoS and may have access to several additional QoSs. When the job is submitted, the submitter may request a specific QoS or just allow the default QoS to be used. Once a job is submitted, a user may adjust the QoS of the job at any time using the [setqos](#) command. The `setqos` command will only allow the user to modify the QoS of that user's jobs and only change the QoS to a QoS that this user has access to. Moab administrators may change the QoS of any job to any value.

Jobs can be granted access to QoS privileges if the QoS is listed in the system default configuration [QDEF](#) (QoS default) or [QLIST](#) (QoS access list), or if the QoS is specified in the [QDEF](#) or [QLIST](#) of a [user](#), [group](#), [account](#), or [class](#) associated with that job. Alternatively, a user may access QoS privileges if that user is listed in the QoSs [MEMBERULIST](#) attribute.

The [mdiag -q](#) command can be used to obtain information about the current QoS configuration including specified credential access.

## QoS Enabled Privileges

The privileges enabled via QoS settings may be broken into the following categories:

- [Special Prioritization on page 499](#)
- [Service Access and Constraints on page 500](#)
- [Usage Limits and Overrides on page 503](#)
- [Service Access Thresholds on page 504](#)
- [Preemption Management on page 504](#)

All privileges are managed via the [QOSCFG](#) parameter.

### Special Prioritization

Attribute name	Description
<b>FSTARGET</b>	Specifies QoS <a href="#">fairshare</a> target.
<b>FSWEIGHT</b>	Sets QoS fairshare weight offset affecting a job's <a href="#">fairshare</a> priority component.

Attribute name	Description
<b>PRIORITY</b>	Assigns priority to all jobs requesting particular QoS.
<b>QTTARGET</b>	Sets QoS queuetime target affecting a job's <a href="#">target</a> priority component and QoS delivered.
<b>QTWEIGHT</b>	Sets QoS queuetime weight offset affecting a job's <a href="#">service</a> priority component.
<b>XFTARGET</b>	Sets QoS XFactor target affecting a job's <a href="#">target</a> priority component and QoS delivered.
<b>XFWEIGHT</b>	Sets QoS XFactor weight offset affecting a job's <a href="#">service</a> priority component.

Example 3-125:

```
# assign priority for all qos geo jobs
QOSCFG[geo] PRIORITY=10000
```

## Service Access and Constraints

The QoS facility can be used to enable special services and to disable default services. These services are enabled/disabled by setting the QoS **QFLAGS** attribute.

Flag Name	Description
<b>DEADLINE</b>	Job may request an absolute or relative completion <a href="#">deadline</a> and Moab will reserve resources to meet that deadline. (An alternative priority based deadline behavior is discussed in the <a href="#">PRIORITY FACTORS</a> section.)
<b>DEDICATED</b>	Moab dedicates all resources of an allocated node to the job meaning that the job will not share a node's compute resources with any other job.
<b>ENABLEUSERRSV</b>	Allow user or personal <a href="#">reservations</a> to be created and managed.
<b>IGNALL</b>	Scheduler ignores all resource usage policies for jobs associated with this QoS.

Flag Name	Description
<b>JOBPRIOACCRUALPOLICY</b>	<p>Specifies how Moab should track the dynamic aspects of a job's priority. The two valid values are <i>ACCRUE</i> and <i>RESET</i>.</p> <ul style="list-style-type: none"> <li>• <i>ACCRUE</i> indicates that the job will accrue queue time based priority from the time it is submitted unless it violates any of the policies not specified in <a href="#">JOBPRIOEXCEPTIONS</a>.</li> <li>• <i>RESET</i> indicates that it will accrue priority from the time it is submitted unless it violates any of the <a href="#">JOBPRIOEXCEPTIONS</a>. However, with <i>RESET</i>, if the job does violate <a href="#">JOBPRIOEXCEPTIONS</a> then its queue time based priority will be reset to 0.</li> </ul> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p><b>i</b> <b>JOBPRIOACCRUALPOLICY</b> is a global parameter, but can be configured to work only in <b>QOSCFG</b>:</p> <pre style="border: 1px dashed #0070C0; border-radius: 5px; padding: 5px; display: inline-block;">QOSCFG[arrays] JOBPRIOACCRUALPOLICY=ACCRUE</pre> </div> <p>The following old <b>JOBPRIOACCRUALPOLICY</b> values have been deprecated and should be adjusted to the following values:</p> <ul style="list-style-type: none"> <li>• QUEUEPOLICY = ACCRUE and JOBPRIOEXCEPTIONS SOFTPOLICY,HARDPOLICY</li> <li>• QUEUEPOLICYRESET = RESET and JOBPRIOEXCEPTIONS SOFTPOLICY,HARDPOLICY</li> <li>• ALWAYS = ACCRUE and JOBPRIOEXCEPTIONS ALL</li> <li>• FULLPOLICY = ACCRUE and JOBPRIOEXCEPTIONS NONE</li> <li>• FULLPOLICYRESET = RESET and JOBPRIOEXCEPTIONS NONE</li> </ul>
<b>JOBPRIOEXCEPTIONS</b>	<p>Specifies exceptions for calculating a job's dynamic priority (QUEUE TIME, XFACTOR, TARGETQUEUE TIME). Valid values are a comma delimited list of any of the following: <i>DEFER</i>, <i>DEPENDS</i>, <i>SOFTPOLICY</i>, <i>HARDPOLICY</i>, <i>IDLEPOLICY</i>, <i>USERHOLD</i>, <i>BATCHHOLD</i>, and <i>SYSTEMHOLD</i> (<i>ALL</i> or <i>NONE</i> can also be specified on their own).</p> <p>Normally, when a job violates a policy, is placed on hold, or has an unsatisfied dependency, it will not accrue priority. Exceptions can be configured to allow a job to accrue priority in spite of any of these violations. With <i>DEPENDS</i> a job will increase in priority even if there exists an unsatisfied dependency. With <i>SOFTPOLICY</i>, <i>HARDPOLICY</i>, or <i>IDLEPOLICY</i> a job can accrue priority despite violating a specific limit. With <i>DEFER</i>, <i>USERHOLD</i>, <i>BATCHHOLD</i>, or <i>SYSTEMHOLD</i> a job can accrue priority despite being on hold.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p><b>i</b> <b>JOBPRIOEXCEPTIONS</b> is a global parameter, but can be configured to work only in <b>QOSCFG</b>:</p> <pre style="border: 1px dashed #0070C0; border-radius: 5px; padding: 5px; display: inline-block;">QOSCFG[arrays] JOBPRIOEXCEPTIONS=IDLEPOLICY</pre> </div>
<b>NOBF</b>	Job is not considered for backfill.

Flag Name	Description
<b>NORESERVATION</b>	Job should never reserve resources regardless of priority.
<b>NTR</b>	<p>Job is prioritized as next to run (NTR) and backfill is disabled to prevent other jobs from jumping in front of ones with the NTR flag.</p> <div style="border: 1px solid black; padding: 10px; margin-top: 10px;"> <p><b>i</b> It is important to note that jobs marked with this flag should not be blocked. If they are, Moab will stop scheduling because if a job is marked with this flag, no other jobs will be run until the flagged NTR (Next to Run) job starts. Consider using the <b>PRIORITY</b> attribute of the <a href="#">QOSCFG[&lt;QOSID&gt;]</a> on page 1022 parameter instead, when possible. Or, as you may encounter a scheduling delay for NTR-flagged jobs to start, consider using the <a href="#">RESERVATIONDEPTH</a> and <a href="#">RESERVATIONQOSLIST</a> parameters to provide better scheduling flow. See <a href="#">Reservation Policies</a> on page 457 (especially the section on Assigning Per-QoS Reservation Creation Rules) for more information.</p> </div>
<b>PREEMPTCONFIG</b>	User jobs may specify options to alter how preemption impacts the job such as <a href="#">min-preempttime</a> .
<b>PREEMPTTEE</b>	Job may be preempted by higher priority <b>PREEMPTOR</b> jobs.
<b>PREEMPTFSV</b>	Job may be preempted by higher priority <b>PREEMPTOR</b> jobs if it exceeds its <a href="#">fairshare</a> target when started.
<b>PREEMPTOR</b>	Job may preempt lower priority <b>PREEMPTTEE</b> jobs.
<b>PREEMPTSPV</b>	Job may be preempted by higher priority <b>PREEMPTOR</b> jobs if it currently violates a <a href="#">soft usage policy</a> limit.
<b>PROVISION</b>	If the job cannot locate available resources with the needed OS or software, the scheduler may provision a number of nodes to meet the needed OS or software requirements.
<b>RESERVEALWAYS</b>	Job should create resource reservation regardless of job priority.
<b>RUNNOW</b>	<p>Boosts a job's system priority and makes the job a preemptor.</p> <div style="border: 1px solid black; padding: 10px; margin-top: 10px;"> <p><b>i</b> RUNNOW overrides resource restrictions such as MAXJOB or MAXPROC.</p> </div>
<b>TRIGGER</b>	The job is able to directly specify triggers.

Flag Name	Description
<b>USERRESERVED[:&lt;RSVID&gt;]</b>	Job may only use resources within accessible reservations. If <RSVID> is specified, job may only use resources within the specified reservation.

Example 3-126: For lowprio QoS job, disable backfill and make job preemptible

```
QOSCFG[lowprio] QFLAGS=NOBF,PREEMPTEE
```

Example 3-127: Bind all jobs to chemistry reservation

```
QOSCFG[chem-b] QFLAGS=USERRESERVED:chemistry
```

### Other QoS Attributes

In addition to the flags, there are attributes that alter service access.

Attribute name	Description
<b>SYSPRIO</b>	Sets the system priority on jobs associated with this QoS.

Example 3-128: All jobs submitted under a QoS sample receive a system priority of 1

```
QOSCFG[sample] SYSPRIO=1
```

### Per QoS Required Reservations

If desired, jobs associated with a particular QoS can be locked into a reservation or reservation group using the **REQRID** attribute. For example, to force jobs using QoS *jasper* to only use the resources within the *failsafe* standing reservation, use the following:

```
QOSCFG[jasper] REQRID=failsafe
...
```

### Usage Limits and Overrides

All credentials, including QoS, allow specification of job usage limits as described in the [Basic Fairness Policies](#) overview. In such cases, jobs are constrained by the most limiting of all applicable policies. With QoSs, an override limit may also be specified and with this limit, jobs are constrained by the override, regardless of other limits specified. The following parameters can override the throttling policies from other credentials:

**OMAXJOB**, **OMAXNODE**, **OMAXPE**, **OMAXPROC**, **OMAXPS**, **OMAXJPROC**, **OMAXJPS**, **OMAXJWC**, and **OMAXJNODE**.

(See [Usage Limits/Throttling Policies Override Limits](#).)

Example 3-129:

```
# staff QoS should have a limit of 48 jobs, ignoring the user limit
USERCFG[DEFAULT]    MAXJOB=10
QOSCFG[staff]       OMAXJOB=48
```

### Service Access Thresholds

Jobs can be granted access to services such as [preemption](#) and [reservation creation](#), and they can be granted access to resource reservations. However, with QoS thresholds, this access can be made conditional on the current queue time and XFactor metrics of an idle job. The following table lists the available QoS service thresholds:

Threshold attribute	Description
<b>PREEMPTQTTRESHOLD</b>	A job with this QoS becomes a preemptor if the specified queue time threshold is reached.
<b>PREEMPTXFTHRESHOLD</b>	A job with this QoS becomes a preemptor if the specified XFactor threshold is reached.
<b>RSVQTTRESHOLD</b>	A job with this QoS can create a <a href="#">job reservation</a> to guarantee resource access if the specified queue time threshold is reached.
<b>RSVXFTHRESHOLD</b>	A job with this QoS can create a <a href="#">job reservation</a> to guarantee resource access if the specified XFactor threshold is reached.
<b>ACLQTTRESHOLD</b>	A job with this QoS can access reservations with a corresponding QoS ACL only if the specified queue time threshold is reached.
<b>ACLXFTHRESHOLD</b>	A job with this QoS can access reservations with a corresponding QoS ACL only if the specified XFactor threshold is reached.
<b>TRIGGERQTTRESHOLD</b>	If a job with this QoS fails to run before this threshold is reached, any failure triggers associated with this QoS will fire.

### Preemption Management

Job [preemption](#) facilities can be controlled on a per-QoS basis using the [PREEMPTTEE](#) and [PREEMPTOR](#) flags. Jobs that are preemptible can optionally be constrained to only be preempted in a particular manner by specifying the QoS **PREEMTPOLICY** attribute as in the following example:

```
QOSCFG[special] QFLAGS=PREEMPTTEE PREEMTPOLICY=CHECKPOINT
```

For preemption to be effective, a job must be marked as a preemptee and must be enabled for the requested preemption type. For example, if the [PREEMTPOLICY](#) is set to suspend, a potential target job must be both a preemptee and marked with the job flag **SUSPENDABLE**. (See [suspension](#) for more

information.) If the target job is not suspendable, it will be either requeued or canceled. Likewise, if the **PREEMTPOLICY** is set to *requeue*, the job will be requeued if it is marked restartable. Otherwise, it will be canceled.

The minimum time a job must run before being considered eligible for preemption can also be configured on a per-QoS basis using the **PREEMPTMINTIME** parameter, which is analogous to the [JOBPREEMPTMINACTIVETIME](#). Conversely, **PREEMPTMAXTIME** sets a threshold for which a job is no longer eligible for preemption; see [JOBPREEMPTMAXACTIVETIME](#) for analogous details.

The **PREEMPTTEES** attribute allows you to specify which QoSs that a job in a specific QoS is allowed to preempt. The **PREEMPTTEES** list is a comma-delimited list of QoS IDs. When a **PREEMPTTEES** attribute is specified, a job using that QoS can only preempt jobs using QoSs listed in the **PREEMPTTEES** list. In turn, those QoSs must be flagged as **PREEMPTTEE** as in the following example:

```
QOSCFG[a] QFLAGS=PREEMPTOR PREEMPTTEES=b, c
QOSCFG[b] QFLAGS=PREEMPTTEE
QOSCFG[c] QFLAGS=PREEMPTTEE
```

*In the example, jobs in the 'a' QoS can only preempt jobs in the b and c QoSs.*

## Managing QoS Access

### Specifying Credential Based QoS Access

You can define the privileges allowed within a QoS by using the **QOSCFG** parameter; however, in most cases access to the QoS is enabled via credential specific **\*CFG** parameters, specifically the [USERCFG](#), [GROUPCFG](#), [ACCOUNTCFG](#), and [CLASSCFG](#) parameters, which allow defining QoS access lists and QoS defaults. Specify credential specific QoS access by using the **QLIST** and/or **QDEF** attributes of the associated credential parameter.

### QoS Access via Logical OR

To enable QoS access, the **QLIST** and/or **QDEF** attributes of the appropriate user, group, account, or class/queue should be specified as in the following example:

```
# user john's jobs can access QOS geo, chem, or staff with geo as default
USERCFG[john] QDEF=geo QLIST=geo,chem,staff
# group system jobs can access the development qos
GROUPCFG[systems] QDEF=development
# class batch jobs can access the normal qos
CLASSCFG[batch] QDEF=normal
```

By default, jobs may request a QoS if access to that QoS is allowed by any of the job's credentials. (In the previous example, a job from user *john* submitted to the class *batch* could request QoSs *geo*, *chem*, *staff*, or *normal*).

### QoS Access via Logical AND

If desired, QoS access can be masked or logically AND'd if the QoS access list is specified with a terminating ampersand (&) as in the following example:

```
# user john's jobs can access QoS geo, chem, or staff with geo as default
USERCFG[john]      QDEF=geo  QLIST=geo,chem,staff
# group system jobs can access the development qos
GROUPCFG[systems] QDEF=development
# class batch jobs can access the normal qos
CLASSCFG[batch]   QDEF=normal
# class debug jobs can only access the development or lowpri QoSs regardless of other
credentials
CLASSCFG[debug]   QLIST=development,lowpri&
```

### Specifying QoS Based Access

QoS access may also be specified from within the QoS object using the QoS **MEMBERLIST** attribute as in the following example:

```
# define qos premiere and grant access to users steve and john
QOSCFG[premiere]  PRIORITY=1000  QFLAGS=PREEMPTOR  MEMBERLIST=steve,john
```

**i** By default, if a job requests a QoS that it cannot access, Moab places a hold on that job. The [QOSREJECTPOLICY](#) can be used to modify this behavior.

## Requesting QoS Services at Job Submission

By default, jobs inherit a default QoS based on the user, group, class, and account associated with the job. If a job has access to multiple QoS levels, the submitter can explicitly request a particular QoS using the [QoS](#) resource manager [extension](#) as in the following example:

```
> msub -l nodes=1,walltime=100,qos=special3 job.cmd
```

## Restricting Access to Special Attributes

By default, Moab allows all users access to special attributes such as [node access policy](#). By enabling the QoS facility **SPECATTRS**, the access to these policies can be restricted. For example, to enable the facility, in the moab.cfg file, specify `QOSCFG[DEFAULT] SPECATTRS=`. Then, to allow access to the special attributes, indicate which special attributes a specific QoS may access.

```
QOSCFG[DEFAULT] SPECATTRS=
QOSCFG[high]   SPECATTRS=NACCESSPOLICY
```

- [Backfill](#) on page 508
- [Node Set Overview](#) on page 514

## Optimization Overview

Moab optimizes cluster performance. Every policy, limit, and feature is designed to allow maximum scheduling flexibility while enforcing the required constraints. A driving responsibility of the scheduler is to do all in its power to maximize system use and to minimize job response time while honoring the policies that make up the site's mission goals.

However, as all jobs are not created equal, optimization must be abstracted slightly further to incorporate this fact. Cluster optimization must also focus on targeted cycle delivery. In the scientific HPC community, the true goal of a cluster is to maximize delivered research. For businesses and other organizations, the purposes may be slightly different, but all organizations agree on the simple tenet that the cluster should optimize the site's mission goals.

To obtain this goal, the scheduler has several levels of optimization it performs:

Level	Description
<b>Workload Ordering</b>	<a href="#">Prioritizing workload</a> and utilizing <a href="#">backfill</a>
<b>Intelligent Resource Allocation</b>	Selecting those resources that best meet the job's needs or best enable future jobs to run (see <a href="#">node allocation</a> )
<b>Maximizing Intra-Job Efficiency</b>	Selecting the type of nodes, collection of nodes, and proximity of nodes required to maximize job performance by minimizing both job compute and inter-process communication time (see <a href="#">node sets</a> and <a href="#">node allocation</a> )
<b>Job Pre-emption</b>	Preempting jobs to allow the most important jobs to receive the best response time (see <a href="#">pre-emption</a> )
<b>Utilizing Flexible Policies</b>	Using policies that minimize blocking and resource fragmentation while enforcing needed constraints (see <a href="#">soft throttling policies</a> and <a href="#">reservations</a> )

# Backfill

- [Backfill Overview](#)
- [Backfill Algorithms](#)
- [Configuring Backfill](#)

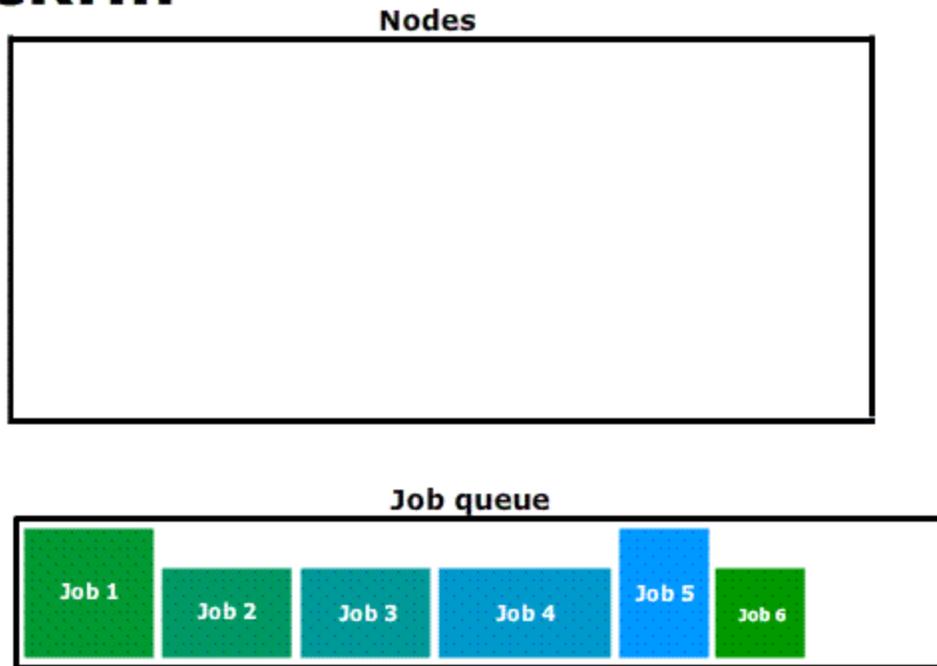

## Backfill Overview

Backfill is a scheduling optimization that allows a scheduler to make better use of available resources by running jobs out of order. When Moab schedules, it prioritizes the jobs in the queue according to a number of factors and then orders the jobs into a highest priority first (or priority FIFO) sorted list. It starts the jobs one by one stepping through the priority list until it reaches a job it cannot start. Because all jobs and reservations possess a start time and a wallclock limit, Moab can determine the completion time of all jobs in the queue. Consequently, Moab can also determine the earliest the needed resources will become available for the highest priority job to start.

Backfill operates based on this earliest job start information. Because Moab knows the earliest the highest priority job can start, and which resources it will need at that time, it can also determine which jobs can be started without delaying this job. Enabling backfill allows the scheduler to start other, lower-priority jobs so long as they do not delay the highest priority job. If backfill is enabled, Moab protects the highest priority job's start time by creating a job reservation to reserve the needed resources at the appropriate time. Moab then can start any job that will not interfere with this reservation.

Image 3-6: Scheduling with backfill

# Backfill

Backfill offers significant scheduler performance improvement. In a typical large system, enabling backfill increases system utilization by about 20% and improves turnaround time by an even greater amount. Because of the way it works, essentially filling in holes in node space, backfill tends to favor smaller and shorter running jobs more than larger and longer running ones. It is common to see over 90% of these small and short jobs backfilled. Consequently, sites will see marked improvement in the level of service delivered to the small, short jobs and moderate to little improvement for the larger, long ones.

With most algorithms and policies, there is a trade-off. Backfill is not an exception but the negative effects are minor. Because backfill locates jobs to run from throughout the idle job queue, it tends to diminish the influence of the job prioritization a site has chosen and thus may negate some desired workload steering attempts through this prioritization. Although by default the start time of the highest priority job is protected by a reservation, there is nothing to prevent the third priority job from starting early and possibly delaying the start of the second priority job. This issue is addressed along with its trade-offs [later](#) in this section.

Another problem is a little more subtle. Consider the following scenario involving a two-processor cluster. Job A has a four-hour wallclock limit and requires one processor. It started one hour ago (time zero) and will reach its wallclock limit in three more hours. Job B is the highest priority idle job and requires two processors for one hour. Job C is the next highest priority job and requires one processor for two hours. Moab examines the jobs and correctly determines that job A must finish in three hours and thus, the earliest job B can start is in three hours. Moab also determines that job C can start and finish in less than this amount of time. Consequently, Moab starts job C on the idle processor at time one. One hour later (time two), job A completes early. Apparently, the user overestimated the amount of time job A would need by a few hours. Since job B is now the highest priority job, it should be able to run. However, job C, a lower priority job was started an hour ago and the resources needed for job B are not available. Moab re-evaluates job B's reservation and determines that it can slide forward an hour. At time three, job B starts.

In review, backfill provided positive benefits. Job A successfully ran to completion. Job C was started immediately. Job B was able to start one hour sooner than its original target time, although, had backfill not been enabled, job B would have been able to run two hours earlier.

The scenario just described occurs quite frequently because user estimates for job duration are generally inaccurate. Job wallclock estimate accuracy, or wallclock accuracy, is defined as the ratio of wall time required to actually run the job divided by the wall time requested for the job. Wallclock accuracy varies from site to site but the site average is rarely better than 50%. Because the quality of the walltime estimate provided by the user is so low, job reservations for high priority jobs are often later than they need to be.

Although there do exist some minor drawbacks with backfill, its net performance impact on a site's workload is very positive. While a few of the highest priority jobs may get temporarily delayed, their position as highest priority was most likely accelerated by the fact that jobs in front of them were able to start earlier due to backfill. Studies have shown that only a very small number of jobs are truly delayed and when they are, it is only by a fraction of their total queue time. At the same time, many jobs are started significantly earlier than would have occurred without backfill.

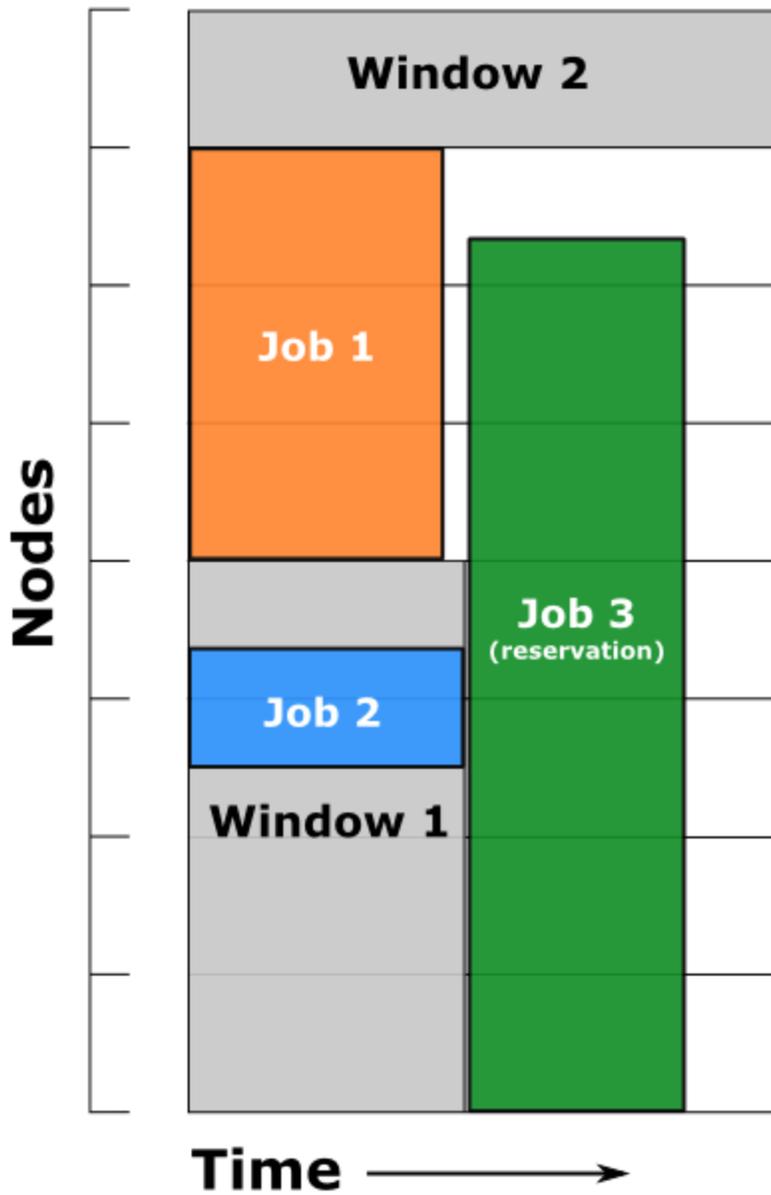

The following image demonstrates how Moab might schedule a queue using backfill.

## Backfill Algorithms

The algorithm behind Moab backfill scheduling is straightforward, although there are a number of issues and parameters that should be highlighted. First of all, Moab makes two backfill scheduling passes. For each pass, Moab selects a list of jobs that are eligible for backfill. On the first pass, only those jobs that meet the constraints of the soft [fairness throttling policies](#) are considered and scheduled. The second pass expands this list of jobs to include those that meet the hard (less constrained) fairness throttling policies.

The second important concept regarding Moab backfill is the concept of backfill windows. The figure below shows a simple batch environment containing two running jobs and a reservation for a third job. The present time is represented by the leftmost end of the box with the future moving to the right. The light gray boxes represent currently idle nodes that are eligible for backfill. For this example, let's assume that the space represented covers 8 nodes and a 2 hour time frame. To determine backfill windows, Moab analyzes the idle nodes essentially looking for largest node-time rectangles. It determines that there are two backfill windows. The first window, Window 1, consists of 4 nodes that are available for only one hour (because some of the nodes are blocked by the reservation for Job 3). The second window contains only one node but has no time limit because this node is not blocked by the reservation for Job 3. It is important to note that these backfill windows overlap.

Image 3-7: Backfillable nodes create backfill windows 1 and 2

Once the backfill windows have been determined, Moab begins to traverse them. The current behavior is to traverse these windows widest window first (most nodes to fewest nodes). As each backfill window is evaluated, Moab applies the backfill algorithm specified by the [BACKFILLPOLICY](#) parameter.

If the *FIRSTFIT* algorithm is applied, the following steps are taken:

1. The list of feasible backfill jobs is filtered, selecting only those that will actually fit in the current backfill window.
2. The first job is started.
3. While backfill jobs and idle resources remain, repeat step 1.

If *NONE* is set, the backfill policy is disabled.

Other backfill policies behave in a generally similar manner. The [parameters](#) documentation provides further details.

## Liberal versus Conservative Backfill

By default, Moab reserves only the highest priority job resulting in a liberal and aggressive backfill. This reservation guarantees that backfilled jobs will not delay the highest priority job, although they may delay other jobs. The parameter [RESERVATIONDEPTH](#) controls how conservative or liberal the backfill policy is. This parameter controls how deep down the queue priority reservations will be made. While increasing this parameter improves guarantees that priority jobs will not be bypassed, it reduces the freedom of the scheduler to backfill resulting in somewhat lower system utilization. The significance of the trade-offs should be evaluated on a site by site basis.

## Configuring Backfill

### Backfill Policies

Backfill is enabled in Moab by specifying the [BACKFILLPOLICY](#) parameter. By default, backfill is enabled in Moab using the *FIRSTFIT* algorithm. However, this parameter can also be set to *NONE* (disabled).

The number of reservations that protect the resources required by priority jobs can be controlled using [RESERVATIONDEPTH](#). This depth can be distributed across job QoS levels using [RESERVATIONQOSLIST](#).

### Backfill Chunking

In a batch environment saturated with serial jobs, serial jobs will, over time, dominate the resources available for backfill at the expense of other jobs. This is due to the time-dimension fragmentation associated with running serial jobs. For example, given an environment with an abundance of serial jobs, if a multi-processor job completes freeing processors, one of three things will happen:

1. The freed resources are allocated to another job requiring the same number of processors.
2. Additional jobs may complete at the same time allowing a larger job to allocate the aggregate resources.
3. The freed resources are allocated to one or more smaller jobs.

In environments where the scheduling iteration is much higher than the average time between completing jobs, case 3 occurs far more often than case 2, leading to smaller and smaller jobs populating the system over time.

To address this issue, the scheduler incorporates the concept of chunking. Chunking allows the scheduler to favor case 2 maintaining a more controlled balance between large and small jobs. The idea of chunking involves establishing a time-based threshold during which resources available for backfill are

aggregated. This threshold is set using the parameter [BFCHUNKDURATION](#). When resources are freed, they are made available only to jobs of a certain size (set using the parameter [BFCHUNKSIZE](#)) or larger. These resources remain protected from smaller jobs until either additional resources are freed up and a larger job can use the aggregate resources, or until the **BFCHUNKDURATION** threshold time expires.

**i** Backfill chunking is only activated when a job of size **BFCHUNKSIZE** or larger is blocked in backfill due to lack of resources.

It is important to note that the optimal settings for these parameters is very site-specific and will depend on the workload (including the average job turnaround time, job size, and mix of large to small jobs), cluster resources, and other scheduling environmental factors. Setting too restrictive values needlessly reduces utilization while settings that are too relaxed do not allowed the desired aggregation to occur.

**i** Backfill chunking is only enabled in conjunction with the *FIRSTFIT* backfill policy.

## Virtual Wallclock Time Scaling

In most environments, users submit jobs with rough estimations of the wallclock times. Within the HPC industry, a job typically runs for 40% of its specified wallclock time. Virtual Wallclock Time Scaling takes advantage of this fact to implement a form of optimistic backfilling. Jobs that are eligible for backfilling and not restricted by other policies are virtually scaled by the [BFVIRTUALWALLTIMESCALINGFACTOR](#) (assuming that the jobs finish before this new virtual wallclock limit). The scaled jobs are then compared to backfill windows to see if there is space and time for them to be scheduled. The scaled jobs are only scheduled if there is no possibility that it will conflict with a standing or administrator reservation. Conflicts with such reservations occur if the virtual wallclock time overlaps a reservation, or if the original non-virtual wallclock time overlaps a standing or administrator reservation. Jobs that can fit into an available backfill window without having their walltime scaled are backfilled "as-is" (meaning, without virtually scaling the original walltime).

**i** Virtual Wallclock Time Scaling is only enabled when the [BFVIRTUALWALLTIMESCALINGFACTOR](#) parameter is defined.

If a virtually-scaled job fits into a window, and is backfilled, it will run until completion or until it comes within one scheduling iteration ([RMPOLLINTERVAL](#) defines the exact time of an iteration) of the virtual wallclock time expiration. In the latter case the job's wallclock time is restored to its original time and Moab checks and resolves conflicts caused by this "expansion." Conflicts may occur when the backfilled job is restored to its full duration resulting in reservation overlap. The [BFVIRTUALWALLTIMECONFLICTPOLICY](#) parameter controls how Moab handles these conflicts.

If the **BFVIRTUALWALLTIMECONFLICTPOLICY** parameter is set to *NONE* or is not specified, the overlapped job reservations are rescheduled.

  - [Nested Node Sets](#)
- [Requesting Node Sets for Job Submission](#)
- [Configuring Node Sets for Classes](#)

### Node Set Usage Overview

While backfill improves the scheduler's performance, this is only half the battle. The efficiency of a cluster, in terms of actual work accomplished, is a function of both scheduling performance and individual job efficiency. In many clusters, job efficiency can vary from node to node as well as with the node mix allocated. Most parallel jobs written in popular languages such as MPI or PVM do not internally load balance their workload and thus run only as fast as the slowest node allocated. Consequently, these jobs run most effectively on homogeneous sets of nodes. However, while many clusters start out as homogeneous, they quickly evolve as new generations of compute nodes are integrated into the system. Research has shown that this integration, while improving scheduling performance due to increased scheduler selection, can actually decrease average job efficiency.

A feature called node sets allows jobs to request sets of common resources without specifying exactly what resources are required. Node set policy can be specified globally or on a per-job basis. In addition to their use in forcing jobs onto homogeneous nodes, these policies may also be used to guide jobs to one or more types of nodes on which a particular job performs best, similar to job preferences available in other systems. For example, an I/O intensive job may run best on a certain range of processor speeds, running slower on slower nodes, while wasting cycles on faster nodes. A job may specify `ANYOF:FEATURE:bigmem,fastos` to request nodes with the `bigmem` or `fastos` feature. Alternatively, if a simple feature-homogeneous node set is desired, `ONEOF:FEATURE` may be specified. On the other hand, a job may request a feature based node set with the configuration `ONEOF:FEATURE:bigmem,fastos`, in which case Moab will first attempt to locate adequate nodes where all nodes contain the `bigmem` feature. If such a set cannot be found, Moab will look for sets of

nodes containing the other specified features. In highly heterogeneous clusters, the use of node sets improves job throughput by 10 to 15%.

Node sets can be requested on a system wide or per job basis. System wide configuration is accomplished via the **NODESET\*** parameters while per job specification occurs via the [resource manager extensions](#).

 The GLOBAL node is included in all feature node sets.

When creating node sets, you have the option of using a fixed configuration or of creating node sets dynamically (by using the `msub` command). This topic explains how to set up both node set use cases.

## Node Set Configuration Examples

Global node sets are defined using the [NODESETPOLICY](#), [NODESETATTRIBUTE](#), [NODESETLIST](#), and [NODESETISOPTIONAL](#) parameters. As stated before, you can create node sets dynamically (see [Dynamic example on page 517](#)) or with a fixed configuration (see [Fixed configuration example on page 515](#)). The use of these parameters can be best highlighted with two examples.

### Fixed configuration example

In this example, a large site possesses a Myrinet based interconnect and wishes to, whenever possible, allocate nodes within Myrinet switch boundaries. To accomplish this, they could assign node attributes to each node indicating which switch it was associated with (`switchA`, `switchB`, and so forth) and then use the following system wide node set configuration:

```
NODESETPOLICY      ONEOF
NODESETATTRIBUTE   FEATURE
NODESETISOPTIONAL TRUE
NODESETLIST        switchA,switchB,switchC,switchD
...
```

### Node Set Policy

In the preceding example, the [NODESETPOLICY](#) parameter is set to the policy **ONEOF** and tells Moab to allocate nodes within a single attribute set. Other node set policies are listed in the following table:

Policy	Description
<b>ANYOF</b>	Select resources from all sets contained in node set list. The job could span multiple node sets.
<b>FIRSTOF</b>	Select resources from first set to match specified constraints.
<b>ONEOF</b>	Select a single set that contains adequate resources to support job.

### Node Set Attribute

The example's [NODESETATTRIBUTE](#) parameter is set to **FEATURE**, specifying that the node sets are to be constructed along node feature boundaries.

You could also set the **NODESETATTRIBUTE** to *VARATTR*, specifying that node sets are to be constructed according to VARATTR values on the job.

### Node Set Constraint Handling

The next parameter, **NODESETISOPTIONAL**, indicates that Moab should not delay the start time of a job if the desired node set is not available but adequate idle resources exist outside of the set. Setting this parameter to *TRUE* basically tells Moab to attempt to use a node set if it is available, but if not, run the job as soon as possible anyway.

**i** Setting **NODESETISOPTIONAL** to *FALSE* will force the job to always run in a complete nodeset regardless of any start delay this imposes.

### Node Set List

Finally, the **NODESETLIST** value of *switchA switchB...* tells Moab to only use node sets based on the listed feature values. This is necessary since sites will often use node features for many purposes and the resulting node sets would be of little use for switch proximity if they were generated based on irrelevant node features indicating things such as processor speed or node architecture.

To add nodes to the **NODESETLIST**, you must configure features on your nodes using the **NODECFG FEATURES** on page 558 attribute.

```
NODECFG[node01] FEATURES=switchA
NODECFG[node02] FEATURES=switchA
NODECFG[node03] FEATURES=switchB
```

*Nodes node01 and node02 contain the switchA feature, and node node03 contains the switchB feature.*

### Node Set Priority

When resources are available in more than one resource set, the **NODESETPRIORITYTYPE** parameter allows control over how the best resource set is selected. Legal values for this parameter are described in the following table:

Priority Type	Description	Details
<b>AFFINITY</b>	Avoid a resource set with negative <a href="#">affinity</a> .	Choosing this type causes Moab to select a node set with no negative affinity nodes (nodes that have a reservation that with negative affinity). If all node sets have negative affinity, then Moab will select the first matching node set.

Priority Type	Description	Details
<b>BESTFIT</b>	Select the smallest resource set possible.	Choosing this type causes Moab, when selecting a node set, to eliminate sets that do not have all the required resources. From the remaining sets, Moab chooses the set with the least amount of resources. This priority type most closely matches the job requirements in order to waste the least amount of resources.  This type minimizes fragmentation of larger resource sets.
<b>MINLOSS</b>	Select the resource set that results in the minimal wasted resources assuming no internal job load balancing is available. (Assumes parallel jobs only run as fast as the slowest allocated node.)	Choosing this type works only when using the following configuration: <b>NODESETATTRIBUTE FEATURE</b> In a <i>SHAREDMEM</i> environment (See <a href="#">Moab-NUMA Integration Guide on page 1255</a> for more information.), Moab will select the node set based on NUMA properties (the smallest feasible node set).
<b>WORSTFIT</b>	Select the largest resource set possible.	This type causes Moab, when choosing a node set, to eliminate sets that do not have all the required resources. From the remaining sets, Moab chooses the set with the greatest amount of resources.  This type minimizes fragmentation of smaller resource sets, but increases fragmentation of larger resource sets.

## Dynamic example

In this example, a site wants to be able to dynamically specify which *VARATTR* values the node set will be based on. To accomplish this, they could use the following configuration in the `moab.cfg` file:

```
NODESETISOPTIONAL FALSE
NODESETPOLICY      FIRSTOF
NODESETATTRIBUTE   VARATTR
```

### Node Set Attribute

The example's [NODESETATTRIBUTE](#) parameter is set to *VARATTR* specifying that the node sets are to be constructed by job *VARATTR* values that are specified dynamically in the `msub` command.

### Node Set Policy

In the preceding example, the [NODESETPOLICY](#) parameter is set to the policy *FIRSTOF* and tells Moab to allocate nodes from the first set that matches specified constraints.

### Node Set Constraint Handling

The parameter, [NODESETISOPTIONAL](#), indicates that Moab should not delay the start time of a job if the desired node set is not available but adequate idle resources exist outside of the set. Setting this

parameter to *FALSE* will force the job to always run in a complete node set regardless of any start delay this imposes.

### *msub example*

With the configuration (above) set in the `moab.cfg`, Moab is configured for dynamic node sets. You can create node sets dynamically by using the `msub -l` command. (For more information, see [Resource Manager Extensions on page 618](#).) Use the following format:

```
msub -l nodeset=FIRSTOF:VARATTR:<var>[=<value>],...
```

For example, if you wanted to create a dynamic node set for the Provo datacenter:

```
msub -l nodeset=FIRSTOF:VARATTR: datacenter=Provo
```

*This command causes Moab to set datacenter=Provo as the node set.*

**i** You can specify more than one VARATTR in the command. For example, if you want to create a dynamic node set for the Provo datacenter and the SaltLake datacenter:

```
msub -l nodeset=FIRSTOF:VARATTR: datacenter=Provo: datacenter=SaltLake
```

If you specify only `datacenter` (without specifying a value, such as `=Provo`), Moab will look up all possible values (values reported on the node for that VARATTR), and then choose one. So if, for example, you have nodes that have VARATTRs `datacenter=Provo`, `datacenter=SaltLake`, and `datacenter=StGeorge`, then specifying `msub -l nodeset=FIRSTOF:VARATTR:datacenter` will cause the job to run in Provo *or* SaltLake *or* StGeorge.

You should also note that Moab also adds the VARATTR (whether you specify it or if Moab chooses it) to the required attribute (REQATTR) of the job. For example, if you specify `datacenter=Provo` as the VARATTR, `datacenter=Provo` will also be added to the job REQATTR. Likewise, if you specify only `datacenter`, and Moab chooses `datacenter=SaltLake`, then `datacenter=SaltLake` will be added to the job REQATTR.

If you do not request a VARATTR in the nodeset of the `msub -l` command, the job will run as if it did not use node sets at all, and nothing will be added to its REQATTR.

**i** If you manually specify a different REQATTR on a job (for example, `datacenter=SaltLake`) from the node set VARATTR (for example, `datacenter=Provo`), the job will never run.

## NODESETPLUS

Moab supports additional NodeSet behavior by specifying the [NODESETPLUS](#) parameter. Possible values when specifying this parameter are *SPANEVENLY* and *DELAY*.

**i** Neither *SPANEVENLY* nor *DELAY* will work with multi-req jobs or preemption.

Value	Description
<b>SPANEVENLY</b>	Moab attempts to fit all jobs within one node set, or it spans any number of node sets evenly. When a job specifies a <a href="#">NODESETDELAY</a> , Moab attempts to contain the job within a single node set; if unable to do so, it spans node sets evenly, unless doing so would delay the job beyond the requested <b>NODESETDELAY</b> .
<b>DELAY</b>	Moab attempts to schedule the job within a nodeset for the configured <a href="#">NODESETDELAY</a> . If Moab cannot find space for the job to start within <b>NODESETDELAY</b> (Moab considers future workload to determine if space will open up in time and might create a future reservation), then Moab schedules the job and ignores the nodeset requirement.

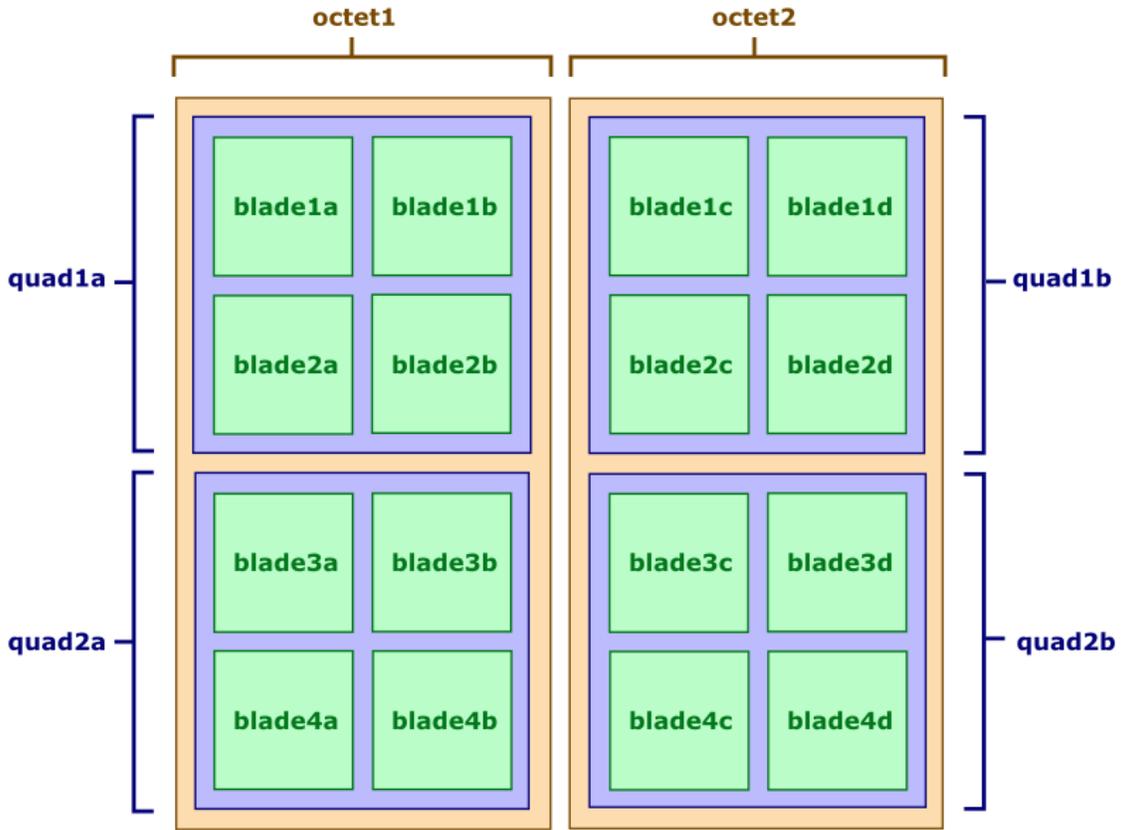

### Nested Node Sets

Moab attempts to fit jobs on node sets in the order they are specified in the **NODESETLIST**. You can create nested node sets by listing your node sets in a specific order. Here is an example of a "smallest to largest" nested node set:

```
NODESETPOLICY ONEOF
NODESETATTRIBUTE FEATURE
NODESETISOPTIONAL FALSE
NODESETLIST blade1a,blade1b,blade2a,blade2b,blade3a,
blade3b,blade4a,blade4b,quad1a,quad1b,quad2a,
quad2b,octet1,octet2,sixteen
```

The accompanying cluster would look like this:

Image 3-8: Octet, quad, and blade node sets on a cluster

In this example, Moab tries to fit the job on the nodes in the blade sets first. If that doesn't work, it moves up to the nodes in the quad sets (a set of four blade sets). If the quads are insufficient, it tries the nodes in the octet sets (a set of four quad node sets).

## Requesting Node Sets for Job Submission

On a per job basis, each user can specify the equivalent of all parameters except **NODESETDELAY**. As mentioned previously, this is accomplished using the [resource manager extensions](#).

## Configuring Node Sets for Classes

Classes can be configured with a default node set. In the configuration file, specify **DEFAULT.NODESET** with the following syntax: `DEFAULT.NODESET=<SETTYPE>:<SETATTR>[:<SETLIST>[,<SETLIST>]...]`. For example, in a heterogeneous cluster with two different types of processors, the following configuration confines jobs assigned to the `amd` class to run on either `ATHLON` or `OPTERON` processors:

```
CLASSCFG [amd] DEFAULT.NODESET=ONEOF:FEATURE:ATHLON,OPTERON
...
```

### Moab Performance Evaluation Overview

Moab Workload Manager tracks numerous performance statistics for jobs, accounting, users, groups, accounts, classes, QoS, the system, and so forth. These statistics can be accessed through various commands or [Moab Cluster Manager/Monitor](#).

### Accounting: Job and System Statistics

Moab provides extensive accounting facilities that allow resource usage to be tracked by resources (compute nodes), jobs, users, and other objects. The accounting facilities may be used in conjunction with, and correlated with, the accounting records provided by the resource and allocation manager.

Moab maintains both raw persistent data and a large number of processed in memory statistics allowing instant summaries of cycle delivery and system utilization. With this information, Moab can assist in accomplishing any of the following tasks:

- Determining cumulative cluster performance over a fixed time frame.
- Graphing changes in cluster utilization and responsiveness over time.
- Identifying which compute resources are most heavily used.
- Charting resource usage distribution among users, groups, projects, and classes.
- Determining allocated resources, responsiveness, and failure conditions for jobs completed in the past.
- Providing real-time statistics updates to external accounting systems.

This section describes how to accomplish each of these tasks using Moab tools and accounting information.

- [Accounting Overview](#)
- [Real-Time Statistics](#)
- [FairShare Usage Statistics](#)

## Accounting Overview

Moab provides accounting data correlated to most major objects used within the cluster scheduling environment. These records provide job and reservation accounting, resource accounting, and credential-based accounting.

### Job and Reservation Accounting

As each job or reservation completes, Moab creates a complete persistent trace record containing information about who ran, the time frame of all significant events, and what resources were allocated. In addition, actual execution environment, failure reports, requested service levels, and other pieces of key information are also recorded. A complete description of each accounting data field can be found within section [Workload Traces](#).

### Resource Accounting

The load on any given node is available historically allowing identification of not only its usage at any point in time, but the actual jobs which were running on it. [Moab Cluster Manager](#) can show load information (assuming load is configured as a generic metric), but not the individual jobs that were running on a node at some point in the past. For aggregated, historical statistics covering node usage and availability, the `showstats` command may be run with the `-n` flag.

### Credential Accounting

Current and historical usage for users, groups, account, QoSs, and classes are determined in a manner similar to that available for evaluating nodes. For aggregated, historical statistics covering credential usage and availability, the `showstats` command may be run with the corresponding credential flag.

If needed, detailed credential accounting can also be enabled globally or on a credential by credential basis. With detailed credential accounting enabled, real-time information regarding per-credential usage over time can be displayed. To enable detailed per credential accounting, the **ENABLEPROFILING** attribute must be specified for credentials that are to be monitored. For example, to track detailed credentials, the following should be used:

```
USERCFG [DEFAULT]      ENABLEPROFILING=TRUE
QOSCFG [DEFAULT]      ENABLEPROFILING=TRUE
CLASSCFG [DEFAULT]    ENABLEPROFILING=TRUE
GROUPCFG [DEFAULT]    ENABLEPROFILING=TRUE
ACCOUNTCFG [DEFAULT]  ENABLEPROFILING=TRUE
```

Credential level profiling operates by maintaining a number of time-based statistical records for each credential. The parameters [PROFILECOUNT](#) and [PROFILEDURATION](#) control the number and duration of the statistical records.

## Real-Time Statistics

Moab provides real-time statistical information about how the machine is running from a scheduling point of view. The [showstats](#) command is actually a suite of commands providing detailed information on an overall scheduling basis as well as a per user, group, account and node basis. This command gets its information from in memory statistics that are loaded at scheduler start time from the scheduler checkpoint file. (See [Checkpoint/Restart](#) for more information.) This checkpoint file is updated periodically and when the scheduler is shut down allowing statistics to be collected over an extended time frame. At any time, real-time statistics can be reset using the [mschedctl -f](#) command.

In addition to the `showstats` command, the [showstats -f](#) command also obtains its information from the in memory statistics and checkpoint file. This command displays a processor-time based matrix of scheduling performance for a wide variety of metrics. Information such as backfill effectiveness or average job queue time can be determined on a job size/duration basis.

## FairShare Usage Statistics

Regardless of whether fairshare is enabled, detailed credential based fairshare statistics are maintained. Like job traces, these statistics are stored in the directory pointed to by the [STATDIR](#) parameter. Fairshare stats are maintained in a separate statistics file using the format `FS.<EPOCHTIME>` (`FS.982713600`, for example) with one file created per fairshare window. (See the [Fairshare Overview](#) for more information.) These files are also flat text and record credential based usage statistics. Information from these files can be seen via the [mdiag -f](#) command.

## Testing New Versions and Configurations

- [MONITOR Mode](#)
- [INTERACTIVE Mode](#)

## MONITOR Mode

Moab supports a scheduling mode called *MONITOR*. In this mode, the scheduler initializes, contacts the resource manager and other peer services, and conducts scheduling cycles exactly as it would if running in *NORMAL* or production mode. Job are prioritized, reservations created, policies and limits enforced, and administrator and end-user commands enabled. The key difference is that although live resource management information is loaded, *MONITOR* mode disables Moab's ability to start, preempt, cancel, or otherwise modify jobs or resources. Moab continues to attempt to schedule exactly as it would in *NORMAL* mode but its ability to actually impact the system is disabled. Using this mode, a site can quickly verify correct resource manager configuration and scheduler operation. This mode can also be used to validate new policies and constraints. In fact, Moab can be run in *MONITOR* mode on a production system while another scheduler or even another version of Moab is running on the same

system. This unique ability can allow new versions and configurations to be fully tested without any exposure to potential failures and with no cluster downtime.

To run Moab in *MONITOR* mode, simply set the **MODE** attribute of the **SCHEDCFG** parameter to *MONITOR* and start Moab. Normal scheduler commands can be used to evaluate configuration and performance. [Diagnostic commands](#) can be used to look for any potential issues. Further, the Moab log file can be used to determine which jobs Moab attempted to start, and which resources Moab attempted to allocate.

If another instance of Moab is running in production and a site administrator wants to evaluate an alternate configuration or new version, this is easily done but care should be taken to avoid conflicts with the primary scheduler. Potential conflicts include statistics files, logs, checkpoint files, and user interface ports. One of the easiest ways to avoid these conflicts is to create a new test directory with its own log and stats subdirectories. The new `moab.cfg` file can be created from scratch or based on the existing `moab.cfg` file already in use. In either case, make certain that the **PORT** attribute of the **SCHEDCFG** parameter differs from that used by the production scheduler by at least two ports. If testing with the production binary executable, the `MOABHOMEDIR` environment variable should be set to point to the new test directory to prevent Moab from loading the production `moab.cfg` file.

## INTERACTIVE Mode

*INTERACTIVE* mode allows for evaluation of new versions and configurations in a manner different from *MONITOR* mode. Instead of disabling all resource and job control functions, Moab sends the desired change request to the screen and asks for permission to complete it. For example, before starting a job, Moab may print something like the following to the screen:

```
Command: start job 1139.ncsa.edu on node list test013,test017,test018,test021
Accept: (y/n) [default: n]?
```

The administrator must specifically accept each command request after verifying it correctly meets desired site policies. Moab then executes the specified command. This mode is highly useful in validating scheduler behavior and can be used until configuration is appropriately tuned and all parties are comfortable with the scheduler's performance. In most cases, sites will want to set the scheduling mode to *NORMAL* after verifying correct behavior.

## Job Holds

### Holds and Deferred Jobs

Moab supports job holds applied by users ([user holds](#)), administrators ([system holds](#)), and resource managers ([batch holds](#)). There is also a temporary hold known as a [job defer](#).

### User Holds

User holds are very straightforward. Many, if not most, resource managers provide interfaces by which users can place a hold on their own job that tells the scheduler not to run the job while the hold is in place. Users may use this capability because the job's data is not yet ready, or they want to be present when the job runs to monitor results. Such user holds are created by, and under the control of a non-privileged user and may be removed at any time by that user. As would be expected, users can only place holds on their jobs. Jobs with a user hold in place will have a Moab state of `Hold` or `UserHold` depending on the resource manager being used.

### System Holds

The system hold is put in place by a system administrator either manually or by way of an automated tool. As with all holds, the job is not allowed to run so long as this hold is in place. A batch administrator can place and release system holds on any job regardless of job ownership. However, unlike a user hold, normal users cannot release a system hold even on their own jobs. System holds are often used during system maintenance and to prevent particular jobs from running in accordance with current system needs. Jobs with a system hold in place will have a Moab state of `Hold` or `SystemHold` depending on the resource manager being used.

## Batch Holds

Batch holds are placed on a job by the scheduler itself when it determines that a job cannot run. The reasons for this vary but can be displayed by issuing the `checkjob<JOBID>` command. Possible reasons are included in the following list:

- No Resources — The job requests resources of a type or amount that do not exist on the system.
- System Limits — The job is larger or longer than what is allowed by the specified system policies.
- Bank Failure — The allocations bank is experiencing failures.
- No Allocations — The job requests use of an account that is out of allocations and no fallback account has been specified.
- RM Reject — The resource manager refuses to start the job.
- RM Failure — The resource manager is experiencing failures.
- Policy Violation — The job violates certain throttling policies preventing it from running now and in the future.
- No QoS Access — The job does not have access to the QoS level it requests.

Jobs which are placed in a batch hold will show up within Moab in the state `BatchHold`.

## Job Defer

In most cases, a job violating these policies is not placed into a batch hold immediately; rather, it is deferred. The parameter `DEFERTIME` indicates how long it is deferred. At this time, it is allowed back into the idle queue and again considered for scheduling. If it again is unable to run at that time or at any time in the future, it is again deferred for the timeframe specified by `DEFERTIME`. A job is released and deferred up to `DEFERCOUNT` times at which point the scheduler places a batch hold on the job and waits for a system administrator to determine the correct course of action. Deferred jobs have a Moab state of `Deferred`. As with jobs in the `BatchHold` state, the reason the job was deferred can be determined by use of the `checkjob` command.

At any time, a job can be released from any hold or deferred state using the `releasehold` command. The Moab logs should provide detailed information about the cause of any batch hold or job deferral.

**i** Under Moab, the reason a job is deferred or placed in a batch hold is stored in memory but is not checkpointed. Thus this information is available only until Moab is recycled at which point the `checkjob` command no longer displays this reason information.

## Job Priority Management

Job priority management is controlled via both configured and manual intervention mechanisms.

- Priority Configuration - see [Job Prioritization](#)
- Manual Intervention with [setspri](#)

## Suspend/Resume Handling

When supported by the resource manager, Moab can suspend and resume jobs. A user can suspend his/her own jobs, but only an administrator can resume them. By default, a job is suspended for one minute before it can resume. You can modify this default time using the [MINADMINSTIME](#) parameter.

A job must be marked as `suspendable` for Moab to suspend and resume it. To do so, either submit the job with the `suspendable` flag attached to it or configure a credential to pass the flag to its associated jobs. These methods are demonstrated in the examples below:

```
msub -l flags=suspendable
```

```
GROUPCFG[default] JOBFLAGS=SUSPENDABLE
```

Once the job is suspendable, Moab allows you to suspend jobs using the two following methods: (1) manually on the command line and (2) automatically in the `moab.cfg` file.

To manually suspend jobs, use the [mjobctl](#) command as demonstrated in the following example:

```
> mjobctl -s job05
```

*Moab suspends job05, preventing it from running immediately in the job queue.*

If you are an administrator and want to resume a job, use the `mjobctl` command as demonstrated in the following example:

```
> mjobctl -r job05
```

*Moab removes job05 from a suspended state and allows it to run.*

You can also configure the Moab preemption policy to suspend and resume jobs automatically by setting the [PREEMTPOLICY](#) parameter to `SUSPEND`. A sample Moab configuration looks like this:

```
PREEMTPOLICY SUSPEND
...
USERCFG[tom] JOBFLAGS=SUSPENDABLE
```

Moab suspends jobs submitted by user `tom` if necessary to make resources available for jobs with higher priority.

If your resource manager has a native interface, you must configure [JOBSUSPENDURL](#) to suspend and resume jobs.

For more information about suspending and resuming jobs in Moab, see the following sections:

- manual preemption with the [mjobctl](#) command
- [Job preemption](#)

## Checkpoint/Restart Facilities

Checkpointing records the state of a job, allowing for it to restart later without interruption to the job's execution. Checkpointing can be performed manually, as the result of [triggers](#) or [events](#), or in conjunction with various [QoS](#) policies.

Moab's ability to checkpoint is dependent upon both the cluster's [resource manager](#) and operating system. In most cases, two types of checkpoint are enabled, including (1) checkpoint and continue and (2) checkpoint and terminate. While either checkpointing method can be activated using the [mjobctl](#) command, only the checkpoint and terminate type is used by internal scheduling and event managements facilities.

Checkpointing behavior can be configured on a per-resource manager basis using various attributes of the [RMCFG](#) parameter.

## Job Dependencies

- [Basic Job Dependency Support](#)
  - [Job Dependency Syntax](#)

### Basic Job Dependency Support

By default, basic single step job dependencies are supported through completed/failed step evaluation. Basic dependency support does not require special configuration and is activated by default. Dependent jobs are only supported through a resource manager and therefore submission methods depend upon the specific resource manager being used. For the [TORQUE qsub](#) command, the semantics listed in the section below can be used with the `-W x=depend=<STRING>` or `-W depend=<STRING>` flag; for the Moab [msub](#) command, the `-l depend=<STRING>` or `-W x=depend=<STRING>` flag. For other resource managers, consult the resource manager specific documentation.

**i** If you are submitting a job with a dependency in a grid environment via `msub`, you need to use the `-l` option instead of `-w`. You must always use `-W depend=` or `-W x=depend=` for `qsub` dependencies.

## Job Dependency Syntax

Dependency	Format	Description
<b>after</b>	<code>after:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time after specified jobs have started execution.
<b>afterany</b>	<code>afterany:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time after all specified jobs have completed regardless of completion status.
<b>afterok</b>	<code>afterok:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may be start at any time after all specified jobs have successfully completed.
<b>afternotok</b>	<code>afternotok:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time after all specified jobs have completed unsuccessfully.
<b>before</b>	<code>before:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time before specified jobs have started execution.
<b>beforeany</b>	<code>beforeany:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time before all specified jobs have completed regardless of completion status.
<b>beforeok</b>	<code>beforeok:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time before all specified jobs have successfully completed.
<b>beforenotok</b>	<code>beforenotok:&lt;job&gt;</code> <code>[:&lt;job&gt;]...</code>	Job may start at any time before any specified jobs have completed unsuccessfully.
<b>on</b>	<code>on:&lt;count&gt;</code>	Job may start after <i>&lt;count&gt;</i> dependencies on other jobs have been satisfied.
<b>synccount</b>	<code>synccount:&lt;count&gt;</code>	Job is the first in a set of jobs to be executed at the same time. <i>&lt;count&gt;</i> is the number of additional jobs in the set, which can be up to 5. synccount is valid for single-request jobs with TORQUE as the resource manager.
<b>syncwith</b>	<code>syncwith:&lt;job&gt;</code>	Job is an additional member of a set of jobs to be executed at the same time. Moab supports up to 5 jobs. syncwith is valid for single-request jobs with TORQUE as the resource manager.

**i** `<job>={JOBNAME.jobname|jobid}`

When using JobName dependencies, prepend "JOBNAME." to avoid ambiguity.

**i** The `before` dependencies do not work with jobs submitted with `msub`; they work only with `qsub`.

Any of the dependencies containing `before` must be used in conjunction with the `on` dependency. So, if job A must run before job B, job B must be submitted with `depend=on:1`, as well as job A having `depend=before:A`. This means job B cannot run until one dependency of another job on job B has been fulfilled. This prevents job B from running until job A can be successfully submitted.

When you submit a dependency job and the dependency is not met, the job will remain idle in the queue indefinitely. To configure Moab to automatically cancel these failed dependency jobs, set the [CANCELFAILEDDEPENDENCYJOBS](#) on [page 1390](#) scheduler flag.

## Job Defaults and Per Job Limits

### Job Defaults

Job defaults can be specified on a per queue basis. These defaults are specified using the [CLASSCFG](#) parameter. The following table shows the applicable attributes:

Attribute	Format	Example
<b>DEFAULT.FEATURES</b>	comma-delimited list of node features	<pre>CLASSCFG[batch] DEFAULT.FEATURES=fast,io</pre> <p><i>Jobs submitted to class batch will request nodes features <b>fast</b> and <b>io</b>.</i></p>
<b>DEFAULT.WCLIMIT</b>	[[DD:]HH:]MM:]SS	<pre>CLASSCFG[batch] DEFAULT.WCLIMIT=1:00:00</pre> <p><i>Jobs submitted to class batch will request one hour of walltime by default.</i></p>

### Per Job Maximum Limits

Job maximum limits can be specified on a per queue basis. These defaults are specified using the [CLASSCFG](#) parameter. The following table shows the applicable attributes:

Attribute	Format	Example
<b>MAX.WCLIMIT</b>	[[ [DD:]HH:]MM:] SS	<pre>CLASSCFG[batch] MAX.WCLIMIT=1:00:00</pre> <p><i>Jobs submitted to class batch can request no more than one hour of walltime.</i></p>

## Per Job Minimum Limits

Furthermore, minimum job defaults can be specified with the [CLASSCFG](#) parameter. The following table shows the applicable attributes:

Attribute	Format	Example
<b>MIN.PROC</b>	<integer>	<pre>CLASSCFG[batch] MIN.PROC=10</pre> <p><i>Jobs submitted to class batch can request no less than ten processors.</i></p>

## General Job Policies

- [Multi-Node Support](#)
- [Multi-Req Support](#)
- [Job Size Policy](#)
- [Malleable Job Support](#)
- [Enabling Job User Proxy](#)

There are a number of configurable policies that help control advanced job functions. These policies help determine allowable job sizes and structures.

### Multi-Node Support

You can configure the ability to allocate resources from multiple nodes to a job with the [MAX.NODE](#) limit.

## Multi-Req Support

Jobs can specify multiple types of resources for allocation. For example, a job could request 4 nodes with 256 MB of memory and 8 nodes with feature `fast` present.

Resources specified in a multi-req job are delimited with a plus sign (+).

Neither *SPANEVENLY* nor *DELAY* values of the NODESETPLUS parameter will work with multi-req jobs or preemption.

*Example 3-130:*

```
-l nodes=4:ppn=1+10:ppn=5+2:ppn=2
```

*This example requests 4 nodes with 1 proc each, 10 nodes with 5 procs each, and 2 nodes with 2 procs each. The total number of processors requested is  $(4*1) + (10*5) + (2*2)$ , or 58 processors.*

*Example 3-131:*

```
-l nodes=15+1:ppn=4
```

*The job submitted in this example requests a total of 16 nodes. 15 of these nodes have no specific requirements, but the remaining node must have 4 processors.*

*Example 3-132:*

```
-l nodes=3:fast+1:io
```

*The job requests a total of 4 nodes: 3 nodes with the **fast** feature and 1 node with the **io** feature.*

## Job Size Policy

Moab allows jobs to request resource ranges. Using this range information, the scheduler is able to maximize the amount of resources available to the job while minimizing the amount of time the job is blocked waiting for resources. The [JOBSIZEPOLICY](#) parameter can be used to set this behavior according to local site needs.

**i** Job resource ranges may only be specified when using a local queue as described in the [Using a Local Queue](#) section.

## Malleable Job Support

A job can specify whether it is able to use more processors or less processors and what effect, if any, that has on its wallclock time. For example, a job may run for 10 minutes on 1 processor, 5 minutes on 2 processors and 3 minutes on 3 processors. When a job is submitted with a task request list attached, Moab determines which task request fits best and molds the job based on its specifications. To submit a job with a task request list and allow Moab to mold it based on the current scheduler environment, use the [TRL](#) flag in the Resource Manager Extension.

## Enabling Job User Proxy

By default, user proxying is disabled. To be enabled, it must be authorized using the **PROXYLIST** attribute of the [USERCFG](#) parameter. This parameter can be specified either as a comma-delimited list of users or as the keyword *validate*. If the keyword *validate* is specified, the [RMCFG](#) attribute **JOBVALIDATEURL** should be set and used to confirm that the job's owner can proxy to the job's execution user. An example script performing this check for ssh-based systems is provided in the `tools` directory (See [Job Validate Tool Overview](#)).

For some resource managers (RM), proxying must also be enabled at the RM level. The following example shows how ssh-based proxying can be accomplished in a Moab+TORQUE with SSH environment.

**i** To validate proxy users, Moab must be running as root.

## Example 3-133: SSH Proxy Settings

```
USERCFG[DEFAULT] PROXYLIST=validate
RMCFG[base] TYPE=<resource manager>
JOBVALIDATEURL=exec://$HOME/tools/job.validate.sshproxy.pl
```

```
> qmgr -c 's s allow proxy user=true'
> su - testuser
> qsub -I -u testuser2
qsub: waiting for job 533.igt.org to start
qsub: job 533.igt.org ready
testuser2@igt:~$
```

*In this example, the validate tool, 'job.validate.sshproxy.pl', can verify proxying is allowed by becoming the submit user and determining if the submit user can achieve passwordless access to the specified execution user. However, site-specific tools can use any method to determine proxy access including a flat file look-up, database lookup, querying of an information service such as NIS or LDAP, or other local or remote tests. For example, if proxy validation is required but end-user accounts are not available on the management node running Moab, the job validate service could perform the validation test on a representative remote host such as a login host.*

 This feature supports qsub only.

The job validate tool is highly flexible allowing any combination of job attributes to be evaluated and tested using either local or remote validation tests. The validate tool allows not only pass/fail responses but also allows the job to be modified, or rejected in a custom manner depending on the site or the nature of the failure.

## Related topics

- [Usage Limits](#)

## Using a Local Queue

Moab allows jobs to be submitted directly to the scheduler. With a local queue, Moab is able to directly manage the job or translate it for resubmission to a standard resource manager queue. There are multiple advantages to using a local queue:

- Jobs may be translated from one resource manager job submission language to another (such as submitting a PBS job and running it on an LSF cluster).
- Jobs may be migrated from one local resource manager to another.
- Jobs may be migrated to remote systems using Moab peer-to-peer functionality.
- Jobs may be dynamically modified and optimized by Moab to improve response time and system utilization.
- Jobs may be dynamically modified to account for system hardware failures or other issues.
- Jobs may be dynamically modified to conform to site policies and constraints.
- Grid jobs are supported.

## Local Queue Configuration

A local queue is configured just like a standard resource manager queue. It may have defaults, limits, resource mapping, and credential access constraints. The following table describes the most common settings:

Default queue	
<b>Format</b>	<code>RMCFG[internal] DEFAULTCLASS=&lt;CLASSID&gt;</code>
<b>Description</b>	<p>The job class/queue assigned to the job if one is not explicitly requested by the submitter.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> All jobs submitted directly to Moab are initially received by the pseudo-resource manager <i>internal</i>. Therefore, default queue configuration may only be applied to it.</p> </div>
<b>Example</b>	<code>RMCFG[internal] DEFAULTCLASS=batch</code>

Class default resource requirements	
<b>Format</b>	<code>CLASSCFG[&lt;CLASSID&gt;] DEFAULT.FEATURES=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;]</code> <code>DEFAULT.MEM=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] DEFAULT.NODE=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;]</code> <code>DEFAULT.NODESET=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] DEFAULT.PROC=&lt;X&gt; CLASSCFG</code> <code>[&lt;CLASSID&gt;] DEFAULT.WCLIMIT=&lt;X&gt;</code>
<b>Description</b>	The settings assigned to the job if not explicitly set by the submitter. Default values are available for node features, per task memory, node count, nodeset configuration, processor count, and wallclock limit.
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <code>CLASSCFG[batch] DEFAULT.WCLIMIT=4 DEFAULT.FEATURES=matlab</code> </div> <p>or</p> <div style="border: 1px dashed #ccc; padding: 5px;"> <code>CLASSCFG[batch] DEFAULT.WCLIMIT=4</code>  <code>CLASSCFG[batch] DEFAULT.FEATURES=matlab</code> </div>

Class maximum resource limits	
<b>Format</b>	<code>CLASSCFG[&lt;CLASSID&gt;] MAX.FEATURES=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] MAX.NODE=&lt;X&gt;</code> <code>CLASSCFG[&lt;CLASSID&gt;] MAX.PROC=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] MAX.WCLIMIT=&lt;X&gt;</code>

### Class maximum resource limits

<b>Description</b>	The maximum node features, node count, processor count, and wallclock limit allowed for a job submitted to the class/queue. If these limits are not satisfied, the job is not accepted and the submit request fails. <b>MAX.FEATURES</b> indicates that only the listed features may be requested by a job.
<b>Example</b>	<pre>CLASSCFG[smalljob] MAX.PROC=4 MAX.FEATURES=slow,matlab</pre> <p>or</p> <pre>CLASSCFG[smalljob] MAX.PROC=4 CLASSCFG[smalljob] MAX.FEATURES=slow,matlab</pre>

### Class minimum resource limits

<b>Format</b>	<pre>CLASSCFG[&lt;CLASSID&gt;] MIN.FEATURES=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] MIN.NODE=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] MIN.PROC=&lt;X&gt; CLASSCFG[&lt;CLASSID&gt;] MIN.WCLIMIT=&lt;X&gt;</pre>
<b>Description</b>	The minimum node features, node count, processor count, and wallclock limit allowed for a job submitted to the class/queue. If these limits are not satisfied, the job is not accepted and the submit request fails. <b>MIN.FEATURES</b> indicates that only the listed features may be requested by a job.
<b>Example</b>	<pre>CLASSCFG[bigjob] MIN.PROC=4 MIN.WCLIMIT=1:00:00</pre> <p>or</p> <pre>CLASSCFG[bigjob] MIN.PROC=4 CLASSCFG[bigjob] MIN.WCLIMIT=1:00:00</pre>

### Class access

<b>Format</b>	<pre>CLASSCFG[&lt;CLASSID&gt;] REQUIREUSERLIST=&lt;USERID&gt; [, &lt;USERID&gt;] ...</pre>
<b>Description</b>	The list of users who may submit jobs to the queue.
<b>Example</b>	<pre>CLASSCFG[math] REQUIREUSERLIST=john,steve</pre>

Available resources	
<b>Format</b>	CLASSCFG [<CLASSID>] HOSTLIST=<HOSTID>[, <HOSTID>] . . .
<b>Description</b>	The list of nodes that jobs in the queue may use.
<b>Example</b>	<code>CLASSCFG[special] HOSTLIST=node001,node003,node13</code>

Class mapping between multiple sites is described in the section on Moab grid facilities.

If a job is submitted directly to the resource manager used by the local queue, the class default resource requirements are not applied. Also, if the job violates a local queue limitation, the job is accepted by the resource manager, but placed in the Blocked state.

## Job Deadlines

- [Deadline Overview](#)
- [Setting Job Deadlines via QoS on page 542](#)
  - [Setting Job Deadlines at Job Submission on page 543](#)
  - [Submitting a Job to a QoS with a Preconfigured Deadline on page 543](#)
- [Job Termination Date](#)
- [Conflict Policies](#)

### Deadline Overview

Job deadlines may be specified on a per job and per credential basis and are also supported using both absolute and QoS based specifications. A job requesting a deadline is first evaluated to determine if the deadline is acceptable. If so, Moab adds it to the list of deadline jobs and allocates resources to guarantee that all accepted deadline jobs are able to complete on or before their requested deadline. Once the scheduler confirms that all deadlines can be satisfied, it then optimizes resource allocation (in priority order) attempting to execute all jobs at the earliest possible time.

### Setting Job Deadlines via QoS

Two types of job deadlines exist in Moab. The priority-based deadline linearly increases a job's priority as its deadline approaches (See [Deadline \(DEADLINE\) Subcomponent on page 387](#) for more information). The QoS method allows you to set a job completion time on job submission if, and only if, it requests and is allowed to access a QoS with the [DEADLINE QFLAG](#) set. This method is more powerful than the priority method, because Moab will attempt to make a reservation for the job as soon as the job enters the queue in order to meet the deadline, essentially bumping it to the front of the queue.

When a job is submitted to a QoS with the **DEADLINE** flag set, the job's `-l deadline` attribute is honored. If such QoS access is not available, or if resources do not exist at job submission time to allow the deadline to be satisfied, the job's deadline request is ignored.

Two methods exist for setting deadlines with a QoS:

- Submitting a job to a deadline-enabled QoS and specifying a deadline using `msub -l`.
- Submitting a job to a deadline-enabled QoS with a **QTTARGET** specified.

## Setting Job Deadlines at Job Submission

This method of setting a job deadline allows you to specify a job deadline as you submit the job. You can set the deadline as either an exact date and time or as an amount of time after job submission (i.e. three hours after submission).

### To specify a deadline on job submission

1. In `moab.cfg`, create a QoS with the **DEADLINE** flag enabled.

```
...
QOSCFG[special] QFLAGS=DEADLINE
```

*Jobs requesting the QoS *special* may submit jobs with a deadline that Moab will honor.*

2. Submit a job to the QoS and set a deadline. This can be either absolute or relative.

- a. For an absolute deadline, use the format `hh:mm:ss_mm/dd/yy`. The following configuration sets a deadline for a job to finish by 8 a.m. on March 15th, 2013.

```
msub -l qos=special deadline=08:00:00_03/15/13 job.sh
```

*The job must finish running by 8 A.M. on March 15, 2013.*

- b. For a relative deadline, or the completion deadline of the job relative to its submission time, use the time format `[ [DD:]HH:]MM:]SS`.

```
msub -l qos=special deadline=5:00:00 job.sh
```

*The job's deadline is 5 hours after its submission.*

## Submitting a Job to a QoS with a Preconfigured Deadline

You may also set a relative job deadline by limiting the job's queue time. This method allows you to preconfigure the deadline rather than giving the power to specify a deadline to the user submitting the job. For jobs requesting these QoSes, Moab identifies and sets job deadlines to satisfy the corresponding response time targets.

### To submit a job to a QoS with a preconfigured deadline

1. In `moab.cfg`, create a QoS with both the **DEADLINE QFLAG** and a response time target (**QTTARGET**). The **QTTARGET** is the maximum amount of time that Moab should allow the job to be idle in the

queue.

```
...
QOSCFG[special2] QFLAGS=DEADLINE QTTARGET=1:00:00
```

*Given this configuration, a job requesting QoS special2 must spend a maximum of one hour in the queue.*

2. Submit a job requesting the special2 quality of service.

```
msub -l qos=special2 walltime=2:00:00 job.sh
```

*This two-hour job has a completion time deadline set to three hours after its submission (one hour of target queue time and two hours of run time).*

## Job Termination Date

In addition to job completion targets, jobs may also be submitted with a [TERMTIME](#) attribute. The scheduler attempts to complete the job prior to the termination date, but if it is unsuccessful, it will terminate (cancel) the job once the termination date is reached.

## Conflict Policies

The specific policy can be configured using the [DEADLINEPOLICY](#) parameter. Moab does not have a default policy for this parameter.

Policy	Description
<b>CANCEL</b>	The job is canceled and the user is notified that the deadline could not be satisfied.
<b>HOLD</b>	The job has a batch hold placed on it indefinitely. The administrator can then decide what action to take.
<b>RETRY</b>	The job continually retries each iteration to meet its deadline; note that when used with <code>QTTARGET</code> the job's deadline continues to slide with relative time.
<b>IGNORE</b>	The job has its request ignored and is scheduled as normal.

**i** Deadline scheduling may not function properly with per partition scheduling enabled. Check that **PARALLELATIONPOLICY** is disabled to ensure **DEADLINEPOLICY** will work correctly.

### Job Array Overview

You can submit an array of jobs to Moab via the [msub](#) command. Array jobs are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if `235[1]` is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Sub-jobs of an array are executed in sub-job index order.

Moab job arrays are different from TORQUE job arrays.

### Enabling Job Arrays

To enable job arrays, include the [ENABLEJOBARRAYS](#) parameter in the Moab configuration file (`moab.cfg`).

### Sub-job Definitions

Like a normal job, an array job submits a job script, but it additionally has a start index (`sidx`) and an end index (`eidx`); array jobs also have increment (`incr`) values, which Moab uses to create sub-jobs, all executing the same script. The model for sub-job creation follows the formula of end index minus start index plus increment divided by the increment value:  $(eidx - sidx + incr) / incr$ .

To illustrate, suppose an array job has a start index of 1, an end index of 100, and an increment of 1. This is an array job that creates  $(100 - 1 + 1) / 1 = 100$  sub-jobs with indexes of 1, 2, 3, ..., 100. An increment of 2 produces  $(100 - 1 + 2) / 2 = 50$  sub-jobs with indexes of 1, 3, 5, ..., 99. An increment of 2 with a start index of 2 produces  $(100 - 2 + 2) / 2 = 50$  sub-jobs with indexes of 2, 4, 6, ..., 100. Again, sub-jobs are jobs in their own right that have a slightly different job naming convention `jobID[subJobIndex]` (e.g. `mycluster.45[37]` or `45[37]`).

## Using Environment Variables to Specify Array Index Values

The script can use an environment variable to obtain the array index value to form data file and/or directory names unique to an array job's particular sub-job. The following two environment variables are supplied so job scripts can recognize what index in the array they are in; use the [msub](#) command with the [-V](#) option to pass the environment parameters to the resource manager, or include the parameters in a job script; for example: `#PBS -V MOAB_JOBARRAYRANGE`.

Environment Parameter	Description
<b>MOAB_JOBARRAYINDEX</b>	<p>Used to create dataset file names, directory names, and so forth, when splitting up a single problem into multiple jobs.</p> <p>For example, a user may split up a problem into 20 separate jobs, each with its own input and output data files whose names contain the numbers 1-20.</p> <p>To illustrate, assume a user submits the 20 sub-jobs using two msub commands; one to submit the ten even-numbered jobs and one to submit the ten odd-numbered jobs.</p> <pre>msub -t job1. [1-20:2] msub -t job2. [2-20:2]</pre> <p>The MOAB_JOBARRAYINDEX environment variable value would populate each of the two job arrays' ten sub-jobs as 1, 3, 5, 7, 9, 11, 13, 15, 17 and 19 for the first array job's ten sub-jobs, and 2, 4, 6, 8, 10, 12, 14, 16, 18, and 20 for the second array job's ten sub-jobs.</p>
<b>MOAB_JOBARRAYRANGE</b>	The count of jobs in the array.

### Control

Users can control individual sub-jobs in the same manner as normal jobs. In addition, an array job represents its group of sub-jobs and any user or administrator commands performed on an array job apply to its sub-jobs; for example, the command [canceljob <arrayJobId>](#) cancels all sub-jobs that belong to the array job. For more information about job control, see the documentation for the [mjobctl](#) command.

### Reporting

In the first example below, the parts unique to array subjobs are in red.

```

$ checkjob -v Moab.1[1]
job Moab.1[1]

AName: Moab
State: Running
Creds: user:user1 group:usergroup1
WallTime: 00:00:17 of 8:20:00

1 blocked job

Total jobs: 11
    
```

*Moab.1 has five sub-jobs running. Moab.2 has one sub-job running, four waiting to run, and one that is currently blocked.*

## Job Array Cancellation Policies

Job arrays can be canceled based on the success or failure of the first sub-job, the first success or failure of any sub-job, or if any sub-job exits with a specified exit code. The job array cancellation policies are:

Cancel Policy	Description	Exclusivity
<b>CancelOnFirstFailure</b>	Cancels the job array if the first sub-job ( <b>JOBARRAYINDEX = 1</b> ) fails. <pre>&gt; msub -t myarray[1-1000]%50 -1 ...,flags=CancelOnFirstFailure</pre>	Mutually exclusive
<b>CancelOnFirstSuccess</b>	Cancels the job array if the first sub-job ( <b>JOBARRAYINDEX = 1</b> ) succeeds. <pre>&gt; msub -t myarray[1-1000]%50 -1 ...,flags=CancelOnFirstSuccess</pre>	
<b>CancelOnAnyFailure</b>	Cancels the job array if any sub-job fails. <pre>&gt; msub -t myarray[1-1000]%50 -1 ...,flags=CancelOnAnyFailure</pre>	

Cancel Policy	Description	Exclusivity
<b>CancelOnAnySuccess</b>	<p>Cancels the job array if any sub-job succeeds.</p> <pre>&gt; msub -t myarray[1-1000]%50 -l ...,flags=CancelOnAnySuccess</pre>	
<b>CancelOnExitCode</b>	<p>Cancels the job array if any sub-job returns the specified exit code.</p> <pre>&gt; msub -t myarray[1-1000%50] -l ...,flags=CancelOnExitCode:&lt;error code list&gt;</pre> <p>The syntax for the error code list are ranges specified with a dash and individual codes delimited by a plus (+) sign, such as: 1-4+9+15 Exit codes 1-387 are accepted.</p>	

Up to two cancellation policies can be specified for an array and the two policies must be delimited by a colon (:). The two "first sub-job" policies are mutually exclusive, as are the three "any sub-job" policies. You can use either "first sub-job" policy with one of the "any sub-job" policies, as shown in this example:

```
> msub -t myarray[1-1000]%50 -l ...,flags=CancelOnFirstFailure:CancelOnExitCode:3-7+11
```

## Examples

Operations can be performed on individual jobs, a selection of jobs in a job array, or on the entire array.

### Submitting Job Arrays

The syntax for submitting job arrays is: `msub -t [<jobname>]<indexlist>[%<limit>] arrayscript.sh`

The `<jobname>` and `<limit>` are optional. The jobname does not override the `jobID` Moab assigns to the array. When submitting an array with a jobname, Moab returns the `jobID`, which is the scheduler name followed by a unique ID.

For example, if the scheduler name in `moab.cfg` is *Moab* (`SCHEDCFG[Moab]`), submitting an array with a jobname responds like this:

```
> msub -t myarray[1-10] job.sh
Moab.6
```

To specify that only a certain number of sub-jobs in the array can run at a time, use the percent sign (%) delimiter. In this example, only five sub-jobs in the array can run at a time:

```
> msub -t myarray[1-1000]%5
```

To submit a specific set of array sub-jobs, use the comma delimiter in the array index list:

```
> msub -t myarray[1,2,3,4]
> msub -t myarray[1-5,7,10]
```

You can use the `checkjob` command on either the `jobID` or the `jobname` you specified.

```
> msub -t myarray[1-2] job.sh

Moab.10

$ checkjob -v myarray
  job Moab.10

AName: myarray
Job Array Info:
  Name: Moab.10
  1 : Moab.10[1] : Running
  2 : Moab.10[2] : Running

Sub-jobs:          2
Active:            2 ( 100.0% )
Eligible:          0 ( 0.0% )
Blocked:           0 ( 0.0% )
Completed:         0 ( 0.0% )

State: Idle
Creds: user:tuser1 group:tgroup1
WallTime: 00:00:00 of 99:23:59:59
SubmitTime: Thu Jun 2 16:37:17
          (Time Queued Total: 00:00:33 Eligible: 00:00:00)

Total Requested Tasks: 1

Req[0] TaskCount: 1 Partition: ALL
```

To submit a job with a step size, use a colon in the array range and specify how many jobs to step. In the example below, a step size of 2 is requested. The sub-jobs will be numbered according to the step size inside the index limit. The array master job name will be the same as explained above.

```

$ msub -t myarray[2-10:2] job.sh

job Moab.15

$ checkjob -v myarray #or you could use 'checkjob -v Moab.15'
job Moab.15

AName: myarray
Job Array Info:
  Name: Moab.15
  2 : Moab.15[2] : Running
  4 : Moab.15[4] : Running
  6 : Moab.15[6] : Running
  8 : Moab.15[8] : Running
 10 : Moab.15[10] : Running

Sub-jobs:          5
Active:            5 ( 100.0% )
Eligible:          0 (  0.0% )
Blocked:           0 (  0.0% )
Completed:         0 (  0.0% )

State: Idle
Creds: user:tuser1 group:tgroup1
WallTime: 00:00:00 of 99:23:59:59
SubmitTime: Thu Jun  2 16:37:17
  (Time Queued Total: 00:00:33 Eligible: 00:00:00)

Total Requested Tasks: 1

Req[0] TaskCount: 1 Partition: ALL

```

- [Managing Consumable Generic Resources on page 573](#)
- [Enabling Generic Metrics on page 575](#)
- [Enabling Generic Events on page 578](#)

## Overview

Moab has a very flexible and generalized definition of a [node](#). This flexible definition, together with the fact that Moab must inter-operate with many resource managers of varying capacities, requires that Moab must possess a complete set of mechanisms for managing nodes that in some cases may be redundant with resource manager facilities.

### Resource Manager Specified 'Opaque' Attributes

Many resource managers support the concept of opaque node attributes, allowing a site to assign arbitrary strings to a node. These strings are opaque in the sense that the resource manager passes them along to the scheduler without assigning any meaning to them. Nodes possessing these opaque attributes can then be requested by various jobs. Using certain Moab parameters, sites can assign a meaning within Moab to these opaque node attributes and extract specific node information. For example, setting the parameter [FEATUREPROCSPEEDHEADER](#) `xps` causes a node with the opaque string `xps950` to be assigned a processor speed of 950 MHz within Moab.

### Scheduler Specified Default Node Attributes

Some default node attributes can be assigned on a rack or partition basis. In addition, many node attributes can be specified globally by configuring the *DEFAULT* node template using the [NODECFG](#) parameter (i.e., `NODECFG[DEFAULT] PROCSPEED=3200`). Unless explicitly specified otherwise, nodes inherit node attributes from the associated rack or partition or from the default node template. See the [Partition Overview](#) for more information.

### Scheduler Specified Node Attributes

The **NODECFG** parameter also allows direct per-node specification of virtually all node attributes supported via other mechanisms and also provides a number of additional attributes not found elsewhere. For example, a site administrator may want to specify something like the following:

```
NODECFG[node031] MAXJOB=2 PROCSPEED=600 PARTITION=small
```

These approaches may be mixed and matched according to the site's local needs. Precedence for the approaches generally follows the order listed earlier in cases where conflicting node configuration information is specified through one or more mechanisms.

## Node Location

Nodes can be assigned three types of location information based on partitions, racks, and queues.

- [Partitions](#)
- [Racks](#)
- [Queues](#)
  - [TORQUE/OpenPBS Queue to Node Mapping](#)

- [Node Selection/Specification](#)

## Partitions

The first form of location assignment, the partition, allows nodes to be grouped according to physical resource constraints or policy needs. By default, jobs are not allowed to span more than one partition so partition boundaries are often valuable if an underlying network topology make certain resource allocations undesirable. Additionally, per-partition policies can be specified to grant control over how scheduling is handled on a partition by partition basis. See the [Partition Overview](#) for more information.

## Racks

Rack-based location information is orthogonal to the partition based configuration and is mainly an organizational construct. In general rack based location usage, a node is assigned both a rack and a slot number. This approach has descended from the IBM SP2 organizational approach in which a rack can contain any number of slots but typically contains between 1 and 99. Using the rack and slot number combo, individual compute nodes can be grouped and displayed in a more ordered manner in certain Moab commands (i.e., [showstate](#)). Currently, rack information can only be specified directly by the system via the SDR interface on SP2/Loadleveler systems. In all other systems, this information must be specified using an information service or specified manually using the [RACK](#), [SLOT](#), and [SIZE](#) attributes of the [NODECFG](#) parameter.

**i** Sites may arbitrarily assign nodes to racks and rack slots without impacting scheduling behavior. Neither rack numbers nor rack slot numbers need to be contiguous; their use is simply for convenience purposes in displaying and analyzing compute resources.

*Example 3-134:*

```
NODECFG[node024] RACK=1 SLOT=1
NODECFG[node025] RACK=1 SLOT=2
NODECFG[node026] RACK=2 SLOT=1 PARTITION=special
...
```

When specifying node and rack information, slot values must be in the range of 1 to 99, and racks must be in the range of 1 to 399.

## Queues

Some resource managers allow queues (or classes) to be defined and then associated with a subset of available compute resources. With systems such as Loadleveler or PBSPro these queue to node mappings are automatically detected. On resource managers that do not provide this service, Moab provides alternative mechanisms for enabling this feature.

### TORQUE/OpenPBS Queue to Node Mapping

Under [TORQUE](#), queue to node mapping can be accomplished by using the [qmgr](#) command to set the queue [acl\\_hosts](#) parameter to the mapping hostlist desired. Further, the [acl\\_host\\_enable](#) parameter should be set to `False`.

**i** Setting `acl_hosts` and then setting `acl_host_enable` to `True` constrains the list of hosts from which jobs may be submitted to the queue.

The following example highlights this process and maps the queue debug to the nodes `host14` through .

```
> qmgr
Max open servers: 4
Qmgr: set queue debug acl_hosts = "host14,host15,host16,host17"
Qmgr: set queue debug acl_host_enable = false
Qmgr: quit
```

**i** All queues that do not have `acl_hosts` specified are global; that is, they show up on every node. To constrain these queues to a subset of nodes, each queue requires its own `acl_hosts` parameter setting.

## Node Selection

When selecting or specifying nodes either via command line tools or via configuration file based lists, Moab offers three types of node expressions that can be based on node lists, exact lists, node ranges, or regular expressions.

### Node Lists

Node lists can be specified as one or more comma or whitespace delimited node IDs. Specified node IDs can be based on either short or fully qualified hostnames. Each element will be interpreted as a regular expression.

```
SRCFG[basic]  HOSTLIST=cl37.icluster,ax45,ax46
...
```

### Exact Lists

When Moab receives a list of nodes it will, by default, interpret each element as a regular expression. To disable this and have each element interpreted as a string node name, the `l:` can be used as in the following example:

```
> setres l:n00,n01,n02
```

### Node Range

Node lists can be specified as one or more comma or whitespace delimited node ranges. Each node range can be based using either `<STARTINDEX>-<ENDINDEX>` or `<HEADER>[<STARTINDEX>-<ENDINDEX>]` format. To explicitly request a range, the node expression must be preceded with the string `r:` as in the following example:

```
> setres r:37-472,513,516-855
```

When you specify a `<HEADER>` for the range, note that it must only contain alphabetical characters. As always, the range must be numeric.

```
CLASSCFG[long] HOSTLIST=r:anc-b[37-472]
```

**i** Only one expression is allowed with node ranges.

**i** By default, Moab attempts to extract a node's node index assuming this information is built into the node's naming convention. If needed, this information can be explicitly specified in the Moab configuration file using `NODECFG`'s **NODEINDEX** attribute, or it can be extracted from alternately formatted node IDs by specifying the `NODEIDFORMAT` parameter.

## Node Regular Expression

Node lists may also be specified as one or more comma or whitespace delimited regular expressions. Each node regular expression must be specified in a format acceptable by the standard C regular expression libraries that allow support for wildcard and other special characters such as the following:

- \* (asterisk)
- . (period)
- [ ] (left and right bracket)
- ^ (caret)
- \$ (dollar)

Node lists are by default interpreted as a regular expression but can also be explicitly requested with the string `X:` as in the following examples:

```
# select nodes c130 thru c155
SRCFG[basic] HOSTLIST=x:c1[34],c15[0-5]
...
```

```
# select nodes c130 thru c155
SRCFG[basic] HOSTLIST=c1[34],c15[0-5]
...
```

**i** To control node selection search ordering, set the **OBJECTELIST** parameter to one of the following options: `exact`, `range`, `regex`, `rangere`, or `rerange`.

## Node Attributes

- [Configurable Node Attributes on page 556](#)
- [Node Features/Node Properties on page 565](#)

## Configurable Node Attributes

Nodes can possess a large number of attributes describing their configuration which are specified using the `NODECFG` parameter. The majority of these attributes such as operating system or configured

network interfaces can only be specified by the direct resource manager interface. However, the number and detail of node attributes varies widely from resource manager to resource manager. Sites often have interest in making scheduling decisions based on scheduling attributes not directly supplied by the resource manager. Configurable node attributes are listed in the following table; click an attribute for more detailed information:

- |                                             |                                                |                                           |

Attribute	Description
<b>ACCESS</b>	Specifies the node access policy that can be one of <i>SHARED</i> , <i>SHAREDONLY</i> , <i>SINGLEJOB</i> , <i>SINGLETASK</i> , or <i>SINGLEUSER</i> . See <a href="#">Node Access Policies</a> for more details. <pre>{ NODECFG[node013] ACCESS=singlejob }</pre>
<b>ARCH</b>	Specifies the node's processor architecture. <pre>{ NODECFG[node013] ARCH=opteron }</pre>
<b>COMMENT</b>	Allows an organization to annotate a node via the configuration file to indicate special information regarding this node to both users and administrators. The <b>COMMENT</b> value may be specified as a quote delimited string as shown in the example that follows. Comment information is visible using <a href="#">checknode</a> , <a href="#">mdiag</a> , <a href="#">Moab Cluster Manager</a> , and <a href="#">Moab Access Portal</a> . <pre>{ NODECFG[node013] COMMENT="Login Node" }</pre>
<b>ENABLEPROFILING</b>	Allows an organization to track node state over time. This information is available using <a href="#">showstats -n</a> . <pre>{ NODECFG[DEFAULT] ENABLEPROFILING=TRUE }</pre>

Attribute	Description
<p><b>FEATURES</b></p>	<p>Not all resource managers allow specification of opaque <a href="#">node features</a> (also known as node properties). For these systems, the <a href="#">NODECFG</a> parameter can be used to directly assign a list of node features to individual nodes. To append node features, use <code>FEATURES=&lt;X&gt;</code>; to overwrite or remove a node's features, you must update them in your Moab configuration file or resource manager.</p> <pre data-bbox="540 495 1409 541">NODECFG[node013] FEATURES=gpfs,fastio</pre> <p data-bbox="586 558 1360 636"><i>Node node013 now has features <b>gpfs</b> and <b>fastio</b> in addition to any other features configured in this file or the resource manager.</i></p> <div data-bbox="540 663 1409 751"> <p><b>i</b> The total number of supported node features is limited as described in the <a href="#">Adjusting Default Limits</a> section.</p> </div> <div data-bbox="540 768 1409 951"> <p><b>i</b> If supported by the resource manager, the resource manager specific manner of requesting node features/properties within a job may be used. (Within <b>TORQUE</b>, use <code>qsub -l nodes=&lt;NODECOUNT&gt;:&lt;NODEFEATURE&gt;</code>.) However, if either not supported within the resource manager or if support is limited, the Moab <a href="#">feature</a> resource manager extension may be used.</p> </div>
<p><b>FLAGS</b></p>	<p>Specifies various flags that should be set on the given node. Node flags must be set using the <a href="#">mschedctl -m config</a> command. Do not set node flags in the <code>moab.cfg</code> file. Flags set in <code>moab.cfg</code> may conflict with settings controlled automatically by resource managers, Moab Web Services.</p> <ul style="list-style-type: none"> <li>• <b>globalvars</b> - The node has variables that may be used by triggers.</li> <li>• <b>novmmigrations</b> - Excludes this hypervisor from VM auto-migrations. This means that VMs cannot automatically migrate to or from this hypervisor while this flag is set.</li> </ul> <pre data-bbox="618 1287 1409 1333">NODECFG[node1] FLAGS=NoVMMigrations</pre> <p data-bbox="667 1350 1360 1581"><i>To allow VMs to resume migrating, remove this flag using <code>mschedctl -m config 'NODECFG[node1] FLAGS=NoVMMigrations'</code> or use a resource manager to unset the flag. Because both Moab and the RM report the <b>novmmigration</b> flag and the RM's setting always overrides the Moab setting, you cannot remove the flag via the Moab command when the RM is reporting it.</i></p>

Attribute	Description
<p><b>GRES</b></p>	<p>Many resource managers do not allow specification of consumable generic node resources. For these systems, the <a href="#">NODECFG</a> parameter can be used to directly assign a list of consumable generic attributes to individual nodes or to the special pseudo-node <a href="#">global</a>, which provides shared cluster (floating) consumable resources. To set/overwrite a node's generic resources, use <code>GRES=&lt;NAME&gt;[:&lt;COUNT&gt;]</code>. (See <a href="#">Managing Consumable Generic Resources</a>.)</p> <pre data-bbox="565 527 1433 573">NODECFG [node013] GRES=quickcalc:20</pre>
<p><b>MAXIOIN</b></p>	<p>Maximum input allowed on node before it is marked busy.</p>
<p><b>MAXJOB</b></p>	<p>See <a href="#">Node Policies</a> for details.</p>
<p><b>MAXJOBPERUSER</b></p>	<p>See <a href="#">Node Policies</a> for details.</p>
<p><b>MAXPE</b></p>	<p>See <a href="#">Node Policies</a> for details.</p>
<p><b>MAXPEPERJOB</b></p>	<p>Maximum allowed Processor Equivalent per job on this node. A job will not be allowed to run on this node if its PE exceeds this number.</p> <pre data-bbox="565 1010 1433 1083">NODECFG [node024] MAXPEPERJOB=10000 ...</pre>
<p><b>MAXPROC</b></p>	<p>Maximum dedicated processors allowed on this node. No jobs are scheduled on this node when this number is reached. See <a href="#">Node Policies</a> for more information.</p> <pre data-bbox="565 1209 1433 1283">NODECFG [node024] MAXPROC=8 ...</pre>
<p><b>NETWORK</b></p>	<p>The ability to specify which networks are available to a given node is limited to only a few resource managers. Using the <b>NETWORK</b> attribute, administrators can establish this node to network connection directly through the scheduler. The <a href="#">NODECFG</a> parameter allows this list to be specified in a comma-delimited list.</p> <pre data-bbox="565 1472 1433 1545">NODECFG [node024] NETWORK=GigE ...</pre>
<p><b>NODEINDEX</b></p>	<p>The node's index. See <a href="#">Node Location</a> for details.</p>

Attribute	Description
<p><b>OS</b></p>	<p>This attribute specifies the node's operating system.</p> <pre data-bbox="537 369 1406 415">NODECFG[node013] OS=suse10</pre> <div data-bbox="537 443 1406 562" style="border: 1px solid #005596; padding: 5px; margin-top: 10px;"> <p><b>i</b> Because the TORQUE operating system overwrites the Moab operating system, change the operating system with <a href="#">opsys on page 2794</a> instead of <b>OS</b> if you are using TORQUE.</p> </div>
<p><b>OSLIST</b></p>	<p>This attribute specifies the list of operating systems the node can run.</p> <pre data-bbox="537 663 1406 709">NODECFG[compute002] OSLIST=linux,windows</pre>
<p><b>OVERCOMMIT</b></p>	<p>Specifies the high-water limit for over-allocation of processors or memory on a hypervisor. This setting is used to protect hypervisors from having too many VMs placed on them, regardless of the utilization level of those VMs. Possible attributes include DISK, MEM, PROC, and SWAP. Usage is <code>&lt;attr&gt;:&lt;integer&gt;</code>.</p> <pre data-bbox="537 905 1406 951">NODECFG[node012] OVERCOMMIT=PROC:2,MEM:4</pre>
<p><b>PARTITION</b></p>	<p>See <a href="#">Node Location</a> for details.</p>
<p><b>POWERPOLICY</b></p>	<p>The <b>POWERPOLICY</b> can be set to <i>OnDemand</i> or <i>STATIC</i>. It defaults to <i>STATIC</i> if not set. If set to <i>STATIC</i>, Moab will never automatically change the power status of a node. If set to <i>OnDemand</i>, Moab will turn the machine off and on based on workload and global settings. See Green Computing for further details.</p>
<p><b>PREEMPTMAXCPULOAD</b></p>	<p>If the node CPU load exceeds the specified value, any batch jobs running on the node are preempted using the preemption policy specified with the node's <a href="#">PREEMTPOLICY</a> attribute. If this attribute is not specified, the global default policy specified with <a href="#">PREEMTPOLICY</a> parameter is used. See <a href="#">Sharing Server Resources</a> for further details.</p> <pre data-bbox="537 1430 1406 1514">NODECFG[node024] PRIORITY=-150 COMMENT="NFS Server Node" NODECFG[node024] PREEMTPOLICY=CANCEL PREEMPTMAXCPULOAD=1.2 ...</pre>

Attribute	Description
<p><b>PREEMPTMINMEMAVAIL</b></p>	<p>If the available node memory drops below the specified value, any batch jobs running on the node are preempted using the preemption policy specified with the node's <a href="#">PREEMTPOLICY</a> attribute. If this attribute is not specified, the global default policy specified with <a href="#">PREEMTPOLICY</a> parameter is used. See <a href="#">Sharing Server Resources</a> for further details.</p> <pre data-bbox="565 499 1433 590"> NODECFG[node024] PRIORITY=-150 COMMENT="NFS Server Node" NODECFG[node024] PREEMTPOLICY=CANCEL PREEMPTMINMEMAVAIL=256 ...</pre>
<p><b>PREEMTPOLICY</b></p>	<p>If any node preemption policies are triggered (such as <a href="#">PREEMPTMAXCPULOAD</a> or <a href="#">PREEMPTMINMEMAVAIL</a>) any batch jobs running on the node are preempted using this preemption policy if specified. If not specified, the global default preemption policy specified with <a href="#">PREEMTPOLICY</a> parameter is used. See <a href="#">Sharing Server Resources</a> for further details.</p> <pre data-bbox="565 821 1433 911"> NODECFG[node024] PRIORITY=-150 COMMENT="NFS Server Node" NODECFG[node024] PREEMTPOLICY=CANCEL PREEMPTMAXCPULOAD=1.2 ...</pre>
<p><b>PRIORITY</b></p>	<p>The <b>PRIORITY</b> attribute specifies the fixed node priority relative to other nodes. It is only used if <a href="#">NODEALLOCATIONPOLICY</a> is set to <i>PRIORITY</i>. The default node priority is 0. A default cluster-wide node priority may be set by configuring the <b>PRIORITY</b> attribute of the <i>DEFAULT</i> node. See <a href="#">Priority Node Allocation</a> for more details.</p> <pre data-bbox="565 1104 1433 1194"> NODEALLOCATIONPOLICY PRIORITY NODECFG[node024] PRIORITY=120 ...</pre>

Attribute	Description
<p><b>PRIORITYF</b></p>	<p>The <b>PRIORITYF</b> attribute specifies the function to use when calculating a node's allocation priority specific to a particular job. It is only used if <a href="#">NODEALLOCATIONPOLICY</a> is set to <i>PRIORITY</i>. The default node priority function sets a node's priority exactly equal to the configured node priority. The priority function allows a site to indicate that various environmental considerations such as node load, reservation affinity, and ownership be taken into account as well using the following format:</p> <pre>&lt;COEFFICIENT&gt; * &lt;ATTRIBUTE&gt; [ + &lt;COEFFICIENT&gt; * &lt;ATTRIBUTE&gt; ] ...</pre> <p>&lt;ATTRIBUTE&gt; is an attribute from the table found in the <a href="#">Priority Node Allocation</a> section.</p> <p>A default cluster-wide node priority function may be set by configuring the <b>PRIORITYF</b> attribute of the <i>DEFAULT</i> node. See <a href="#">Priority Node Allocation</a> for more details.</p> <pre>NODEALLOCATIONPOLICY  PRIORITY NODECFG[node024]  PRIORITYF='APROC + .01 * AMEM - 10 * JOBCOUNT' ...</pre>
<p><b>PROCSPEED</b></p>	<p>Knowing a node's processor speed can help the scheduler improve intra-job efficiencies by allocating nodes of similar speeds together. This helps reduce losses due to poor internal job load balancing. Moab's <a href="#">Node Set</a> scheduling policies allow a site to control processor speed based allocation behavior.</p> <p>Processor speed information is specified in MHz and can be indicated directly using <a href="#">NODECFG</a> or through use of the <a href="#">FEATUREPROCSPEEDHEADER</a> parameter.</p>
<p><b>PROVRM</b></p>	<p>Provisioning resource managers can be specified on a per node basis. This allows flexibility in mixed environments. If the node does not have a provisioning resource manager, the default provisioning resource manager will be used. The default is always the first one listed in <code>moab.cfg</code>.</p> <pre>RMCFG[prov]  TYPE=NATIVE  RESOURCETYPE=PROV RMCFG[prov]  PROVDURATION=10:00 RMCFG[prov]  NODEMODIFYURL=exec://\$HOME/tools/os.switch.pl ... NODECFG[node024]  PROVRM=prov</pre>
<p><b>RACK</b></p>	<p>The rack associated with the node's physical location. Valid values range from 1 to 400. See <a href="#">Node Location</a> for details.</p>
<p><b>RADISK</b></p>	<p>Jobs can request a certain amount of disk space through the <a href="#">RM Extension String's DDISK</a> parameter. When done this way, Moab can track the amount of disk space available for other jobs. To set the total amount of disk space available the <b>RADISK</b> parameter is used.</p>

Attribute	Description
<p><b>RCDISK</b></p>	<p>Jobs can request a certain amount of disk space (in MB) through the <a href="#">RM Extension String's DDISK</a> parameter. When done this way, Moab can track the amount of disk space available for other jobs. The <b>RCDISK</b> attribute constrains the amount of disk reported by a resource manager while the <b>RADISK</b> attribute specifies the amount of disk available to jobs. If the resource manager does not report available disk, the <b>RADISK</b> attribute should be used.</p>
<p><b>RCMEM</b></p>	<p>Jobs can request a certain amount of real memory (RAM) in MB through the <a href="#">RM Extension String's DMEM</a> parameter. When done this way, Moab can track the amount of memory available for other jobs. The <b>RCMEM</b> attribute constrains the amount of RAM reported by a resource manager while the <b>RAMEM</b> attribute specifies the amount of RAM available to jobs. If the resource manager does not report available disk, the <b>RAMEM</b> attribute should be used.</p> <p>Please note that memory reported by the resource manager will override the configured value unless a trailing caret (^) is used.</p> <div data-bbox="565 835 1433 905" style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>NODECFG [node024] RCMEM=2048 ...</pre> </div> <div data-bbox="613 911 1385 999" style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <p><i>If the resource manager does not report any memory, then Moab will assign node0242048 MB of memory.</i></p> </div> <div data-bbox="565 1024 1433 1094" style="border: 1px dashed gray; padding: 5px; margin-bottom: 10px;"> <pre>NODECFG [node024] RCMEM=2048^ ...</pre> </div> <div data-bbox="613 1100 1385 1188" style="border: 1px dashed gray; padding: 5px;"> <p><i>Moab will assign 2048 MB of memory to node024 regardless of what the resource manager reports.</i></p> </div>
<p><b>RCPROC</b></p>	<p>The <b>RCPROC</b> specifies the number of processors available on a compute node.</p> <div data-bbox="565 1287 1433 1356" style="border: 1px dashed gray; padding: 5px;"> <pre>NODECFG [node024] RCPROC=8 ...</pre> </div>

Attribute	Description
<p><b>RCSWAP</b></p>	<p>Jobs can request a certain amount of swap space in MB.</p> <div data-bbox="537 359 1409 512" style="border: 1px solid #0070C0; padding: 5px; margin-bottom: 10px;"> <p><b>i</b> <b>RCSWAP</b> works similarly to <b>RCMEM</b>. Setting <b>RCSWAP</b> on a node will set the swap but can be overridden by swap reported by the resource manager. If the trailing caret (^) is used, Moab will ignore the swap reported by the resource manager and use the configured amount.</p> </div> <div data-bbox="537 533 1409 604" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <pre>NODECFG[node024] RCSWAP=2048 ...</pre> </div> <div data-bbox="586 611 1360 699" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <p><i>If the resource manager does not report any memory, Moab will assign node024 <b>2048</b> MB of swap.</i></p> </div> <div data-bbox="537 720 1409 791" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <pre>NODECFG[node024] RCSWAP=2048^ ...</pre> </div> <div data-bbox="586 798 1360 886" style="border: 1px dashed #ccc; padding: 5px;"> <p><i>Moab will assign <b>2048</b> MB of swap to node024 regardless of what the resource manager reports.</i></p> </div>
<p><b>SIZE</b></p>	<p>The number of slots or size units consumed by the node. This value is used in graphically representing the cluster using <a href="#">showstate</a> or <a href="#">Moab Cluster Manager</a>. See <a href="#">Node Location</a> for details. For display purposes, legal size values include <b>1, 2, 3, 4, 6, 8, 12, and 16</b>.</p> <div data-bbox="537 1079 1409 1150" style="border: 1px dashed #ccc; padding: 5px;"> <pre>NODECFG[node024] SIZE=2 ...</pre> </div>
<p><b>SLOT</b></p>	<p>The first slot in the rack associated with the node's physical location. Valid values range from 1 to <b>MMAK_RACKSIZE</b> (default=<b>64</b>). See <a href="#">Node Location</a> for details.</p>
<p><b>SPEED</b></p>	<p>Because today's processors have multiple cores and adjustable clock frequency, this feature has no meaning and will be deprecated.</p> <div data-bbox="537 1379 1409 1440" style="border: 1px solid #0070C0; padding: 5px;"> <p><b>i</b> The <b>SPEED</b> specification must be in the range of 0.01 to 100.0.</p> </div>
<p><b>TRIGGER</b></p>	<p>See <a href="#">About object triggers on page 745</a> for information.</p>
<p><b>VARIABLE</b></p>	<p>Variables associated with the given node, which can be used in job scheduling. See <a href="#">-l PREF</a>.</p> <div data-bbox="537 1646 1409 1717" style="border: 1px dashed #ccc; padding: 5px;"> <pre>NODECFG[node024] VARIABLE=var1 ...</pre> </div>

Attribute	Description
<b>VMOCTHRESHOLD</b>	Specifies the high-water threshold for utilization of resources on a server (i.e. processor and memory). This setting is used to protect hypervisors from becoming too highly utilized and thus negatively impacting the performance of VMs running on the hypervisor. Possible attributes include <code>PROC</code> and <code>MEM</code> .  <code>NODECFG [node024] VMOCTHRESHOLD=PROC=2, MEM=2</code>

## Node Features/Node Properties

A node feature (or node property) is an opaque string label that is associated with a compute node. Each compute node may have any number of node features assigned to it, and jobs may request allocation of nodes that have specific features assigned. Node features are labels and their association with a compute node is not conditional, meaning they cannot be consumed or exhausted.

Node features may be assigned by the resource manager, and this information may be imported by Moab or node features may be specified within Moab directly. Moab supports hyphens and underscores in node feature names.

As a convenience feature, certain node attributes can be specified via node features using the parameters listed in the following table:

PARAMETER	DESCRIPTION
<b>FEATURENODETYPEHEADER</b>	Set <a href="#">Node Type</a>
<b>FEATUREPARTITIONHEADER</b>	Set <a href="#">Partition</a>
<b>FEATUREPROCSPEEDHEADER</b>	Set <a href="#">Processor Speed</a>
<b>FEATURERACKHEADER</b>	Set <a href="#">Rack</a>
<b>FEATURESLOTHEADER</b>	Set <a href="#">Slot</a>

Example 3-135:

```
FEATUREPARTITIONHEADER par
FEATUREPROCSPEEDHEADER cpu
```

- Differences between Node Features and [Managing Consumable Generic Resources](#)

## Node Specific Policies

Node policies within Moab allow specification of not only how the node's load should be managed, but who can use the node, and how the node and jobs should respond to various events. These policies allow a site administrator to specify on a node by node basis what the node will and will not support. Node policies may be applied to specific nodes or applied system-wide using the specification `NODECFG [DEFAULT] . . . .`

### Node Usage/Throttling Policies

#### MAXJOB

This policy constrains the number of total independent jobs a given node may run simultaneously. It can only be specified via the [NODECFG](#) parameter.

**i** On Cray XT systems, use the NID (node id) instead of the node name. For more information, see [Configuring the moab.cfg file](#).

#### MAXJOBPERUSER

Constrains the number of total independent jobs a given node may run simultaneously associated with any single user. It can only be specified via the [NODECFG](#) parameter.

#### MAXJOBPERGROUP

Constrains the number of total independent jobs a given node may run simultaneously associated with any single group. It can only be specified via the [NODECFG](#) parameter.

#### MAXLOAD

**MAXLOAD** constrains the CPU load the node will support as opposed to the number of jobs. This maximum load policy can also be applied system wide using the parameter [NODEMAXLOAD](#).

#### MAXPE

This policy constrains the number of total dedicated processor-equivalents a given node may support simultaneously. It can only be specified via the **NODECFG** parameter.

#### MAXPROC

This policy constrains the number of total dedicated processors a given node may support simultaneously. It can only be specified via the **NODECFG** parameter.

## MAXPROCUSER

This policy constrains the number of total processors a given node may have dedicated to any single user. It can only be specified via the **NODECFG** parameter.

## MAXPROCERGROUP

This policy constrains the number of total processors a given node may have dedicated to any single group. It can only be specified via the **NODECFG** parameter.

**i** Node throttling policies are used strictly as constraints. If a node is defined as having a single processor or the **NODEACCESSPOLICY** is set to **SINGLETASK**, and a **MAXPROC** policy of 4 is specified, Moab will not run more than one task per node. A node's configured processors must be specified so that multiple jobs may run and then the **MAXJOB** policy will be effective. The number of configured processors per node is specified on a resource manager specific basis. PBS, for example, allows this to be adjusted by setting the number of virtual processors with the `np` parameter for each node in the PBS `nodes` file.

Example 3-136:

```
NODECFG[node024] MAXJOB=4 MAXJOBPERUSER=2
NODECFG[node025] MAXJOB=2
NODECFG[node026] MAXJOBPERUSER=1
NODECFG[DEFAULT] MAXLOAD=2.5
...
```

## Node Access Policies

While most sites require only a single cluster wide node access policy (commonly set using **NODEACCESSPOLICY**), it is possible to specify this policy on a node by node basis using the **ACCESS** attributes of the **NODECFG** parameter. This attribute may be set to any of the valid node access policy values listed in the [Node Access Policies](#) section.

Example 3-137:

To set a global policy of **SINGLETASK** on all nodes except nodes 13 and 14, use the following:

```
# by default, enforce dedicated node access on all nodes
NODEACCESSPOLICY SINGLETASK
# allow nodes 13 and 14 to be shared
NODECFG[node13] ACCESS=SHARED
NODECFG[node14] ACCESS=SHARED
```

# Managing Shared Cluster Resources (Floating Resources)

This section describes how to configure, request, and reserve cluster file system space and bandwidth, [software licenses](#), and generic cluster resources.

## Shared Cluster Resource Overview

Shared cluster resources such as file systems, networks, and licenses can be managed through creating a pseudo-node. You can configure a pseudo-node via the [NODECFG](#) parameter much as a normal node would be but additional information is required to allow the scheduler to contact and synchronize state with the resource.

In the following example, a license manager is added as a cluster resource by defining the *GLOBAL* pseudo-node and specifying how the scheduler should query and modify its state.

```
NODECFG[GLOBAL] RMLIST=NATIVE
NODECFG[GLOBAL] QUERYCMD=/usr/local/bin/flquery.sh
NODECFG[GLOBAL] MODIFYCMD=/usr/local/bin/flmodify.sh
```

In some cases, pseudo-node resources may be very comparable to node-locked [generic resources](#) however there are a few fundamental differences which determine when one method of describing resources should be used over the other. The following table contrasts the two resource types.

Attribute	Pseudo-Node	Generic Resource
<b>Node-Locked</b>	No - Resources can be encapsulated as an independent node.	Yes - Must be associated with an existing compute node.
<b>Requires exclusive batch system control over resource</b>	No - Resources (such as file systems and licenses) may be consumed both inside and outside of batch system workload.	Yes - Resources must only be consumed by batch workload. Use outside of batch control results in loss of resource synchronization.
<b>Allows scheduler level allocation of resources</b>	Yes - If required, the scheduler can take external administrative action to allocate the resource to the job.	No - The scheduler can only maintain logical allocation information and cannot take any external action to allocate resources to the job.

## Configuring Generic Consumable Floating Resources

Consumable floating resources are configured in the same way as node-locked [generic](#) resources with the exception of using the *GLOBAL* node instead of a particular node.

```
NODECFG[GLOBAL] GRES=tape:4,matlab:2
...
```

*In this setup, four resources of type [tape](#) and 2 of type [matlab](#) are floating and available across all nodes.*

## Requesting Consumable Floating Resources

Floating resources are requested on a per task basis using native resource manager job submission methods or using the [GRES](#) resource manager extensions.

## Configuring Cluster File Systems

Moab allows both the file space and bandwidth attributes of a cluster file system to be tracked, reserved, and scheduled. With this capability, a job or reservation may request a particular quantity of file space and a required amount of I/O bandwidth to this file system. While file system resources are managed as a cluster generic resource, they are specified using the **FS** attribute of the **NODECFG** parameter as in the following example:

```
NODECFG[GLOBAL] FS=PV1:10000@100,PV2:5000@100
...
```

*In this example, PV1 defines a 10 GB file system with a maximum throughput of 100 MB/s while PV2 defines a 5 GB file system also possessing a maximum throughput of 100 MB/s.*

A job may request cluster file system resources using the `fs` resource manager extension. For a TORQUE based system, the following could be used:

```
>qsub -l nodes=1,walltime=1:00:00 -W x=fs:10@50
```

## Configuring Cluster Licenses

Jobs may request and reserve software licenses using native methods or using the **GRES** resource manager extension. If the cluster license manager does not support a query interface, license availability may be specified within Moab using the **GRES** attribute of the **NODECFG** parameter.

*Example 3-138: Configure Moab to support four floating **quickcalc** and two floating **matlab** licenses.*

```
NODECFG[GLOBAL] GRES=quickcalc:4,matlab:2
...
```

*Example 3-139: Submit a **TORQUE** job requesting a node-locked or floating **quickcalc** license.*

```
> qsub -l nodes=1,software=quickcalc,walltime=72000 testjob.cmd
```

## Configuring Generic Resources as Features

Moab can be configured to treat generic resources as features in order to provide more control over server access. For instance, if a node is configured with a certain **GRES** and that **GRES** is turned off, jobs requesting the node will not run. To turn a GRES into a feature, set the **FEATUREGRES** attribute of **GRES\_CFG** to **TRUE** in the `moab.cfg` file.

```
GRES_CFG[gres1] FEATUREGRES=TRUE
```

*Moab now treats gres1 as a scheduler-wide feature rather than a normal generic resource.*

Note that jobs are submitted normally using the same GRES syntax.

**i** If you are running a grid, verify that `FEATUREGRES=TRUE` is set on all members of the grid.

**i** You can safely upgrade an existing cluster to use the feature while jobs are running. If you are in a grid, upgrade all clusters at the same time.

Two methods exist for managing GRES features: via Moab commands and via the resource manager. Using Moab commands means that feature changes are not checkpointed; they do not remain in place when Moab restarts. Using the resource manager causes changes to be reported by the RM, so any changes made before a Moab restart are still present after it.

These methods are mutually exclusive. Use one or the other, but do not mix methods.

## Managing Feature GRES via Moab Commands

In the following example, *gres1* and *gres2* are configured in the `moab.cfg` file. *gres1* is not currently functioning correctly, so it is set to 0, turning the feature off. Values above 0 and non-specified values turn the feature on.

```
NODECFG[GLOBAL] GRES=gres1:0
NODECFG[GLOBAL] GRES=gres2:10000
GRESCFG[gres1] FEATUREGRES=TRUE
GRESCFG[gres2] FEATUREGRES=TRUE
```

*Moab now treats gres1 and gres2 as features.*

To verify that this is set up correctly, run `mdiag -S -v`. It returns the following:

```
> mdiag -S -v
...
Scheduler FeatureGres: gres1:off,gres2:on
```

Once Moab has started, use `mschedctl -m` to modify whether the feature is turned on or off.

```
mschedctl -m sched featuregres:gres1=on
INFO: FeatureGRes 'gres1' turned on
```

You can verify that the feature turned on or off by once again running `mdiag -S -v`.

**i** If Moab restarts, it will not checkpoint the state of these changed feature general resources. Instead, it will read the `moab.cfg` file to determine whether the feature GRES is on or off.

With feature GRES configured, jobs are submitted normally, requesting GRES type *gres1* and *gres2*. Moab ignores GRES counts and reads the feature simply as on or off.

```
> msub -l nodes=1,walltime=600,gres=gres1

1012
> checkjob 1012
job 1012

AName: STDIN
State: Running
.....
StartTime: Tue Jul 3 15:33:28
Feature GRes: gres1
Total Requested Tasks: 1
```

If you request a feature that is currently turned off, the state is not reported as Running, but as Idle. A message like the following returns:

```
BLOCK MSG: requested feature gres 'gres2' is off
```

## Managing Feature GRES via the Resource Manager

You can automate the process of having a feature GRES turn on and off by setting up an external tool and configuring Moab to query the tool the same way that Moab queries a license manager. For example:

```
RMCFG[myRM] CLUSTERQUERYURL=file:/// $HOME/tools/myRM.dat TYPE=NATIVE
RESOURCE TYPE=LICENSE

GRES CFG[gres1] FEATUREGRES=TRUE
GRES CFG[gres2] FEATUREGRES=TRUE
```

*LICENSE means that the RM does not contain any compute resources and that Moab should not attempt to use it to manage any jobs (start, cancel, submit, etc.).*

The `myRM.dat` file should contain something like the following:

```
GLOBAL state=Idle cres=gres1:0,gres2:10
```

External tools can easily update the file based on filesystem availability. Switching any of the feature GRES to 0 turns it off and switching it to a positive value turns it on. If you use this external mechanism, you do not need to use `mschedctl -m` to turn a feature GRES on or off. You also do not need to worry about whether Moab has checkpointed the information or not, since the information is provided by the RM and not by any external commands.

## Managing Node State

There are multiple models in which Moab can operate allowing it to either honor the node state set by an external service or locally determine and set the node state. This section covers the following:

- identifying meanings of particular node states
- specifying node states within locally developed services and resource managers
- adjusting node state within Moab based on load, policies, and events

## Node State Definitions

State	Definition
<b>Down</b>	Node is either not reporting status, is reporting status but failures are detected, or is reporting status but has been marked down by an administrator.
<b>Idle</b>	Node is reporting status, currently is not executing any workload, and is ready to accept additional workload.

State	Definition
<b>Busy</b>	Node is reporting status, currently is executing workload, and cannot accept additional workload due to load.
<b>Running</b>	Node is reporting status, currently is executing workload, and can accept additional workload.
<b>Drained</b>	Node is reporting status, currently is not executing workload, and cannot accept additional workload due to administrative action.
<b>Draining</b>	Node is reporting status, currently is executing workload, and cannot accept additional workload due to administrative action.

## Specifying Node States within Native Resource Managers

Native resource managers can report node state implicitly and explicitly, using **NODESTATE**, **LOAD**, and other attributes. See [Managing Resources Directly with the Native Interface](#) for more information.

## Moab Based Node State Adjustment

Node state can be adjusted based on reported processor, memory, or other load factors. It can also be adjusted based on reports of one or more resource managers in a multi-resource manager configuration. Also, both generic events and generic metrics can be used to adjust node state.

- TORQUE [health scripts](#) (allow compute nodes to detect and report site specific failures).

## Adjusting Scheduling Behavior Based on Reported Node State

Based on reported node state, Moab can support various policies to make better use of available resources. For more information, see the [Green computing overview on page 723](#).

### Down State

- [JOBACTIONONNODEFAILURE](#) parameter (cancel/requeue jobs if allocated nodes fail).
- [Triggers](#) (take specified action if failure is detected).

## Managing Consumable Generic Resources

- Configuring Node-Locked Consumable Generic Resources
  - Requesting Consumable Generic Resources
- Managing Generic Resource Race Conditions

Each time a job is allocated to a compute node, it consumes one or more types of resources. Standard resources such as CPU, memory, disk, network adapter bandwidth, and swap are automatically tracked and consumed by Moab. However, in many cases, additional resources may be provided by nodes and consumed by jobs that must be tracked. The purpose of this tracking may include accounting, billing, or the prevention of resource over-subscription. Generic consumable resources may be used to manage software licenses, I/O usage, bandwidth, application connections, or any other aspect of the larger compute environment; they may be associated with compute nodes, networks, storage systems, or other real or virtual resources.

These additional resources can be managed within Moab by defining one or more generic resources. The first step in defining a generic resource involves naming the resource. Generic resource availability can then be associated with various compute nodes and generic resource usage requirements can be associated with jobs.

### Differences Between Node Features and Consumable Resources

A [node feature](#) (or node property) is an opaque string label that is associated with a compute node. Each compute node may have any number of node features assigned to it and jobs may request allocation of nodes that have specific features assigned. Node features are labels and their association with a compute node is not conditional, meaning they cannot be consumed or exhausted.

### Configuring Node-locked Consumable Generic Resources

Consumable generic resources are supported within Moab using either direct configuration or resource manager auto-detect (as when using TORQUE and [accelerator hardware](#)). For direct configuration, node-locked consumable generic resources (or generic resources) are specified using the **NODECFG** parameter's **GRES** attribute. This attribute is specified using the format `<ATTR>:<COUNT>` as in the following example:

```
NODECFG[titan001] GRES=tape:4
NODECFG[login32] GRES=matlab:2,prime:4
NODECFG[login33] GRES=matlab:2
...
```

 By default, Moab supports up to 128 independent generic resource types.

### Requesting Consumable Generic Resources

Generic resources can be requested on a per task or per job basis using the [GRES resource manager extension](#). If the generic resource is located on a compute node, requests are by default interpreted as a per task request. If the generic resource is located on a shared, cluster-level resource (such as a network or storage system), then the request defaults to a per job interpretation.

**1** Generic resources are specified per task, not per node. When you submit a job, each processor becomes a task. For example, a job asking for `nodes=3:ppn=4,gres=test:5` asks for 60 gres of type test ((3\*4 processors)\*5).

If using [TORQUE](#), the [GRES](#) or [software](#) resource can be requested as in the following examples:

#### Example 3-140: Per Task Requests

```
NODECFG[compute001] GRES=dvd:2 SPEED=2200
NODECFG[compute002] GRES=dvd:2 SPEED=2200
NODECFG[compute003] GRES=dvd:2 SPEED=2200
NODECFG[compute004] GRES=dvd:2 SPEED=2200
NODECFG[compute005] SPEED=2200
NODECFG[compute006] SPEED=2200
NODECFG[compute007] SPEED=2200
NODECFG[compute008] SPEED=2200
```

```
# submit job which will allocate only from nodes 1 through 4 requesting one dvd per
task
> qsub -l nodes=2,walltime=100,gres=dvd job.cmd
```

*In this example, Moab determines that compute nodes exist that possess the requested generic resource. A compute node is a node object that possesses processors on which compute jobs actually execute. License server, network, and storage resources are typically represented by non-compute nodes. Because compute nodes exist with the requested generic resource, Moab interprets this job as requesting two compute nodes each of which must also possess a DVD generic resource.*

#### Example 3-141: Per Job Requests

```
NODECFG[network] PARTITION=shared GRES=bandwidth:2000000
```

```
# submit job which will allocate 2 nodes and 10000 units of network bandwidth
> qsub -l nodes=2,walltime=100,gres=bandwidth:10000 job.cmd
```

*In this example, Moab determines that there exist no compute nodes that also possess the generic resource `bandwidth` so this job is translated into a multiple-requirement—multi-req—job. Moab creates a job that has a requirement for two compute nodes and a second requirement for 10000 bandwidth generic resources. Because this is a multi-req job, Moab knows that it can locate these needed resources separately.*

## Using Generic Resource Requests in Conjunction with other Constraints

Jobs can explicitly specify generic resource constraints. However, if a job also specifies a [hostlist](#), the hostlist constraint overrides the generic resource constraint if the request is for per task allocation. In the Per Task Requests example, if the job also specified a hostlist, the `DVD` request is ignored.

## Requesting Resources with No Generic Resources

In some cases, it is valuable to allocate nodes that currently have no generic resources available. This can be done using the special value `none` as in the following example:

```
> qsub -l nodes=2,walltime=100,gres=none job.cmd
```

*In this case, the job only allocates compute nodes that have no generic resources associated with them.*

## Requesting Generic Resources Automatically within a Queue/Class

Generic resource constraints can be assigned to a queue or class and inherited by any jobs that do not have a **gres** request. This allows targeting of specific resources, automation of co-allocation requests, and other uses. To enable this, use the [DEFAULT.GRES](#) attribute of the [CLASSCFG](#) parameter as in the following example:

```
CLASSCFG[viz] DEFAULT.GRES=graphics:2
```

For each node requested by a *viz* job, also request two graphics cards.

## Managing Generic Resource Race Conditions

A software license race condition "window of opportunity" opens when Moab checks a license server for sufficient available licenses and closes when the user's software actually checks out the software licenses. The time between these two events can be seconds to many minutes depending on overhead factors such as node OS provisioning, job startup, licensed software startup, and so forth.

During this window, another Moab-scheduled job or a user or job external to the cluster or cloud can obtain enough software licenses that by the time the job attempts to obtain its software licenses, there are an insufficient quantity of available licenses. In such cases a job will sit and wait for the license, and while it waits it occupies but does not use resources that another job could have used. Use the **STARTDELAY** parameter to prevent such a situation.

```
GRESCFG[<license>] STARTDELAY=<window_of_opportunity>
```

With the **STARTDELAY** parameter enabled (on a per generic resource basis) Moab blocks any idle jobs requesting the same generic resource from starting until the *<window\_of\_opportunity>* passes. The window is defined by the customer on a per generic resource basis.

## Enabling Generic Metrics

- [Configuring Generic Metrics](#)
- [Example Generic Metric Usage](#)

Moab allows organizations to enable generic performance metrics. These metrics allow decisions to be made and reports to be generated based on site specific environmental factors. This increases Moab's awareness of what is occurring within a given cluster environment, and allows arbitrary information to

be associated with resources and the workload within the cluster. Uses of these metrics are widespread and can cover anything from tracking node temperature, to memory faults, to application effectiveness.

- Execute triggers when specified thresholds are reached
- Modify node allocation affinity for specific jobs
- Initiate automated notifications when thresholds are reached
- Display current, average, maximum, and minimum metrics values in reports and charts within [Moab Cluster Manager](#)

## Configuring Generic Metrics

A new generic metric is automatically created and tracked at the server level if it is reported by either a node or a job.

To associate a generic metric with a job or node, a [native resource manager](#) must be set up and the `GMETRIC` attribute must be specified. For example, to associate a generic metric of `temp` with each node in a [TORQUE](#) cluster, the following could be reported by a native resource manager:

```
# temperature output
node001 GMETRIC[temp]=113
node002 GMETRIC[temp]=107
node003 GMETRIC[temp]=83
node004 GMETRIC[temp]=85
...
```

Generic metrics are tracked as floating point values allowing virtually any number to be reported.

In the preceding example, the new metric, `temp`, can now be used to monitor system usage and performance or to allow the scheduler to take action should certain thresholds be reached. Some uses include the following:

- Executing [triggers](#) based on generic metric thresholds
- Adjust a node's [availability](#) for accepting additional workload
- Adjust a node's [allocation priority](#)
- Initiate administrator [notification](#) of current, minimum, maximum, or average generic metric values
- Use metrics to report resource and job performance
- Use metrics to report resource and job failures
- Using job profiles to allow Moab to learn which resources best run which applications
- Tracking effective application efficiency to identify resource brown outseven when no node failure is obvious
- Viewing current and [historical](#) cluster-wide generic metric values to identify failure, performance, and usage
- Enable charging policies based on consumption of generic metrics patterns

- View changes in generic metrics on nodes, jobs, and cluster wide over time
- Submit jobs with generic metric based [node-allocation requirements](#)

Generic metric values can be viewed using [checkjob](#), [checknode](#), [mdiag -n,mdiag -j](#), or [Moab Cluster Manager](#) Charting and Reporting Features.

Historical job and node generic metric statistics can be cleared using the [mjobctl](#) and [mnodectl](#) commands.

## Example Generic Metric Usage

As an example, consider a cluster with two primary purposes for generic metrics. The first purpose is to track and adjust scheduling behavior based on node temperature to mitigate overheating nodes. The second purpose is to track and charge for utilization of a locally developed data staging service.

The first step in enabling a generic metric is to create probes to monitor and report this information. Depending on the environment, this information may be distributed or centralized. In the case of temperature monitoring, this information is often centralized by a hardware monitoring service and available via command line or an API. If monitoring a locally developed data staging service, this information may need to be collected from multiple remote nodes and aggregated to a central location. The following are popular freely available monitoring tools:

Tool	Link
<b>BigBrother</b>	<a href="http://www.bb4.org">http://www.bb4.org</a>
<b>Ganglia</b>	<a href="http://ganglia.sourceforge.net">http://ganglia.sourceforge.net</a>
<b>Monit</b>	<a href="http://www.tildeslash.com/monit">http://www.tildeslash.com/monit</a>
<b>Nagios</b>	<a href="http://www.nagios.org">http://www.nagios.org</a>

Once the needed probes are in place, a [native resource manager](#) interface must be created to report this information to Moab. Creating a native resource manager interface should be very simple, and in most cases a script similar to those found in the `$TOOLS_DIR($PREFIX/tools)` directory can be used as a template. For this example, we will assume centralized information and will use the RM script that follows:

```
#!/usr/bin/perl
# 'hwctl outputs information in format '<NODEID> <TEMP>'
open(TQUERY,"/usr/sbin/hwctl -q temp |");
while (<TQUERY>)
{
    my $nodeid,$temp = split /\w+/;
    $dstage=GetDSUsage($nodeid);
    print "$nodeid GMETRIC[temp]=$temp GMETRIC[dstage]=$dstage
";
}
```

With the script complete, the next step is to integrate this information into Moab. This is accomplished with the following configuration line:

```
RMCFG[local] TYPE=NATIVE CLUSTERQUERYURL=file://$TOOLS_DIR/node.query.local.pl
...
```

*Moab can now be recycled and temperature and data staging usage information will be integrated into Moab compute node reports.*

If the [checknode](#) command is run, output similar to the following is reported:

```
> checknode cluster013
...
Generic Metrics: temp=113.2,dstage=23748
...
```

*Moab Cluster Manager reports full current and historical generic metric information in its visual cluster overview screen.*

The next step in configuring Moab is to inform Moab to take certain actions based on the new information it is tracking. For this example, there are two purposes. The first purpose is to get jobs to avoid hot nodes when possible. This is accomplished using the **GMETRIC** attribute of the [Node Allocation Priority](#) function as in the following example:

```
NODEALLOCATIONPOLICY PRIORITY
NODECFG[DEFAULT] PRIORITYF=PRIORITY-10*GMETRIC[temp]
...
```

This simple priority function reduces the priority of the hottest nodes making such less likely to be allocated. See [Node Allocation Priority Factors](#) for a complete list of available priority factors.

The example cluster is also interested in notifying administrators if the temperature of a given node ever exceeds a critical threshold. This is accomplished using a [trigger](#). The following line will send email to administrators any time the temperature of a node exceeds 120 degrees.

```
NODECFG[DEFAULT] TRIGGER=atype=mail,etype=threshold,threshold=gmetric[temp]
>120,action='warning: node $OID temp high'
...
```

## Related topics

## Enabling Generic Events

- [Configuring Generic Events](#)
  - [Action Types](#)
  - [Named Events](#)

- [Generic Metric \(GMetric\) Events](#)
- [Reporting Generic Events](#)
  - [Using Generic Events for VM Detection](#)
- [Generic Events Attributes](#)
- [Manually Creating Generic Events](#)

Generic events are used to identify failures and other occurrences that Moab or other systems must be made aware. This information may result in automated resource recovery, notifications, adjustments to statistics, or changes in policy. Generic events also have the ability to carry an arbitrary human readable message that may be attached to associated objects or passed to administrators or external systems. Generic events typically signify the occurrence of a specific event as opposed to [generic metrics](#) which indicate a change in a measured value.

Using generic events, Moab can be configured to automatically address many failures and environmental changes improving the overall performance. Some sample events that sites may be interested in monitoring, recording, and taking action on include:

- Machine Room Status
  - Excessive Room Temperature
  - Power Failure or Power Fluctuation
  - Chiller Health
- Network File Server Status
  - Failed Network Connectivity
  - Server Hardware Failure
  - Full Network File System
- Compute Node Status
  - Machine Check Event (MCE)
  - Network Card (NIC) Failure
  - Excessive Motherboard/CPU Temperature
  - Hard Drive Failures

## Configuring Generic Events

Generic events are defined in the `moab.cfg` file and have several different configuration options. The only required option is **action**.

The full list of configurable options for generic events is contained in the following table:

Attribute	Description
<b>ACTION</b>	Comma-delimited list of actions to be processed when a new event is received.
<b>ECOUNT</b>	Number of events that must occur before launching action.  <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; background-color: #e6f2ff;">  Action will be launched each &lt;ECOUNT&gt; event if rearm is set.                 </div>
<b>REARM</b>	Minimum time between events specified in [ [ DD: ] HH: ] MM: ] SS format.
<b>SEVERITY</b>	An arbitrary severity level from 1 through 4, inclusive. SEVERITY appears in the output of <code>mdiag -n -v -v --xml</code> .  <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; background-color: #e6f2ff;">  The severity level will not be used for any other purpose.                 </div>

### Action Types

The impact of the event is controlled using the **ACTION** attribute of the **GEVENTCFG** parameter. The **ACTION** attribute is comma-delimited and may include any combination of the actions in the following table:

Value	Description
<b>DISABLE</b> [:<OTYPE>:<OID>]	Marks event object (or specified object) down until event report is cleared.
<b>EXECUTE</b>	Executes a script at the provided path. The value of <i>EXECUTE</i> is not contained in quotation marks. Arguments are allowed at the end of the path and are separated by question marks (?). <a href="#">Trigger variables</a> (such as <i>\$OID</i> ) are allowed.
<b>NOTIFY</b>	Notifies administrators of the event occurrence.
<b>OBJECTXMLSTDIN</b>	If the <i>EXECUTE</i> action type is also specified, this flag passes an XML description of the firing gevent to the script.
<b>OFF</b>	Powers off node or resource.
<b>ON</b>	Powers on node or resource.
<b>PREEMPT</b> [:<POLICY>]	Preempts workload associated with object (valid for node, job, reservation, partition, resource manager, user, group, account, class, QoS, and cluster objects).

Value	Description
<b>RECORD</b>	Records events to the event log. The record action causes a line to be added to the event log regardless of whether or not <a href="#">RECORDEVENTLIST</a> includes GEVENT.
<b>RESERVE</b> <b>[:&lt;DURATION&gt;]</b>	Reserves node for specified duration (default: 24 hours).
<b>RESET</b>	Resets object (valid for nodes - causes reboot).
<b>SIGNAL[:&lt;SIGNO&gt;]</b>	Sends signal to associated jobs or services (valid for node, job, reservation, partition, resource manager, user, group, account, class, QoS, and cluster objects).

This is an example of using `objectxmlstdin` with a `gevent`:

```
<gevent name="bob" statuscode="0" time="1320334763">Testing</gevent>
```

## Named Events

In general, generic events are named, with the exception of those based on [generic metrics](#). Names are used primarily to differentiate between different events and do not have any intrinsic meaning to Moab. It is suggested that the administrator choose names that denote specific meanings within the organization.

*Example 3-142:*

```
# Note: cpu failures require admin attention, create maintenance reservation
GEVENTCFG[cpufail] action=notify,record,disable,reserve rearm=01:00:00# Note: power
failures are transient, minimize future use
GEVENTCFG[powerfail] action=notify,record, rearm=00:05:00
# Note: fs full can be automatically fixed
GEVENTCFG[fsfull] action=notify,execute:/home/jason/MyPython/cleartmp.py?${OID}?nodefix
# Note: memory errors can cause invalid job results, clear node immediately
GEVENTCFG[badmem] action=notify,record,preempt,disable,reserve
```

## Generic Metric (GMetric) Events

GMetric events are generic events based on [generic metrics](#). They are used for executing an action when a generic metric passes a defined threshold. Unlike named events, GMetric events are not named and use the following format:

```
GEVENTCFG [GMETRIC<COMPARISON>VALUE] ACTION=...
```

*Example 3-143:*

```
GEVENTCFG [cputemp>150] action=off
```

This form of generic events uses the GMetric name, as returned by a **GMETRIC** attribute in a [native Resource Manager](#) interface.

**i** Only one generic event may be specified for any given generic metric.

Valid comparative operators are shown in the following table:

Type	Comparison	Notes
>	greater than	Numeric values only
> =	greater than or equal to	Numeric values only
= =	equal to	Numeric values only
<	less than	Numeric values only
< =	less than or equal to	Numeric values only
< >	not equal	Numeric values only

## Reporting Generic Events

Unlike [generic metrics](#), generic events can be optionally configured at the global level to adjust rearm policies, and other behaviors. In all cases, this is accomplished using the [GEVENTCFG](#) parameter.

To report an event associated with a job or node, use the [native Resource Manager](#) interface or the [mjobctl](#) or [mnodectl](#) commands. You can report generic events on the scheduler with the [mschedctl](#) command.

If using the native Resource Manager interface, use the [GEVENT](#) attribute as in the following example:

```
node001 GEVENT[hitemp]='temperature exceeds 150 degrees'
node017 GEVENT[fullfs]='/var/tmp is full'
```

**i** The time at which the event occurred can be passed to Moab to prevent multiple processing of the same event. This is accomplished by specifying the event type in the format `<GEVENTID> [:<EVENTTIME>]` as in what follows:

```
node001 GEVENT[hitemp:1130325993]='temperature exceeds 150 degrees'
node017 GEVENT[fullfs:1130325142]='/var/tmp is full'
```

## Using Generic Events for VM Detection

To enable Moab to detect a virtual machine (VM) reported by a generic event, do the following:

1. Set up your resource manager to detect virtual machine creation and to submit a generic event to Moab.
2. Configure `moab.cfg` to recognize a generic event.

```
GEVENTCFG[NewVM] ACTION=execute:/opt/moab/AddVM.py,OBJECTXMLSTDIN
```

3. Report the event.

```
> mschedctl -c gevent -n NewVM -m "VM=newVMName"
```

*With the `ObjectXMLStdin` action set, Moab sends an XML description of the generic event to the script, so the message passes through.*

The following sample Perl script submits a VMTracking job for the new VM:

```
#!/usr/bin/perl

# in moab.cfg: GEVENTCFG[NewVM] ACTION=execute:$TOOLSDDIR/newvm_event.pl,OBJECTXMLSTDIN
# trigger gevent with: mschedctl -c gevent -n NewVM -m "VM=TestVM1"
# input to this script: <gevent name="NewVM" statuscode="0"
time="1318500261">VM=TestVM1</gevent>

use strict;

my $vmidVarName = "preVMID";
my $vmTemplate = "existingVM";
my $vmOwner = "operator";

$ENV{MOABHOMEDIR} = '/opt/moab';

my $xml = join "", <STDIN>;
my ($vmid) = ($xml =~ m/VM=([^\<]+\</>)/);
if ( defined $vmid )
{
    my $cmd = qq| $ENV{MOABHOMEDIR}/bin/mvmctl -q $vmid --xml |;
    my $vmxml = ` $cmd `;
    my ($hv, $os, $proc, $disk, $mem) = (undef, undef, undef, undef, undef);
    ($hv) = ($vmxml =~ m/CONTAINERNODE="([^\"]+)/);
    ($os) = ($vmxml =~ m/OS="([^\"]+)/);
    ($proc) = ($vmxml =~ m/RCPROC="([^\"]+)/);
    ($mem) = ($vmxml =~ m/RCMEM="([^\"]+)/);
    ($disk) = ($vmxml =~ m/RCDISK="([^\"]+)/);
    die "Error parsing VM XML. Invalid VMID $vmid or $hv || $os || $proc || $mem ||
    $disk?
    "
        if ( ! defined $hv || !defined $os || !defined $proc || !defined $mem || !defined
    $disk );

    $cmd = qq| $ENV{MOABHOMEDIR}/bin/msub -l
    hostlist=$hv,os=$os,nodes=1:ppn=$proc,mem=$mem,file=$disk,template=$vmTemplate,VAR=$vm
    idVarName=$vmid --proxy=$vmOwner /dev/null |;
    my $msubout = ` $cmd `;
    die "Error executing msub. Output is:
    $msubout
    " if ( $? );
} else {
    die "Error parsing VMID from GEVENT message
    ";
}
```

## Generic Events Attributes

Each node will record the following about reported generic events:

- status - is event active
- message - human readable message associated with event
- count - number of event incidences reported since statistics were cleared
- time - time of most recent event

Each event can be individually cleared, annotated, or deleted by cluster administrators using a [mnodectl](#) command.

 Generic events are only available in Moab 4.5.0 and later.

## Manually Creating Generic Events

Generic events may be manually created on a physical node or VM.

To add GEVENT event with message "hello" to node02, do the following:

```
> mnodectl -m gevent=event:"hello" node02
```

To add GEVENT event with message "hello" to myvm, do the following:

```
> mvmctl -m gevent=event:"hello" myvm
```

- [Resource Provisioning on page 665](#)
- [Resource Manager Translation on page 672](#)

Moab provides a powerful resource management interface that enables significant flexibility in how resources and workloads are managed. Highlights of this interface are listed in what follows:

Highlight	Description
<b>Support for Multiple Standard Resource Manager Interface Protocols</b>	Manage cluster resources and workloads via PBS, Loadleveler, SGE, LSF, or BProc based resource managers.
<b>Support for Generic Resource Manager Interfaces</b>	Manage cluster resources securely via locally developed or open source projects using simple flat text interfaces or XML over HTTP.
<b>Support for Multiple Simultaneous Resource Managers</b>	Integrate resource and workload streams from multiple independent sources reporting disjoint sets of resources.
<b>Independent Workload and Resource Management</b>	Allow one system to manage your workload (queue manager) and another to manage your resources.
<b>Support for Rapid Development Interfaces</b>	Load resource and workload information directly from a file, a URL, or from the output of a configurable script or other executable.
<b>Resource Extension Information</b>	Integrate information from multiple sources to obtain a cohesive view of a compute resource. (That is, mix information from NIM, OpenPBS, FLEXlm, and a cluster performance monitor to obtain a single node image with a coordinated state and a more extensive list of node configuration and utilization attributes.)

## Resource Manager Overview

For most installations, the Moab Workload Manager uses the services of a resource manager to obtain information about the state of compute resources (nodes) and workload (jobs). Moab also uses the

resource manager to manage jobs, passing instructions regarding when, where, and how to start or otherwise manipulate jobs.

Moab can be configured to manage more than one resource manager simultaneously, even resource managers of different types. Using a local queue, jobs may even be migrated from one resource manager to another. However, there are currently limitations regarding jobs submitted directly to a resource manager (not to the local queue.) In such cases, the job is constrained to only run within the bound of the resource manager to which it was submitted.

  - [Resource Manager Flow](#)
- [Resource Manager Specific Details \(Limitations/Special Features\)](#)
- [Synchronizing Conflicting Information](#)
- [Evaluating Resource Manager Availability and Performance](#)

## Scheduler/Resource Manager Interactions

Moab interacts with all resource managers using a common set of commands and objects. Each resource manager interfaces, obtains, and translates Moab concepts regarding workload and resources into native resource manager objects, attributes, and commands.

Information on creating a new scheduler resource manager interface can be found in the [Adding New Resource Manager Interfaces](#) section.

### Resource Manager Commands

For many environments, Moab interaction with the resource manager is limited to the following objects and functions:

Object	Function	Details
Job	Query	Collect detailed state, requirement, and utilization information about jobs
	Modify	Change job state and/or attributes
	Start	Execute a job on a specified set of resources
	Cancel	Cancel an existing job
	Preempt/Resume	Suspend, resume, checkpoint, restart, or requeue a job

Object	Function	Details
Node	Query	Collect detailed state, configuration, and utilization information about compute resources
	Modify	Change node state and/or attributes
Queue	Query	Collect detailed policy and configuration information from the resource manager

Using these functions, Moab is able to fully manage workload, resources, and cluster policies. More detailed information about resource manager specific capabilities and limitations for each of these functions can be found in the individual resource manager overviews. (LL, PBS, LSF, SGE, BProc, or [WIKI](#)).

Beyond these base functions, other commands exist to support advanced features such as provisioning and cluster level resource management.

### Resource Manager Flow

In general, Moab interacts with resource managers in a sequence of steps each scheduling iteration. These steps are outlined in what follows:

1. load global resource information
2. load node specific information (optional)
3. load job information
4. load queue/policy information (optional)
5. cancel/preempt/modify jobs according to cluster policies
6. start jobs in accordance with available resources and policy constraints
7. handle user commands

Typically, each step completes before the next step is started. However, with current systems, size and complexity mandate a more advanced parallel approach providing benefits in the areas of reliability, concurrency, and responsiveness.

### Resource Manager Specific Details (Limitations/Special Features)

- TORQUE
  - [TORQUE Homepage](#)
- SLURM/Wiki
  - [SLURM Integration Guide](#)
  - [Wiki Overview](#)

## Synchronizing Conflicting Information

Moab does not trust resource manager information. Node, job, and policy information is reloaded on each iteration and discrepancies are detected. Synchronization issues and allocation conflicts are logged and handled where possible. To assist sites in minimizing stale information and conflicts, a number of policies and parameters are available.

- Node State Synchronization Policies (see [NODESYNCTIME](#) on page 1010)
- Stale Data Purging (see [JOBPURGETIME](#) on page 985)
- Thread Management (preventing resource manager failures from affecting scheduler operation)
- Resource Manager Poll Interval (see [RMPOLLINTERVAL](#) on page 1036)
- Node Query Refresh Rate (see [NODEPOLLFREQUENCY](#) on page 1006)

## Evaluating Resource Manager Availability and Performance

Each resource manager is individually tracked and evaluated by Moab. Using the [mdiag -R](#) on page 203 command, a site can determine how a resource manager is configured, how heavily it is loaded, what failures, if any, have occurred in the recent past, and how responsive it is to requests.

## Defining and Configuring Resource Manager Interfaces

Moab resource manager interfaces are defined using the [RMCFG](#) on page 1035 parameter. This parameter allows specification of key aspects of the interface. In most cases, only the **TYPE** attribute needs to be specified and Moab determines the needed defaults required to activate and use the selected interface. In the following example, an interface to a Loadleveler resource manager is defined.

ADMINEXEC	
<b>Description</b>	Normally, when the <b>JOBSUBMITURL</b> is executed, Moab will drop to the UID and GID of the user submitting the job. Specifying an <b>ADMINEXEC</b> of <i>jobsubmit</i> causes Moab to use its own UID and GID instead (usually root). This is useful for some native resource managers where the <b>JOBSUBMITURL</b> is not a user command (such as <i>qsub</i> ) but a script that interfaces directly with the resource manager.
<b>Example</b>	<pre>RMCFG[base] ADMINEXEC=jobsubmit</pre> <p><i>Moab will not use the user's UID and GID for executing the <b>JOBSUBMITURL</b>.</i></p>

AUTHTYPE	
<b>Format</b>	One of <i>CHECKSUM</i> , <i>OTHER</i> , <i>PKI</i> , <i>SECUREPORT</i> , or <i>NONE</i> .
<b>Default</b>	<i>CHECKSUM</i>
<b>Description</b>	Specifies the security protocol to be used in scheduler-resource manager communication. <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> Only valid with WIKI based interfaces.</p> </div>
<b>Example</b>	<pre>RMCFG[base] AUTHTYPE=CHECKSUM</pre> <p><i>Moab requires a secret key-based checksum associated with each resource manager message.</i></p>

BANDWIDTH	
<b>Format:</b>	<FLOAT>[ {M G T} ]
<b>Default:</b>	-1 (unlimited)
<b>Description:</b>	Specifies the maximum deliverable bandwidth between the Moab server and the resource manager for staging jobs and data. Bandwidth is specified in units per second and defaults to a unit of MB/s. If a unit modifier is specified, the value is interpreted accordingly (M - megabytes/sec, G - gigabytes/sec, T - terabytes/sec).

## BANDWIDTH

## Example:

```
RMCFG[base] BANDWIDTH=340G
```

*Moab will reserve up to 340 GB of network bandwidth when scheduling job and data staging operations to and from this resource manager.*

## CHECKPOINTSIG

## Format

One of *suspend*, *<INTEGER>*, or *SIG<X>*

## Description

Specifies what signal to send the resource manager when a job is checkpointed (See [Checkpoint Overview](#)).

## Example

```
RMCFG[base] CHECKPOINTSIG=SIGKILL
```

*Moab routes the signal **SIGKILL** through the resource manager to the job when a job is checkpointed.*

## CHECKPOINTTIMEOUT

## Format

[ [ [DD:] HH:] MM:] SS

## Default

0 (no timeout)

## Description

Specifies how long Moab waits for a job to checkpoint before canceling it. If set to 0, Moab does not cancel the job if it fails to checkpoint (See [Checkpoint Overview](#)).

## Example

```
RMCFG[base] CHECKPOINTTIMEOUT=5:00
```

*Moab cancels any job that has not exited 5 minutes after receiving a checkpoint request.*

## CLIENT

## Format

<PEER>

## Default

Use name of resource manager for peer client lookup

CLIENT	
<b>Description</b>	If specified, the resource manager will use the peer value to authenticate remote connections. (See configuring peers). If not specified, the resource manager will search for a <a href="#">CLIENTCFG[&lt;X&gt;] on page 937</a> entry of RM: <RMNAME> in the moab-private.cfg file.
<b>Example</b>	<pre>RMCFG[clusterBI] CLIENT=clusterB</pre> <p>Moab will look up and use information for peer <i>clusterB</i> when authenticating the <i>clusterBI</i> resource manager.</p>

CLUSTERQUERYURL	
<b>Format</b>	<p>[file://&lt;path&gt;   http://&lt;address&gt;   &lt;path&gt;]</p> <p>If <i>file://</i> is specified, Moab treats the destination as a flat text file. If <i>http://</i> is specified, Moab treats the destination as a hypertext transfer protocol file. If just a path is specified, Moab treats the destination as an executable.</p>
<b>Description</b>	Specifies how Moab queries the resource manager (See <a href="#">Native RM</a> , <a href="#">URL Notes</a> , and <a href="#">interface details</a> ).
<b>Example</b>	<pre>RMCFG[base] CLUSTERQUERYURL=file:///tmp/cluster.config</pre> <p><i>Moab reads /tmp/cluster.config when it queries base resource manager.</i></p>

CONFIGFILE	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies the resource manager specific configuration file that must be used to enable correct API communication.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; background-color: #E6F2FF;"> <p> Only valid with LL- and SLURM-based interfaces.</p> </div>
<b>Example</b>	<pre>RMCFG[base] TYPE=LL CONFIGFILE=/home/loadl/loadl_config</pre> <p><i>The scheduler uses the specified file when establishing the resource manager/scheduler interface connection.</i></p>

DATARM	
<b>Format</b>	<RM NAME>
<b>Description</b>	If specified, the resource manager uses the given storage resource manager to handle staging data in and out.
<b>Example</b>	<pre>RMCFG[clusterB] DATARM=clusterB_storage</pre> <p><i>When data staging is required by jobs starting/completing on clusterB, Moab uses the storage interface defined by <b>clusterB_storage</b> to stage and monitor the data.</i></p>

DEFAULTCLASS	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the class to use if jobs submitted via this resource manager interface do not have an associated class.
<b>Example</b>	<pre>RMCFG[internal] DEFAULTCLASS=batch</pre> <p><i>Moab assigns the class <b>batch</b> to all jobs from the resource manager internal that do not have a class assigned.</i></p> <p><b>i</b> If you are using PBS as the resource manager, a job will never come from PBS without a class, and the default will never apply.</p>

DEFAULTHIGHSPEEDADAPTER	
<b>Format:</b>	<STRING>
<b>Default:</b>	<i>sn0</i>
<b>Description:</b>	Specifies the default high speed switch adapter to use when starting LoadLeveler jobs (supported in version 4.2.2 and higher of Moab and 3.2 of LoadLeveler).
<b>Example:</b>	<pre>RMCFG[base] DEFAULTHIGHSPEEDADAPTER=sn1</pre> <p><i>The scheduler will start jobs requesting a high speed adapter on sn1.</i></p>

DESCRIPTION	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the human-readable description for the resource manager interface. If white space is used, the description should be quoted.
<b>Example</b>	<pre>RMCFG[torque] DESCRIPTION='TORQUE RM for launching jobs'</pre> <p><i>Moab annotates the TORQUE resource manager accordingly.</i></p>

ENV	
<b>Format</b>	Semi-colon-delimited (;) list of <KEY>=<VALUE> pairs
<b>Default</b>	<i>MOABHOMEDIR=&lt;MOABHOMEDIR&gt;</i>
<b>Description</b>	Specifies a list of environment variables that will be passed to URLs of type <i>exec://</i> for that resource manager.
<b>Example</b>	<pre>RMCFG[base] ENV=HOST=node001;RETRYTIME=50 RMCFG[base] CLUSTERQUERYURL=exec:///opt/moab/tools/cluster.query.pl RMCFG[base] WORKLOADQUERYURL=exec:///opt/moab/tools/ workload.query.pl RMCFG[base] ENV=HOST=node001;RETRYTIME=50 RMCFG[base] CLUSTERQUERYURL=exec:///opt/moab/tools/cluster.query.pl RMCFG[base] WORKLOADQUERYURL=exec:///opt/moab/tools/workload.query.pl</pre> <p><i>The environment variables HOST and RETRYTIME (with values node001 and 50 respectively) are passed to the /opt/moab/tools/cluster.query.pl and /opt/moab/tools/workload.query.pl when they are executed.</i></p>

EPORT	
<b>Format:</b>	<INTEGER>
<b>Description:</b>	Specifies the event port to use to receive resource manager based scheduling events.
<b>Example:</b>	<pre>RMCFG[base] EPORT=15017</pre> <p><i>The scheduler will look for scheduling events from the resource manager host at port 15017.</i></p>

FAILTIME	
<b>Format:</b>	[[ [DD:]HH:]MM:]SS
<b>Description:</b>	Specifies how long a resource manager must be down before any failure triggers associated with the resource manager fire.
<b>Example:</b>	<pre>RMCFG[base] FAILTIME=3:00</pre> <p><i>If the base resource manager is down for three minutes, any resource manager failure triggers fire.</i></p>

FLAGS	
<b>Format</b>	Comma-delimited list of zero or more of the following: <a href="#">asyncdelete</a> , <a href="#">asyncstart</a> , <a href="#">autostart</a> , <a href="#">autosync</a> , <a href="#">client</a> , <a href="#">fullcp</a> , <a href="#">executionServer</a> , <a href="#">grid</a> , <a href="#">hostingCenter</a> , <a href="#">ignqueuestate</a> , <a href="#">private</a> , <a href="#">pushslavejobupdates</a> , <a href="#">report</a> , <a href="#">shared</a> , or <a href="#">static</a>
<b>Description</b>	Specifies various attributes of the resource manager. See <a href="#">Flag Details</a> for more information.
<b>Example</b>	<pre>RMCFG[base] FLAGS=static</pre> <p><i>Moab uses this resource manager to perform a single update of node and job objects reported elsewhere.</i></p>

FNLIST	
<b>Format</b>	Comma-delimited list of zero or more of the following: <a href="#">clusterquery</a> , <a href="#">jobcancel</a> , <a href="#">jobqueue</a> , <a href="#">jobresume</a> , <a href="#">jobstart</a> , <a href="#">jobsuspend</a> , <a href="#">queuequery</a> , <a href="#">resourcequery</a> or <a href="#">workloadquery</a>
<b>Description</b>	By default, a resource manager utilizes all functions supported to query and control batch objects. If this parameter is specified, only the listed functions are used.
<b>Example</b>	<pre>RMCFG[base] FNLIST=queuequery</pre> <p><i>Moab only uses this resource manager interface to load queue configuration information.</i></p>

HOST	
<b>Format</b>	<STRING>
<b>Default</b>	<i>localhost</i>
<b>Description</b>	The host name of the machine on which the resource manager server is running.
<b>Example</b>	<code>RMCFG[base] host=server1</code>

IGNHNODES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether to read in the PBSPro host nodes. This parameter is used in conjunction with <a href="#">USEVNODES on page 611</a> . When both are set to <i>TRUE</i> , the host nodes are not queried.
<b>Example</b>	<code>RMCFG[pbs] IGNHNODES=TRUE</code>

JOBCANCELURL	
<b>Format</b>	<protocol>:// [<host>[:<port>]] [<path>]
<b>Default</b>	---
<b>Description</b>	Specifies how Moab cancels jobs via the resource manager. (See <a href="#">URL Notes</a> below.)
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px;"> <code>RMCFG[base] JOBCANCELURL=exec:///opt/moab/job.cancel.lsf.pl</code> </div> <p><i>Moab executes /opt/moab/job.cancel.lsf.pl to cancel specific jobs.</i></p>

JOBEXTENDDURATION	
<b>Format</b>	[[ [DD:]HH:]MM:]SS [, [[ [DD:]HH:]MM:]SS [!] [<] (or <MIN TIME>[, <MAX TIME>] [!])

JOBEXTENDDURATION	
<b>Default</b>	---
<b>Description</b>	Specifies the minimum and maximum amount of time that can be added to a job's walltime if it is possible for the job to be extended. (See <a href="#">MINWCLIMIT</a> .) As the job runs longer than its current specified minimum wallclock limit (-l <i>minwclimit</i> , for example), Moab attempts to extend the job's limit by the minimum <b>JOBEXTENDDURATION</b> . This continues until either the extension can no longer occur (it is blocked by a reservation or job), the maximum <b>JOBEXTENDDURATION</b> is reached, or the user's specified wallclock limit (-l <i>walltime</i> ) is reached. When a job is extended, it is marked as <b>PREEMPTIBLE</b> , unless the ! is appended to the end of the configuration string. If the < is at the end of the string, however, the job is extended the maximum amount possible.
<b>Example</b>	<pre>RMCFG[base] JOBEXTENDDURATION=30,1:00:00</pre> <p><i>Moab extends a job's walltime by 30 seconds each time the job is about to run out of walltime until it is bound by one hour, a reservation/job, or the job's original "maximum" wallclock limit.</i></p>

JOBIDFORMAT	
<b>Format</b>	<i>INTEGER</i>
<b>Default</b>	---
<b>Description</b>	Specifies that Moab should use numbers to create job IDs. This eliminates multiple job IDs associated with a single job.
<b>Example</b>	<pre>RMCFG[base] JOBIDFORMAT=INTEGER</pre> <p><i>Job IDs are generated as numbers.</i></p>

JOBMODIFYURL	
<b>Format</b>	<protocol>:// [<host>[:<port>]] [<path>]
<b>Default</b>	---
<b>Description</b>	Specifies how Moab modifies jobs via the resource manager. (See <a href="#">URL Notes</a> , and <a href="#">interface details</a> .)

JOBMODIFYURL	
<b>Example</b>	<pre>RMCFG[base] JOBMODIFYURL=exec://\$TOOLSDIR/job.modify.dyn.pl</pre> <p><i>Moab executes /opt/moab/job.modify.dyn.pl to modify specific jobs.</i></p>

JOBRSVRECREATE	
<b>Format</b>	Boolean
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	Specifies whether Moab will re-create a job reservation each time job information is updated by a resource manager (See <a href="#">Considerations for Large Clusters</a> for more information.).
<b>Example</b>	<pre>RMCFG[base] JOBRSVRECREATE=FALSE</pre> <p><i>Moab only creates a job reservation once when the job first starts.</i></p>

JOBSTARTURL	
<b>Format</b>	<protocol>:// [<host>[:<port>]] [<path>]
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	Specifies how Moab starts jobs via the resource manager. (See <a href="#">URL Notes</a> below.)
<b>Example</b>	<pre>RMCFG[base] JOBSTARTURL=http://orion.bsu.edu:1322/moab/jobstart.cgi</pre> <p><i>Moab triggers the jobstart.cgi script via http to start specific jobs.</i></p>

JOBSUBMITURL	
<b>Format</b>	<protocol>:// [<host>[:<port>]] [<path>]
<b>Description</b>	Specifies how Moab submits jobs to the resource manager (See <a href="#">URL Notes</a> below.).

## JOBSUBMITURL

### Example

```
RMCFG[base] JOBSUBMITURL=exec://$TOOLS DIR/job.submit.dyn.pl
```

*Moab submits jobs directly to the database located on host  
dbserver.flc.com*

## JOBSUSPENDURL

### Format

<protocol>:// [<host>[:<port>]] [<path>]

### Description

Specifies how Moab suspends jobs via the resource manager. (See [URL Notes](#) below.)

### Example

```
RMCFG[base] JOBSUSPENDURL=EXEC://$HOME/scripts/job.suspend
```

*Moab executes the job.suspend script when jobs are suspended.*

## JOBVALIDATEURL

### Format

<protocol>:// [<host>[:<port>]] [<path>]

### Description

Specifies how Moab validates newly submitted jobs (See [URL Notes](#) below.). If the [script](#) returns with a non-zero exit code, the job is rejected. (See [User Proxying/Alternate Credentials](#).)

### Example

```
RMCFG[base] JOBVALIDATEURL=exec://$TOOLS/job.validate.pl
```

*Moab executes the 'job.validate.pl' script when jobs are submitted to verify they  
are acceptable.*

## MAXDSOP

### Format

<INTEGER>

### Default

-1 (unlimited)

### Description

Specifies the maximum number of data staging operations that may be simultaneously active.

### Example

```
RMCFG[ds] MAXDSOP=16
```

MAXITERATIONFAILURECOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	80
<b>Description</b>	Specifies the number of times the RM must fail within a certain iteration before Moab considers it down or corrupt. When an RM is down or corrupt, Moab will not attempt to interact with it.
<b>Example</b>	<pre>RMCFG [base] MAXITERATIONFAILURECOUNT=25</pre> <p><i>The RM base must fail 25 times in a single iteration for Moab to consider it down and cease interacting with it.</i></p>

MAXJOBPERMINUTE	
<b>Format</b>	<INTEGER>
<b>Default</b>	-1 (unlimited)
<b>Description</b>	Specifies the maximum number of jobs allowed to start per minute via the resource manager.
<b>Example</b>	<pre>RMCFG [base] MAXJOBPERMINUTE=5</pre> <p><i>The scheduler only allows five jobs per minute to launch via the resource manager base.</i></p>

MAXJOBS	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (limited only by the Moab <b>MAXJOB</b> setting)
<b>Description</b>	<p>Specifies the maximum number of active jobs that this interface is allowed to load from the resource manager.</p> <div style="border: 1px solid #0056b3; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> Only works with Moab peer resource managers at this time.</p> </div>

## MAXJOBS

## Example

```
RMCFG[cluster1] SERVER=moab://cluster1 MAXJOBS=200
```

*The scheduler loads up to 200 active jobs from the remote Moab peer cluster1.*

## MINETIME

## Format

<INTEGER>

## Default

1

## Description

Specifies the minimum time in seconds between processing subsequent scheduling events.

## Example

```
RMCFG[base] MINETIME=5
```

*The scheduler batch-processes scheduling events that occur less than five seconds apart.*

## NMPORT

## Format

<INTEGER>

## Default

(any valid port number)

## Description

Allows specification of the resource manager's node manager port and is only required when this port has been set to a non-default value.

## Example

```
RMCFG[base] NMPORT=13001
```

*The scheduler contacts the node manager located on each compute node at port 13001.*

## NODEFAILURERSVPROFILE

## Format

<STRING>

## Description

Specifies the rsv template to use when placing a reservation onto failed nodes (See also [NODEFAILURERESERVETIME](#) on page 1004.).

## NODEFAILURERSVPROFILE

## Example

```
# moab.cfg
RMCFG[base] NODEFAILURERSVPROFILE=long
RSVPROFILE[long] DURATION=25:00RSVPROFILE[long] USERLIST=john
```

*The scheduler will use the long rsv profile when creating reservations over failed nodes belonging to base.*

## NODESTATEPOLICY

## Format

One of *OPTIMISTIC* or *PESSIMISTIC*

## Default

*PESSIMISTIC*

## Description

Specifies how Moab should determine the state of a node when multiple resource managers are reporting state.

*OPTIMISTIC* specifies that if any resource manager reports a state of up, that state will be used. *PESSIMISTIC* specifies that if any resource manager reports a state of down, that state will be used.

## Example

```
# moab.cfg
RMCFG[native] TYPE=NATIVE NODESTATEPOLICY=OPTIMISTIC
```

## OMAP

## Format

<protocol>:// [<host>[:<port>]] [<path>]

## Description

Specifies an object map file that is used to map credentials and other objects when using this resource manager peer (See [Grid Credential Management](#) for full details).

## Example

```
moab.cfg
RMCFG[peer1] OMAP=file:///opt/moab/omap.dat
```

*When communicating with the resource manager peer1, objects are mapped according to the rules defined in the /opt/moab/omap.dat file.*

## PORT

## Format

<INTEGER>

PORT	
<b>Default</b>	0
<b>Description</b>	Specifies the port on which the scheduler should contact the associated resource manager. The value 0 specifies that the resource manager default port should be used.
<b>Example</b>	<pre>RMCFG[base] TYPE=PBS HOST=cws PORT=20001</pre> <p><i>Moab attempts to contact the PBS server daemon on host cws, port 20001.</i></p>

PROVDURATION	
<b>Format</b>	[ [ [DD:]HH:]MM:]SS
<b>Default</b>	2:30
<b>Description</b>	Specifies the upper bound (walltime) of a provisioning request. After this duration, Moab will consider the provisioning attempt failed.
<b>Example</b>	<pre>RMCFG[base] PROVDURATION=5:00</pre> <p><i>When RM base provisions a node for more than 5 minutes, Moab considers the provisioning as having failed.</i></p>

PTYSTRING	
<b>Format</b>	<STRING>
<b>Default</b>	<i>srun -n1 -N1 --pty</i>

## PTYSTRING

<p><b>Description</b></p>	<p>When a SLURM interactive job is submitted, it builds an <code>salloc</code> command that gets the requested resources and an <code>srun</code> command that creates a terminal session on one of the nodes. The <code>srun</code> command is called the <code>PTYString</code>. <code>PTYString</code> is configured in <code>moab.cfg</code>.</p> <p>There are two special things you can do with <code>PTYString</code>:</p> <ol style="list-style-type: none"> <li>1. You can have <code>PTYSTRING=\$salloc</code> which says to use the default <code>salloc</code> command (<code>SallocDefaultCommand</code>, look in the <code>slurm.conf</code> man page) defined in <code>slurm.conf</code>. Internally, Moab won't add a <code>PTYString</code> because SLURM will call the <code>SallocDefaultCommand</code>.</li> <li>2. As in the example below, you can add <code>\$SHELL</code>. <code>\$SHELL</code> will be expanded to either what you request on the command line (such as <code>msub -S /bin/tcsh -l</code>) or to the value of <code>\$SHELL</code> in your current session.</li> </ol> <p><code>PTYString</code> works only with SLURM.</p>
<p><b>Example</b></p>	<pre>RMCFG[slurm] PTYSTRING="srun -nl -N1 --pty --preserve-env \$SHELL"</pre>

## RESOURCECREATEURL

<p><b>Format</b></p>	<p>&lt;STRING&gt;</p>
<p><b>Default</b></p>	<p>[<i>exec</i>://&lt;path&gt;   <i>http</i>://&lt;address&gt;   &lt;path&gt;]</p> <p>If <i>exec</i>:// is specified, Moab treats the destination as an executable file; if <i>http</i>:// is specified, Moab treats the destination as a hypertext transfer protocol file.</p>
<p><b>Description</b></p>	<p>Specifies a script or method that can be used by Moab to create resources dynamically, such as creating a virtual machine on a hypervisor.</p>
<p><b>Example</b></p>	<pre>RMCFG[base] RESOURCECREATEURL=exec:///opt/script/vm.provision.py</pre> <p><i>Moab invokes the <code>vm.provision.py</code> script, passing in data as command line arguments, to request a creation of new resources.</i></p>

## RESOURCETYPE

<p><b>Format</b></p>	<p>{<i>COMPUTE</i> <i>FS</i> <i>LICENSE</i> <i>NETWORK</i> <i>PROV</i>}</p>
<p><b>Description</b></p>	<p>Specifies which type of resource this resource manager is configured to control. See <a href="#">Native Resource Managers</a> for more information.</p>

## RESOURCETYPE

### Example

```
RMCFG[base] TYPE=NATIVE RESOURCETYPE=FS
```

*Resource manager base will function as a **NATIVE** resource manager and control file systems.*

## RMSTARTURL

### Format

```
[exec://<path> | http://<address> | <path>]
```

If *exec://* is specified, Moab treats the destination as an executable file; if *http://* is specified, Moab treats the destination as a hypertext transfer protocol file.

### Description

Specifies how Moab starts the resource manager.

### Example

```
RMCFG[base] RMSTARTURL=exec:///tmp/nat.start.pl
```

*Moab executes /tmp/nat.start.pl to start the resource manager base.*

## RMSTOPURL

### Format

```
[exec://<path> | http://<address> | <path>]
```

If *exec://* is specified, Moab treats the destination as an executable file; if *http://* is specified, Moab treats the destination as a hypertext transfer protocol file.

### Description

Specifies how Moab stops the resource manager.

### Example

```
RMCFG[base] RMSTOPURL=exec:///tmp/nat.stop.pl
```

*Moab executes /tmp/nat.stop.pl to stop the resource manager base.*

## SBINDIR

### Format

```
<PATH>
```

### Description

For use with TORQUE; specifies the location of the TORQUE system binaries (supported in TORQUE 1.2.0p4 and higher).

SBINDIR	
<b>Example</b>	<pre>RMCFG[base] TYPE=pbs SBINDIR=/usr/local/torque/sbin</pre> <p><i>Moab tells TORQUE that its system binaries are located in /usr/local/torque/sbin.</i></p>
SERVER	
<b>Format</b>	<URL>
<b>Description</b>	Specifies the resource management service to use. If not specified, the scheduler locates the resource manager via built-in defaults or, if available, with an information service.
<b>Example</b>	<pre>RMCFG[base] server=ll://supercluster.org:9705</pre> <p><i>Moab attempts to use the Loadleveler scheduling API at the specified location.</i></p>
SLURMFLAGS	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies characteristics of the SLURM resource manager interface. The <b>COMPRESSOUTPUT</b> flag instructs Moab to use the compact hostlist format for job submissions to SLURM. The flag <b>NODEDELTAQUERY</b> instructs Moab to request delta node updates when it queries SLURM for node configuration.
<b>Example</b>	<pre>RMCFG[slurm] SLURMFLAGS=COMPRESSOUTPUT</pre> <p><i>Moab uses the <b>COMPRESSOUTPUT</b> flag to determine interface characteristics with SLURM.</i></p>
SOFTTERMSIG	
<b>Format</b>	<INTEGER>or SIG<X>
<b>Description</b>	Specifies what signal to send the resource manager when a job reaches its soft wallclock limit. (See <a href="#">JOBMAXOVERRUN</a> .)

## SOFTTERMSIG

## Example

```
RMCFG[base] SOFTTERMSIG=SIGUSR1
```

*Moab routes the signal **SIGUSR1** through the resource manager to the job when a job reaches its soft wallclock limit.*

## STAGETHRESHOLD

## Format

```
[ [DD:]HH:]MM:]SS
```

## Description

Specifies the maximum time a job waits to start locally before considering being migrated to a remote peer. In other words, if a job's start time on a remote cluster is less than the start time on the local cluster, but the difference between the two is less than **STAGETHRESHOLD**, then the job is scheduled locally. The aim is to avoid job/data staging overhead if the difference in start times is minimal.

If this attribute is used, backfill is disabled for the associated resource manager.

## Example

```
RMCFG[remote_cluster] STAGETHRESHOLD=00:05:00
```

*Moab only migrates jobs to remote\_cluster if the jobs can start five minutes sooner on the remote cluster than they could on the local cluster.*

## STARTCMD

## Format

```
<STRING>
```

## Description

Specifies the full path to the resource manager job start client. If the resource manager API fails, Moab executes the specified start command in a second attempt to start the job.

Moab calls the start command with the format `<CMD><JOBID> -H <HOSTLIST>` unless the environment variable `MOABNOHOSTLIST` is set in which case Moab will only pass the job ID.

## Example

```
RMCFG[base] STARTCMD=/usr/local/bin/qrun
```

*Moab uses the specified start command if API failures occur when launching jobs.*

SUBMITCMD	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the full path to the resource manager job submission client.
<b>Example</b>	<pre>RMCFG[base] SUBMITCMD=/usr/local/bin/qsub</pre> <p><i>Moab uses the specified submit command when migrating jobs.</i></p>

SUBMITPOLICY	
<b>Format</b>	One of <i>NODECENTRIC</i> or <i>PROCCENTRIC</i>
<b>Default</b>	<i>PROCCENTRIC</i>
<b>Description</b>	If set to <i>NODECENTRIC</i> , each specified node requested by the job is interpreted as a true compute host, not as a task or processor.
<b>Example</b>	<pre>RMCFG[base] SUBMITPOLICY=NODECENTRIC</pre> <p><i>Moab uses the specified submit policy when migrating jobs.</i></p>

SUSPENDSIG	
<b>Format</b>	<INTEGER> (valid UNIX signal between 1 and 64)
<b>Default</b>	RM-specific default
<b>Description</b>	If set, Moab sends the specified signal to a job when a job suspend request is issued.
<b>Example</b>	<pre>RMCFG[base] SUSPENDSIG=19</pre> <p><i>Moab uses the specified suspend signal when suspending jobs within the base resource manager.</i></p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> <b>SUSPENDSIG</b> should not be used with <a href="#">TORQUE</a> or other PBS-based resource managers.</p> </div>

SYNCJOBID	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Specifies that Moab should migrate jobs to the local resource manager with the job's Moab-assigned job ID. In a grid, the grid-head will only pass dependencies to the underlying Moab if <b>SYNCJOBID</b> is set. This attribute can be used with the <a href="#">JOBIDFORMAT on page 597</a> attribute and <a href="#">PROXYJOBSUBMISSION on page 617</a> flag in order to synchronize job IDs between Moab and the resource manager. For more information about all steps necessary to synchronize job IDs between Moab and TORQUE, see <a href="#">Synchronizing Job IDs in TORQUE and Moab on page 613</a> .
<b>Example</b>	<pre>RMCFG[slurm] TYPE=wiki:slurm SYNCJOBID=TRUE</pre>

SYSTEMMODIFYURL	
<b>Format</b>	<pre>[exec://&lt;path&gt;   http://&lt;address&gt;   &lt;path&gt;]</pre> If <code>exec://</code> is specified, Moab treats the destination as an executable file; if <code>http://</code> is specified, Moab treats the destination as a hypertext transfer protocol file.
<b>Description</b>	Specifies how Moab modifies attributes of the system. This interface is used in <a href="#">data staging</a> .
<b>Example</b>	<pre>RMCFG[base] SYSTEMMODIFYURL=exec:///tmp/system.modify.pl</pre> <i>Moab executes /tmp/system.modify.pl when it modifies system attributes in conjunction with the resource manager base.</i>

SYSTEMQUERYURL	
<b>Format</b>	<pre>[exec://&lt;path&gt;   http://&lt;address&gt;   &lt;path&gt;]</pre> If <code>file://</code> is specified, Moab treats the destination as a flat text file; if <code>http://</code> is specified, Moab treats the destination as a hypertext transfer protocol file; if just a path is specified, Moab treats the destination as an executable.
<b>Description</b>	Specifies how Moab queries attributes of the system. This interface is used in <a href="#">data staging</a> .
<b>Example</b>	<pre>RMCFG[base] SYSTEMQUERYURL=file:///tmp/system.query</pre> <i>Moab reads /tmp/system.query when it queries the system in conjunction with base resource manager.</i>

TARGETUSAGE	
<b>Format</b>	<INTEGER>[%]
<b>Default</b>	90%
<b>Description</b>	Amount of resource manager resources to explicitly use. In the case of a storage resource manager, indicates the target usage of data storage resources to dedicate to active data migration requests. If the specified value contains a percent sign (%), the target value is a percent of the configured value. Otherwise, the target value is considered to be an absolute value measured in megabytes (MB).
<b>Example</b>	<pre>RMCFG[storage] TYPE=NATIVE RESOURCETYPE=storage RMCFG[storage] TARGETUSAGE=80%</pre> <p><i>Moab schedules data migration requests to never exceed 80% usage of the storage resource manager's disk cache and network resources.</i></p>

TIMEOUT	
<b>Format</b>	<INTEGER>
<b>Default</b>	30
<b>Description</b>	Time (in seconds) the scheduler waits for a response from the resource manager.
<b>Example</b>	<pre>RMCFG[base] TIMEOUT=40</pre> <p><i>Moab waits 40 seconds to receive a response from the resource manager before timing out and giving up. Moab tries again on the next iteration.</i></p>

TRIGGER	
<b>Format</b>	<TRIG_SPEC>
<b>Description</b>	A <a href="#">trigger</a> specification indicating behaviors to enforce in the event of certain events associated with the resource manager, including resource manager start, stop, and failure.
<b>Example</b>	<pre>RMCFG[base] TRIGGER=&lt;X&gt;</pre>

TYPE	
<b>Format</b>	<RMTYPE>[:<RMSUBTYPE>] where <RMTYPE> is one of the following: <a href="#">TORQUE</a> , <a href="#">NATIVE</a> , <a href="#">PBS</a> , <a href="#">RMS</a> , <a href="#">SSS</a> , or <a href="#">WIKI</a> and the optional <RMSUBTYPE> value is one of RMS.
<b>Default</b>	PBS
<b>Description</b>	<p>Specifies type of resource manager to be contacted by the scheduler.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #E6F2FF;"> <p><b>i</b> For TYPE WIKI, AUTHTYPE must be set to CHECKSUM. The &lt;RMSUBTYPE&gt; option is currently only used to support Compaq's RMS resource manager in conjunction with PBS. In this case, the value <code>PBS:RMS</code> should be specified.</p> </div>
<b>Example</b>	<pre>RMCFG[clusterA] TYPE=PBS HOST=clusterA PORT=15003 RMCFG[clusterB] TYPE=PBS HOST=clusterB PORT=15005</pre> <p><i>Moab interfaces to two different PBS resource managers, one located on server clusterA at port 15003 and one located on server clusterB at port 15005.</i></p>

USEVNODES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether to schedule on PBS virtual nodes. When set to <i>TRUE</i> , Moab queries PBSPro for vnodes and puts jobs on vnodes rather than hosts. In some systems, such as PBS + Altix, it may not be desirable to read in the host nodes; for such situations refer to the <a href="#">IGNHNODES</a> attribute.
<b>Example</b>	<pre>RMCFG[pbs] USEVNODES=TRUE</pre>

VARIABLES	
<b>Format</b>	<VAR>=<VAL>[, <VAR>=<VAL>]
<b>Description</b>	Opaque resource manager variables.
<b>Example</b>	<pre>RMCFG[base] VARIABLES=SCHEDDHOST=head1</pre> <p><i>Moab associates the variable <code>SCHEDDHOST</code> with the value <code>head1</code> on resource manager base.</i></p>

VERSION	
<b>Format</b>	<STRING>
<b>Default</b>	<i>SLURM: 10200</i> (i.e., 1.2.0)
<b>Description</b>	Resource manager-specific version string.
<b>Example</b>	<pre>RMCFG[base] VERSION=10124</pre> <p><i>Moab assumes that resource manager base has a version number of 1.1.24.</i></p>

VMOWNERRM	
<b>Format</b>	<STRING>
<b>Description</b>	Used with provisioning resource managers that can create VMs. It specifies the resource manager that will own any VMs created by the resource manager.
<b>Example</b>	<pre>RMCFG[torque] RMCFG[prov] RESOURCETYPE=PROV VMOWNERRM=torque</pre>

WORKLOADQUERYURL	
<b>Format</b>	<p><i>[file://&lt;path&gt;   http://&lt;address&gt;   &lt;path&gt;]</i></p> <p>If <i>file://</i> is specified, Moab treats the destination as a flat text file; if <i>http://</i> is specified, Moab treats the destination as a hypertext transfer protocol file; if just a path is specified, Moab treats the destination as an executable.</p>
<b>Description</b>	Specifies how Moab queries the resource manager for workload information. (See <a href="#">Native RM</a> , <a href="#">URL Notes</a> , and <a href="#">interface details</a> .)
<b>Example</b>	<pre>RMCFG[TORQUE] WORKLOADQUERYURL=exec://\$TOOLSDIR/job.query.dyn.pl</pre> <p><i>Moab executes /opt/moab/tools/job.query.dyn.pl to obtain updated workload information from resource manager TORQUE.</i></p>

URL notes

URL parameters can load files by using the *file*, *exec*, and *http* protocols.

For the protocol *file*, Moab loads the data directly from the text file pointed to by path.

```
RMCFG[base] SYSTEMQUERYURL=file:///tmp/system.query
```

For the protocol *exec*, Moab executes the file pointed to by path and loads the output written to STDOUT. If the script requires arguments, you can use a question mark (?) between the script name and the arguments, and an ampersand (&) for each space.

```
RMCFG[base] JOBVALIDATEURL=exec://$TOOLS/job.validate.pl
RMCFG[native] CLUSTERQUERYURL=exec://opt/moab/tools/cluster.query.pl?-group=group1&-arch=x86
```

### Synchronizing Job IDs in TORQUE and Moab

**i** Unless you use an [msub on page 286](#) submit filter or you're in a grid, it is recommended that you use your RM-specific job submission command (for instance, `qsub`).

In order to synchronize your job IDs between TORQUE and Moab you must perform the following steps:

1. Verify that you are using TORQUE version 2.5.6 or later.
2. Set [SYNCJOBID on page 609](#) to *TRUE* in all resource managers.

```
RMCFG[torque] TYPE=PBS SYNCJOBID=TRUE
```

3. Set the [PROXYJOB SUBMISSION on page 617](#) flag. With *PROXYJOB SUBMISSION* enabled, you must run Moab as a TORQUE manager or operator. Verify that other users can submit jobs using [msub on page 286](#). Moab, as a non-root user, should still be able to submit jobs to TORQUE and synchronize job IDs.

```
RMCFG[torque] TYPE=PBS SYNCJOBID=TRUE
RMCFG[torque] FLAGS=PROXYJOB SUBMISSION
```

4. Add [JOBIDFORMAT on page 597](#)=*INTEGER* to the internal RM. Adding this parameter forces Moab to only use numbers as job IDs and those numbers to synchronize across Moab, TORQUE, and the entire grid. This enhances the end-user experience as it eliminates multiple job IDs associated with a single job.

```
RMCFG[torque] TYPE=PBS SYNCJOBID=TRUE
RMCFG[torque] FLAGS=PROXYJOB SUBMISSION

RMCFG[internal] JOBIDFORMAT=INTEGER
```

## Resource Manager Configuration Details

As with all scheduler parameters, follows the syntax described within the [Parameters Overview](#).

### Resource Manager Types

The **RMCFG** parameter allows the scheduler to interface to multiple types of resource managers using the **TYPE** or **SERVER** attributes. Specifying these attributes, any of the following listed resource managers may be supported.

Type	Resource managers	Details
<b>Moab</b>	Moab Workload Manager	Use the Moab peer-to-peer (grid) capabilities to enable grids and other configurations. (See <a href="#">Grid Configuration</a> .)
<b>MWS</b>	Moab Web Services	The MWS resource manager type is a native integration between Moab and MWS. Resource manager data is passed directly between Moab and MWS using JSON (rather than Moab's native WIKI syntax). This simplifies RM configuration for systems where one or more MWS plugins are acting as resource managers. See the "Moab Workload Manager resource manager integration" section of the MWS plugins chapter in the MWS documentation for more information.
<b>Native</b>	Moab <i>Native</i> Interface	Used for connecting directly to scripts, files, and databases. (See <a href="#">Managing Resources Directly with the Native Interface</a> .)
<b>PBS</b>	TORQUE (all versions)	N/A
<b>SSS</b>	Scalable Systems Software Project version 2.0 and higher	N/A
<b>WIKI</b>	<a href="#">Wiki</a> interface specification version 1.0 and higher	Used for LRM, YRM, ClubMASK, BProc, SLURM, and others.

## Resource Manager Name

Moab can support more than one resource manager simultaneously. Consequently, the **RMCFG** parameter takes an index value such as `RMCFG[clusterA]`. This index value essentially names the resource manager (as done by the deprecated parameter **RMNAME**). The resource manager name is used by the scheduler in diagnostic displays, logging, and in reporting resource consumption to the allocation manager. For most environments, the selection of the resource manager name can be arbitrary.

## Resource Manager Location

The **HOST**, **PORT**, and **SERVER** attributes can be used to specify how the resource manager should be contacted. For many resource managers the interface correctly establishes contact using default values. These parameters need only to be specified for resource managers such as the WIKI interface (that do

not include defaults) or with resources managers that can be configured to run at non-standard locations (such as PBS). In all other cases, the resource manager is automatically located.

## Resource Manager Flags

The **FLAGS** attribute can be used to modify many aspects of a resources manager's behavior.

Flag	Description
<b>ASYNCSTART</b>	Jobs started on this resource manager start asynchronously. In this case, the scheduler does not wait for confirmation that the job correctly starts before proceeding. (See <a href="#">Large Cluster Tuning</a> for more information.)
<b>AUTOSTART</b>	Jobs staged to this resource manager do not need to be explicitly started by the scheduler. The resource manager itself handles job launch.
<b>AUTOSYNC</b>	Resource manager starts and stops together with Moab. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> This requires that the resource manager support a resource manager start and stop API or the <a href="#">RMSTARTURL</a> and <a href="#">RMSTOPURL</a> attributes are set.</p> </div>
<b>BECOMEMASTER</b>	Nodes reported by this resource manager will transfer ownership to this resource manager if they are currently owned by another resource manager that does not have this flag set.
<b>CLIENT</b>	A client resource manager object is created for diagnostic/statistical purposes or to configure Moab's interaction with this resource manager. It represents an external entity that consumes server resources or services, allows a local administrator to track this usage, and configures specific policies related to that resource manager. A client resource manager object loads no data and provides no services.
<b>CLOCKSKEWCHECKING</b>	Setting <a href="#">CLOCKSKEWCHECKING</a> allows you to configure clock skew adjustments. Most of the time it is sufficient to use an NTP server to keep the clocks in your system synchronized.
<a href="#">COLLAPSEDVIEW</a>	Does not work — not supported The resource manager masks details about local workload and resources and presents only information relevant to the remote server.
<b>DYNAMICCRED</b>	The resource manager creates credentials within the cluster as needed to support workload. (See <a href="#">Identity Manager Overview</a> .)
<b>EXECUTIONSERVER</b>	The resource manager is capable of launching and executing batch workload.

Flag	Description
<b>FSISREMOTE</b>	Add this flag if the working file system doesn't exist on the server to prevent Moab from validating files and directories at migration.
<b>FULLCP</b>	Always checkpoint full job information (useful with <a href="#">Native</a> resource managers).
<b>HOSTINGCENTER</b>	The resource manager interface is used to negotiate an adjustment in dynamic resource access.
<b>IGNQUEUESTATE</b>	The queue state reported by the resource manager should be ignored. May be used if queues must be disabled inside of a particular resource manager to allow an external scheduler to properly operate.
<b>IGNWORKLOADSTATE</b>	When this flag is applied to a native resource manager, any jobs that are reported via that resource manager's "workload query URL" have their reported state ignored. For example, if an RM has the <i>IgnWorkloadState</i> flag and it reports that a set of jobs have a state of "Running," this state is ignored and the jobs will either have a default state set or will inherit the state from another RM reporting on that same set of jobs. This flag only changes the behavior of RMs of type <i>NATIVE</i> .
<b>LOCALWORKLOADEXPORT</b>	When set, destination peers share information about local and remote jobs, allowing job management of different clusters at a single peer. For more information, see <a href="#">Workload Submission and Control</a> .
<b>MIGRATEALLJOBATTRIBUTES</b>	When set, this flag causes additional job information to be migrated to the resource manager; additional job information includes things such as node features applied via <code>CLASSCFG[name] DEFAULT.FEATURES</code> , the account to which the job was submitted, and job walltime limit.
<b>NOAUTORES</b>	If the resource manager does not report CPU usage to Moab because CPU usage is at 0%, Moab assumes full CPU usage. When set, Moab recognizes the resource manager report as 0% usage. This is only valid for PBS.
<b>NOCREATERESOURCE</b>	To use resources discovered from this resource manager, they must be created by another resource manager first. For example, if you set <i>NOCREATERESOURCE</i> on RM A, which reports nodes 1 and 2, and RM B only reports node 1, then node 2 will not be created because RM B did not report it.
<b>PRIVATE</b>	The resources and workload reported by the resource manager are not reported to non-administrator users.

Flag	Description
<b>PROXYJOB SUBMISSION</b>	Enables Admin proxy job submission, which means administrators may submit jobs in behalf of other users.
<b>PUSHSLAVEJOBUPDATES</b>	Enables job changes made on a grid slave to be pushed to the grid head or master. Without this flag, jobs being reported to the grid head do not show any changes made on the remote Moab server (via <a href="#">mjobctl</a> and so forth).
<b>RECORDGPUMETRICS</b>	Enables the recording of GPU metrics for nodes.
<b>RECORDMICMETRICS</b>	Enables the recording of MIC metrics for nodes.
<b>REPORT</b>	N/A
<b>SHARED</b>	Resources of this resource manager may be scheduled by multiple independent sources and may not be assumed to be owned by any single source.
<b>STATIC</b>	This resource manager only provides partial object information and this information does not change over time. Consequently, this resource manager may only be called once per object to modify job and node information.
<b>USERSPACEISSEPARATE</b>	This tells Moab to ignore validating the user's uid and gid in the case that information doesn't exist on the Moab server.

### Example

```
# resource manager 'torque' should use asynchronous job start
# and report resources in 'grid' mode
RMCFG[torque] FLAGS=asyncstart,grid
```

## Scheduler/Resource Manager Interactions

In the simplest configuration, Moab interacts with the resource manager using the following four primary functions:

Function	Description
<b>GETJOBINFO</b>	Collect detailed state and requirement information about idle, running, and recently completed jobs.
<b>GETNODEINFO</b>	Collect detailed state information about idle, busy, and defined nodes.

Function	Description
<b>STARTJOB</b>	Immediately start a specific job on a particular set of nodes.
<b>CANCELJOB</b>	Immediately cancel a specific job regardless of job state.

Using these four simple commands, Moab enables nearly its entire suite of scheduling functions. More detailed information about resource manager specific requirements and semantics for each of these commands can be found in the specific resource manager (such as [WIKI](#)) overviews.

In addition to these base commands, other commands are required to support advanced features such as suspend/resume, gang scheduling, and scheduler initiated checkpoint restart.

Information on creating a new scheduler resource manager interface can be found in the [Adding New Resource Manager Interfaces](#) section.

## Resource Manager Extensions

- [Resource Manager Extension Specification](#)
- [Resource Manager Extension Values](#)
- [Resource Manager Extension Examples](#)

All resource managers are not created equal. There is a wide range in what capabilities are available from system to system. Additionally, there is a large body of functionality that many, if not all, resource managers have no concept of. A good example of this is job QoS. Since most resource managers do not have a concept of quality of service, they do not provide a mechanism for users to specify this information. In many cases, Moab is able to add capabilities at a global level. However, a number of features require a *per job* specification. Resource manager extensions allow this information to be associated with the job.

### Resource Manager Extension Specification

Specifying resource manager extensions varies by resource manager. TORQUE, OpenPBS, PBSPro, Loadleveler, LSF, S3, and Wiki each allow the specification of an *extension* field as described in the following table:

Resource manager	Specification method
<b>TORQUE 2.0+</b>	-l <pre>&gt; qsub -l nodes=3,qos=high sleepy.cmd</pre>

Resource manager	Specification method
<b>TORQUE 1.x/OpenPBS</b>	<p><code>-W x=</code></p> <pre>&gt; qsub -l nodes=3 -W x=qos:high sleepy.cmd</pre> <p><b>i</b> OpenPBS does not support this ability by default but can be patched as described in the <a href="#">PBS Resource Manager Extension Overview</a>.</p>
<b>Loadleveler</b>	<p><code>#@comment</code></p> <pre>#@nodes = 3 #@comment = qos:high</pre>
<b>LSF</b>	<p><code>-ext</code></p> <pre>&gt; bsub -ext advres:system.2</pre>
<b>PBSPro</b>	<p><code>-l</code></p> <pre>&gt; qsub -l advres=system.2</pre> <p><b>i</b> Use of PBSPro resources requires configuring the <code>server_priv/resourcedef</code> file to define the needed extensions as in the following example:</p> <pre>advres type=string qos type=string sid type=string sjid type=string</pre>
<a href="#">Wiki</a>	<p><code>comment</code></p> <pre>comment=qos:high</pre>

## Resource Manager Extension Values

Using the resource manager specific method, the following job extensions are currently available:

[ADVRES on page 620](#)  
[BANDWIDTH on page 620](#)  
[CPUCLOCK on page 621](#)  
[DDISK on page 623](#)  
[DEADLINE on page 623](#)  
[DEPEND on page 624](#)  
[DMEM on page 624](#)  
[EPILOGUE on page 624](#)  
[EXCLUDENODES on page 625](#)  
[FEATURE on page 625](#)  
[GATTR on page 625](#)  
[GEOMETRY on page 626](#)  
[GMETRIC on page 626](#)  
[GPUs on page 626](#)  
[GRES](#)  
[HOSTLIST on page 628](#)  
[JGROUP on page 629](#)  
[JOBFLAGS](#)  
[JOBREJECTPOLICY on page 630](#)  
[MAXMEM on page 630](#)

[MAXPROC on page 631](#)  
[MEM on page 631](#)

[TRL](#)  
[VAR on page 645](#)  
[VC on page 646](#)  
[VMEM on page 646](#)

## ADVRES

### Format

[!] <RSVID>

### Description

Specifies that reserved resources are required to run the job. If <RSVID> is specified, then only resources within the specified reservation may be allocated (see [Job to Reservation Binding](#)). You can request to not use a specific reservation by using `advres=!<reservationname>`.

### Example

```
> qsub -l advres=grid.3
```

*Resources for the job must come from grid.3.*

```
> qsub -l advres=!grid.5
```

*Resources for the job must not come from grid.5*

## BANDWIDTH

### Format

<DOUBLE> (in MB/s)

### Description

Minimum available network bandwidth across allocated resources (See [Network Management](#)).

### Example

```
> bsub -ext bandwidth=120 chemjob.txt
```

CPUCLOCK	
<b>Format</b>	<STRING>

## CPUCLOCK

## Description

Specify the CPU clock frequency for each node requested for this job. A **cpuclock** request applies to every processor on every node in the request. Specifying varying CPU frequencies for different nodes or different processors on nodes in a single job request is not supported.

Not all CPUs support all possible frequencies or ACPI states. If the requested frequency is not supported by the CPU, the nearest frequency is used.

Using **cpuclock** sets **NODEACCESSPOLICY** to **SINGLEJOB**.

ALPS 1.4 or later is required when using **cpuclock** on Cray.

The clock frequency can be specified via:

- a number that indicates the clock frequency (with or without the SI unit suffix).
- a Linux power governor policy name. The governor names are:
  - **performance**: This governor instructs Linux to operate each logical processor at its maximum clock frequency.  
This setting consumes the most power and workload executes at the fastest possible speed.
  - **powersave**: This governor instructs Linux to operate each logical processor at its minimum clock frequency.  
This setting executes workload at the slowest possible speed. This setting does not necessarily consume the least amount of power since applications execute slower, and may actually consume more energy because of the additional time needed to complete the workload's execution.
  - **ondemand**: This governor dynamically switches the logical processor's clock frequency to the maximum value when system load is high and to the minimum value when the system load is low.  
This setting causes workload to execute at the fastest possible speed or the slowest possible speed, depending on OS load. The system switches between consuming the most power and the least power.

The power saving benefits of **ondemand** might be non-existent due to frequency switching latency if the system load causes clock frequency changes too often.

This has been true for older processors since changing the clock frequency required putting the processor into the C3 "sleep" state, changing its clock frequency, and then waking it up, all of which required a significant amount of time.

Newer processors, such as the Intel Xeon E5-2600 Sandy Bridge processors, can change clock frequency dynamically and much faster.

- **conservative**: This governor operates like the **ondemand** governor but is more conservative in switching between frequencies. It switches more gradually and uses all possible clock frequencies.  
This governor can switch to an intermediate clock frequency if it seems appropriate to the system load and usage, which the **ondemand** governor does not do.
- an ACPI performance state (or P-state) with or without the P prefix. P-states are a special

CPUCLOCK	
	<p>range of values (0-15) that map to specific frequencies. Not all processors support all 16 states, however, they all start at P0. P0 sets the CPU clock frequency to the highest performance state which runs at the maximum frequency. P15 sets the CPU clock frequency to the lowest performance state which runs at the lowest frequency.</p> <p>When reviewing job or node properties when <b>cpuclock</b> was used, be mindful of unit conversion. The OS reports frequency in Hz, not MHz or GHz.</p>
<b>Example</b>	<pre>msub -l cpuclock=1800,nodes=2 script.sh msub -l cpuclock=1800mhz,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to 1800 MHz.</i></p> <pre>msub -l cpuclock=performance,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to the performance power governor policy.</i></p> <pre>msub -l cpuclock=3,nodes=2 script.sh msub -l cpuclock=p3,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to a performance state of 3.</i></p>

DDISK	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Dedicated disk per task in MB.
<b>Example</b>	<pre>&gt; qsub -l ddisk=2000</pre>

DEADLINE	
<b>Format</b>	<p>Relative time: [ [ [DD:] HH:] MM:] SS</p> <p>Absolute time: hh:mm:ss_mm/dd/yy</p>
<b>Description</b>	Either the relative completion deadline of job (from job submission time) or an absolute deadline in which you specify the date and time the job will finish.

DEADLINE	
<b>Example:</b>	<pre>&gt; qsub -l deadline=2:00:00,nodes=4 /tmp/bio3.cmd</pre> <p><i>The job's deadline is 2 hours after its submission.</i></p>

DEPEND	
<b>Format</b>	[<DEPENDTYPE>:] [{jobname jobid}.] <ID>[: [{jobname jobid}.] <ID>]...
<b>Description</b>	Allows specification of job dependencies for compute or system jobs. If no ID prefix (jobname or jobid) is specified, the ID value is interpreted as a job ID.
<b>Example</b>	<pre># submit job which will run after job 1301 and 1304 complete &gt; msub -l depend=orion.1301:orion.1304 test.cmd orion.1322 # submit jobname-based dependency job &gt; msub -l depend=jobname.data1005 dataet1.cmd orion.1428</pre>

DMEM	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Dedicated memory per task in bytes.
<b>Example</b>	<pre>&gt; msub -l dmem=20480</pre> <p><i>Moab will dedicate 20 MB of memory to the task.</i></p>

EPILOGUE	
<b>Format</b>	<STRING>

EPILOGUE	
<b>Description</b>	<p>Specifies a user owned epilogue script which is run before the system epilogue and <code>epilogue.user</code> scripts at the completion of a job. The syntax is <code>epilogue=&lt;file&gt;</code>. The file can be designated with an absolute or relative path.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> This parameter works only with TORQUE.</p> </div>
<b>Example</b>	<pre>&gt; msub -l epilogue=epilogue_script.sh job.sh</pre>

EXCLUDENODES	
<b>Format</b>	<code>{&lt;nodeid&gt; &lt;node_range&gt;}[:...]</code>
<b>Description</b>	Specifies nodes that should not be considered for the given job.
<b>Example</b>	<pre>&gt; msub -l excludenodes=k1:k2:k[5-8] # Comma separated ranges work only with SLURM &gt; msub -l excludenodes=k[1-2,5-8]</pre>

FEATURE	
<b>Format</b>	<code>&lt;FEATURE&gt;[{: }&lt;FEATURE&gt;]...</code>
<b>Description</b>	<p>Required list of node attribute/node <a href="#">features</a>.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> If the <i>pipe</i> ( ) character is used as a delimiter, the features are logically OR'd together and the associated job may use resources that match any of the specified features.</p> </div>
<b>Example</b>	<pre>&gt; qsub -l feature='fastos:bigio' testjob.cmd</pre>

GATTR	
<b>Format</b>	<code>&lt;STRING&gt;</code>
<b>Description</b>	Generic job attribute associated with job. The maximum size for an attribute is 63 bytes (the core Moab size limit of 64, including a null byte)
<b>Example</b>	<pre>&gt; qsub -l gattr=bigjob</pre>

GEOMETRY	
<b>Format:</b>	{ (<TASKID>[, <TASKID>[, ...]]) [ (<TASKID>[, ...]) ... ] }
<b>Description:</b>	Explicitly specified task geometry.
<b>Example:</b>	<pre>&gt; qsub -l nodes=2:ppn=4 -W x=geometry:'{(0,1,4,5) (2,3,6,7)}' quanta2.cmd</pre> <p><i>The job quanta2.cmd runs tasks 0, 1, 4, and 5 on one node, while tasks 2, 3, 6, and 7 run on another node.</i></p>

GMETRIC	
<b>Format</b>	Generic metric requirement for allocated nodes where the requirement is specified using the format <GMNAME>[:{lt:, le:, eq:, ge:, gt:, ne:}<VALUE>]
<b>Description</b>	Indicates generic constraints that must be found on all allocated nodes. If a <VALUE> is not specified, the node must simply possess the generic metric (See <a href="#">Generic Metrics</a> for more information.).
<b>Example</b>	<pre>&gt; qsub -l gmetric=bioversion:ge:133244 testj.txt</pre>

GPUs	
<b>Format</b>	<pre>msub -l nodes=&lt;VALUE&gt;:ppn=&lt;VALUE&gt;:gpus=&lt;VALUE&gt;[:mode] [:reseterr]</pre> <p>Where mode is one of:</p> <ul style="list-style-type: none"> <li><i>exclusive</i> - The default setting. The GPU is used exclusively by one process thread.</li> <li><i>exclusive_thread</i> - The GPU is used exclusively by one process thread.</li> <li><i>exclusive_process</i> - The GPU is used exclusively by one process regardless of process thread.</li> </ul> <p>If present, <code>reseterr</code> resets the ECC memory bit error counters. This only resets the volatile error counts, or errors since the last reboot. The permanent error counts are not affected.</p> <p>Moab passes the <code>mode</code> and <code>reseterr</code> portion of the request to TORQUE for processing.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> Moab does not support requesting GPUs as a GRES. Submitting <code>msub -l gres=gpus:x</code> does not work.</p> </div>
<b>Description</b>	Moab schedules GPUs as a special type of <a href="#">node-locked generic resources</a> . When <a href="#">TORQUE reports GPUs</a> to Moab, Moab can schedule jobs and correctly assign GPUs to ensure that jobs are scheduled efficiently. To have Moab schedule GPUs, configure them in TORQUE then submit jobs using the "GPU" attribute. Moab automatically parses the "GPU" attribute and assigns them in the correct manner. For information about GPU metrics, see <a href="#">GPGPUMetrics</a> .

## GPUs

## Examples

```
> msub -l nodes=2:ppn=2:gpus=1:exclusive_process:reseterr
```

*Submits a job that requests 2 tasks, 2 processors and 1 GPU per task (2 GPUs total). Each GPU runs only threads related to the task and resets the volatile ECC memory big error counts at job start time.*

```
> msub -l nodes=4:gpus=1,tpn=2
```

*Submits a job that requests 4 tasks, 1 GPU per node (4 GPUs total), and 2 tasks per node. Each GPU is dedicated exclusively to one task process and the ECC memory bit error counters are not reset.*

```
> msub -l nodes=4:gpus=1:reseterr
```

*Submits a job that requests 4 tasks, 1 processor and 1 GPU per task (4 GPUs total). Each GPU is dedicated exclusively to one task process and resets the volatile ECC memory bit error counts at job start time.*

```
> msub -l nodes=4:gpus=2+1:ppn=2,walltime=600
```

*Submits a job that requests two different types of tasks, the first is 4 tasks, each with 1 processor and 2 gpus, and the second is 1 task with 2 processors. Each GPU is dedicated exclusively to one task process and the ECC memory bit error counters are not reset.*

## GRES and SOFTWARE

## Format

Percent sign (%) delimited list of generic resources where each resource is specified using the format `<RESTYPE>[+|:]<COUNT>`

## Description

Indicates generic resources required by the job. If the generic resource is node-locked, it is a per-task count. If a `<COUNT>` is not specified, the resource count defaults to 1.

## Example

```
> qsub -W x=GRES:tape+2%matlab+3 testj.txt
```

When specifying more than one generic resource with -l, use the percent (%) character to delimit them.

```
> qsub -l gres=tape+2%matlab+3 testj.txt
> qsub -l software=matlab:2 testj.txt
```

HOSTLIST	
<b>Format</b>	Comma (,) or plus (+) delimited list of hostnames. Ranges and regular expressions are supported in <code>msub</code> only.
<b>Description</b>	<p>Indicates an <i>exact set</i>, <i>superset</i>, or <i>subset</i> of nodes on which the job must run. Use the caret (^) or asterisk (*) characters to specify a host list as <i>superset</i> or <i>subset</i> respectively.</p> <p>An exact set is defined without a caret or asterisk. An exact set means <i>all</i> the hosts in the specified hostlist must be selected for the job.</p> <p>A subset means the specified hostlist is used first to select hosts for the job. If the job requires more hosts than are in the subset hostlist, they will be obtained from elsewhere if possible. If the job does not require all of the nodes in the subset hostlist, it will use only the ones it needs.</p> <p>A superset means the hostlist is the <i>only</i> source of hosts that should be considered for running the job. If the job can't find the necessary resources in the superset hostlist it should <i>not</i> run. No other hosts should be considered in allocating the job.</p>

## HOSTLIST

## Examples

```
> msub -l hostlist=nodeA+nodeB+nodeE
```

```
hostlist=foo[1-5]
```

*This is an exact set of (foo1,foo2,...,foo5). The job must run on all these nodes.*

```
hostlist=foo1+foo[3-9]
```

*This is an exact set of (foo1,foo3,foo4,...,foo9). The job must run on all these nodes.*

```
hostlist=foo[1,3-9]
```

*This is an exact set of the same nodes as the previous example.*

```
hostlist=foo[1-3]+bar[72-79]
```

*This is an exact set of (foo1,foo2,foo3,bar72,bar73,...,bar79). The job must run on all these nodes.*

```
hostlist=^node[1-50]
```

*This is a superset of (node1,node2,...,node50). These are the only nodes that can be considered for the job. If the necessary resources for the job are not in this hostlist, the job is not run. If the job does not require all the nodes in this hostlist, it will use only the ones that it needs.*

```
hostlist=*node[15-25]
```

*This is a subset of (node15,node16,...,node25). The nodes in this hostlist are considered first for the job. If the necessary resources for the job are not in this hostlist, Moab tries to obtain the necessary resources from elsewhere. If the job does not require all the nodes in this hostlist, it will use only the ones that it needs.*

## JGROUP

## Format

```
<JOBGROUPID>
```

## Description

ID of job group to which this job belongs (different from the GID of the user running the job).

## Example

```
> msub -l JGROUP=bluegroup
```

JOBFLAGS (aka FLAGS)	
<b>Format</b>	One or more of the following colon delimited job flags including ADVRES[:RSVID], NOQUEUE, NORMSTART, PREEMPTEE, PREEMPTOR, RESTARTABLE, or SUSPENDABLE (see <a href="#">job flag overview</a> for a complete listing).
<b>Description</b>	Associates various flags with the job.
<b>Example</b>	<pre>&gt; qsub -l nodes=1,walltime=3600,jobflags=advres myjob.py</pre>

JOBREJECTPOLICY	
<b>Format:</b>	One or more of <i>CANCEL</i> , <i>HOLD</i> , <i>IGNORE</i> (beta), <i>MAIL</i> , or <i>RETRY</i>
<b>Default:</b>	<i>HOLD</i>
<b>Details:</b>	<p>Specifies the action to take when the scheduler determines that a job can never run. <i>CANCEL</i> issues a call to the resource manager to cancel the job. <i>HOLD</i> places a batch hold on the job preventing the job from being further evaluated until released by an administrator.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin: 5px 0;"> <p> Administrators can dynamically alter job attributes and possibly <i>fix</i> the job with <a href="#">mjobctl -m</a>.</p> </div> <p>With <i>IGNORE</i> (currently in beta), the scheduler will allow the job to exist within the resource manager queue but will neither process it nor report it. <a href="#">MAIL</a> will send email to both the admin and the user when rejected jobs are detected. If <i>RETRY</i> is set, then Moab will allow the job to remain idle and will only attempt to start the job when the policy violation is resolved. Any combination of attributes may be specified. See <a href="#">QOSREJECTPOLICY</a>.</p> <p>This is a per-job policy specified with <a href="#">msub -l JOBREJECTPOLICY</a> also exists as a global parameter.</p>
<b>Example:</b>	<pre>&gt; msub -l jobrejectpolicy=cancel:mail</pre>

MAXMEM	
<b>Forma:</b>	<INTEGER> (in megabytes)
<b>Description</b>	Maximum amount of memory the job may consume across all tasks before the <a href="#">JOBMEM</a> action is taken.
<b>Example</b>	<pre>&gt; qsub -W x=MAXMEM:1000mb bw.cmd</pre> <div style="border: 1px dashed #000; border-radius: 5px; padding: 5px; margin: 5px 0;"> <p>If a <a href="#">RESOURCELIMITPOLICY</a> is set for per-job memory utilization, its action will be taken when this value is reached.</p> </div>

MAXPROC	
<b>Format</b>	<INTEGER>
<b>Description</b>	Maximum CPU load the job may consume across all tasks before the <a href="#">JOBPROC</a> action is taken.
<b>Example</b>	<pre>&gt; qsub -W x=MAXPROC:4 bw.cmd</pre> <p><i>If a <a href="#">RESOURCELIMITPOLICY</a> is set for per-job processor utilization, its action will be taken when this value is reached.</i></p>

MEM	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specify the maximum amount of physical memory used by the job. If you do not specify MB or GB, Moab uses bytes if your resource manager is TORQUE and MB if your resource manager is Native.
<b>Example</b>	<pre>&gt; msub -l nodes=4:ppn=2,mem=1024mb</pre> <p><i>The job must have 4 compute nodes with 2 processors per node. The job is limited to 1024 MB of memory.</i></p>

MICs	
<b>Format</b>	<pre>msub -l nodes=&lt;VALUE&gt;;ppn=&lt;VALUE&gt;;mics=&lt;VALUE&gt;[:mode]</pre> <p>Where mode is one of:</p> <ul style="list-style-type: none"> <li><i>exclusive</i> - The default setting. The MIC is used exclusively by one process thread.</li> <li><i>exclusive_thread</i> - The MIC is used exclusively by one process thread.</li> <li><i>exclusive_process</i> - The MIC is used exclusively by one process regardless of process thread.</li> </ul> <p>Moab passes the mode portion of the request to TORQUE for processing.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> Moab does not support requesting MICs as a GRES. Submitting <code>msub -l gres=mics:x</code> does not work.</p> </div>
<b>Description</b>	Moab schedules MICs as a special type of <a href="#">node-locked generic resources</a> . When <a href="#">TORQUE reports MICs</a> to Moab, Moab can schedule jobs and correctly assign MICs to ensure that jobs are scheduled efficiently. To have Moab schedule MICs, configure them in TORQUE then submit jobs using the "MIC" attribute. Moab automatically parses the "MIC" attribute and assigns them in the correct manner.

MICs	
<b>Examples</b>	<pre>&gt; msub -l nodes=2:ppn=2:mics=1:exclusive_process</pre> <p><i>Submits a job that requests 2 tasks, 2 processors and 1 MIC per task (2 MICs total). Each MIC runs only threads related to the task.</i></p>
	<pre>&gt; msub -l nodes=4:mics=1,tpn=2</pre> <p><i>Submits a job that requests 4 tasks, 1 MIC per node (4 MICs total), and 2 tasks per node. Each MIC is dedicated exclusively to one task process.</i></p>
	<pre>&gt; msub -l nodes=4:mics=1</pre> <p><i>Submits a job that requests 4 tasks, 1 processor and 1 MIC per task (4 MICs total). Each MIC is dedicated exclusively to one task process.</i></p>
	<pre>&gt; msub -l nodes=4:mics=2+1:ppn=2,walltime=600</pre> <p><i>Submits a job that requests two different types of tasks, the first is 4 tasks, each with 1 processor and 2 MICs, and the second is 1 task with 2 processors. Each MIC is dedicated exclusively to one task process.</i></p>

MINPREEMPTTIME	
<b>Format</b>	[ [DD:]HH:]MM:]SS
<b>Description</b>	<p>Minimum time job must run before being eligible for preemption.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> Can only be specified if associated <a href="#">QoS</a> allows per-job preemption configuration by setting the <a href="#">preemptconfig</a> flag.</p> </div>
<b>Example</b>	<pre>&gt; qsub -l minpreempttime=900 bw.cmd</pre> <p><i>Job cannot be preempted until it has run for 15 minutes.</i></p>

MINPROCSPEED	
<b>Format</b>	<INTEGER>
<b>Default</b>	0

MINPROCSPEED	
<b>Description</b>	Minimum <a href="#">processor speed</a> (in MHz) for every node that this job will run on.
<b>Example</b>	<pre>&gt; qsub -W x=MINPROCSPEED:2000 bw.cmd</pre> <p><i>Every node that runs this job must have a processor speed of at least 2000 MHz.</i></p>

MINWCLIMIT	
<b>Format</b>	[ [DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	Minimum wallclock limit job must run before being eligible for extension (See <a href="#">JOBEXTENDDURATION</a> or <a href="#">JOBEXTENDSTARTWALLTIME</a> ).
<b>Example</b>	<pre>&gt; qsub -l minwclimit=300,walltime=16000 bw.cmd</pre> <p><i>Job will run for at least 300 seconds but up to 16,000 seconds if possible (without interfering with other jobs).</i></p>

MSTAGEIN	
<b>Format</b>	[<SRCURL>[ <SRCRUL>... ]%]<DSTURL>

## MSTAGEIN

**Descrip-  
tion**

Indicates a job has [data staging](#) requirements. The source URL(s) listed will be transferred to the execution system for use by the job. If more than one source URL is specified, the destination URL must be a directory.

The format of `<SRCURL>` is: `[PROTO://] [HOST] [:PORT] [/PATH]` where the path is local.

The format of `<DSTURL>` is:  
`[PROTO://] [HOST] [:PORT] [/PATH]` where the path is remote.

PROTO can be any of the following protocols: ssh, file, or gsiftp.

HOST is the name of the host where the file resides.

PATH is the path of the source or destination file. The destination path may be a directory when sending a single file and must be a directory when sending multiple files. If a directory is specified, it must end with a forward slash (/).

Valid variables include:

`$JOBID`

`$HOME` - Path the script was run from

`$RHOME` - Home dir of the user on the remote system

`$SUBMITHOST`

`$DEST` - This is the Moab where the job will run

`$LOCALDATASTAGEHEAD`

If no destination is given, the protocol and file name will be set to the same as the source.

The `$RHOME` (remote home directory) variable is for when a user's home directory on the compute node is different than on the submission host.

**Examp-  
le:**

```
> msub -
Wx='mstagein=file://$HOME/helperscript.sh|file:///home/dev/datafile.txt%ssh://host/hom
e/dev/' script.sh
```

Copy `helperscript.sh` and `datafile.txt` from the local machine to `/home/dev/` on host for use in execution of `script.sh`. `$HOME` is a path containing a preceding / (i.e. `/home/adaptive`)

## MSTAGEOUT

**Forma-  
t**

`[<SRCURL>[|<SRCURL>... ]%]<DSTURL>`

## MSTAGEOUT

**Descri-  
ption**

Indicates whether a job has [data staging](#) requirements. The source URL(s) listed will be transferred from the execution system after the completion of the job. If more than one source URL is specified, the destination URL must be a directory.

The format of `<SRCURL>` is: `[PROTO://] [HOST] [:PORT] [/PATH]` where the path is remote.

The format of `<DSTURL>` is: `[PROTO://] [HOST] [:PORT] [/PATH]` where the path is local.

PROTO can be any of the following protocols: ssh, file, or gsiftp.

HOST is the name of the host where the file resides.

PATH is the path of the source or destination file. The destination path may be a directory when sending a single file and must be a directory when sending multiple files. If a directory is specified, it must end with a forward slash (/).

Valid variables include:

`$JOBID`

`$HOME` - Path the script was run from

`$RHOME` - Home dir of the user on the remote system

`$SUBMITHOST`

`$DEST` - This is the Moab where the job will run

`$LOCALDATASTAGEHEAD`

 If no destination is given, the protocol and file name will be set to the same as the source.

 The `$RHOME` (remote home directory) variable is for when a user's home directory on the compute node is different than on the submission host.

**Examp-  
le**

```
> msub -W
x='mstageout=ssh://$DEST/$HOME/resultfile1.txt|ssh://host/home/dev/resultsript.sh%file
: //home/dev/' script.sh
```

*Copy resultfile1.txt and resultsript.sh from the execution system to /home/dev/ after the execution of script.sh is complete. \$HOME is a path containing a preceding / (i.e. /home/adaptive).*

## NACCESSPOLICY

**Format**

One of [SHARED](#), [SINGLEJOB](#), [SINGLETASK](#), [SINGLEUSER](#), or [UNIQUEUSER](#)

NACCESSPOLICY	
<b>Description</b>	<p>Specifies how node resources should be accessed. (See <a href="#">Node Access Policies</a> for more information).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> The <b>naccesspolicy</b> option can only be used to make node access more constraining than is specified by the system, partition, or node policies. If the effective node access policy is <b>shared</b>, <b>naccesspolicy</b> can be set to <b>singleuser</b>, if the effective node access policy is <b>singlejob</b>, <b>naccesspolicy</b> can be set to <b>singletask</b>.</p> </div>
<b>Example</b>	<pre>&gt; qsub -l naccesspolicy=singleuser bw.cmd</pre> <pre>&gt; bsub -ext naccesspolicy=singleuser lancer.cmd</pre> <p><i>Job can only allocate free nodes or nodes running jobs by same user.</i></p>

NALLOCPOLICY	
<b>Format</b>	One of the valid settings for the parameter <a href="#">NODEALLOCATIONPOLICY</a>
<b>Description</b>	Specifies how node resources should be selected and allocated to the job. (See <a href="#">Node Allocation Policies</a> for more information.)
<b>Example</b>	<pre>&gt; qsub -l nallocpolicy=minresource bw.cmd</pre> <p><i>Job should use the <b>minresource</b> node allocation policy.</i></p>

NCPUS	
<b>Format</b>	<INTEGER>
<b>Description</b>	<p>The number of processors in one task where a task cannot span nodes. If <b>NCPUS</b> is used, then the resource manager's <a href="#">SUBMITPOLICY</a> should be set to <b>NODECENTRIC</b> to get correct behavior. <code>-l ncpus=&lt;#&gt;</code> is equivalent to <code>-l nodes=1 :ppn=&lt;#&gt;</code> when <b>JOBNODEMATCHPOLICY</b> is set to <b>EXACTNODE</b>. <b>NCPUS</b> is used when submitting jobs to an SMP. When using <a href="#">GPUs</a> to submit to an SMP, use <code>-l ncpus=&lt;#&gt;:GPUs=&lt;#&gt;</code>.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> You cannot request both <b>ncpus</b> and <b>nodes</b> in the same job.</p> </div>

NMATCHPOLICY	
<b>Format</b>	One of the valid settings for the parameter <a href="#">JOBNODEMATCHPOLICY</a>
<b>Description</b>	Specifies how node resources should be selected and allocated to the job.
<b>Example</b>	<pre>&gt; qsub -l nodes=2 -W x=nmatchpolicy:exactnode bw.cmd</pre> <p><i>Job should use the EXACTNODEJOBNODEMATCHPOLICY.</i></p>

NODESET	
<b>Format</b>	<SETTYPE>:<SETATTR>[:<SETLIST>]
<b>Description</b>	Specifies nodeset constraints for job resource allocation (See the <a href="#">NodeSet Overview</a> for more information.).
<b>Example</b>	<pre>&gt; qsub -l nodeset=ONEOF:FEATURE:fastos:hiprio:bigmem bw.cmd</pre>

NODESETCOUNT	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies how many node sets a job uses.
<b>Example</b>	<pre>&gt; msub -l nodesetcount=2</pre>

NODESETDELAY	
<b>Format</b>	[ [ [DD:]HH:]MM:]SS
<b>Description</b>	Causes Moab to attempt to span a job evenly across nodesets unless doing so delays the job beyond the requested <b>NODESETDELAY</b> .
<b>Example</b>	<pre>&gt; qsub -l nodesetdelay=300,walltime=16000 bw.cmd</pre>

NODESETISOPTIONAL	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Specifies whether the nodeset constraint is optional (See the <a href="#">NodeSet Overview</a> for more information).
	 Requires SCHEDCFG[] <a href="#">FLAGS</a> =allowperjobnodesetisoptional.
<b>Example</b>	<pre>&gt; msub -l nodesetisoptional=true bw.cmd</pre>

OPSYS	
<b>Format</b>	<OperatingSystem>
<b>Description</b>	Specifies the job's required operating system.
<b>Example</b>	<pre>&gt; qsub -l nodes=1,opsys=rh73 chem92.cmd</pre>

PARTITION	
<b>Format</b>	<STRING>[:<STRING>]...
<b>Description</b>	Specifies the <a href="#">partition</a> (or partitions) in which the job must run.
	 The job must have access to this partition based on system wide or credential based partition access lists.
<b>Example</b>	<pre>&gt; qsub -l nodes=1,partition=math:geology</pre> <i>The job must only run in the <b>math</b> partition or the <b>geology</b> partition.</i>

PLACEMENT	
<b>Format</b>	[numa=X] [[:]sockets=Y] [[:]usetreads]
<b>Description</b>	Specifies the task placement of jobs.

PLACEMENT	
<b>Example</b>	<pre>&gt; msub -l nodes=4:ppn=2,placement=numa=2</pre> <p><i>This means to place the job on 4 compute nodes with 2 processors per node, with 2 different NUMA nodes per compute node, and 1 processor per NUMA node.</i></p>
PMEM	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies the maximum amount of physical memory used by any single process of the job.
<b>Example</b>	<pre>&gt; msub -l nodes=4:ppn=2,pmem=1024mb</pre> <p><i>The job must have 4 compute nodes with 2 processors per node, and each process of the job is limited to 1024 MB of physical memory.</i></p>
PREF	
<b>Format</b>	[{feature variable}:]<STRING>[:<STRING>]...
	<p><b>i</b> If feature or variable are not specified, then feature is assumed.</p>
<b>Description</b>	<p>Specifies which <a href="#">node features</a> are preferred by the job and should be allocated if available. If preferred node criteria are specified, Moab favors the allocation of matching resources but is not bound to only consider these resources.</p> <p><b>i</b> Preferences are not honored unless the <a href="#">node allocation</a> policy is set to <a href="#">PRIORITY</a> and the <a href="#">PREF</a> priority component is set within the node's <a href="#">PRIORITYF</a> attribute.</p>
<b>Example</b>	<pre>&gt; qsub -l nodes=1,pref=bigmem</pre> <p><i>The job may run on any nodes but prefers to allocate nodes with the <b>bigmem</b> feature.</i></p>
PROCS	
<b>Format</b>	<INTEGER>

PROCS	
<b>Description</b>	<p>Requests a specific amount of processors for the job. Instead of users trying to determine the amount of nodes they need, they can instead decide how many processors they need and Moab will automatically request the appropriate amount of nodes from the RM. This also works with feature requests, such as <code>procs=12[:feature1[:feature2[-]]]</code>.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> Using this resource request overrides any other processor or node related request, such as <code>nodes=4</code>.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 5px;">&gt; msub -l procs=32 myjob.pl</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"><i>Moab will request as many nodes as is necessary to meet the 32-processor requirement for the job.</i></p>

PROLOGUE	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies a user owned prologue script which will be run after the system prologue and <code>prologue.user</code> scripts at the beginning of a job. The syntax is <code>prologue=&lt;file&gt;</code>. The file can be designated with an absolute or relative path.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> This parameter works only with TORQUE.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">&gt; msub -l prologue=prologue_script.sh job.s</pre>

PVMEM	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specify the maximum amount of virtual memory used by any single process in the job.
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 5px;">&gt; msub -l nodes=4:ppn=2,pvmem=1024mb</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"><i>The job must have 4 compute nodes with 2 processors per node, and each process of the job is limited to 1024 MB of virtual memory.</i></p>

QoS	
<b>Format</b>	<STRING>
<b>Description</b>	Requests the specified QoS for the job.
<b>Example</b>	<pre>&gt; qsub -l walltime=1000,qos=highprio biojob.cmd</pre>

QUEUEJOB	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Indicates whether or not the scheduler should queue the job if resources are not available to run the job immediately
<b>Example</b>	<pre>&gt; msub -l nodes=1,queuejob=false test.cmd</pre>

REQATTR	
<b>Format</b>	Required node attributes with version number support: <i>reqattr</i> =[<must must not should should not>]:<ATTRIBUTE>[> = < =] <VERSION>
<b>Description</b>	<p>Indicates required node attributes. Values may include letters, numbers, dashes, underscores, and spaces.</p> <p>You can choose one of four requirement types for each node attribute you request:</p> <ul style="list-style-type: none"> <li>• <b>must</b> – The node on which this job runs must include the attribute at the value specified. If no node matches this requirement, Moab will not schedule the job.</li> <li>• <b>must not</b> – The node on which this job runs must not include the attribute at the value specified. If no node matches this requirement, Moab will not schedule the job.</li> <li>• <b>should</b> – If possible, the node on which this job runs should include the attribute at the value specified. If no node matches this requirement, Moab selects a node without it.</li> <li>• <b>should not</b> – If possible, the node on which this job runs should not include the attribute at the value specified. If no node matches this requirement, Moab selects a node without it.</li> </ul> <p>If you do not specify a requirement type, Moab assumes "must."</p> <p>For information about using reqattr to request dynamic features, see <a href="#">Configuring dynamic features in TORQUE and Moab on page 647</a>.</p>
<b>Example</b>	<pre>&gt; qsub -l reqattr=matlab=7.1 testj.txt</pre>

RESFAILPOLICY	
<b>Format</b>	One of <i>CANCEL</i> , <i>HOLD</i> , <i>IGNORE</i> , <i>NOTIFY</i> , or <i>REQUEUE</i>
<b>Description</b>	Specifies the action to take on an executing job if one or more allocated nodes fail. This setting overrides the global value specified with the <a href="#">NODEALLOCRESFAILUREPOLICY</a> parameter.
<b>Example</b>	<pre>&gt; msub -l resfailpolicy=ignore</pre> <p><i>For this particular job, ignore node failures.</i></p>

RMTYPE	
<b>Format</b>	<STRING>
<b>Description</b>	One of the resource manager types currently available within the cluster or grid. Typically, this is one of <i>PBS</i> , <i>LSF</i> , <i>LL</i> , <i>SGE</i> , <i>SLURM</i> , <i>BProc</i> , and so forth.
<b>Example</b>	<pre>&gt; msub -l rmttype=ll</pre> <p>Only run job on a Loadleveler destination resource manager.</p>

SIGNAL	
<b>Format</b>	<INTEGER>[@<OFFSET>]
<b>Description</b>	Specifies the pre-termination signal to be sent to a job prior to it reaching its walltime limit or being terminated by Moab. The optional offset value specifies how long before job termination the signal should be sent. By default, the pre-termination signal is sent one minute before a job is terminated
<b>Example</b>	<pre>&gt; msub -l signal=32@120 bio45.cmd</pre>

SPRIORITY	
<b>Format</b>	<INTEGER>
<b>Default</b>	0

SPRIORITY	
<b>Description</b>	Allows Moab administrators to set a system priority on a job (similar to <a href="#">setspri</a> ). This only works if the job submitter is an administrator.
<b>Example</b>	<pre>&gt; qsub -l nodes=16,spriority=100 job.cmd</pre>

TEMPLATE	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies a job template to be used as a <a href="#">set</a> template. The requested template must have SELECT-T=TRUE (See <a href="#">Job Templates</a> ).
<b>Example</b>	<pre>&gt; msub -l walltime=1000,nodes=16,template=biojob job.cmd</pre>

TERMTIME	
<b>Format</b>	<TIMESPEC>
<b>Default</b>	0
<b>Description</b>	Specifies the time at which Moab should cancel a queued or active job (See <a href="#">Job Deadline Support</a> ).
<b>Example</b>	<pre>&gt; msub -l nodes=10,walltime=600,termtime=12:00_Jun/14 job.cmd</pre>

TPN	
<b>Format</b>	<INTEGER>[+]
<b>Default</b>	0

TPN	
<b>Description</b>	<p>Tasks per node allowed on allocated hosts. If the plus (+) character is specified, the tasks per node value is interpreted as a minimum tasks per node constraint; otherwise it is interpreted as an exact tasks per node constraint.</p> <p><b>Differences between TPN and PPN:</b></p> <p>There are two key differences between the following: (A) <code>qsub -l nodes=12:ppn=3</code> and (B) <code>qsub -l nodes=12,tpn=3</code>.</p> <p>The first difference is that <b>ppn</b> is interpreted as the <i>minimum</i> required tasks per node while <b>tpn</b> defaults to exact tasks per node; case (B) executes the job with exactly 3 tasks on each allocated node while case (A) executes the job with at least 3 tasks on each allocated node-  <code>nodeA: 4, nodeB: 3, nodeC: 5</code></p> <p>The second major difference is that the line, <code>nodes=X:ppn=Y</code> actually requests <math>X*Y</math> tasks, whereas <code>nodes=X, tpn=Y</code> requests only X tasks.</p> <p><b>TPN with TORQUE as an RM:</b></p> <p>Moab interprets nodes loosely as procs. TORQUE interprets nodes as the number of nodes from the actual number of nodes that you have in your nodes file, not your total number of procs. This means that if TORQUE is your resource manager and you specify <code>msub -l nodes=16:tpn=8</code> but do not have 16 nodes, TORQUE will not run the job. Instead, you should specify <code>msub -l procs=16:tpn=8</code>.</p> <p>To resolve the problem long term, you can also set <code>server resources_available.nodect</code> to the total number of procs in your system and use <code>msub -l nodes=16:tpn=8</code> as you would in a non-TORQUE Moab environment. For more information, see <a href="#">resources available on page 2634</a> in the TORQUE Administrator Guide.</p>
<b>Example</b>	<pre>&gt; msub -l nodes=10,walltime=600,tpn=4 job.cmd</pre>

TRIG	
<b>Format:</b>	<TRIGSPEC>
<b>Description:</b>	<p>Adds trigger(s) to the job (See <a href="#">Creating a trigger on page 748</a> for specific syntax.).</p> <div style="border: 1px solid #0070c0; padding: 5px; background-color: #e6f2ff;"> <p> Job triggers can only be specified if allowed by the QoS flag <code>trigger</code>. See <a href="#">Enabling job triggers on page 755</a> for more information.</p> </div>
<b>Example:</b>	<pre>&gt; qsub -l trig=etype=start\&amp;atype=exec\&amp;action="/tmp/email.sh job.cmd"</pre>

TRL (Format 1)	
<b>Format</b>	<INTEGER>[@<INTEGER>] [:<INTEGER>[@<INTEGER>]] . . .

TRL (Format 1)	
<b>Default:</b>	0
<b>Description:</b>	Specifies alternate task requests with their optional walltimes (See <a href="#">Malleable Jobs</a> ).
<b>Example:</b>	<pre>&gt; msub -l trl=2@500:4@250:8@125:16@62 job.cmd</pre> <p>or</p> <pre>&gt; qsub -l trl=2:3:4</pre>

TRL (Format 2)	
<b>Format</b>	<INTEGER>-<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies a range of task requests that require the same walltime (See <a href="#">Malleable Jobs</a> ).
<b>Example</b>	<pre>&gt; msub -l trl=32-64 job.cmd</pre> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> For optimization purposes Moab does not perform an exhaustive search of all possible values but will at least do the beginning, the end, and 4 equally distributed choices in between.</p> </div>

VAR	
<b>Format</b>	<ATTR>[:<VALUE>]
<b>Description</b>	Adds a generic variable or variables to the job.
<b>Example</b>	<pre>&gt; msub -l VAR=testvar1:testvalue1</pre> <p style="text-align: center;"><i>Single variable</i></p> <pre>&gt; msub -l VAR=testvar1:testvalue1+testvar2:testvalue2+testvar3:testvalue3</pre> <p style="text-align: center;"><i>Multiple variables</i></p>

VC	
<b>Format</b>	vc=<NAME>
<b>Description</b>	Submits the job or workflow to a virtual container (VC).
<b>Example</b>	<code>vc=vc13</code>

VMEM	
<b>Format:</b>	<INTEGER>
<b>Description:</b>	Specify the maximum amount of virtual memory used by all concurrent processes in the job.
<b>Example:</b>	<pre>&gt; msub -l nodes=4:ppn=2,vmem=1024mb</pre> <p><i>The job must have 4 compute nodes with 2 processors per node, and the job is limited to 1024 MB of virtual memory.</i></p>

## Resource Manager Extension Examples

If more than one extension is required in a given job, extensions can be concatenated with a semicolon separator using the format <ATTR>:<VALUE>[;<ATTR>:<VALUE>]...

Example 3-144:

```
#@comment="HOSTLIST:node1,node2;QoS:special;SID:silverA"
```

*Job must run on nodes node1 and node2 using the QoS special. The job is also associated with the system ID silverA allowing the silver daemon to monitor and control the job.*

Example 3-145:

```
# PBS -W x="\NODESET:ONEOF:NETWORK;DMEM:64\""
```

*Job will have resources allocated subject to network based nodeset constraints. Further, each task will dedicate 64 MB of memory.*

Example 3-146:

```
> qsub -l nodes=4,walltime=1:00:00 -W x="FLAGS:ADVRES:john.1"
```

*Job will be forced to run within the john.1 reservation.*

## Configuring dynamic features in TORQUE and Moab

Used together, the [reqattr](#) RM extension and TORQUE [\\$varattr on page 2799](#) parameter allow you to create jobs that request resources that may change or disappear. For example, if you wanted a job to request a certain version of Octave but different versions are configured on each node and updated at any time, you can create a script that searches for the feature and version on the nodes at a specified interval. Your Moab job can then retrieve the dynamic node attributes from the latest poll and use them for scheduling.

This functionality is available when you use the TORQUE `$varattr` parameter to configure a script that regularly retrieves updates on the nodes' feature(s) and the `reqattr` RM extension to require a feature with a certain value.

### To set up a dynamic feature in TORQUE and Moab

1. Create a script that pulls the information you need. For instance, the following script pulls the version of Octave on each node and prints it.

```
#!/bin/bash
# pull the version string for octave and print it for $varattr
version_str=`octave -v | grep version`
[[ $version_str =~ ([:digit:]).[:digit:].[:digit:] ]]
echo "Octavē: ${BASH_REMATCH[1]}"
```

2. Use the TORQUE `$varattr` parameter to configure the script. Specify both the number of seconds between each time TORQUE runs the script and the path to the script. If you set the seconds to `-1`, the script will run just once. You may include arguments if desired. In the following example, the `varattr` parameter specifies that TORQUE calls the Octave script every 30 seconds.

```
$varattr 30 /usr/local/scripts/octave.sh
```

3. Submit your job in Moab, specifying `reqattr` as a resource. In this example, the job requests a node where the octave feature has a value of 3.2.4 (that the node has Octave version 3.2.4 installed).

```
> msub -l rerqattr=octave=3.2.4 myJob.sh
```

*Your job requests a node with Octave version 3.2.4. TORQUE passes the most recent (pulled within the last 30 seconds) version of Octave on each node. Moab then schedules the job on a node that currently has Octave 3.2.4.*

## PBS Resource Manager Extensions

Resource manager extensions within PBS are used by setting the `-W` flag. To enable this flag, some versions of PBS must be rebuilt. [TORQUE](#) and recent OSCAR distributions come with the flag enabled by default. Most other versions do not. The required steps are documented in what follows:

- 1.

```
> qterm -t quick
#shutdown PBS server
```

cd to the directory from which you executed the PBS 'configure' at install time

```
> make distclean  
> ./configure <WITH OPTIONS>
```

2. Create [addparam](#) script  
(`chmod +x addparam`)

3. 

```
> addparam x  
> make
```

Backup current `$PBS_HOMEDIR` directory contents

 `$PBS_HOMEDIR` defaults to `/usr/spool/PBS`.

4. 

```
> make install
```

Restore old `$PBS_HOMEDIR` directory contents

5. 

```
> pbs_server # restart PBS server
```

A job's QOS level can then be specified using the `qsub -W` flag. For example, `qsub -W x=iQOS:hi -l nodes=4 ...`

```

#!/bin/sh
#script:  addparam
#usage:  addparam $Parameter [S|L]
NewParameter=$1
ParameterType=x$2
if [ ! -d src/include ]; then
    echo "error: `basename $0` src/include doesn't exist, run configure"
    1>&2
    exit 1
fi
# run make in this directory to pull over the template files
cd src/include
if make
then
    if grep -q "\"$NewParameter\"" site_*.h 2>/dev/null; then
        echo "parameter $NewParameter previously added"
        exit 0
    fi
fi
chmod +w site_job_attr_enum.h
echo "
    JOB_SITE_ATR_$1,
" >> site_job_attr_enum.h
chmod +w site_job_attr_def.h
if [ $ParameterType = "xS" ]
then
    echo "
        {   \"$NewParameter\",
            decode_str,
            encode_str,
            set_str,
            comp_str,
            free_str,
            NULL_FUNC,
            READ_WRITE,
            ATR_TYPE_STR,
            PARENT_TYPE_JOB
        },
" >> site_job_attr_def.h
else
    echo "
        {   \"$NewParameter\",
            decode_l,
            encode_l,
            set_l,
            comp_l,
            free_null,
            NULL_FUNC,
            READ_WRITE,
            ATR_TYPE_LONG,
            PARENT_TYPE_JOB
        },
" >> site_job_attr_def.h
fi
exit 0

```

## Adding New Resource Manager Interfaces

Moab interfaces with numerous resource management systems. Some of these interact through a resource manager specific interface (OpenPBS/PBSPro, Loadleveler, LSF), while others interact through

generalized interfaces such as SSS or Wiki (See the [Wiki Overview](#)). For most resource managers, either route is possible depending on where it is easiest to focus development effort. Use of Wiki generally requires modifications on the resource manager side while creation of a new resource manager specific Moab interface would require more changes to Moab modules.

Regardless of the interface approach selected, adding support for a new resource manager is typically a straightforward process for about 95% of all supported features. The final 5% of features usually requires a bit more effort as each resource manager has a number of distinct concepts that must be addressed.

- [Resource Manager Specific Interfaces](#)
- [Wiki Interface](#)
- [SSS Interface](#)

## Resource Manager Specific Interfaces

If you require tighter integration and need additional instruction, see [Managing Resources Directly with the Native Interface](#). If you would like consultation on support for a new resource manager type, please [contact](#) the Professional Services group at Adaptive Computing.

## Wiki Interface

The Wiki interface is already defined as a resource manager type, so no modifications are required within Moab. Additionally, no resource manager specific library or header file is required. However, within the resource manager, internal job and node objects and attributes must be manipulated and placed within Wiki based interface concepts as defined in the [Wiki Overview](#). Additionally, resource manager parameters must be created to allow a site to configure this interface appropriately.

## SSS Interface

The SSS interface is an XML based generalized resource manager interface. It provides an extensible, scalable, and secure method of querying and modifying general workload and resource information.

  - [Interfacing to Supermon](#)
- [Configuring Resource Types](#)
- [Creating New Tools to Manage the Cluster](#)

## Native Interface Overview

The Native interface allows a site to augment or even fully replace a resource manager for managing resources. In some situations, the full capabilities of the resource manager are not needed and a lower cost or lower overhead alternative is preferred. In other cases, the nature of the environment may make use of a resource manager impossible due to lack of support. Still, in other situations it is desirable to provide information about additional resource attributes, constraints, or state from alternate sources.

In any case, Moab provides the ability to directly query and manage resources along side of or without the use of a resource manager. This interface, called the NATIVE interface can also be used to launch, cancel, and otherwise manage jobs. This NATIVE interface offers several advantages including the following:

- No cost associated with purchasing a resource manager
- No effort required to install or configure the resource manager
- Ability to support abstract resources
- Ability to support abstract jobs
- Ability to integrate node availability information from multiple sources
- Ability to augment node configuration and utilization information provided by a resource manager

However, the NATIVE interface may also have some drawbacks.

- No support for standard job submission languages
- Limited default configured and utilized resource tracking (additional resource tracking available with additional effort)

At a high level, the native interface works by launching threaded calls to perform standard resource manager activities such as managing resources and jobs. The desired calls are configured within Moab and used whenever an action or updated information is required.

## Configuring the Native Interface

Using the native interface consists of defining the interface type and location. As mentioned earlier, a single object may be fully defined by multiple interfaces simultaneously with each interface updating a particular aspect of the object.

## Configuring the Resource Manager

The Native resource manager must be configured using the [RMCFG](#) parameter. To specify the native interface, the **TYPE** attribute must be set to *NATIVE*.

```
RMCFG[local] TYPE=NATIVE
RMCFG[local] CLUSTERQUERYURL=exec:///tmp/query.sh
```

## Reporting Resources

To indicate the source of the resource information, the **CLUSTERQUERYURL** attribute of the [RMCFG](#) parameter should be specified. This attribute is specified as a URL where the protocols *FILE*, *EXEC* and *SQL* are allowed. If a protocol is not specified, the protocol *EXEC* is assumed.

Format	Description
<b>EXEC</b>	Execute the script specified by the URL path. Use the script stdout as data.
<b>FILE</b>	Load the file specified by the URL path. Use the file contents as data.
<b>SQL</b>	Load data directly from an SQL database using the FULL format described below.

Moab considers a NativeRM script to have failed if it returns with a non-zero exit code or if the [CHILDSTDERRCHECK](#) parameter is set and its appropriate conditions are met. In addition, the NativeRM script associated with a job submit URL will be considered as having failed if its standard output stream contains the text `ERROR`.

This simple example queries a file on the server for information about every node in the cluster. This differs from Moab remotely querying the status of each node individually.

```
RMCFG[local] TYPE=NATIVE
RMCFG[local] CLUSTERQUERYURL=file:///tmp/query.txt
```

## Generating Cluster Query Data

### Flat Cluster Query Data

If the *EXEC* or *FILE* protocol is specified in the **CLUSTERQUERYURL** attribute, the data should provide flat text strings indicating the state and attributes of the node. The format follows the [Moab Resource Manager Language Interface Specification](#) where attributes are delimited by white space rather than ';' (See [Resource Data Format](#)):

Describes any set of node attributes with format: `<NAME><ATTR>=<VAL> [<ATTR>=<VAL>] . . .`

<b>&lt;NAME&gt;</b>	Name of node
<b>&lt;ATTR&gt;</b>	Node attribute

<b>&lt;VAL&gt;</b>	Value of node attribute
--------------------	-------------------------

```
n17 CPROC=4 AMEMORY=100980 STATE=idle
```

## Interfacing to FLEXlm

Moab can interface with FLEXlm to provide scheduling based on [license](#) availability. Informing Moab of license dependencies can reduce the number of costly licenses required by your cluster by allowing Moab to intelligently schedule around license limitations.

Provided with Moab in the tools directory is a Perl script, `license.mon.flexLM.pl`. This script queries a FLEXlm license server and gathers data about available licenses. This script then formats this data for Moab to read through a native interface. This script can easily be used by any site to help facilitate FLEXlm integration--the only modification necessary to the script is setting the `@FLEXlmCmd` to specify the local command to query FLEXlm. To make this change, edit `license.mon.flexLM.pl` and, near the top of the file, look for the line:

```
my @FLEXlmCmd = ("SETME");
```

Set the `@FLEXlmCmd` to the appropriate value for your system to query a license server and license file (if applicable). If `lmutil` is not in the `PATH` variable, specify its full path. Using the `lmutil -a` argument will cause it to report all licenses. The `-c` option can be used to specify an optional license file.

To test this script, run it manually. If working correctly, it will produce output similar to the following:

```
> ./license.mon.flexLM.pl
GLOBAL UPDATETIME=1104688300 STATE=idle ARES=autoCAD:130,id1_mpeg:160
CRES=autoCAD:200,id1_mpeg:330
```

If the output looks incorrect, set the `$LOGLEVEL` variable inside of `license.mon.flexLM.pl`, run it again, and address the reported failure.

Once the license interface script is properly configured, the next step is to add a *license* native resource manager to Moab via the `moab.cfg` file:

```
RMCFG[FLEXlm] TYPE=NATIVE RESOURCETYPE=LICENSE
RMCFG[FLEXlm] CLUSTERQUERYURL=exec://$TOOLS_DIR/flexlm/license.mon.flexLM.pl
...
```

Once this change is made, restart Moab. The command `mdiag -R` can be used to verify that the resource manager is properly configured and is in the state `Active`. Detailed information regarding configured and utilized licenses can be viewed by issuing the `mdiag -n`. Floating licenses (non-node-locked) will be reported as belonging to the `GLOBAL` node.

**i** Due to the inherent conflict with the plus sign (+), the provided license manager script replaces occurrences of the plus sign in license names with the underscore symbol (`_`). This replacement requires that licenses with a plus sign in their names be requested with an underscore in place of any plus signs.

## Interfacing to Multiple License Managers Simultaneously

If multiple license managers are used within a cluster, Moab can interface to each of them to obtain the needed license information. In the case of FLEXlm, this can be done by making one copy of the `license.mon.flexLM.pl` script for each license manager and configuring each copy to point to a different license manager. Then, within Moab, create one native resource manager interface for each license manager and point it to the corresponding script as in the following example:

```

RMCFG [FLEXlm1]    TYPE=NATIVE RESOURCETYPE=LICENSE
RMCFG [FLEXlm1]    CLUSTERQUERYURL=exec://$TOOLSDIR/flexlm/license.mon.flexLM1.pl
RMCFG [FLEXlm2]    TYPE=NATIVE RESOURCETYPE=LICENSE
RMCFG [FLEXlm2]    CLUSTERQUERYURL=exec://$TOOLSDIR/flexlm/license.mon.flexLM2.pl
RMCFG [FLEXlm3]    TYPE=NATIVE RESOURCETYPE=LICENSE
RMCFG [FLEXlm3]    CLUSTERQUERYURL=exec://$TOOLSDIR/flexlm/license.mon.flexLM3.pl
...

```

**i** For an overview of license management, including job submission syntax, see [License Management](#).

**i** It may be necessary to increase the default limit, `MMAx_GRES`. See [Appendix D](#) for more implementation details.

## Interfacing to Nagios

Moab can interface with Nagios to provide scheduling based on network hosts and services availability.

Nagios installation and configuration documentation can be found at [Nagios.org](http://Nagios.org).

Provided with Moab in the tools directory is a Perl script, `node.query.nagios.pl`. This script reads the Nagios `status.dat` file and gathers data about network hosts and services. This script then formats data for Moab to read through a native interface. This script can be used by any site to help facilitate Nagios integration. To customize the data that will be formatted for Moab, make the changes in this script.

You may need to customize the associated configuration file in the `etc` directory, `config.nagios.pl`. The `statusFile` line in this script tells Moab where the Nagios `status.dat` file is located. Make sure that the path name specified is correct for your site. Note that the interval which Nagios updates the Nagios `status.dat` file is specified in the Nagios `nagios.cfg` file. Refer to Nagios documentation for further details.

To make these changes, familiarize yourself with the format of the Nagios `status.dat` file and make the appropriate additions to the script to include the desired Moab RM language (formerly WIKI) Interface attributes in the Moab output.

To test this script, run it manually. If working correctly, it will produce output similar to the following:

```

> ./node.query.nagios.pl
gateway STATE=Running
localhost STATE=Running CPULOAD=1.22 ADISK=75332

```

Once the Nagios interface script is properly configured, the next step is to add a Nagios native resource manager to Moab via the `moab.cfg` file:

```

RMCFG[nagios] TYPE=NATIVE
RMCFG[nagios] CLUSTERQUERYURL=exec://$TOOLS_DIR/node.query.nagios.pl
...

```

Once this change is made, restart Moab. The command `mdiag -R` can be used to verify that the resource manager is properly configured and is in the state `Active`. Detailed information regarding configured Nagios node information can be viewed by issuing the `mdiag -n -v`.

```

> mdiag -n -v
compute node summary
Name           State  Procs      Memory      Disk      Swap

WARNING: node 'localhost' has no configured processors
-----
Total Nodes: 2 (Active: 2 Idle: 0 Down: 0)

```

## Interfacing to Supermon

Moab can integrate with Supermon to gather additional information regarding the nodes in a cluster. A Perl script is provided in the tools directory that allows Moab to connect to the Supermon server. By default the Perl script assumes that Supermon has been started on port 2709 on localhost. These defaults can be modified by editing the respective parameter in `config.supermon.pl` in the `etc` directory. An example setup is shown below.

```

RMCFG[TORQUE] TYPE=pbs
RMCFG[supermon] TYPE=NATIVE CLUSTERQUERYURL=exec://$HOME/tools/node.query.supermon.pl

```

To confirm that Supermon is properly connected to Moab, issue `mdiag -R -v`. The output should be similar to the following example, specifically there are no errors about the `CLUSTERQUERYURL`.

```

diagnosing resource managers
RM[TORQUE] State: Active
  Type:          PBS ResourceType: COMPUTE
  Server:        keche
  Version:       '2.2.0-snap.200707181818'
  Job Submit URL: exec:///usr/local/bin/qsub
  Objects Reported: Nodes=3 (6 procs) Jobs=0
  Flags:        executionServer
  Partition:    TORQUE
  Event Management: EPORT=15004 (no events received)
  Note: SSS protocol enabled
  Submit Command: /usr/local/bin/qsub
  DefaultClass: batch
  RM Performance: AvgTime=0.26s MaxTime=1.04s (4 samples)
  RM Languages:  PBS
  RM Sub-Languages: -
RM[supermon] State: Active
  Type:          NATIVE ResourceType: COMPUTE
  Cluster Query URL: exec://$HOME/node.query.supermon.pl
  Objects Reported: Nodes=3 (0 procs) Jobs=0
  Partition:    supermon
  Event Management: (event interface disabled)
  RM Performance: AvgTime=0.03s MaxTime=0.11s (4 samples)
  RM Languages:  NATIVE
  RM Sub-Languages: -

Note: use 'mrmctl -f messages ' to clear stats/failures

```

Run the Perl script by itself. The script's results should look similar to this:

```

vm01 GMETRIC[CPULOAD]=0.571428571428571 GMETRIC[NETIN]=133 GMETRIC[NETOUT]=702 GMETRIC
[NETUSAGE]=835
vm02 GMETRIC[CPULOAD]=0.428571428571429 GMETRIC[NETIN]=133 GMETRIC[NETOUT]=687 GMETRIC
[NETUSAGE]=820
keche GMETRIC[CPULOAD]=31 GMETRIC[NETIN]=5353 GMETRIC[NETOUT]=4937 GMETRIC[NETUSAGE]
=10290

```

If the preceding functioned properly, issue a `checknode` command on one of the nodes that Supermon is gathering statistics for. The output should look similar to below.

```

node keche

## Configuring Resource Types

Native Resource managers can also perform special tasks when they are given a specific resource type. These types are specified using the [RESOURCE TYPE](#) attribute of the [RMCFG](#) parameter.

Type	Description
<b>COMPUTE</b>	Normal compute resources (no special handling)
<b>FS</b>	File system resource manager (see <a href="#">Multiple Resource Managers</a> for an example)
<b>LICENSE</b>	Software license manager (see <a href="#">Interfacing with FLEXlm</a> and <a href="#">License Management</a> )
<b>NETWORK</b>	Network resource manager
<b>PROV</b>	Provisioning resource manager. This is the RM Moab uses to modify the OS of a node (not a VM) and to power a node on or off.

## Creating New Tools to Manage the Cluster

Using the scripts found in the `$TOOLS DIR ($INSTDIR/tools)` directory as a template, new tools can be quickly created to monitor or manage most any resource. Each tool should be associated with a particular resource manager service and specified using one of the following resource manager URL attributes.

CLUSTERQUERYURL	
<b>Description</b>	Queries resource state, configuration, and utilization information for compute nodes, networks, storage systems, software licenses, and other resources. For more details, see <a href="#">RM configuration</a> .
<b>Output</b>	Node status and configuration for one or more nodes. See <a href="#">Resource Data Format</a> .
<b>Example</b>	<pre>RMCFG[v-stor] CLUSTERQUERYURL=exec://\$HOME/storquery.pl</pre> <p><i>Moab will execute the storquery.pl script to obtain information about 'v-stor' resources.</i></p>

JOBMODIFYURL	
<b>Description</b>	Modifies a job or application. For more details, see <a href="#">RM configuration</a> .

JOBMODIFYURL	
<b>Input</b>	<code>[-j &lt;JOBEXPR&gt;] [--s[et] --c[lear] --i[ncrement] --d[ecrement]] &lt;ATTR&gt; [=&lt;VALUE&gt;] [&lt;ATTR&gt;[=&lt;VALUE&gt;]]...</code>
<b>Example</b>	<pre>RMCFG[v-stor] JOBMODIFYURL=exec://\$HOME/jobmodify.pl</pre> <p><i>Moab will execute the jobmodify.pl script to modify the specified job.</i></p>

JOBREQUEUEURL	
<b>Description</b>	Requeues a job.
<b>Input</b>	<code>&lt;JOBID&gt;</code>
<b>Example</b>	<pre>RMCFG[v-stor] JOBREQUEUEURL=exec://\$HOME/requeue.pl</pre> <p><i>Moab will execute the requeue.pl script to requeue jobs.</i></p>

JOBRESUMEURL	
<b>Description</b>	Resumes a suspended job or application.
<b>Input</b>	<code>&lt;JOBID&gt;</code>
<b>Example</b>	<pre>RMCFG[v-stor] JOBRESUMEURL=exec://\$HOME/jobresume.pl</pre> <p><i>Moab will execute the jobresume.pl script to resume suspended jobs.</i></p>

JOBSTARTURL	
<b>Description</b>	Launches a job or application on a specified set of resources.

JOBSTARTURL	
<b>Input</b>	<JOBID><TASKLIST><USERNAME> [ARCH=<ARCH>] [OS=<OPSYS>] [IDATA=<STAGEINFILEPATH>[, <STAGEINFILEPATH>]...] [EXEC=<EXECUTABLEPATH>]
<b>Example</b>	<pre>RMCFG[v-stor] JOBSTARTURL=exec://\$HOME/jobstart.pl</pre> <p><i>Moab will execute the jobstart.pl script to execute jobs.</i></p>

JOBSUBMITURL	
<b>Description</b>	Submits a job to the resource manager, but it does not execute the job. The job executes when the <b>JOBSTARTURL</b> is called.
<b>Input</b>	[ACCOUNT=<ACCOUNT>] [ERROR=<ERROR>] [GATTR=<GATTR>] [GNAME=<GNAME>] [GRES=<GRES>:<Value>[, <GRES>:<Value>]*] [HOSTLIST=<HOSTLIST>] [INPUT=<INPUT>] [IWD=<IWD>] [NAME=<NAME>] [OUTPUT=<OUTPUT>] [RCLASS=<RCLASS>] [REQUEST=<REQUEST>] [RFEATURES=<RFEATURES>] [RMFLAGS=<RMFLAGS>] [SHELL=<SHELL>] [TASKLIST=<TASKLIST>] [TASKS=<TASKS>] [TEMPLATE=<TEMPLATE>] [UNAME=<UNAME>] [VARIABLE=<VARIABLE>] [WCLIMIT=<WCLIMIT>] [ARGS=<Value>[ <Value>]*]
	<div style="border: 1px solid black; padding: 5px;"> <p><b>i</b> ARGS must be the last submitted attribute because there can be multiple space-separated values for ARGS.</p> </div>
<b>Example</b>	<pre>RMCFG[v-stor] JOBSUBMITURL=exec://\$HOME/jobsubmit.pl</pre> <p><i>Moab submits the job to the jobsubmit.pl script for future job execution.</i></p>

JOBSUSPENDURL	
<b>Description</b>	Suspends in memory an active job or application.
<b>Input</b>	<JOBID>
<b>Example</b>	<pre>RMCFG[v-stor] JOBSUSPENDURL=exec://\$HOME/jobsuspend.pl</pre> <p><i>Moab will execute the jobsuspend.pl script to suspend active jobs.</i></p>

NODEMODIFYURL	
<b>Description</b>	Provide method to dynamically modify/provision compute resources including operating system, applications, queues, node features, power states, etc.
<b>Input</b>	<NODEID>[, <NODEID>] [--force] [--set <ATTR>=<VAL> --clear <ATTR>} ATTR is one of the node attributes listed in <a href="#">Resource Data Format</a>
<b>Example</b>	<pre>RMCFG[warewulf] NODEMODIFYURL=exec://\$HOME/provision.pl</pre> <p><i>Moab will reprovision compute nodes using the provision.plscript.</i></p>

NODEPOWERURL	
<b>Description</b>	Allows Moab to issue IPMI power commands.
<b>Input</b>	<NODEID>[, <NODEID>] ON   OFF
<b>Example</b>	<pre>RMCFG[node17rm] NODEPOWERURL=exec://\$TOOLS DIR/ipmi.power.pl</pre> <p><i>Moab will issue a power command contained in the ipmi.power.plscript.</i></p>

SYSTEMMODIFYURL	
<b>Description</b>	Provide method to dynamically modify aspects of the compute environment which are directly associated with cluster resources. For more details, see <a href="#">RM configuration</a> .

SYSTEMQUERYURL	
<b>Description</b>	Provide method to dynamically query aspects of the compute environment which are directly associated with cluster resources. For more details, see <a href="#">RM configuration</a> .
<b>Input</b>	default <ATTR> ATTR is one of images
<b>Output</b>	<STRING>

## SYSTEMQUERYURL

### Example

```
RMCFG[warewulf] SYSTEMQUERYURL=exec://$HOME/checkimage.pl
```

*Moab will load the list of images available from warewulf using the `checkimage.pl` script.*

## WORKLOADQUERYURL

### Description:

Provide method to dynamically query the system workload (jobs, services, etc.) of the compute environment which are associated with managed resources.

**i** Job/workload information should be reported back from the URL (script, file, web service, etc.) using the [Moab RM language](#) (formerly WIKI).

For more details, see [RM configuration](#).

### Output:

<STRING>

### Example:

```
RMCFG[xt] WORKLOADQUERYURL=exec://$HOME/job.query.xt3.pl
```

*Moab will load job/workload information by executing the `job.query.xt3.pl` script.*

## Utilizing Multiple Resource Managers

### Multi-RM Overview

In many instances a site may have certain resources controlled by different resource managers. For example, a site may use a particular resource manager for licensing software for jobs, another resource manager for managing file systems, another resource manager for job control, and another for node monitoring. Moab can be configured to communicate with each of these resource managers, gathering all their data and incorporating such into scheduling decisions. With a more distributed approach to resource handling, failures are more contained and scheduling decisions can be more intelligent.

## Configuring Multiple Independent Resource Manager Partitions

Moab must know how to communicate with each resource manager. In most instances, this is simply done by configuring a [query command](#).

## Migrating Jobs between Resource Managers

With multi-resource manager support, a job may be submitted either to a local resource manager queue or to the Moab global queue. In most cases, submitting a job to a resource manager queue constrains the job to only run within the resources controlled by that resource manager. However, if the job is submitted to the Moab global queue, it can use resources of any active resource manager. This is accomplished through job translation and staging.

When Moab evaluates resource availability, it determines the cost in terms of both data and job staging. If staging a job's executable or input data requires a significant amount of time, Moab integrates data and compute resource availability to determine a job's earliest potential start time on a per resource manager basis and makes an optimal scheduling decision accordingly. If the optimal decision requires a data stage operation, Moab reserves the required compute resources, stages the data, and then starts the job when the required data and compute resources are available.

## Aggregating Information into a Cohesive Node View

Using the native interface, Moab can actually perform most of these functions without the need for an external resource manager. First, configure the native resource managers:

```
RMCFG[base]      TYPE=PBS
RMCFG[network]  TYPE=NATIVE
RMCFG[network]  CLUSTERQUERYURL=/tmp/network.sh
RMCFG[fs]       TYPE=NATIVE
RMCFG[fs]       CLUSTERQUERYURL=/tmp/fs.sh
```

The network script can be as simple as the following:

```
> _RX=`/sbin/ifconfig eth0 | grep "RX by" | cut -d: -f2 | cut -d' ' -f1`; \
> _TX=`/sbin/ifconfig eth0 | grep "TX by" | cut -d: -f3 | cut -d' ' -f1`; \
> echo `hostname` GMETRIC[netusage]=`echo "$_RX + $_TX" | bc`;
```

The preceding script would output something like the following:

```
node01 GMETRIC[netusage]=10928374
```

Moab grabs information from each resource manager and includes its data in the final view of the node.

```

> checknode node01
node node01
State: Running (in current state for 00:00:20)
Configured Resources: PROCS: 2 MEM: 949M SWAP: 2000M disk: 1000000
Utilized Resources: SWAP: 9M
Dedicated Resources: PROCS: 1 disk: 1000
Opsys: Linux-2.6.5-1.358 Arch: linux
Speed: 1.00 CPUload: 0.320
Location: Partition: DEFAULT Rack/Slot: NA
Network Load: 464.11 b/s
Network: DEFAULT
Features: fast
Classes: [batch 1:2][serial 2:2]
Total Time: 00:30:39 Up: 00:30:39 (100.00%) Active: 00:09:57 (32.46%)
Reservations:
  Job '5452'(x1) -00:00:20 -> 00:09:40 (00:10:00)
JobList: 5452

```

Notice that the Network Load is now being reported along with disk usage.

### Example File System Utilization Tracker (per user)

The following configuration can be used to track file system usage on a per user basis:

```

.....
RMCFG[file] TYPE=NATIVE
RMCFG[file] RESOURCETYPE=FS
RMCFG[file] CLUSTERQUERYURL=/tmp/fs.pl
.....

```

Assuming that `/tmp/fs.pl` outputs something of the following [format](#):

```

DEFAULT STATE=idle AFS=<fs id="user1" size="789456"></fs><fs
id="user2" size="123456"></fs>

```

This will track disk usage for users `user1` and `user2` every 24 hours.

## License Management

- [License Management Overview](#)
- [Controlling and Monitoring License Availability](#)
- [Requesting Licenses w/in Jobs](#)

### License Management Overview

Software license management is typically enabled in one of two models: node-locked and floating. Under a node-locked license, use of a given application is constrained to certain hosts. For example, `node013` may support up to two simultaneous jobs accessing application `matlab`. In a floating license model, a limited number of software licenses are made available cluster wide, and these licenses may be used on any combination of compute hosts. In each case, these licenses are consumable and application access is denied once they are gone.

Moab supports both node-locked and floating license models and even allows mixing the two models simultaneously. Moab monitors license usage and only launches an application when required software license availability is guaranteed. In addition, Moab also reserves licenses in conjunction with future jobs to ensure these jobs can run at the appropriate time.

**i** By default, Moab supports up to 128 independent license types.

**i** Moab license recognition is case insensitive. This means that two licenses with the same spelling and different capitalization are still recognized as the same license. When this occurs, Moab considers the license invalid.

## Controlling and Monitoring License Availability

Moab can use one of three methods to determine license availability. These methods include locally specifying [consumable generic resources](#), obtaining consumable generic resource information from the [resource manager](#), and interfacing directly with a [license manager](#).

### Local Consumable Resources

Both node-locked and floating licenses can be locally specified within Moab using the [NODECFG](#) parameter. In all cases, this is accomplished by associating the license with a node using the [GRES](#) (or generic resource) attribute. If floating, the total cluster-wide license count should be associated with the GLOBAL node. If node-locked, the per node license count should be associated with each compute host (or globally using the *DEFAULT* node). For example, if a site has two node-locked licenses for application *EvalA* and six floating licenses for application *EvalB*, the following configuration could be used:

```
NODECFG [node001]  GRES=EvalA:2
NODECFG [node002]  GRES=EvalA:2
NODECFG [GLOBAL]   GRES=EvalB:6
...
```

### Resource Manager Based Consumable Resources

Some resource managers support the ability to define and track generic resource usage at a per node level. In such cases, support for node-locked licenses may be enabled by specifying this information within the resource manager. Moab automatically detects and schedules these resources. For example, in the case of [TORQUE](#), this can be accomplished by adding generic resource specification lines to the [MOM configuration](#) file.

### Interfacing to an External License Manager

Moab may also obtain live software license information from a running license manager. Direct interfaces to supported license managers such as FlexLM may be created using the [Native Resource Manager](#) feature. A complete example on interfacing to an external license manager is provided in the [FLEXlm](#) section of the native resource manager overview.

### Interfacing to Multiple License Managers

Moab may interface to multiple external license managers simultaneously simply by defining additional native resource manager interfaces. See the FLEXlm [Native Resource Manager Overview](#) for more information.

## Requesting Licenses within Jobs

Requesting use of software licenses within jobs is typically done in one of two ways. In most cases, the native resource manager job submission language provides a direct method of license specification; for example, in the case of [TORQUE](#), OpenPBS, or PBSPro, the [software](#) argument could be specified using the format `<SOFTWARE_NAME>[+<LICENSE_COUNT>]` as in the following example:

```
> qsub -l nodes=2,software=blast cmdscript.txt
```

**i** The license count is a job total, not a per task total, and the license count value defaults to 1.

An alternative to direct specification is the use of the Moab [resource manager extensions](#). With these extensions, licenses can be requested as generic resources, using the [GRES](#) attribute. The job in the preceding example could also be requested using the following syntax:

```
> qsub -l nodes=2 -W x=GRES:blast cmdscript.txt
```

In each case, Moab automatically determines if the software licenses are node-locked or floating and applies resource requirements accordingly.

If a job requires multiple software licenses, whether of the same or different types, a user would use the following syntax:

```
> qsub -l nodes=2 -W x=GRES:blast+2 cmdscript.txt # two 'blast' licenses required
> qsub -l nodes=2 -W x=GRES:blast+2%bkeep+3 cmdscript.txt # two 'blast' and three
'bkeep' licenses are required
```

- Multi-Cluster License Sharing with [Moab Workload Manager for Grids](#) Interfaces

## Resource Provisioning

- [Resource Provisioning Overview](#)
- [Configuring Provisioning](#)

## Resource Provisioning Overview

When processing a resource request, Moab attempts to match the request to an existing available resource. However, if the scheduler determines that the resource is not available or will not be available

due to load or policy for an appreciable amount of time, it can select a resource to modify to meet the needs of the current requests. This process of modifying resources to meet existing needs is called provisioning.

Currently, there are two types of provisioning supported: operating system (OS) and application. As its name suggests, OS provisioning allows the scheduler to modify the operating system of an existing compute node while application level provisioning allows the scheduler to request that a software application be made available on a given compute node. In each case, Moab evaluates the costs of making the change in terms of time and other resources consumed before making the decision. Only if the benefits outweigh the costs will the scheduler initiate the change required to support the current workload.

Preemption (requeueing) does not work with dynamic provisioning.

## Configuring Provisioning

Enabling provisioning consists of configuring an interface to a provisioning manager, specifying which nodes can take advantage of this service, and what the estimated cost and duration of each change will be. This interface can be used to contact provisioning software such as [xCat](#) or HP's Server Automation tool. Additionally, locally developed systems can be interfaced via a script or web service.

# Managing Networks

## Network Management Overview

Network resources can be tightly integrated with the rest of a compute cluster using the Moab multi-resource manager management interface. This interface has the following capabilities:

- Dynamic per job and per partition [VLAN](#) creation and management
- Monitoring and reporting of network health and failure events
- Monitoring and reporting of network load
- Creation of subnets with guaranteed performance criteria
- Automated workload-aware configuration and router maintenance
- Intelligent network-aware scheduling algorithms

## Dynamic VLAN Creation

Most sites using dynamic VLAN's operate under the following assumptions:

- Each compute node has access to two or more networks, one of which is the compute network, and another which is the administrator network.
- Each compute node may only access other compute nodes via the compute network.
- Each compute node may only communicate with the head node via the administrator network.
- Logins on the head node may not be requested from a compute node.

In this environment, organizations may choose to have VLANs automatically configured that encapsulate individual jobs. These VLAN's essentially disconnect the job from either incoming or outgoing communication with other compute nodes.

## Configuring VLANs

Automated VLAN management can be enabled by setting up a network resource manager that supports dynamic VLAN configuration and a QoS to request this feature. The example configuration highlights this setup:

```
...
RMCFG[cisco] TYPE=NATIVE RESOURCETYPE=NETWORK FLAGS=VLAN
RMCFG[cisco] CLUSTERQUERYURL=exec://$TOOLSDIR/node.query.cisco.pl
RMCFG[cisco] SYSTEMMODIFYURL=exec://$TOOLSDIR/system.modify.cisco.pl
QOSCFG[netsecure] SECURITY=VLAN
```

## Requesting a VLAN

VLANs can be requested on a per job basis directly using the associated resource manager extension or indirectly by requesting a QoS with a VLAN security requirement.

```
> qsub -l nodes=256,walltime=24:00:00,qos=netsecure biojob.cmd
143325.umc.com submitted
```

## Network Load and Health Monitoring

Network-level load and health monitoring is enabled by supporting the cluster query action in the network resource manager and specifying the appropriate **CLUSTERQUERYURL** attribute in the associated resource manager interface. Node (virtual node) query commands ([mnodectl](#), [checknode](#)) can be used to view this load and health information that will also be correlated with associated workload and written to persistent accounting records. Network load and health based event information can also be fed into [generic events](#) and used to drive appropriate event based [triggers](#).

At present, load and health attributes such as fan speed, temperature, port failures, and various core switch failures can be monitored and reported. Additional failure events are monitored and reported as support is added within the network management system.

## Providing Per-QoS and Per-Job Bandwidth Guarantees

Intra-job bandwidth guarantees can be requested on a per job basis using the [BANDWIDTH](#) resource manager extensions. If specified, Moab does not allow a job to start unless these criteria can be satisfied via proper resource allocation or dynamic network partitions. As needed, Moab makes future resource reservations to be able to guarantee required allocations.

**Example 3-147:**

```
> qsub -l nodes=24,walltime=8:00:00,bandwidth=1000 hex3chem.cmd
job 44362.qjc submitted
```

**i** If dynamic network partitions are enabled, a **NODEMODIFYURL** attribute must be properly configured to drive the network resource manager. See [Native Resource Manager Overview](#) for details.

## Enabling Workload-Aware Network Maintenance

Network-aware maintenance is enabled by supporting the modify action in the network resource manager and specifying the appropriate **NODEMODIFYURL** attribute in the associated resource manager interface. Administrator resource management commands, ([mnodectl](#) and [mrmctl](#)), will then be routed directly through the resource manager to the network management system. In addition, reservation and real-time generic event and generic metric [triggers](#) can be configured to intelligently drive these facilities for maintenance and auto-recovery purposes.

Maintenance actions can include powering on and off the switch as well as rebooting/recycling all or part of the network. Additional operations are enabled as supported by the underlying networks.

## Creating a Resource Management Interface for a New Network

Many popular networks are supported using interfaces provided in the Moab `tools` directory. If a required network interface is not available, a new one can be created using the following guidelines:

### General Requirements

In all cases, a network resource manager should respond to a cluster query request by reporting a single node with a node name that will not conflict with any existing compute nodes. This node should report as a minimum the **state** attribute.

### Monitoring Load

Network load is reported to Moab using the generic resource bandwidth. For greatest value, both configured and used bandwidth (in megabytes per second) should be reported as in the following example:

```
force10 state=idle ares=bandwidth:5466 cres=bandwidth:10000
```

### Monitoring Failures

Network warning and failure events can be reported to Moab using the **gevent** metric. If automated responses are enabled, embedded epochtime information should be included.

```
force10 state=idle gevent[checksum]='ECC failure detected on port 13'
```

## Controlling Router State

Router power state can be controlled as a system modify interface is created that supports the commands on, off, and reset.

## Creating VLANs

VLAN creation, management, and reporting is more advanced requiring persistent VLAN ID tracking, global pool creation, and other features. Use of existing routing interface tools as templates is highly advised. VLAN management requires use of both the cluster query interface and the system modify interface.

## Per-Job Network Monitoring

It is possible to gather network usage on a per job basis using the [Native](#) Interface. When the native interface has been configured to report [netin](#) and [netout](#) Moab automatically gathers this data through the life of a job and reports total usage statistics upon job completion.

```
...
node99 netin=78658 netout=1256
...
```

This information is visible to users and administrators via command-line utilities, the web portal, and the desktop graphical interfaces.

- [Configuring Moab's IPMI Tools](#)
- [Configuring Moab](#)
- [Ensuring Proper Setup](#)

## IPMI Overview

The Intelligent Platform Management Interface (IPMI) specification defines a set of common interfaces system administrators can use to monitor system health and manage the system. The IPMI interface can monitor temperature and other sensor information, query platform status and power-on/power-off compute nodes. As IPMI operates independently of the node's OS interaction with the node can happen

even when powered down. Moab can use IPMI to monitor temperature information, check power status, power-up, power-down, and reboot compute nodes.

## Node IPMI Configuration

IPMI must be enabled on each node in the compute cluster. This is usually done either through the node's BIOS or by using a boot CD containing IPMI utilities provided by the manufacturer. With regard to configuring IPMI on the nodes, be sure to enable IPMI-over-LAN and set a common login and password on all the nodes. Additionally, you must set a unique IP address for each node's BMC. Take note of these addresses as you will need them when reviewing the [Creating the IPMI BMC-Node Map File](#) section.

## Installing IPMITool

[IPMITool](#) is an open-source tool used to retrieve sensor information from the IPMI Baseboard Management Controller (BMC) or to send remote chassis power control commands. The IPMITool developer provides Fedora Core binary packages as well as a source tarball on the [IPMITool download page](#). Download and install IPMITool on the Moab head node and make sure the `ipmitool` binary is in the current shell PATH.

Proper IPMI setup and IPMITool configuration can be confirmed by issuing the following command on the Moab head node.

```
> ipmitool -I lan -U username -P password -H BMC IP chassis status
```

The output of this command should be similar to the following.

```
System Power          : off
Power Overload        : false
Power Interlock       : inactive
Main Power Fault      : false
Power Control Fault   : false
Power Restore Policy  : previous
Last Power Event      :
Chassis Intrusion     : inactive
Front-Panel Lockout   : inactive
Drive Fault           : false
Cooling/Fan Fault     : false
```

## Creating the IPMI BMC-Node Map File [OPTIONAL]

Since the BMC can be controlled via LAN, it is possible for the BMC to have its own unique IP address. Since this IP address is separate from the IP address of the node, a simple mapping file is required for Moab to know each node's BMC address. The file is a flat text file and should be stored in the Moab home directory. If a mapping file is needed, specify the name in the `config.ipmi.pl` configuration file in the `etc/` directory. The following is an example of the mapping file:

```
#<NodeID> <BMC IP>
node01 10.10.10.101
node02 10.10.10.102
node03 10.10.10.103
node04 10.10.10.104
node05 10.10.10.105
# NodeID = the name of the nodes returned with "mdiag -n"
# BMC IP = the IP address of the IPMI BMC network interface
```

Note that only the nodes specified in this file are queried for IPMI information. Also note that the mapping file is disabled by default and the nodes that are returned from Moab with `mdiag -n` are the ones that are queried for IPMI sensor data.

## Configuring the Moab IPMI Tools

The `tools/` subdirectory in the install directory already contains the Perl scripts needed to interface with IPMI. The following is a list of the Perl scripts that should be in the `tools/` directory; confirm these are present and executable.

```
ipmi.mon.pl      # The daemon front-end called by Moab
ipmi.power.pl   # The power control script called by Moab
__mon.ipmi.pl   # The IPMI monitor daemon that updates and caches IPMI data from nodes
```

Next, a few configuration settings need to be adjusted in the `config.ipmi.pl` file found in the `etc` subdirectory. The IPMI-over-LAN username and password need to be set to the values that were set in the [Node IPMI Configuration](#) section. Also, the IPMI query daemon's polling interval can be modified by adjusting `$pollInterval`. This specifies how often the IPMI-enabled nodes are queried to retrieve sensor data.

## Configuring Moab

To allow Moab to use the IPMI tools, a native resource manager is configured. To do this, the following lines must be added to `moab.cfg`:

```
...
# IPMI - Node monitor script
RMCFG[ipminative] TYPE=NATIVE CLUSTERQUERYURL=exec://$TOOLSDIR/ipmi.mon.pl
...
```

Next, the following lines can be added to allow Moab to issue IPMI power commands.

```
...
# IPMI - Power on/off/reboot script
RMCFG[ipminative] NODEPOWERURL=exec://$TOOLSDIR/ipmi.power.pl
...
```

Moab can be configured to perform actions based on sensor data. For example, Moab can shut down a compute node if its CPU temperature exceeds 100 degrees Celsius, or it can power down idle compute nodes if workload is low. Generic event thresholds are used to tell Moab to perform certain duties given certain conditions. The following example is of a way for Moab to recognize it should power off a compute node if its CPU0 temperature exceeds 100 degrees Celsius.

```
...
# IPMI - Power off compute node if its CPU0 temperature exceeds 100 degrees Celsius.
GEVENTCFG[CPU0_TEMP>100] action=off
...
```

## Ensuring Proper Setup

Once the preceding steps have been taken, Moab should be started as normal. The IPMI monitoring daemon should start automatically, which can be confirmed with the following:

```
moab@headnode:~/ $ ps aux | grep _mon
moab 11444 0.0 0.3 6204 3172 pts/3 S 10:54 0:00 /usr/bin/perl -w
/opt/moab/tools/_mon.ipmi.pl --start
```

After a few minutes, IPMI data should be retrieved and cached. This can be confirmed with the following command:

```
moab@headnode:~/ $ cat spool/ipmicache.gm
node01 GMETRIC[CPU0_TEMP]=49
node01 GMETRIC[CPU1_TEMP]=32
node01 GMETRIC[SYS_TEMP]=31
node01 POWER=ON
```

Finally, issue the following to ensure Moab is grabbing the IPMI data. Temperature data should be present in the Generic Metrics row.

```
moab@headnode:~/ $ checknode node01
node node01
State: Idle (in current state for 00:03:12)
Configured Resources: PROCS: 1 MEM: 2000M SWAP: 3952M DISK: 1M
Utilized Resources: ---
Dedicated Resources: ---
Generic Metrics: CPU0_TEMP=42.00,CPU1_TEMP=30.00,SYS_TEMP=29.00
...
```

## Resource Manager Translation

- [Translation Overview](#)
- [Translation Enablement Steps](#)

### Translation Overview

Resource manager translation allows end-users to continue to use existing job command scripts and familiar job management and resource query commands. This is accomplished by emulating external commands, routing the underlying queries to Moab, and then formatting the responses in a familiar manner. Using translation, job submission clients, job query clients, job control clients, and resource query clients can be emulated making switching from one resource manager to another transparent and preserving investment in legacy scripts, tools, and experience.

## Translation Enablement Steps

To enable translation, you must:

- Edit the Moab tools configuration file.
- Copy, rename, and link the emulation scripts to a shorter, easier-to-use name.

### Configure Translation Tools

Located in the `$MOABHOMEDIR/etc` directory are tools-specific configuration files. For each resource manager that has installed translation tools, edit the Moab tools configuration file in the `etc` directory. For example, if enabling LSF translation, do the following:

```
> vi $MOABHOMEDIR/etc/config.moab.pl
# Set the PATH to include directories for moab client commands - mjobctl, etc.
$ENV{PATH} = "/opt/moab/bin:$ENV{PATH}";
```

### Add Translation Tools

In a directory accessible to users, create links to (or copy) the emulation scripts you want your users to use. For example, the emulation script `tools/bjobs.lsf.pl` could be copied to `bin/bjobs`, or, a symbolic link could be created in `bin/bjobs` that points to `tools/bjobs.lsf.pl`.

```
> ln -s tools/bjobs.lsf.pl bin/bjobs
> ln -s tools/bhosts.lsf.pl bin/bhosts
```

## Troubleshooting and System Maintenance

- [Internal Diagnostics/Diagnosing System Behavior and Problems on page 673](#)
- [Logging Overview on page 676](#)
- [Object Messages on page 682](#)
- [Notifying Administrators of Failures on page 684](#)
- [Issues with Client Commands on page 685](#)
- [Tracking System Failures on page 686](#)
- [Problems with Individual Jobs on page 688](#)
- [Diagnostic Scripts on page 689](#)

### Internal Diagnostics/Diagnosing System Behavior and Problems

Moab provides a number of commands for diagnosing system behavior. These diagnostic commands present detailed state information about various aspects of the scheduling problem, summarize

performance, and evaluate current operation reporting on any unexpected or potentially erroneous conditions found. Where possible, Moab's diagnostic commands even correct detected problems if desired.

At a high level, the diagnostic commands are organized along functionality and object based delineations. Diagnostic commands exist to help prioritize workload, evaluate fairness, and determine effectiveness of scheduling optimizations. Commands are also available to evaluate reservations reporting state information, potential reservation conflicts, and possible corruption issues. Scheduling is a complicated task. Failures and unexpected conditions can occur as a result of resource failures, job failures, or conflicting policies.

Moab's diagnostics can intelligently organize information to help isolate these failures and allow them to be resolved quickly. Another powerful use of the diagnostic commands is to address the situation in which there are no hard failures. In these cases, the jobs, compute nodes, and scheduler are all functioning properly, but the cluster is not behaving exactly as desired. Moab diagnostics can help a site determine how the current configuration is performing and how it can be changed to obtain the desired behavior.

## The mdiag Command

The cornerstone of Moab's diagnostics is the [mddiag](#) command. This command provides detailed information about scheduler state and also performs a large number of internal sanity checks presenting problems it finds as warning messages.

Currently, the `mddiag` command provides in-depth analysis of the following objects and subsystems:

Object/Subsystem	mddiag Flag	Use
<b>Account</b>	-a	Shows detailed account configuration information.
<b>Blocked</b>	<a href="#">-b</a>	Indicates why blocked (ineligible) jobs are not allowed to run.
<b>Class</b>	-c	Shows detailed class configuration information.
<b>Config</b>	-C	Shows configuration lines from <code>moab.cfg</code> and whether or not they are valid.
<b>FairShare</b>	<a href="#">-f</a>	Shows detailed fairshare configuration information as well as current fair-share usage.
<b>Group</b>	-g	Shows detailed group information.
<b>Job</b>	<a href="#">-j</a>	Shows detailed job information. Reports corrupt job attributes, unexpected states, and excessive job failures.
<b>Frame/Rack</b>	-m	Shows detailed frame/rack information.

Object/Subsystem	mdiag Flag	Use
<b>Node</b>	-n	Shows detailed node information. Reports unexpected node states and resource allocation conditions.
<b>Priority</b>	<u>-p</u>	Shows detailed job priority information including priority factor contributions to all idle jobs.
<b>QoS</b>	-q	Shows detailed QoS information.
<b>Reservation</b>	<u>-r</u>	Shows detailed reservation information. Reports reservation corruption and unexpected reservation conditions.
<b>Resource Manager</b>	<u>-R</u>	Shows detailed resource manager information. Reports configured and detected state, configuration, performance, and failures of all configured resource manager interfaces.
<b>Standing Reservations</b>	<u>-s</u>	Shows detailed standing reservation information. Reports reservation corruption and unexpected reservation conditions.
<b>Scheduler</b>	<u>-S</u>	Shows detailed scheduler state information. Indicates if scheduler is stopped, reports status of grid interface, and identifies and reports high-level scheduler failures.
<b>Partition</b>	-t	Shows detailed partition information.
<b>User</b>	<u>-u</u>	Shows detailed user information.

## Other Diagnostic Commands

Beyond `mdiag`, the [checkjob](#) and [checknode](#) commands also provide detailed information and sanity checking on individual jobs and nodes respectively. These commands can indicate why a job cannot start, which nodes can be available, and information regarding the recent events impacting current job or nodes state.

## Using Moab Logs for Troubleshooting

Moab logging is extremely useful in determining the cause of a problem. Where other systems may be cursed for not providing adequate logging to diagnose a problem, Moab may be cursed for the opposite reason. If the logging level is configured too high, huge volumes of log output may be recorded, potentially obscuring the problems in a flood of data. Intelligent searching combined with the use of the [LOGLEVEL](#) and [LOGFACILITY](#) parameters can mine out the needed information. Key information associated with various problems is generally marked with the keywords WARNING, ALERT, or ERROR. See the [Logging Overview](#) for further information.

## Automating Recovery Actions after a Failure

The [RECOVERYACTION](#) parameter of [SCHEDCFG](#) can be used to control scheduler action in the case of a catastrophic internal failure. Valid actions include die, ignore, restart, and trap.

Recovery Mode	Description
<b>die</b>	Moab will exit and, if core files are externally enabled, create a core file for analysis (This is the default behavior.).
<b>ignore</b>	Moab will ignore the signal and continue processing. This may cause Moab to continue running with corrupt data which may be dangerous. Use this setting with caution.
<b>restart</b>	When a SIGSEGV is received, Moab will relaunch using the current checkpoint file, the original launch environment, and the original command line flags. The receipt of the signal will be logged but Moab will continue scheduling. Because the scheduler is restarted with a new memory image, no corrupt scheduler data should exist. One caution with this mode is that it may mask underlying system failures by allowing Moab to overcome them. If used, the event log should be checked occasionally to determine if failures are being detected.
<b>trap</b>	When a SIGSEGV is received, Moab stays alive but enters diagnostic mode. In this mode, Moab stops scheduling but responds to client requests allowing analysis of the failure to occur using internal diagnostics available via the <a href="#">mdiag</a> command.

## Logging Overview

The Moab Workload Manager provides the ability to produce detailed logging of all of its activities. This is accomplished using verbose server logging, event logging, and system logging facilities.

- [Log Facility Configuration](#) on page 677
- [Standard Log Format](#) on page 678
- [Searching Moab Logs](#) on page 679
- [Event Logs](#) on page 679
  - [Event Log Format](#) on page 679
  - [Exporting Events in Real-Time](#) on page 681
- [Logging Overview](#) on page 676
- [Enabling Syslog](#) on page 681
- [Managing Verbosity](#) on page 682

## Log Facility Configuration

The [LOGFILE](#) and/or [LOGDIR](#) parameters within the `moab.cfg` file specify the destination of this logging information. Logging information will be written in the file `<MOABHOMEDIR>/<LOGDIR><LOGFILE>` unless `<LOGDIR>` or `<LOGFILE>` is specified using an absolute path. If the log file is not specified or points to an invalid file, all logging information is directed to `STDERR`. However, because of the sheer volume of information that can be logged, it is not recommended that this be done while in production. By default, [LOGDIR](#) and [LOGFILE](#) are set to `log` and `moab.log` respectively, resulting in scheduler logs being written to `<MOABHOMEDIR>/log/moab.log`.

The parameter [LOGFILEMAXSIZE](#) determines how large the log file is allowed to become before it is rolled and is set to 10 MB by default. When the log file reaches this specified size, the log file is rolled. The parameter [LOGFILEROLLDEPTH](#) controls the number of old logs maintained and defaults to 3. Rolled log files have a numeric suffix appended indicating their order.

The parameter [LOGLEVEL](#) controls the verbosity of the information. [LOGLEVEL](#) values between 1 and 6 are used to control the amount of information logged with 1 being the least verbose (recording only the worst events that occur) while 6 is the most verbose. The amount of information provided at each log level is approximately an order of magnitude greater than what is provided at the log level immediately below it. The first three log levels (1-3) measure the severity of an event and the rest of the levels (4-6) measure verbosity and how much detail is logged.

If a problem is detected, you may want to increase the [LOGLEVEL](#) value to get more details. However, doing so will cause the logs to roll faster and will also cause a lot of possibly unrelated information to clutter up the logs. Also be aware of the fact that high [LOGLEVEL](#) values results in large volumes of possibly unnecessary file I/O to occur on the scheduling machine. Consequently, it is not recommended that high [LOGLEVEL](#) values be used unless tracking a problem or similar circumstances warrant the I/O cost.

If high log levels are desired for an extended period of time and your Moab home directory is located on a network file system, performance may be improved by moving your log directory to a local file system using the [LOGDIR](#) parameter.

Visibility	LOGLEVEL value	Description
FATAL	n/a	FATAL events are errors that render part of the system unusable. An example would be failing to create a connection to a database. FATAL event logging cannot be suppressed.
ERROR	1	This is the minimum level of logging that Moab accepts. ERROR events are problems that occur in circumstances where a user's goal has failed. For example, when a user submits a job but the job fails to start, the cause of the failure will be an error. Not all failures are ERROR events, such as failing to open a file because it does not exist. Like FATAL events, ERROR events cannot be suppressed.

Visibility	LOGLEVEL value	Description
WARNING	2	WARNING events are problems that have user consequences that Moab cannot easily evaluate. Their impact has to be judged by users. An example would be if a user job asked Moab to copy a folder and Moab was unable to copy one file in the folder because the file was a temp file and was opened exclusively by another process. The user might consider that failure irrelevant. WARNING event logging can be suppressed at user discretion.
INFO	3	INFO events are occurrences that might be interesting but do not represent problems. An example would be the transition to a "terminated phase" when a service is successfully terminated. This event is potentially interesting to both human and automated observers but is not a problem in any sense.
TRACE1	4	These log levels are generally not used in production environments. They are used mainly by Adaptive Computing developers to analyze various issues. Setting LOGLEVEL to one of these levels could seriously impact performance due to Moab attempting to write to the log potentially hundreds of times per second.
TRACE2	5	
TRACE3	6	

A final log related parameter is **LOGFACILITY**. This parameter can be used to focus logging on a subset of scheduler activities. This parameter is specified as a list of one or more scheduling facilities as listed in the parameters documentation.

Example 3-148:

```
# moab.cfg
# allow up to 30 100MB logfiles
LOGLEVEL          3
LOGDIR            /var/tmp/moab
LOGFILEMAXSIZE   100000000
LOGFILEROLLDEPTH 30
```

## Standard Log Format

Each log event line follows a standard, tab-delimited log format:

**timestamp** <tab> **thread ID** <tab> **visibility** <tab> **origin** <tab> **event code** <tab> **scope IDs** <tab> **message**

- **timestamp:** Timestamps are given in local time, in [ISO 8601 format](#), with a 4-digit timezone offset suffix. For example, 2012-01-27T15:18:30.000-0700.
- **thread ID:** The ID of the thread that is producing the log output.
- **visibility:** Visibility is either a severity (FATAL, ERROR, WARNING, INFO) or a trace level (TRACE1, TRACE2, TRACE3).
- **origin:** Origin is where the log event came from.

- **event code:** The event code provides a way to determine what kind of event happened. For a full list of event codes, see [Event Dictionary on page 1098](#).
- **scope IDs:** The scope ID associates the event with a specific job or service.
- **message:** Messages can give details about the event and possibly some action information to resolve issues.

## Searching Moab Logs

While major failures are reported via the `mdiag -S` command, these failures can also be uncovered by searching the logs using the `grep` command as in the following:

```
> grep -E "WARNING|ALERT|ERROR" moab.log
```

On a production system working normally, this list usually includes some ALERT and WARNING messages. The messages are usually self-explanatory, but if not, viewing the log can give context to the message.

If a problem is occurring early when starting the Moab scheduler (before the configuration file is read) Moab can be started up using the `-L <LOGLEVEL>` flag. If this is the first flag on the command line, then the **LOGLEVEL** is set to the specified level immediately before any setup processing is done and additional logging is recorded.

If problems are detected in the use of one of the client commands, the client command can be re-issued with the `--loglevel=<LOGLEVEL>` command line argument specified. This argument causes log information to be written to STDERR as the client command is running. As with the server, `<LOGLEVEL>` values from 0 to 9 are supported.

The **LOGLEVEL** can be changed dynamically by use of the `mschedctl -m` command, or by modifying the `moab.cfg` file and restarting the scheduler. Also, if the scheduler appears to be hung or is not properly responding, the log level can be incremented by one by sending a **SIGUSR1** signal to the scheduler process. Repeated **SIGUSR1** signals continue to increase the log level. The **SIGUSR2** signal can be used to decrease the log level by one.

If an unexpected problem does occur, save the log file as it is often very helpful in isolating and correcting the problem.

## Event Logs

Major events are reported to both the Moab log file as well as the Moab event log. By default, the event log is maintained in the statistics directory and rolls on a daily basis, using the naming convention `events.WWW_MMM_DD_YYYY` as in `events.Tue_Mar_18_2008`.

### Event Log Format

The event log contains information about major job, reservation, node, and scheduler events and failures and reports this information in the following format:

```
<EVENTTIME> <EPOCHTIME>:<EID> <OBJECT> <OBJECTID> <EVENT> <DETAILS>
```

Example 3-149:

```

VERSION 500
07:03:21 110244322:0 sched clusterA start
07:03:26 110244327:1 rsv system.1 start 1124142432 1324142432 2 2 0.0 2342155.3
node1|node2 NA RSV=%=system.1=
07:03:54 110244355:2 job 1413 end 8 16 llw mcc 432000 Completed [batch:1]
11 08708752 1108703981 ...
07:04:59 110244410:3 rm base failure cannot connect to RM
07:05:20 110244431:4 sched clusterA stop admin
...
    
```

The parameter [RECORDEVENTLIST](#) can be used to control which events are reported to the event log. See the sections on [job](#) and [reservation](#) trace format for more information regarding the values reported in the details section for those records.

### Record Type Specific Details Format

The format for each record type is unique and is described in the following table:

Record Type	Event Types	Description
<b>gevent</b>	See <a href="#">Enabling Generic Events</a> for gevent information.	 Generic events are included within node records. See <a href="#">node</a> detail format that follows.
<b>job</b>	<i>JOBCANCEL, JOBCHECKPOINT, JOBEND, JOBHOLD, JOBMIGRATE, JOBMODIFY, JOBPREEMPT, JOBREJECT, JOBRESUME, JOBSTART, JOBSUBMIT</i>	See <a href="#">Workload Accounting Records</a> .
<b>node</b>	<i>NODEDOWN, NODEFAILURE, NODEUP</i>	The following fields are displayed in the event file in a space-delimited line as long as Moab has information pertaining to it: state, partition, disk, memory, maxprocs, swap, os, rm, nodeaccesspolicy, class, and message, where state is the node's current state and message is a human readable message indicating reason for node state change.
<b>rm</b>	<i>RMDOWN, RMPOLLEND, RMPOLLSTART, RMUP</i>	Human readable message indicating reason for resource manager state change.  For <i>SCHEDCOMMAND</i> , only create/modify commands are recorded. No record is created for general list/query commands. <i>ALLSCHEDCOMMAND</i> does the same thing as <i>SCHEDCOMMAND</i> , but it also logs info query commands.

Record Type	Event Types	Description
<b>trigger</b>	<i>TRIGEND, TRIGFAILURE, TRIGSTART</i>	<p>&lt;ATTR&gt;=&lt;VALUE&gt; [ &lt;ATTR&gt;=&lt;VALUE&gt; ] . . .</p> <p>where &lt;ATTR&gt; is one of the following: actiondata, actiontype, description, ebuf, eventtime, eventtype, flags, name, objectid, object-type, obuf, offset, period, requires, sets, threshold, timeout, and so forth.</p> <p>See <a href="#">About object triggers on page 745</a> for more information.</p>
<b>vm</b>	<i>VMCREATE, VMDESTROY, VMMIGRATE, VMPOWEROFF, VMPOWERON</i>	The following fields are displayed in the event file in a space-delimited line as long as Moab has information pertaining to it: name, sovereign, powerstate, parentnode, swap, memory, disk, maxprocs, opsys, class, and variables, where class and variables may have 0 or multiple entries.

## Exporting Events in Real-Time

Moab event information can be exported to external systems in real-time using the [ACCOUNTINGINTERFACEURL](#) parameter. When set, Moab activates this URL each time one of the default events or one of the events specified by the [RECORDEVENTLIST](#) occurs.

While various protocols can be used, the most common protocol is `exec`, which indicates that Moab should launch the specified tool or script and pass in event information as command line arguments. This tool can then select those events and fields of interest and re-direct them as appropriate providing significant flexibility and control to the organization.

### Exec Protocol Format

When a URL with an `exec` protocol is specified, the target is launched with the event fields passed in as STDIN. These fields appear exactly as they do in the [event logs](#) with the same values and order.

 The `tools/sql` directory included with the Moab distribution contains `event.create.sql.pl`, a sample accounting interface processing script that may be used as a template.

## Enabling Syslog

In addition to the log file, the Moab scheduler can report events it determines to be critical to the UNIX syslog facility via the daemon facility using priorities ranging from `INFO` to `ERROR`. (See [USESYSLOG](#)). The verbosity of this logging is not affected by the [LOGLEVEL](#) parameter. In addition to errors and critical events, user commands that affect the state of the jobs, nodes, or the scheduler may also be logged to syslog. Moab syslog messages are reported using the `INFO`, `NOTICE`, and `ERR` syslog priorities.

By default, messages are logged to syslog's user facility. However, using the [USESYSLOG](#) parameter, Moab can be configured to use any of the following:

- *user*
- *daemon*

- [local0](#)
- [local1](#)
- [local2](#)
- [local3](#)
- [local4](#)
- [local5](#)
- [local6](#)
- [local7](#)

## Managing Verbosity

In very large systems, a highly verbose log may roll too quickly to be of use in tracking specific targeted behaviors. In these cases, one or more of the following approaches may be of use:

- Use the [LOGFACILITY](#) parameter to log only functions and services of interest.
- Use [syslog](#) to maintain a permanent record of critical events and failures.
- Specify higher object loglevels on jobs, nodes, and reservations of interest (such as `NODECFG [orion13] LOGLEVEL=6`).
- Increase the range of events reported to the event log using the [RECORDEVENTLIST](#) parameter.
- Review object messages for required details.
- Run Moab in [monitor](#) mode using [IGNOREUSERS](#), [IGNOREJOBS](#), [IGNORECLASSES](#), or [IGNORENODES](#).

### Related topics

- [RECORDEVENTLIST](#) parameter
- [USESYSLOG](#) parameter

- [Simulation Workload Trace Overview](#)
- [mschedctl -L](#) command

## Object Messages

### Object Message Overview

Messages can be associated with the scheduler, jobs, and nodes. Their primary use is a line of communication between resource managers, the scheduler, and end-users. When a node goes offline, or when a job fails to run, both the resource manager and the scheduler will post messages to the object's message buffer, giving the administrators and end-users a reason for the failure. They can also be used as a way for different administrators and users to send messages associated with the various objects.

For example, an administrator can set the message `Node going down for maintenance Apr/6/08 12pm,` on node `node01`, which would then be visible to other administrators.

## Viewing Messages

To view messages associated with a job (either from users, the resource manager, or Moab), run the [checkjob](#) command.

To view messages associated with a node (either from users, the resource manager, or Moab), run the [checknode](#) command.

To view system messages, use the [mschedctl -l](#) message command.

To view the messages associated with a credential, run the [mcredctl -c](#) command.

## Creating Messages

To create a message use the [mschedctl -c message](#) *<STRING>* [-o *<OBJECTTYPE>*:*<OBJECTID>*] [-w *<ATTRIBUTE>*=*<VALUE>* [-w ... ] ] command.

The *<OBJECTTYPE>* can be one of the following:

- node
- job
- rsv
- user
- acct
- qos
- class
- group

The *<ATTRIBUTE>* can be one of the following:

- owner
- priority
- expiretime
- type

Valid types include:

- annotation
- other
- hold
- pendactionerror

## Deleting Messages

Deleting, or removing, messages is straightforward. The commands used depend on the type of object to which the message is attached:

- Scheduler: Use the "[mschedctl](#) -d message:<INDEX>" command (where INDEX is the index of the message you want to delete).
- Node: Use the [mnodectl](#)<NODE> -d message:<INDEX> command.

## Notifying Administrators of Failures

### Enabling Administrator Email

In the case of certain events, Moab can automatically send email to administrators. To enable mail notification, the [MAILPROGRAM](#) parameter must be set to *DEFAULT* or point to the locally available mail client. With this set, policies such as [JOBREJECTPOLICY](#) will send email to administrators if set to a value of *MAIL*.

### Handling Events with the Notification Routine

Moab possesses a primitive event management system through the use of the notify program. The program is called each time an event of interest occurs. Currently, most events are associated with failures of some sort but use of this facility need not be limited in this way. The [NOTIFICATIONPROGRAM](#) parameter allows a site to specify the name of the program to run. This program is most often locally developed and designed to take action based on the event that has occurred. The location of the notification program may be specified as a relative or absolute path. If a relative path is specified, Moab looks for the notification relative to the \$(INSTDIR)/tools directory. In all cases, Moab verifies the existence of the notification program at start up and disables it if it cannot be found or is not executable.

The notification program's action may include steps such as reporting the event via email, adjusting scheduling parameters, rebooting a node, or even recycling the scheduler.

For most events, the notification program is called with command line arguments in a simple <EVENTTYPE>: <MESSAGE> format. The following event types are currently enabled:

Event Type	Format	Description
<b>JOBCORRUPTION</b>	<MESSAGE>	An active job is in an unexpected state or has one or more allocated nodes that are in unexpected states.
<b>JOBHOLD</b>	<MESSAGE>	A job hold has been placed on a job.
<b>JOBWCVIOLATION</b>	<MESSAGE>	A job has exceeded its wallclock limit.
<b>RESERVATIONCORRUPTION</b>	<MESSAGE>	Reservation corruption has been detected.

Event Type	Format	Description
<b>RESERVATIONCREATED</b>	<RSVNAME> <RSVTYPE> <NAME> <PRESENTTIME> <STARTTIME> <ENDTIME> <NODECOUNT>	A new reservation has been created.
<b>RESERVATIONDESTROYED</b>	<RSVNAME> <RSVTYPE> <PRESENTTIME> <STARTTIME> <ENDTIME> <NODECOUNT>	A reservation has been destroyed.
<b>RMFAILURE</b>	<MESSAGE>	The interface to the resource manager has failed.

Perhaps the most valuable use of the notify program stems from the fact that additional notifications can be easily inserted into Moab to handle site specific issues. To do this, locate the proper block routine, specify the correct conditional statement, and add a call to the routine `notify(<MESSAGE>);`.

## Issues with Client Commands

- [Client Overview](#)
- [Diagnosing Client Problems](#)

### Client Overview

Moab client commands are implemented as links to the executable `mclient`. When a Moab client command runs, the client executable determines the name under which it runs and behaves accordingly. At the time Moab was configured, a home directory was specified. The Moab client attempts to open the configuration file, `moab.cfg`, in the `etc/` folder of this home directory on the node where the client command executes. This means that the home directory specified at configure time must be available on all hosts where the Moab client commands are executed. This also means that a `moab.cfg` file must be available in the `etc/` folder of this home directory. When the clients open this file, they will try to load the **SCHEDCFG** parameter to determine how to contact the Moab server.

The home directory value specified at configure time can be overridden by creating an `/etc/moab.cfg` file or by setting the `MOABHOMEDIR` environment variable.

Once the client has determined where the Moab server is located, it creates a message, adds an encrypted checksum, and sends the message to the server. The Moab client and Moab server must use a

shared secret key for this to work. When the Moab server receives the client request and verifies the message, it processes the command and returns a reply.

## Diagnosing Client Problems

The easiest way to determine where client failures are occurring is to use built-in Moab logging. On the client side, use the `--loglevel` flag. For example:

```
> showq --loglevel=9
```

*This will display verbose logging information regarding the loading of the configuration file, connecting to the Moab server, sending the request, and receiving a response.*

This information almost always reveals the source of the problem. If it does not, the next step is to look at the Moab server side logs; this is done using the following steps:

- Stop Moab scheduling so that the only activity is handling Moab client requests.

```
> mschedctl -s
```

- Set the logging level to *very* verbose.

```
> mschedctl -m loglevel 7
```

- Watch Moab activity.

```
> tail -f log/moab.log | more
```

Now, in a second window, issue any failing client command, such as [showq](#).

The `moab.log` file will record the client request and any reasons it was rejected.

## Tracking System Failures

### System Failures

The scheduler has a number of dependencies that may cause failures if not satisfied. These dependencies are in the areas of disk space, network access, memory, and processor utilization.

#### Disk Space

The scheduler uses a number of files. If the file system is full or otherwise inaccessible, the following behaviors might be noted:

Unavailable File	Behavior
<code>moab.pid</code>	Scheduler cannot perform single instance check.

Unavailable File	Behavior
<b>moab.ck*</b>	Scheduler cannot store persistent record of reservations, jobs, policies, summary statistics, and so forth.
<b>moab.cfg</b> <b>/moab.dat</b>	Scheduler cannot load local configuration.
<b>log/*</b>	Scheduler cannot log activities.
<b>stats/*</b>	Scheduler cannot write job records.

**i** When possible, configure Moab to use local disk space for configuration files, statistics files, and logs files. If any of these files are located in a networked file system (such as NFS, DFS, or AFS) and the network or file server experience heavy loads or failures, Moab server may appear sluggish or unresponsive and client command may fail. Use of local disk space eliminates susceptibility to this potential issue.

## Network

The scheduler uses a number of socket connections to perform basic functions. Network failures may affect the following facilities.

Network Connection	Behavior
<b>scheduler client</b>	Scheduler client commands fail.
<b>resource manager</b>	Scheduler is unable to load/update information regarding nodes and jobs.
<b>allocation manager</b>	Scheduler is unable to validate account access or reserve/debit account balances.

## Memory

Depending on cluster size and configuration, the scheduler may require up to 120 MB of memory on the server host. If inadequate memory is available, multiple aspects of scheduling may be negatively affected. The scheduler log files should indicate if memory failures are detected and mark any such messages with the ERROR or ALERT keywords.

## Processor Utilization

On a heavily loaded system, the scheduler may appear sluggish and unresponsive. However, no direct failures should result from this slowdown. Indirect failures may include timeouts of peer services (such as the resource manager or allocation manager) or timeouts of client commands. All timeouts should be recorded in the scheduler log files.

## Internal Errors

The Moab scheduling system contains features to assist in diagnosing internal failures. If the scheduler exits unexpectedly, the scheduler logs may provide information regarding the cause. If no reason can be determined, use of a debugger may be required.

### Logs

The first step in any exit failure is to check the last few lines of the scheduler log. In many cases, the scheduler may have exited due to misconfiguration or detected system failures. The last few lines of the log should indicate why the scheduler exited and what changes would be required to correct the situation. If the scheduler did not intentionally exit, increasing the `LOGLEVEL` parameter to `7`, or higher, may help isolate the problem.

## Reporting Failures

If an internal failure is detected on your system, the information of greatest value to developers in isolating the problem will be the output of the `gdb` where subcommand and a printout of all variables associated with the failure. In addition, a level 7 log covering the failure can also help in determining the environment that caused the failure. If you encounter such and require assistance, please submit a ticket at the following address:

<http://www.adaptivecomputing.com/services/techsupport.php>

If you do not already have a support username and password, please create a free account [to request a support ticket](#)

## Problems with Individual Jobs

To determine why a particular job will not start, there are several helpful commands:

### [checkjob -v](#)

`checkjob` evaluates the ability of a job to start immediately. Tests include resource access, node state, job constraints (such as `startdate`, `taskspernode`, and `QoS`). Additionally, command line flags may be specified to provide further information.

Flag	Description
<code>-l &lt;POLICYLEVEL&gt;</code>	Evaluates impact of throttling policies on job feasibility.
<code>-n &lt;NODENAME&gt;</code>	Evaluates resource access on specific node.
<code>-r &lt;RESERVATION_LIST&gt;</code>	Evaluates access to specified reservations.

### [checknode](#)

Displays detailed status of node.

[mddiag -b](#)

Displays various reasons job is considered blocked or non-queued.

[mddiag -j](#)

Displays high level summary of job attributes and performs sanity check on job attributes/state.

[showbf -v](#)

Determines general resource availability subject to specified constraints.

## Diagnostic Scripts

Moab Workload Manager provides diagnostic scripts that can help aid in monitoring the state of the scheduler, resource managers, and other important components of the cluster software stack. These scripts can also be used to help diagnose issues that may need to be resolved with the help of Adaptive Computing support staff. This section introduces available diagnostic scripts.

### support-diag.py

The `support-diag.py` script has a two-fold purpose. First, it can be used by a Moab trigger or cron job to create a regular snapshot of the state of Moab. The script captures the output of several Moab diagnostic commands (such as `showq`, `mddiag -n`, and `mddiag -S`), gathers configuration/log files, and records pertinent operating system information. This data is then compressed in a time-stamped tarball for easy long-term storage.

Second, the script provides Adaptive Computing support personnel with a complete package of information that can be used to help diagnose configuration issues or system bugs. After capturing the state of Moab, the resulting tarball can be sent to your Adaptive Computing support contact for further diagnosis.

The script asks you for the trouble ticket number, `-t <TICKET#>`, or `-n`. If you chose to enter `-t <TICKET#>` the script uploads your support diagnostic output to Adaptive Computing Customer Support. The upload and ticket number request can be prevented using the `-n` option.

### Synopsis

```
support-diag.py [<options>]
```

### Arguments

Argument	Description
<code>-h, --help</code>	Show this help message and exit.
<code>-q, --diag-torque-off, --without-torque</code>	Disable TORQUE diagnostics.

Argument	Description
<code>-p TMPDIR, --tmp-dir=TMPDIR</code>	Use a different tmp directory to store output.
<code>-n, --no-upload</code>	Do not upload to Adaptive Computing.
<code>-t TICKET#</code>	Support ticket number.
<code>-f, --full-mode</code>	Gather additional logs, stats and, <code>moab.db</code> files.
<code>-u TIMEOUT, --moab-timeout=TIMEOUT</code>	Define Moab command timeout (Default 300 seconds).
<code>-d, --debug-mode</code>	<code>support-diag</code> print debug variables.
<code>-o, --offline-mode</code>	Gather offline logging only.
<code>-r, --ftp</code>	Use ftp instead of scp.
<code>-V, --version</code>	Print version information.

## support.diag.pl

 This script is deprecated with the 8.0 release. Use the `support-diag.py` script instead.

The `support.diag.pl` script has a two-fold purpose. First, it can be used by a Moab trigger or cron job to create a regular snapshot of the state of Moab. The script captures the output of several Moab diagnostic commands (such as `showq`, `mdiag -n`, and `mdiag -S`), gathers configuration/log files, and records pertinent operating system information. This data is then compressed in a time-stamped tarball for easy long-term storage.

The second purpose of the `support.diag.pl` script is to provide Adaptive Computing support personnel with a complete package of information that can be used to help diagnose configuration issues or system bugs. After capturing the state of Moab, the resulting tarball could be sent to your Adaptive Computing support contact for further diagnosis.

The `support.diag.pl` will ask you for the trouble ticket number then guide you through the process of uploading the data to Adaptive Computing Customer Support. The uploading and ticket number request may be prevented using the `--no-upload` and `--support-ticket=<SUPPORT_TICKET_ID>` flags detailed in the Arguments table that follows.

### Synopsis

```
support.diag.pl [--include-log-lines=<NUM>] [--diag-torque]
```

## Arguments

Argument	Description
<code>--include-log-lines=&lt;NUM&gt;</code>	Instead of including the entire <code>moab.log</code> file, only the last <code>&lt;NUM&gt;</code> lines are captured in the diagnostics.
<code>--diag-torque</code>	Diagnostic commands pertinent to the TORQUE resource manager are included.
<code>--no-upload</code>	Prevents the system from asking the user if they want to upload the tarball to Adaptive Computing Customer Support.
<code>--support-ticket=&lt;SUPPORT_TICKET_ID&gt;</code>	Prevents the system from asking the user for a support ticket number.

## Improving User Effectiveness

- [User Feedback Loops on page 691](#)
- [User Level Statistics on page 692](#)
- [Enhancing Wallclock Limit Estimates on page 693](#)
- [Job Start Time Estimates on page 693](#)
- [Providing Resource Availability Information on page 694](#)
- [Collecting Performance Information on Individual Jobs on page 694](#)

## User Feedback Loops

Almost invariably, real world systems outperform simulated systems, even when all policies, reservations, workload, and resource distributions are fully captured and emulated. What is it about real world usage that is not emulated via a simulation? The answer is the user feedback loop, the impact of users making decisions to optimize their level of service based on real time information.

A user feedback loop is created any time information is provided to a user that modifies job submission or job management behavior. As in a market economy, the cumulative effect of many users taking steps to improve their individual scheduling performance results in better job packing, lower queue time, and better overall system utilization. Because this behavior is beneficial to the system at large, system administrators and management should encourage this behavior and provide the best possible information to them.

There are two primary types of information that help users make improved decisions: cluster wide resource availability information and per job resource utilization information.

## Improving Job Size/Duration Requests

Moab provides a number of informational commands that help users make improved job management decisions based on real-time cluster wide resource availability information. These commands include [showbf](#), [showstats -f](#), and [showq](#). Using these commands, a user can determine what resources are available and what job configurations statistically receive the best scheduling performance.

## Improving Resource Requirement Specification

A job's resource requirement specification tells the scheduler what type of compute nodes are required to run the job. These requirements may state that a certain amount of memory is required per node or that a node has a minimum processor speed. At many sites, users will determine the resource requirements needed to run an initial job. Then, for the next several years, they will use the same basic batch command file to run all of their remaining jobs even though the resource requirements of their subsequent jobs may be very different from their initial run. Users often do not update their batch command files even though these constraints may be unnecessarily limiting the resources available to their jobs for two reasons: (1) users do not know how much their performance will improve if better information were provided and (2) users do not know exactly what resources their jobs are using and are afraid to lower their job's resource requirements since doing so might cause their job to fail.

To help with determining accurate per job resource utilization information, Moab provides the [FEEDBACKPROGRAM](#) facility. This tool allows sites to send detailed resource utilization information back to users via email, to store it in a centralized database for report preparation, or use it in other ways to help users refine their batch jobs.

## User Level Statistics

Besides displaying job queues, end-users can display a number of their own statistics. The [showstats -u <USER\\_ID>](#) command displays current and historical statistics for a user as seen in what follows:

```

$ showstats -u john
statistics initialized Wed Dec 31 17:00:00

      |----- Active -----|----- Completed -----
-----|
user      Jobs Procs ProcHours Jobs   %   PHReq   %   PHDed   %   FSTgt   AvgXF
MaxXF   AvgQH  Effic  WCAcc
john      1     1     30.96   9   0.00  300.0   0.00  148.9   0.00  -----  0.62
0.00     4.33 100.00  48.87
    
```

Users can query available system resources with the [showbf](#) command. This can aid users in requesting node configurations that are idle. Also, users can use the [checkjob](#) command to determine what parameter(s) are restricting their job from running. Moab performs better with more accurate wallclock estimates.

 Moab must use an ODBC-compliant database to report statistics with Viewpoint reports.

## Enhancing Wallclock Limit Estimates

As explained in the previous section, `showstats -u <USER_ID>` reports statistics for a given user. The `showstats -u` command can be accessed by all users. They can use fields such as `PHReq`, `PHDed`, or `WCAcc` to gauge wallclock estimates. Accurate wallclock estimates allow a job to be scheduled as soon as possible in a slot that it will fit in. Low or high estimates can cause a job to be scheduled in a less favorable position.

## Job Start Time Estimates

Each user can use the `showstart` command to display estimated start and completion times. The following example illustrates a typical response from issuing this command:

```
> showstart orion.13762
job orion.13762 requires 2 procs for 0:33:20
Estimated Rsv based start in           1:04:55 on Fri Jul 15 12:53:40
Estimated Rsv based completion in      2:44:55 on Fri Jul 15 14:33:40
Estimated Priority based start in      5:14:55 on Fri Jul 15 17:03:40
Estimated Priority based completion in  6:54:55 on Fri Jul 15 18:43:40
Estimated Historical based start in    00:00:00 on Fri Jul 15 11:48:45
Estimated Historical based completion in 1:40:00 on Fri Jul 15 13:28:45
Best Partition: fast
```

## Estimation Types

### Reservation-Based Estimates

Reservation-based start time estimation incorporates information regarding current administrative, user, and job reservations to determine the earliest time the specified job can allocate the needed resources and start running. In essence, this estimate indicates the earliest time the job will start, assuming this job is the highest priority job in the queue.

**i** For reservation-based estimates, the information provided by this command is more highly accurate if the job is highest priority, if the job has a reservation, or if the majority of the jobs that are of higher priority have reservations. Consequently, site administrators wanting to make decisions based on this information may want to consider using the `RESERVATIONDEPTH` parameter to increase the number of priority-based reservations. This can be set so that most, or even all, idle jobs receive priority reservations and make the results of this command generally useful. The only caution of this approach is that increasing the `RESERVATIONDEPTH` parameter more tightly constrains the decisions of the scheduler and may result in slightly lower system utilization (typically less than 8% reduction).

### Backlog/Priority Estimates

Priority-based job start analysis determines when the queried job will fit in the queue and determines the estimated amount of time required to complete the jobs currently running or scheduled to run before this job can start.

In all cases, if the job is running, this command returns the time the job starts. If the job already has a reservation, this command returns the start time of the reservation.

## Historical Estimates

Historical analysis uses historical queue times for jobs that match a similar processor count and job duration profile. This information is updated on a sliding window that is configurable within `moab.cfg`.

### Related topics

- [ENABLESTARTESTIMATESTATS](#) parameter
- [showstart](#) command

## Providing Resource Availability Information

Moab provides commands to allow the user to query available resources. The [showbf command](#) displays what resources are available for immediate use. Using different command line parameters, such as `-m`, `-n`, and `-q` allows the user to query resources based on memory, nodecount, or QoS respectively.

## Collecting Performance Information on Individual Jobs

Individual job information can be collected from the statistics file in [STATDIR](#), which contains start time, end time, end state, QoS requested, QoS delivered, and so forth for different jobs. Also, Moab optionally provides similar information to a site's feedback program. See section [21.1 User Feedback Overview](#) for more information about the feedback program.

## Cluster Analysis, Testing, and Simulation

- [Testing New Releases and Policies on page 695](#)
- [Testing New Middleware on page 699](#)

Moab has a number of unique features that allow site administrators to visualize current cluster behavior and performance, safely evaluate changes on production systems, and analyze probable future behaviors within a variety of environments.

These capabilities are enabled through a number of Moab facilities that may not appear to be closely related at first. However, taken together, these facilities allow organizations the ability to analyze their cluster without the losses associated with policy conflicts, unnecessary downtime, and faulty systems middleware.

Simulations allow organizations to evaluate many scenarios that could not be properly evaluated in real-world situations. In particular, these evaluations may be impossible due to time constraints, budgetary or personnel limitations, hardware availability, or even policy issues. In such cases, simulations provide information in countless scenarios and can help answer questions such as the following:

- What is the impact of additional hardware on cluster utilization?
- What delays to key projects can be expected with the addition of new users?
- How will new prioritization weights alter cycle distribution among existing workload?
- What total loss of compute resources will result from introducing a maintenance downtime?
- Are the benefits of cycle stealing from non-dedicated desktop systems worth the effort?
- How much will anticipated grid workload delay the average wait time of local jobs?

## Testing New Releases and Policies

- [Moab Evaluation Modes](#)
  - [MONITOR Mode](#)
  - [TEST Mode](#)
  - [INTERACTIVE Mode](#)
- [Testing New Releases](#)
- [Testing New Policies](#)
  - [Verifying Correct Specification of New Policies](#)
  - [Verifying Correct Behavior of New Policies](#)
  - [Determining Long Term Impact of New Policies](#)
- [Moab Side-by-Side](#)

## Moab Evaluation Modes

### MONITOR Mode

Moab supports a scheduling mode called *MONITOR*. In this mode, the scheduler initializes, contacts the resource manager and other peer services, and conducts scheduling cycles exactly as it would if running in *NORMAL* or production mode. Jobs are prioritized, reservations created, policies and limits enforced, and administrator and end-user commands enabled. The key difference is that although live resource management information is loaded, *MONITOR* mode disables Moab's ability to start, preempt, cancel, or otherwise modify jobs or resources. Moab continues to attempt to schedule exactly as it would in *NORMAL* mode, but its ability to actually impact the system is disabled. Using this mode, a site can quickly verify correct resource manager configuration and scheduler operation. This mode can also be used to validate new policies and constraints. In fact, Moab can be run in *MONITOR* mode on a production system while another scheduler or even another version of Moab is running on the same system. This unique ability can allow new versions and configurations to be fully tested without any exposure to potential failures and with no cluster downtime.

To run Moab in *MONITOR* mode, simply set the **MODE** attribute of the **SCHEDCFG** parameter to *MONITOR* and start Moab. Normal scheduler commands can be used to evaluate configuration and performance. [Diagnostic commands](#) can be used to look for any potential issues. Further, the Moab log

file can be used to determine which jobs Moab attempted to start, and which resources Moab attempted to allocate.

If another instance of Moab is running in production and a site administrator wants to evaluate an alternate configuration or new version, this is easily done but care should be taken to avoid conflicts with the primary scheduler. Potential conflicts include statistics files, logs, checkpoint files, and user interface ports. One of the easiest ways to avoid these conflicts is to create a new test directory with its own log and statistics subdirectories. The new `moab.cfg` file can be created from scratch or based on the existing `moab.cfg` file already in use. In either case, make certain that the **PORT** attribute of the **SCHEDCFG** parameter differs from that used by the production scheduler by at least two ports. If testing with the production binary executable, the `MOABHOMEDIR` environment variable should be set to point to the new test directory to prevent Moab from loading the production `moab.cfg` file.

## TEST Mode

*TEST* mode behaves much like *MONITOR* mode with the exception that Moab will log the scheduling actions it would have taken to the `stats/<DAY>.events` file. Using this file, sites can determine the actions Moab would have taken if running in *NORMAL* mode and verify all actions are in agreement with expected behavior.

## INTERACTIVE Mode

*INTERACTIVE* mode allows for evaluation of new versions and configurations in a manner different from *MONITOR* mode. Instead of disabling all resource and job control functions, Moab sends the desired change request to the screen and requests permission to complete it. For example, before starting a job, Moab may print something like the following to the screen:

```
Command: start job 1139.ncsa.edu on node list test013,test017,test018,test021
Accept: (y/n) [default: n]?
```

The administrator must specifically accept each command request after verifying it correctly meets desired site policies. Moab will then execute the specified command. This mode is highly useful in validating scheduler behavior and can be used until configuration is appropriately tuned and all parties are comfortable with the scheduler's performance. In most cases, sites will want to set the scheduling mode to *NORMAL* after verifying correct behavior.

## Testing New Releases

By default, Moab runs in a [mode](#) called *NORMAL*, which indicates that it is responsible for the cluster. It loads workload and resource information, and is responsible for managing that workload according to mission objectives and policies. It starts, cancels, preempts, and modifies jobs according to these policies.

If Moab is configured to use a mode called [TEST](#), it loads all information, performs all analysis, but, instead of actually starting or modifying a job, it merely logs the fact that it would have done so. A test instance of Moab can run at the same time as a production instance of Moab. A test instance of Moab can also run while a production scheduler of another type (such as PBS, LSF, or SLURM) is simultaneously running. This multi-scheduler ability allows stability and performance tests to be conducted that can help answer the following questions:

- What impact do Moab services have on network, processor, and memory load?
- What impact do Moab services have on the underlying resource manager?
- Is Moab able to correctly import resource, workload, policy, and credential information from the underlying resource manager?
- Are Moab's logged scheduling decisions in line with mission objectives?

In test mode, all of Moab's commands and services operate normally allowing the use of client commands to perform analysis. In most cases, the [mdiag](#) command is of greatest value, displaying loaded values as well as reporting detected failures, inconsistencies, and object corruption. The following table highlights the most common diagnostics performed.

Command	Object
<a href="#">mdiag -n</a>	Compute nodes, storage systems, network systems, and generic resources
<a href="#">mdiag -j</a>	Applications and static jobs
<a href="#">mdiag -u</a> <a href="#">mdiag -g</a> <a href="#">mdiag -a</a>	User, group, and account credentials
<a href="#">mdiag -c</a>	Queues and policies
<a href="#">mdiag -R</a>	Resource manager interface and performance
<a href="#">mdiag -S</a>	Scheduler/system level failures introduced by corrupt information

These commands will not only verify proper scheduling objects but will also analyze the behavior of each resource manager, recording failures, and delivered performance. If any misconfiguration, corruption, interface failure, or internal failure is detected, it can be addressed in the test mode instance of Moab with no urgency or risk to production cluster activities.

## Testing New Policies

### Verifying Correct Specification of New Policies

The first aspect of verifying a new policy is verifying correct syntax and semantics. If using [Moab Cluster Manager](#), this step is not necessary as this tool automatically verifies proper policy specification. If manually editing the `moab.cfg` file, the following command can be used for validation:

```
> mdiag -C
```

*This command will validate the configuration file and report any misconfiguration.*

## Verifying Correct Behavior of New Policies

If concern exists over the impact of a new policy, an administrator can babysit Moab by putting it into [INTERACTIVE](#) mode. In this mode, Moab will schedule according to all mission objectives and policies, but before taking any action, it will request that the administrator confirm the action. See the [interactive mode overview](#) for more information.

In this mode, only actions approved by the administrator will be carried out. Once proper behavior is verified, the Moab mode can be set to *NORMAL*.

## Determining Long Term Impact of New Policies

If a new policy has the potential to impact long-term performance or resource distribution, it may be desirable to run a Moab simulation to evaluate this change. Simulations allow locally recorded workload to be translated into simulation jobs and execute on a virtual cluster that emulates local resources. Simulations import all job and resource attributes that are loaded in a production environment as well as all policies specified in any configuration file. While running, all Moab commands and statistics are fully supported.

Using simulation, a control run can be made using the original policies and the behavior of this run compared to a second run that contains the specified change. Moab Cluster Manager's charting, graphing, and reporting features can be used to report on and visualize the differences in these two runs. Typically, a two-month real-time simulation can be completed in under an hour. For more information on simulations, see the Simulation Overview.

## Moab Side-by-Side

Moab provides an additional evaluation method that allows a production cluster or other resource to be logically partitioned along resource and workload boundaries and allows different instances of Moab to schedule different partitions. The parameters [IGNORENODES](#), [IGNORECLASSES](#), [IGNOREJOBS](#), and [IGNOREUSERS](#) are used to specify how the system is to be partitioned. In the following example, a small portion of an existing cluster is partitioned for temporary grid testing so that there is no impact on the production workload.

```
SCHEDCFG[prod] MODE=NORMAL SERVER=orion.cxz.com:42020
RMCFG[TORQUE]  TYPE=PBS
IGNORENODES    node61,node62,node63,node64
IGNOREUSERS    gridtest1,gridtest2
...
SCHEDCFG[prod] MODE=NORMAL SERVER=orion.cxz.com:42030
RMCFG[TORQUE]  TYPE=PBS
IGNORENODES    !node61,node62,node63,node64
IGNOREUSERS    !gridtest1,gridtest2
...
```

*Two completely independent Moab servers schedule the cluster. The first server handles all jobs and nodes except for the ones involved in the test. The second server handles only test nodes and test jobs. While both servers actively talk and interact with a single TORQUE resource manager, the **IGNORE\*** parameters cause them to not schedule, nor even see the other partition and its associated workload.*

- i** When enabling Moab side-by-side, each Moab server should have an independent home directory to prevent logging and statistics conflicts. Also, in this environment, each Moab server should communicate with its client commands using a different port as shown in the previous example.
- i** When specifying the **IGNORENODES** parameter, the exact node names, as returned by the resource manager, should be specified.

Related topics

- [Testing New Versions and Configurations](#)

## Testing New Middleware

Moab can be used to drive new middleware stress testing resource management systems, information services, allocation services, security services, data staging services, and other aspects. Moab is unique when compared to other stress testing tools as it can perform the tests in response to actual or recorded workload traces, performing a playback of events and driving the underlying system as if it were part of the production environment.

This feature can be used to identify scalability issues, pathological use cases, and accounting irregularities in anything from LDAP, to NIS, and NFS.

Using Moab's [time management](#) facilities, Moab can drive the underlying systems in accordance with the real recorded distribution of time, at a multiplier of real time, or as fast as possible.

The following table describes some aspects of cluster analysis that can be driven by Moab.

System	Details
<b>Allocation Manager</b>	Use <i>test</i> or <i>simulation</i> mode to drive scheduling queries, allocation debits, and reservations to accounting packages. Verify synchronization of cluster statistics and stress test interfaces and underlying databases.
<a href="#">On-Demand/Provisioning Services</a>	Use <i>simulation</i> or native resource manager mode to drive triggers and resource management interfaces to enable dynamic provisioning of hardware, operating systems, application software, and services. Test reliability and scalability of data servers, networks, and provisioning software as well as the interfaces and business logic coordinating these changes.
<a href="#">Resource Monitoring</a>	Use <i>test</i> or native resource manager mode to actively load information from compute, network, storage, and software license managers confirming validity of data, availability during failures, and scalability.

With each evaluation, the following tests can be enabled:

- functionality
- reliability
  - hard failure
    - hardware failure - compute, network, and data failures
    - software failure - loss of software services (NIS, LDAP, NFS, database)
    - soft failure
    - network delays, full file system, dropped network packets
  - corrupt data
- performance
- determine peak responsiveness in seconds/request
- determine peak throughput in requests/second
- determine responsiveness under heavy load conditions
- determine throughput under external load conditions
  - large user base (many users, groups, accounts)
  - large workload (many jobs)
  - large cluster (many nodes)
- manageability
  - full accounting for all actions/events
  - actions/failures can be easily and fully diagnosed

**i** If using a native resource manager and you do not want to actually submit real workload, you can set the environment variable `MFORCESUBMIT` to allow virtual workload to be managed without ever launching a real process.

## General Analysis

For all middleware interfaces, Moab provides built-in performance analysis and failure reporting. Diagnostics for these interfaces are available via the [mdia](#) command.

## Native Mode Analysis

Using [native mode](#) analysis, organizations can run Moab in *normal* mode with all facilities fully enabled, but with the resource manager fully emulated. With a native resource manager interface, any arbitrary cluster can be emulated with a simple script or flat text file. Artificial failures can be introduced, jobs can be virtually running, and artificial performance information generated and reported.

In the simplest case, emulation can be accomplished using the following configuration:

```
SCHEDCFG[natcluster] MODE=NORMAL SERVER=test1.bbli.com
ADMINCFG[1] USERS=dev
RMCFG[natcluster] TYPE=NATIVE CLUSTERQUERYURL=file://$HOME/cluster.dat
```

The preceding configuration will load cluster resource information from the file `cluster.dat`. An example resource information file follows:

```
node01 state=idle cproc=2
node02 state=idle cproc=2
node03 state=idle cproc=2
node04 state=idle cproc=2
node05 state=idle cproc=2
node06 state=idle cproc=2
node07 state=idle cproc=2
node08 state=idle cproc=2
```

In actual usage, any number of node attributes may be specified to customize these nodes, but in this example, only the node state and node configured processors attributes are specified.

The **RMCFG** flag *NORMSTART* indicates that Moab should not actually issue a job start command to an external entity to start the job, but rather start the job logically internally only.

If it is desirable to take an arbitrary action at the start of a job, end of a job, or anywhere in between, the **JOBCFG** parameter can be used to create one or more arbitrary [triggers](#) to initiate internal or external events. The triggers can do anything from executing a script, to updating a database, to using a Web service.

Using native resource manager mode, jobs may be introduced using the [msub](#) command according to any arbitrary schedule. Moab will load them, schedule them, and start them according to all site mission objectives and policies and drive all interfaced services as if running in a full production environment.

## Configuring Resources for Simulation

Resource traces fully describe all scheduling relevant aspects of a batch system's compute resources. In most cases, each resource trace describes a single compute node providing information about configured resources, node location, supported classes and queues, and so forth.

The resources Moab uses to simulate are created using Moab RM language. To create a Moab simulation this way, perform the following steps:

1. Load resources into Moab using a native RM. Create a file manually using the format for different resource attributes (see [W.1 Moab Resource Manager Language Data Format on page 1363](#)) or run `mnodectl -q wiki ALL > nodes.dat` to create a resources simulation file from the resources in your environment and write it to a file (in this example, a file called `nodes.dat`). You can modify the resource file to add resources, change attributes, etc.
2. Set up the resource manager interface by inserting the following into your `moab.cfg` file.

```
RMCFG[rmName] TYPE=NATIVE CLUSTERQUERYURL=FILE:///<locationOfFile>/<nameOfFile>
```

For the example in step 1, you would replace `<nameOfFile>` with `nodes.dat`.

3. Restart Moab.

## Sample Resource Trace

```
n8 STATE=Idle PARTITION=base AMEMORY=16000 APROC=4 CMEMORY=16000 CPROC=4 RM=base
NODEACCESSPOLICY=SHARED FEATURE=linux ARCH=x86_64
```

## Workload Event Format

Moab workload [accounting records](#) fully describe all scheduling relevant aspects of batch jobs including resources requested and used, time of all major scheduling events (such as submission time and start time), the job credentials used, and the job execution environment. Each job trace is composed of a single line consisting of whitespace delimited fields as shown in the following table.

**i** Moab can be configured to provide this information in flat text tabular form or in XML format conforming to the SSS 1.0 job description specification.

- [Workload Event Record Format](#)
- [Creating New Workload Accounting Records/Traces](#)
- [Reservation Records/Traces](#)
- [Recording Job events](#)

## Workload Event Record Format

All job events (*JOBSUBMIT*, *JOBSTART*, *JOBEND*, and so forth) provide job data in a standard format as described in the following table:

Field Name	Field Index	Data Format	Default Value	Details
<b>Event Time (Human Readable)</b>	1	HH:MM:SS	-	Specifies time event occurred.
<b>Event Time (Epoch)</b>	2	<epochtime>	-	Specifies time event occurred.
<b>Object Type</b>	3	job	-	Specifies record object type.
<b>Object ID</b>	4	<STRING>	-	Unique object identifier.

Field Name	Field Index	Data Format	Default Value	Details
<b>Object Event</b>	5	one of <i>job-cancel</i> , <i>jobcheckpoint</i> , <i>jobend</i> , <i>job-failure</i> , <i>jobhold</i> , <i>jobmigrate</i> , <i>job-preempt</i> , <i>jobreject</i> , <i>jobresume</i> , <i>jobstart</i> or <i>job-submit</i>	-	Specifies record <a href="#">event type</a> .
<b>Nodes Requested</b>	6	<INTEGER>	0	Number of nodes requested (0 = no node request count specified).
<b>Tasks Requested</b>	7	<INTEGER>	1	Number of tasks requested.
<b>User Name</b>	8	<STRING>	-	Name of user submitting job.
<b>Group Name</b>	9	<STRING>	-	Primary group of user submitting job.
<b>Wallclock Limit</b>	10	<INTEGER>	1	Maximum allowed job duration (in seconds).
<b>Job Event State</b>	11	<STRING>	-	Job <a href="#">state</a> at time of event.
<b>Required Class</b>	12	<STRING>	[DEFAULT:1]	<a href="#">Class/queue</a> required by job specified as square bracket list of <QUEUE> [:<QUEUEINSTANCE>] requirements. (For example: [batch:1]).
<b>Submission Time</b>	13	<INTEGER>	0	Epoch time when job was submitted.
<b>Dispatch Time</b>	14	<INTEGER>	0	Epoch time when scheduler requested job begin executing.
<b>Start Time</b>	15	<INTEGER>	0	Epoch time when job began executing. This is usually identical to Dispatch Time.

Field Name	Field Index	Data Format	Default Value	Details
<b>Completion Time</b>	16	<INTEGER>	0	Epoch time when job completed execution.
<b>Required Node Architecture</b>	17	<STRING>	-	Required node architecture if specified.
<b>Required Node Operating System</b>	18	<STRING>	-	Required node operating system if specified.
<b>Required Node Memory Comparison</b>	19	one of >, >=, =, <=, <	>=	Comparison for determining compliance with required node memory.
<b>Required Node Memory</b>	20	<INTEGER>	0	Amount of required configured RAM (in MB) on each node.
<b>Required Node Disk Comparison</b>	21	one of >, >=, =, <=, <	>=	Comparison for determining compliance with required node disk.
<b>Required Node Disk</b>	22	<INTEGER>	0	Amount of required configured local disk (in MB) on each node.
<b>Required Node Attributes/Features</b>	23	<STRING>	-	Square bracket enclosed list of node features required by job if specified. (For example: [fast][ethernet])
<b>System Queue Time</b>	24	<INTEGER>	0	Epoch time when job met all fairness policies.
<b>Tasks Allocated</b>	25	<INTEGER>	<TASKS REQUESTED>	Number of tasks actually allocated to job. <div style="border: 1px solid black; border-radius: 10px; padding: 5px; margin-top: 10px;">  In most cases, this field is identical to field #7, Tasks Requested.                 </div>
<b>Required Tasks Per Node</b>	26	<INTEGER>	-1	Number of Tasks Per Node required by job or '-1' if no requirement specified.

Field Name	Field Index	Data Format	Default Value	Details
<b>QoS</b>	27	<STRING> [:<STRING>]	-	QoS requested/assigned using the format <QOS_REQUESTED>[:<QOS_DELIVERED>]. (For example: hipriority:bottomfeeder)
<b>JobFlags</b>	28	<STRING> [:<STRING>]...	-	Square bracket delimited list of job attributes. (For example: [BACKFILL][PREEMPTEE])
<b>Account Name</b>	29	<STRING>	-	Name of account associated with job if specified.
<b>Executable</b>	30	<STRING>	-	Name of job executable if specified.
<b>Resource Manager Extension String</b>	31	<STRING>	-	Resource manager specific list of job attributes if specified. See the <a href="#">Resource Manager Extension Overview</a> for more information.
<b>Bypass Count</b>	32	<INTEGER>	-1	Number of times job was bypassed by lower priority jobs via backfill or '-1' if not specified.
<b>ProcSeconds Utilized</b>	33	<DOUBLE>	0	Number of processor seconds actually used by job.
<b>Partition Name</b>	34	<STRING>	[DEFAULT]	Name of partition in which job ran.
<b>Dedicated Processors per Task</b>	35	<INTEGER>	1	Number of processors required per task.
<b>Dedicated Memory per Task</b>	36	<INTEGER>	0	Amount of RAM (in MB) required per task.
<b>Dedicated Disk per Task</b>	37	<INTEGER>	0	Amount of local disk (in MB) required per task.
<b>Dedicated Swap per Task</b>	38	<INTEGER>	0	Amount of virtual memory (in MB) required per task.

Field Name	Field Index	Data Format	Default Value	Details
<b>Start Date</b>	39	<INTEGER>	0	Epoch time indicating earliest time job can start.
<b>End Date</b>	40	<INTEGER>	0	Epoch time indicating latest time by which job must complete.
<b>Allocated Host List</b>	41	<hostname> [, <hostname> ]...	-	Comma delimited list of hosts allocated to job. (For example: node001,node004)
<b>Resource Manager Name</b>	42	<STRING>	-	Name of resource manager if specified.
<b>Required Host List</b>	43	<hostname> [, <hostname> ]...	-	List of hosts required by job. (If the job's taskcount is greater than the specified number of hosts, the scheduler must use these nodes in addition to others; if the job's taskcount is less than the specified number of hosts, the scheduler must select needed hosts from this list.)
<b>Reservation</b>	44	<STRING>	-	Name of reservation required by job if specified.
<b>Application Simulator Data</b>	45	<STRING> [: <STRING>]	-	Name of application simulator module and associated configuration data. (For example: HSM:IN- N=infile.txt:140000;OUT= outfile.txt:500000)
<b>Set Description</b>	46	<STRING>: <STRING> [: <STRING>]	-	Set constraints required by node in the form <SetConstraint>:<SetType>[:<SetList>] where SetConstraint is one of ONEOF, FIRSTOF, or ANYOF, SetType is one of PROCSPEED, FEATURE, or NETWORK, and SetList is an optional colon delimited list of allowed set attributes. (For example: ONEOF:PROCSPEED:350:450:500)

Field Name	Field Index	Data Format	Default Value	Details
<b>Job Message</b>	47	<STRING>	-	Job messages including resource manager, scheduler, and administrator messages if specified.
<b>Job Cost</b>	48	<DOUBLE>	0.0	Cost of executing job incorporating resource consumption metric, resource quantity consumed, and credential, allocated resource, and delivered QoS charge rates.
<b>History</b>	49	<STRING>	-	List of job events impacting resource allocation (XML).  <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF;">  History information is only reported in Moab 5.1.0 and higher.                 </div>
<b>Utilization</b>	50	Comma-delimited list of one or more of the following: <ATTR>= <VALUE> pairs where <VALUE> is a double and <ATTR> is one of the following: network (in MB transferred), license (in license-seconds), storage (in MB-seconds stored), or gmetric: <TYPE>.	-	Cumulative resources used over life of job.
<b>Estimate Data</b>	51	<STRING>	-	List of job estimate usage.
<b>Completion Code</b>	52	<INTEGER>	-	Job exit status/completion code.

Field Name	Field Index	Data Format	Default Value	Details
<b>Extended Memory Load Information</b>	53	<STRING>	-	<b>Deprecated.</b> Extended memory usage statistics (max, mem, avg, and so forth).
<b>Extended CPU Load Information</b>	54	<STRING>	-	Extended CPU usage statistics (max, mem, avg, and so forth).
<b>Generic Metric Averages</b>	55	<STRING>	-1	Generic metric averages.
<b>Effective Queue Duration</b>	56	<INTEGER>	-1	The amount of time, in seconds, that the job was eligible for scheduling.
<b>Job Submission Arguments</b>	57	<STRING>	-	The job's submit arguments and script. This field is enabled by setting <a href="#">STOREJOBSSUBMISSION</a> to <i>TRUE</i> .

**i** If no applicable value is specified, the exact string – should be entered.

**i** Fields that contain a description string such as Job Message use a packed string format. The packed string format replaces white space characters such as spaces and carriage returns with a hex character representation. For example a blank space is represented as \20. Since fields in the event record are space delimited, this preserves the correct order and spacing of fields in the record.

### Sample Workload Trace

```
13:21:05 110244355 job 1413 JOBEND 20 20 josh staff 86400 Removed [batch:1] 887343658
889585185 \
889585185 889585411 ethernet R6000 AIX53 >= 256 >= 0 - 889584538 20 0 0 2 0 test.cmd \
1001 6 678.08 0 1 0 0 0 0 0 - 0 - - - - - 0.0 - - - 0 - -
```

### Creating New Workload Simulation Traces

Because workload [event records](#) and simulation workload traces use the same format, these event records can be used as a starting point for generating a new simulation trace. In the Moab simple case, an event record or collection of event records can be used directly as the value for the [SIMWORKLOADTRACEFILE](#) as in the following example:

1. 

```
# collect all job records for July
> cat /opt/moab/stats/events.*July*2012 | grep JOBEND > /opt/moab/DecJobs.txt
```

```
2. edit moab.cfg for use job records
> vi /opt/moab/etc/moab.cfg
(add 'SIMWORKLOADTRACEFILE /opt/moab/DecJobs.txt')
```

**i** In the preceding example, all non-*JOBEND* events were filtered out. This step is not required but only *JOBEND* events are used in a simulation; other events are ignored by Moab.

### Modifying Existing Job Event Records

When creating a new simulation workload, it is often valuable to start with workload traces representing a well-known or even local workload. These traces preserve distribution information about job submission times, durations, processor count, users, groups, projects, special resource requests, and numerous other factors that effectively represent an industry, user base, or organization.

When modifying records, a field or combination of fields can be altered, new jobs inserted, or certain jobs filtered out.

**i** Because job event records are used for multiple purposes, some of the fields are valuable for statistics or auditing purposes but are ignored in simulations. For the most part, fields representing resource utilization information are ignored while fields representing resource requests are not.

### Modifying Time Distribution Factors of a Workload Trace

In some cases, simulations focus on determining the effects of changing the quantities or types of jobs or on changing policies or job ownership to see changes to system performance and resource utilization. However, other times simulations tend to focus on response-time metrics as job submission and job duration aspects of the workload are modified. Which time-based fields are important to modify depend on the simulation purpose and the setting of the [JOBSUBMISSIONPOLICY](#) parameter.

JOBSUBMISSIONPOLICY Value	Critical Time Based Fields
<b>NORMAL</b>	WallClock Limit Submission Time StartTime Completion Time
<b>CONSTANTJOBDEPTH</b> <b>CONSTANTPSDEPTH</b>	WallClock Limit StartTime Completion Time

**i** Dispatch Time should always be identical to Start Time.

**i** In all cases, the difference of 'Completion Time - Start Time' is used to determine actual job run time.

**i** System Queue Time and Proc-Seconds Utilized are only used for statistics gathering purposes and will not alter the behavior of the simulation.

**i** In all cases, relative time values are important, i.e., Start Time must be greater than or equal to Submission Time and less than Completion Time.

### Creating Workload Traces From Scratch

There is nothing which prevents a completely new workload trace from being created from scratch. To do this, simply create a file with fields matching the format described in the [Workload Event Record Format](#) section.

### Reservation Records/Traces

All reservation events provide reservation data in a standard format as described in the following table:

Field Name	Field Index	Data Format	Default Value	Details
<b>Event Time (Human)</b>	0	[HH:MM:SS]	-	Specifies time event occurred.
<b>Event Time (Epoch)</b>	1	<epochtime>	-	Specifies time event occurred.
<b>Object Type</b>	2	rsv	-	Specifies record object type.
<b>Object ID</b>	3	<STRING>	-	Unique object identifier.
<b>Object Event</b>	4	one of <i>rsvcreate</i> , <i>rsvstart</i> , <i>rsvmodify</i> , <i>rsvfail</i> or <i>rsvend</i>	-	Specifies record event type.
<b>Creation Time</b>	5	<EPOCHTIME>	-	Specifies epoch time of reservation start date.
<b>Start Time</b>	6	<EPOCHTIME>	-	Specifies epoch time of reservation start date.
<b>End Time</b>	7	<EPOCHTIME>	-	Specifies epoch time of reservation end date.

Field Name	Field Index	Data Format	Default Value	Details
<b>Tasks Allocated</b>	8	<INTEGER>	-	Specifies number of tasks allocated to reservation at event time.
<b>Nodes Allocated</b>	9	<INTEGER>	-	Specifies number of nodes allocated to reservation at event time.
<b>Total Active Proc-Seconds</b>	10	<INTEGER>	-	Specifies proc-seconds reserved resources were dedicated to one or more job at event time.
<b>Total Proc-Seconds</b>	11	<INTEGER>	-	Specifies proc-seconds resources were reserved at event time.
<b>Hostlist</b>	12	<comma-delimited list of hostnames>	-	Specifies list of hosts reserved at event time.
<b>Owner</b>	13	<STRING>	-	Specifies reservation <a href="#">ownership</a> credentials.
<b>ACL</b>	14	<STRING>	-	Specifies reservation <a href="#">access control list</a> .
<b>Comment</b>	15	<STRING>	-	Specifies general human readable event message.
<b>Command Line</b>	16	<STRING>	-	Displays the command line arguments used to create the reservation (only shows on the rsvcreate event).

## Recording Job Events

Job events occur when a job undergoes a definitive change in state. Job events include submission, starting, cancellation, migration, and completion. Some site administrators do not want to use an external accounting system and use these logged events to determine their clusters' accounting statistics. Moab can be configured to record these events in the appropriate event file found in the Moab `stats/` directory. To enable job event recording for both local and remotely staged jobs, use the [RECORDEVENTLIST](#) parameter. For example:

```
RECORDEVENTLIST JOBCANCEL, JOBCOMPLETE, JOBSTART, JOBSUBMIT
...
```

*This configuration records an event each time both remote and/or local jobs are canceled, run to completion, started, or submitted. The [Event Logs](#) section details the format of these records.*

## Interactive Simulation Tutorial

This of this section provides an interactive tutorial to demonstrate the basics of the simulator's capacities in Moab. It is an example of what you can do once you have set up simulation. The commands to issue are formatted as follows: > `showq` along with the expected output.

The following commands are used:

- [showq \[-r\] \[-i\]](#)
- [showstats \[-g\] \[-u\] \[-v\]](#)
- [mschedctl -l](#)
- [mschedctl \[{-s|-S} \[I\]\] \[-k\]](#)
- [checkjob](#)
- [mschedctl -m](#)
- [mdiag -n](#)
- [showres \[-n jobid\]](#)
- [setres](#)

## To run through the simulation mode tutorial

1. Run moab.

```
> moab&
```

2. Check the status of the queue (see [Checking the Queue Status](#)).
3. Check the status of the job. If any jobs are not running, find the problem (see [Determining Why Jobs Are Not Running](#)).
4. Advance and check the status of Moab iterations and time in simulation mode (see [Controlling Iterations](#)).
5. View and manage reservations and their nodes and jobs (see [Managing Reservations Applying to the Queue](#)).
6. Verify that the Moab simulation is scheduling fairly (see [Verifying Fair Scheduling](#)).
7. Take down the entire system for maintenance (see [Taking the System Down for Maintenance](#)).

### Checking the Queue Status

Verify that Moab is running by executing `showq`:

```

> showq
active jobs-----
JOBNAME          USERNAME      STATE  PROC   REMAINING          STARTTIME
fr8n01.187.0      570          Running 20  1:00:00:00  Mon Feb 16 11:54:03
fr8n01.189.0      570          Running 20  1:00:00:00  Mon Feb 16 11:54:03
fr8n01.190.0      570          Running 20  1:00:00:00  Mon Feb 16 11:54:03
fr8n01.191.0      570          Running 20  1:00:00:00  Mon Feb 16 11:54:03
fr8n01.276.0      550          Running 20  1:00:00:00  Mon Feb 16 11:54:03
frln04.369.0      550          Running 20  1:00:00:00  Mon Feb 16 11:54:03
frln04.487.0      550          Running 20  1:00:00:00  Mon Feb 16 11:54:03
  7 active jobs    140 of 196 Processors Active (71.43%)
eligible jobs-----
JOBNAME          USERNAME      STATE  PROC   WCLIMIT          QUEUETIME
frln04.362.0      550          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.363.0      550          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.365.0      550          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.366.0      550          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.501.0      570          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.580.0      570          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.597.0      570          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.598.0      570          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
frln04.602.0      570          Idle   20   1:00:00:00  Mon Feb 16 11:53:33
  9 eligible jobs
blocked jobs-----
JOBNAME          USERNAME      STATE  PROC   WCLIMIT          QUEUETIME
0 blocked jobs
Total jobs: 16

```

*Out of the thousands of jobs in the workload trace, only 16 jobs are either active or eligible because of the default settings of the [SIMINITIALQUEUEDEPTH](#) parameter. Sixteen jobs are put in the idle queue, seven of which immediately run. Issuing the command `showq -r` allows a more detailed look at the active (or running) jobs. The output is sorted by job completion time and indicates that the first job will complete in one day (1:00:00:00).*

## Determining Why Jobs Are Not Running

While `showq` details information about the queues, scheduler statistics may be viewed using the [showstats](#) command. The field Current Active/Total Procs shows current system utilization, for example.

```

> showstats
moab active for      00:00:30  stats initialized on Mon Feb 16 11:53:33
Eligible/Idle Jobs:          9/9          (100.000%)
Active Jobs:                  0
Successful/Completed Jobs:    0/0          (0.000%)
Avg/Max QTime (Hours):        0.00/0.00
Avg/Max XFactor:              0.00/0.00
Dedicated/Total ProcHours:    1.17/1.63    (71.429%)

Current Active/Total Procs:      140/196      (71.429%)

Avg WallClock Accuracy:      N/A
Avg Job Proc Efficiency:      N/A
Est/Avg Backlog (Hours):      N/A / N/A

```

You might be wondering why there are only 140 of 196 Processors Active (as shown with `showq`) when the first job (`frln04.362.0`) in the queue only requires 20 processors. We will use the [checkjob](#) command, which reports detailed job state information and diagnostic output for a particular job to determine why it is not running:

```

> checkjob frln04.362.0
job frln04.362.0
State: Idle
...
Network: hps_user  Memory >= 256M  Disk >= 0  Swap >= 0
...
Job Eligibility Analysis -----
job cannot run in partition DEFAULT (idle procs do not meet requirements : 8 of 20
procs found)
idle procs: 56  feasible procs: 8
Rejection Reasons: [Memory : 48][State : 140]

```

*checkjob not only tells us the job's wallclock limit and the number of requested nodes (they're in the ellipsis) but explains why the job was rejected from running. The Job Eligibility Analysis tells us that 48 of the processors rejected this job due to memory limitations and that another 140 processors rejected it because of their state (that is, they're running other jobs). Notice the >= 256 M(B) memory requirement.*

If you run `checkjob` with the ID of a running job, it would also tell us exactly which nodes have been allocated to this job. There is additional information that the [checkjob](#) command page describes in more detail.

### Controlling Iterations

Advancing the simulator an iteration, the following happens:

```

> mschedctl -S
scheduling will stop in 00:00:30 at iteration 1

```

The scheduler control command, [mschedctl](#), controls various aspects of scheduling behavior. It can be used to manage scheduling activity, kill the scheduler, and create resource trace files. The `-S` argument indicates that the scheduler run for a single iteration and stop. Specifying a number, *n*, after `-S` causes the simulator to advance *n* steps. You can determine what iteration you are currently on using `showstats -v`.

```

> showstats -v
current scheduler time: Mon Feb 16 11:54:03 1998 (887655243)
moab active for      00:01:00  stats initialized on Mon Feb 16 11:53:33
statistics for iteration      1  scheduler started on Wed Dec 31 17:00:00
...

```

*The line that starts with statistics for iteration <X> specifies the iteration you are currently on. Each iteration advances the simulator **RMPOLLINTERVAL** seconds. By default, **RMPOLLINTERVAL** is set to 30 seconds.*

To see what **RMPOLLINTERVAL** is set to, use the [showconfig](#) command:

```

> showconfig | grep RMPOLLINTERVAL
RMPOLLINTERVAL      30,30

```

The `showq -r` command can be used to display the running (active) jobs to see what happened in the last iteration:

```

> showq -r
active jobs-----
JOBID          S PAR  EFFIC  XFACTOR  Q      USER   GROUP   MHOST  PROCS
REMAINING      STARTTIME
fr8n01.804.0    R  1  -----    1.0  -      529    519    fr9n16   5
00:05:00 Mon Feb 16 11:54:03
fr8n01.187.0    R  1  -----    1.0  -      570    519    fr7n15  20
1:00:00:00 Mon Feb 16 11:54:03
...
fr8n01.960.0    R  1  -----    1.0  -      588    519    fr9n11  32
1:00:00:00 Mon Feb 16 11:54:03
  9 active jobs      177 of 196 Processors Active (90.31%)
Total jobs:  9

```

*Notice that two new jobs started (without waiting in the eligible queue). Also notice that job fr8n01.187.0, along with the rest that are summarized in the ellipsis, did NOT advance its REMAINING or STARTTIME.*

The simulator needs one iteration to do a sanity check. Setting the parameter **STOPITERATION** to 1 causes Moab to stop after the first scheduling iteration and wait for further instructions.

The `showq -i` command displays the idle (eligible) jobs.

```

> showq -i
eligible jobs-----
JOBID          PRIORITY  XFACTOR  Q      USER   GROUP  PROCS   WCLIMIT

batch Mon Feb 16 11:54:03
14 eligible jobs
Total jobs: 14

```

*Notice how none of the eligible jobs are requesting 19 or fewer jobs (the number of idle processors). Also notice the \* after the job id frln04.362.0. This means that this job now has a reservation.*

## Managing Reservations Applying to the Queue

The `showres` command shows all reservations currently on the system.

```
> showres
ReservationID      Type S      Start      End      Duration  N/P      StartTime
fr8n01.187.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr8n01.189.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr8n01.190.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr8n01.191.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr8n01.276.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr1n04.362.0      Job I      1:00:00:00 2:00:00:00 1:00:00:00 20/20    Tue Feb 17
11:54:03
fr1n04.369.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr1n04.487.0      Job R      00:00:00   1:00:00:00 1:00:00:00 20/20    Mon Feb 16
11:54:03
fr8n01.804.0      Job R      00:00:00   00:05:00   00:05:00   5/5      Mon Feb 16
11:54:03
fr8n01.960.0      Job R      00:00:00   1:00:00:00 1:00:00:00 32/32    Mon Feb 16
11:54:03
10 reservations located
```

*Here, the S column is the job's state (R = running, I = idle). All the active jobs have a reservation along with idle job fr1n04.362.0. This reservation was actually created by the backfill scheduler for the highest priority idle job as a way to prevent starvation while lower priority jobs were being backfilled (The [backfill documentation](#) describes the mechanics of the backfill scheduling more fully).*

To display information about the nodes that job fr1n04.362.0 has reserved, use `showres -n <JOBID>`.

```
> showres -n fr1n04.362.0
reservations on Mon Feb 16 11:54:03
NodeName          Type      ReservationID  JobState Task      Start
Duration  StartTime
fr5n09          Job      fr1n04.362.0  Idle    1  1:00:00:00
1:00:00:00  Tue Feb 17 11:54:03
...
fr7n15          Job      fr1n04.362.0  Idle    1  1:00:00:00
1:00:00:00  Tue Feb 17 11:54:03
20 nodes reserved
```

Now advance the simulator an iteration to allow some jobs to actually run.

```
> mschedctl -S
scheduling will stop in 00:00:30 at iteration 2
```

Next, check the queues to see what happened.

```

> showq
active jobs-----
JOBNAME          USERNAME      STATE  PROC   REMAINING          STARTTIME
fr8n01.804.0      529          Running  5     00:04:30  Mon Feb 16 11:54:03
fr8n01.187.0      570          Running  20    23:59:30  Mon Feb 16 11:54:03
...
    9 active jobs      177 of 196 Processors Active (90.31%)
eligible jobs-----
JOBNAME          USERNAME      STATE  PROC   WCLIMIT          QUEUETIME
...
fr8n01.963.0      586          Idle    32     9:00:00  Mon Feb 16 11:54:33
fr8n01.1016.0    570          Idle    20    1:00:00:00  Mon Feb 16 11:54:33
16 eligible jobs
...

```

Two new jobs, fr8n01.963.0 and fr8n01.1016.0, are in the eligible queue. Also, note that the first job will now complete in 4 minutes 30 seconds rather than 5 minutes because we have just advanced now by 30 seconds, one **RMPOLLINTERVAL**. It is important to note that when the simulated jobs were created, both the job's wallclock limit and its actual run time were recorded. The wallclock limit is specified by the user indicating their best estimate of an upper bound on how long the job will run. The *run time* is how long the job actually ran before completing and releasing its allocated resources. For example, a job with a wallclock limit of 1 hour will be given the needed resources for up to an hour but may complete in only 20 minutes.

Stop the simulation at iteration 6.

```

> mschedctl -s 6I
scheduling will stop in 00:03:00 at iteration 6

```

*The -s 6I argument indicates that the scheduler will stop at iteration 6 and will (I)gnore user input until it gets there. This prevents the possibility of obtaining showq output from iteration 5 rather than iteration 6.*

```

> showq
active jobs-----
JOBNAME          USERNAME      STATE  PROC   REMAINING          STARTTIME
fr8n01.804.0      529          Running  5     00:02:30  Mon Feb 16 11:54:03
...
fr1n04.501.0      570          Running  20    1:00:00:00  Mon Feb 16 11:56:33
fr8n01.388.0      550          Running  20    1:00:00:00  Mon Feb 16 11:56:33
    9 active jobs      177 of 196 Processors Active (90.31%)
...
    14 eligible jobs
...

```

*Job fr8n01.804.0 is still 2 minutes 30 seconds away from completing as expected, but notice that both jobs fr8n01.189.0 and fr8n01.191.0 have completed early. Although they had almost 24 hours remaining of wallclock limit, they terminated. In reality, they probably failed on the real world system where the trace file was being created. Their completion freed up 40 processors which the scheduler was able to immediately use by starting several more jobs.*

Note the system statistics:

```

> showstats
...
Successful/Completed Jobs:          0/2          (0.000%)
...
Avg WallClock Accuracy:             0.150%
Avg Job Proc Efficiency:            100.000%
Est/Avg Backlog (Hours):            0.00/3652178.74

```

A few more fields are filled in now that some jobs have completed providing information on which to generate statistics.

Decrease the default [LOGLEVEL](#) with `mschedctl -m` to avoid unnecessary logging, and speed up the simulation.

```
> mschedctl -m LOGLEVEL 0
INFO: parameter modified
```

*You can use `mschedctl -m` to immediately change the value of any parameter. The change is only made to the currently running Moab server and is not propagated to the configuration file. Changes can also be made by modifying the configuration file and restarting the scheduler.*

Stop at iteration 580 and pull up the scheduler's statistics.

```
> mschedctl -s 580I; showq
scheduling will stop in 4:47:00 at iteration 580
...
  11 active jobs      156 of 196 Processors Active (79.59%)
eligible jobs-----
JOBNAME              USERNAME      STATE  PROC    WCLIMIT      QUEUETIME
fr8n01.963.0         586          Idle   32     9:00:00  Mon Feb 16 11:54:33
fr8n01.1075.0        560          Idle   32    23:56:00  Mon Feb 16 11:58:33
fr8n01.1076.0        560          Idle   16    23:56:00  Mon Feb 16 11:59:33
fr1n04.1953.0        520          Idle   46     7:45:00  Mon Feb 16 12:03:03
...
16 eligible jobs
...
```

*You may note that `showq` hangs a while as the scheduler simulates up to iteration 580. The output shows that currently only 156 of the 196 nodes are busy, yet at first glance 3 jobs, `fr8n01.963.0`, `fr8n01.1075.0`, and `fr8n01.1076.0` appear to be ready to run.*

```

> checkjob fr8n01.963.0; checkjob fr8n01.1075.0; checkjob fr8n01.1076.0
job fr8n01.963.0
...
Network: hps_user  Memory >= 256M  Disk >= 0  Swap >= 0
...
Job Eligibility Analysis -----
job cannot run in partition DEFAULT (idle procs do not meet requirements : 20 of 32

...
job cannot run in partition DEFAULT (idle procs do not meet requirements : 0 of 32
procs found)
idle procs: 40  feasible procs: 0
Rejection Reasons: [Memory : 20][State : 156][ReserveTime : 20]

job fr8n01.1076.0
...
Network: hps_user  Memory >= 256M  Disk >= 0  Swap >= 0
...
job cannot run in partition DEFAULT (idle procs do not meet requirements : 0 of 16
procs found)
idle procs: 40  feasible procs: 0
Rejection Reasons: [Memory : 20][State : 156][ReserveTime : 20]

```

*The checkjob command reveals that job fr8n01.963.0 only found 20 of 32 processors. The remaining 20 idle processors could not be used because the configured memory on the node did not meet the jobs requirements. The other jobs cannot find enough nodes because of ReserveTime. This indicates that the processors are idle, but that they have a reservation in place that will start before the job being checked could complete.*

Verify that the idle nodes do not have enough memory configured and they are already reserved with the [mdiag -n](#) command, which provides detailed information about the state of nodes Moab is currently tracking. The [mdiag](#) command can be used with various flags to obtain detailed information about [accounts](#), [blocked jobs](#), [fair share](#), [groups](#), [jobs](#), [nodes](#), [QoS](#), [reservations](#), the [resource manager](#), and [users](#). The command also performs a number of sanity checks on the data provided and will present warning messages if discrepancies are detected.

```

> mdiag -n -v | grep -e Name -e Idle

Total Nodes: 196 (Active: 156 Idle: 40 Down: 0)

```

*The grep gets the command header and the idle nodes listed. All the idle nodes with 256 MB of memory installed already have a reservation. (See the Rsv column.) The rest of the idle nodes only have 128 MB of memory.*

```

> checknode fr10n09
node fr10n09
State:      Idle (in current state for 4:21:00)
Configured Resources: PROCS: 1 MEM: 256M SWAP: 401G DISK: 9780M
Utilized Resources: [NONE]
Dedicated Resources: [NONE]
..
Total Time: 4:50:00 Up: 4:50:00 (100.00%) Active: 00:34:30 (11.90%)
Reservations:
Job 'fr8n01.963.0' (x1) 3:25:00 -> 12:25:00 (9:00:00)

```

*Using `checknode` revealed that Job `fr8n01.963.0` has the reservation.*

### Moving ahead:

```

> mschedctl -S 500I;showstats -v
scheduling will stop in 4:10:00 at iteration 1080
...
Eligible/Idle Jobs:          16/16          (100.000%)
Active Jobs:                 11
Successful/Completed Jobs:   2/25          (8.000%)
Preempt Jobs:                0
Avg/Max QTime (Hours):      0.00/0.00
Avg/Max XFactor:            0.00/1.04
Avg/Max Bypass:             0.00/13.00
Dedicated/Total ProcHours:   1545.44/1765.63 (87.529%)
Preempt/Dedicated ProcHours: 0.00/1545.44 (0.000%)
Current Active/Total Procs:  156/196        (79.592%)
Avg WallClock Accuracy:     9.960%
Avg Job Proc Efficiency:     100.000%
Min System Utilization:     79.592% (on iteration 33)
Est/Avg Backlog (Hours):    0.00/20289.84

```

*We now know that the scheduler is scheduling efficiently. So far, system utilization as reported by `showstats -v` looks very good.*

### Verifying Fair Scheduling

An important and subjective question is whether the scheduler is scheduling fairly. Look at the user and group statistics to see if there are any glaring problems.

### Taking the System Down for Maintenance

Suppose you need to now take down the entire system for maintenance on Thursday from 2:00 to 8:00 a.m. To do this, create a reservation with [mrsvctl -c](#).

```
> mrsvctl -c -t ALL -s 2:00_02/17 -d 6:00:00
```

Shut down the scheduler.

```
> mschedctl -k
moab will be shutdown immediately
```

# Green computing

## Green computing overview

SearchDataCenter.com defines green computing as the environmentally responsible use of computers and related resources. Such practices include the implementation of energy-efficient central processing units (CPUs), servers, and peripherals as well as reduced resource consumption and proper disposal of electronic waste (e-waste).

The Moab HPC Suites, both Basic Edition and Enterprise Edition, contain power management features that give a Moab administrator the ability to implement policies that can conserve energy and save on operational costs, often without affecting an HPC system's performance with regard to job execution times.

Effective power management means managing power or energy consumption while a compute node is actively running jobs, and when a compute node is idle. Both scenarios require different tools and policies.

- Active compute node power management is mainly performed through control of the clock frequency of the processor(s) on a compute node while a job is executing. Decreasing the clock frequency can reduce energy usage.
- Idle compute node power management is mainly performed by placing a compute node into different low-power states, such as standby and suspend, or no-power states, such as hibernate and shutdown.

The table below identifies the Moab power management features and/or methods available for the different Moab HPC Suite editions.

Feature or Method	Moab HPC Suite Edition	
	Basic	Enterprise
CPU Clock Frequency Control		
• Moab Job Submission Option	X	X
• TORQUE Job Submission Option	X	X
• Moab Job Template Option	X	X
Manual Power Management		
• Moab-based on and off states	-	X
• TORQUE-based low-power and no-power states	X	X

	-	X

## Moab Power Management Methods

Moab supports two separate and mutually-exclusive methods for managing the power state of compute nodes, which affects energy consumption. The first method, introduced in Moab 7.2, allows an administrator to manually power on and power off compute nodes and to create a global set of green policies that automatically perform these two functions based on specific conditions involving idle compute nodes. The second method, introduced in Moab 8.0 and TORQUE 5.0, give an administrator additional power states besides `on` and `off` and offer finer control of green policies at the global, partition, and node levels. Before delving into the theory of operation of these two separate methods, an administrator must understand how Moab views power management regardless of which method is used.

### Moab View of Power Management

Moab is not aware of the actual power state of nodes. From Moab's perspective, nodes are only on or off. If Moab needs a node that is off, it issues a power-on job prior to scheduling the incoming job.

In addition, in order to schedule a job to a compute node, Moab requires the compute node's workload resource manager, which in our example is TORQUE, to report the compute node's state is `idle`. When the compute node's binary power state indicates `on` and the RM indicates the compute node's state is `idle`, Moab will schedule jobs to the compute node. Any value other than `idle` for the node's state and Moab will not schedule a job to the node. If the power state is `off`, Moab issues a power-on job as a dependency to the regular job.

Moab performs compute node power management entirely through power management resource managers, or Power RMs. Each of the two power management methods mentioned above has its own Power RM implementation. The older Moab-only method uses Python-based scripts to implement a power RM while the newer Moab+Moab Web Services (MWS)-based method uses a Java-based MWS RM power management plug-in that runs much simpler Python-based scripts.

These Power RMs perform all power-related management and monitoring, meaning power state control and power state query, respectively, and only report back to Moab whether a compute node is in a state in which it can run jobs (`on`) or not (`off`). All actual power state-aware control and management is performed by the power RMs.

## Moab Power RMs

Adaptive Computing provides two power management methods to handle different site scenarios; mainly for site-specific security policies. The older method handles sites with a security policy that does not permit web service-based services, which can be an attack vector, or sites that do not want to run an MWS service.

The newer method uses the MWS RM plug-in feature, which allows an administrator to instantiate a separate RM power management plug-in instance for different partitions, or different compute nodes for situations where different compute node hardware requires the use of different power management commands run from Python scripts.

## Power Management Scripts

Each power management method, old or new, employs at some point a script that allows the administrator to customize power management for a site, which may be required because the working reference scripts provided by Adaptive Computing (based on OpenIPMI tools) do not use the power management commands specific to the site's vendor-provided hardware.

## Moab System Jobs

Moab performs power management functions through a mechanism known as system jobs. A Moab system job is a special, separately scheduled job that performs some Moab system function (e.g., power management, data-staging) that Moab executes on the Moab head node and not on a compute node. This allows Moab to apply policies such as a job wallclock estimate, etc, to system-related functions, which can aid error recovery procedures, etc.

System jobs perform internal Moab-related functions on Moab's behalf, are nearly always script-based, and usually require some customization by the Moab administrator in order to perform the needed function for the HPC system site. For example, the administrator may have to modify power management scripts so they use a site's hardware vendor-specific power management commands to effect power state changes in compute nodes.

To create a system job, Moab internally submits an administrator-defined script, with a path typically specified as a Moab `*URL` parameter, to itself, which it flags as a system job. Moab schedules the job and because it is flagged as a system job, executes the script on the head node. Moab submits a system job whenever it needs to send a power on or off command to a Power RM. Administrators can easily recognize queued and running power management system jobs in the `showq` command output as their job id has the format `id.poweron` and `id.poweroff`, where `id` is the internally generated Moab job id number and `.poweron` and `.poweroff` are suffixes appended to the job id number that represent Moab's on and off commands sent to Power RMs.

## Green Policies

Moab provides green policies that automate power management for idle compute nodes, which an administrator can modify and/or configure to control the power state of compute nodes not always in use. These policies allow Moab to dynamically control the power state of compute nodes between the active running state or power-on nodes that may be needed. It also allows Moab to power-off nodes that are idle and wasting energy. Which power state such compute nodes enter depends entirely on the commands the administrator configures and/or modifies in a power RM's scripts and, for the newer

Moab+MWS method, on configuration information specified for each MWS RM power management plug-in instance.

The green policies maintain a green idle node pool, the size of which the administrator configures. As jobs start and use idle nodes from the pool, Moab replenishes the pool by performing an `on` command on those compute nodes on which it previously had performed an `off` command, thus bringing them into the idle node pool as they enter into an active running state. When jobs finish and the pool has excess idle nodes, Moab performs an `off` command on the excess nodes, which removes them from the idle pool. Thus, Moab maintains a pool of available idle nodes for immediate use by submitted jobs and reduces energy consumption by powering off any idle nodes in excess of the pool size.

## Theory of Operation

Moab itself operates the same regardless of the method of power management, Moab-only or Moab+MWS, chosen. This is especially true for the green policies as Moab simply uses the configured power management method to carry out the policies. In order to know how to configure the different parts and components of each power management method so they work well together, it is necessary for a site administrator to understand how the power management methods work; that is, how the components work together to implement a power management method.

### Moab-only Method

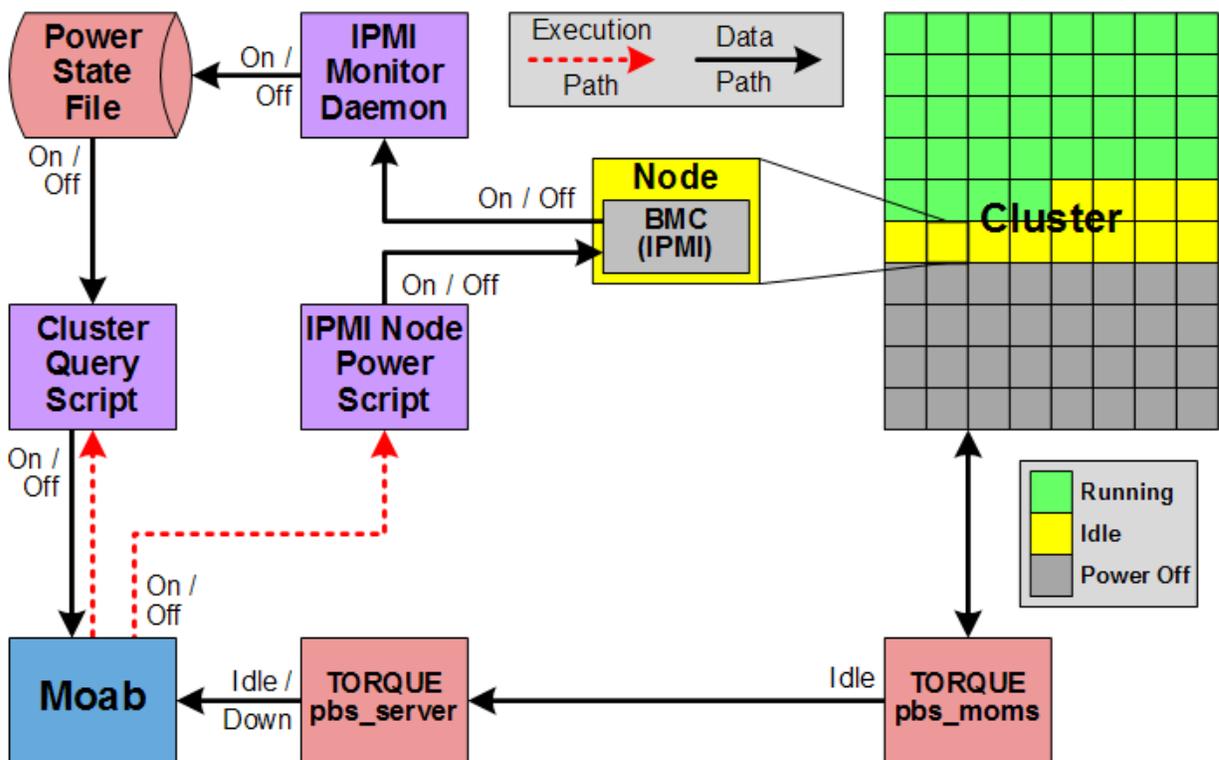

The Moab-only method has a Power RM composed entirely of Python-based scripts. The script must maintain a Power Query daemon that queries the power state of all compute nodes and saves their state for Moab to query, the actual power state query Moab runs to find out the current power state of all compute nodes, and a power state control that places compute nodes into the state of `on` so Moab can schedule jobs to them or into the state of `off` so energy consumption is minimized and operational costs reduced. The administrator determines what the actual power state Moab's `off` represents by configuring the `off` command in the power management control script with the actual hardware vendor-supplied command that effects the desired power state (remember, Moab is not aware of actual power states).

The list below enumerates the advantages and disadvantages of the Moab-only method.

- Advantages
  - Do not have to run the MWS service and its MongoDB database.
  - Power management command scripts execute as Moab system jobs.
  - Ability to customize the node power and cluster query power management scripts
    - For more information on how to specify the node power control script, see the [NODEPOWERURL](#) parameter.
    - For more information on how to specify the power cluster query script, see the [CLUSTERQUERYURL](#) parameter.
  - Moab power control using `mnodectl -m power=[on|off] <nodelist>`.
    - For more information on how to diagnose power states, see [mdiag -n](#).

- Disadvantages
  - More complex scripts to customize.
  - Only global power management control (no partition-based or node-based).
  - Heterogeneous compute node hardware from different vendors requires more modification of the control and query scripts.
  - Reference scripts not scalable (did not take advantage of Python multi-threading).
  - Administrator must maintain complex scripts that must maintain the entire cluster query information.

The following architecture diagram shows the Moab-only architecture and what occurs between its components.

The Python-based IPMI Monitor daemon script running in the background periodically polls the power state of all compute nodes through IPMI using the command customized by the administrator. As it gathers power state information, it saves the information in a text file in a specific format understood by Moab (binary power state). In order to prevent race conditions, it actually writes to a temporary file and then moves the temporary file on top of the permanent file (not shown).

When Moab starts a scheduling cycle/iteration, it directly executes the power RM's Python-based Cluster Query script that reads the permanent text file and delivers the compute node power states to Moab. Moab then performs the scheduling cycle and based on green policies and the state of the HPC cluster will run the IPMI Node Power script as a Moab system job to perform an `on` or `off` (which may be

something different than a `power off`) command using the actual commands customized by the administrator in the script.

## Moab+MWS Method

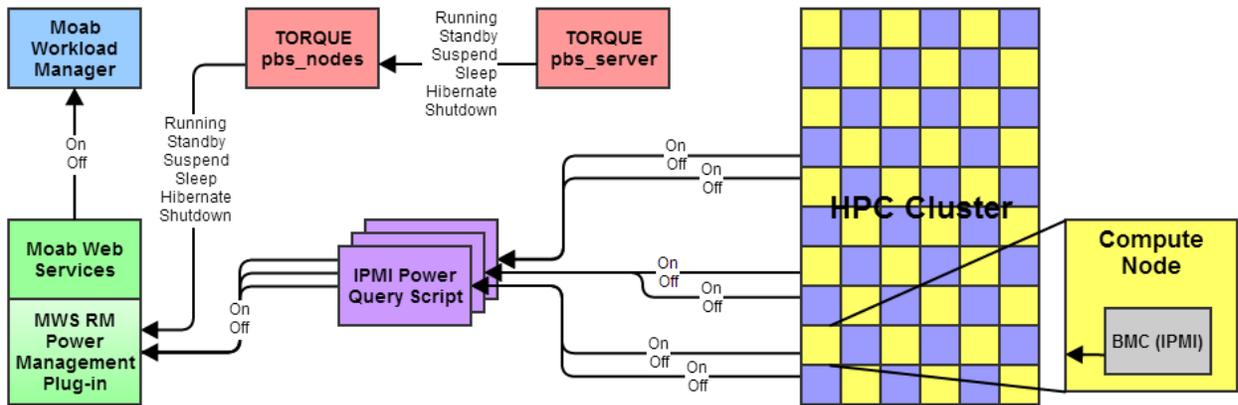

The Moab+MWS method has a Power RM composed of a MWS RM plug-in that encapsulates all power management logic, which itself uses the TORQUE `pbsnodes` command to effect compute node power state changes into low-power and no-power states of standby and suspend, and hibernate and shutdown, respectively, as well as the IPMI Node Power script to effect compute node power on, power off (pull the plug) and awaken (resume active running state from low-power state). The Power RM Power Management plug-in also performs the power query daemon function identified in the Moab-only method using its built-in power management logic, thus handling more actual power states and allowing much better power control than the Moab-only method offers.

The advantages and disadvantages of the Moab+MWS-based method are enumerated below.

- Advantages
  - More power states to choose from.
    - Low-power states of standby and suspend.
    - No-power states of hibernate and shutdown.
    - On and Off (pull the plug) power states still available.
  - TORQUE power control of low-power and no-power states using `pbsnodes -m <state> <nodelist>`.
    - You can view node power states with the `pbsnodes` command.
  - Power management command scripts execute as Moab system jobs.
  - Much simpler `moab.cfg` [customization and maintenance](#).
  - Global, partition-based, and node-based granularity for power management control.
  - Heterogeneous compute node hardware from different vendors handled by creating multiple instances of MWS RM power management plug-in with different configurations.
  - Reference scripts are scalable (use Python multi-threading).
  - The MWS RM architecture is easier to support DRAC, ILO, and other protocols.
- Disadvantages
  - Must run the MWS service and its MongoDB database.
  - Configuration of the MWS RM Power Management plug-in and possible multiple instances.

The following architecture diagrams show the Moab+MWS-based method architecture and what occurs between its components.

The diagram below illustrates power state query:

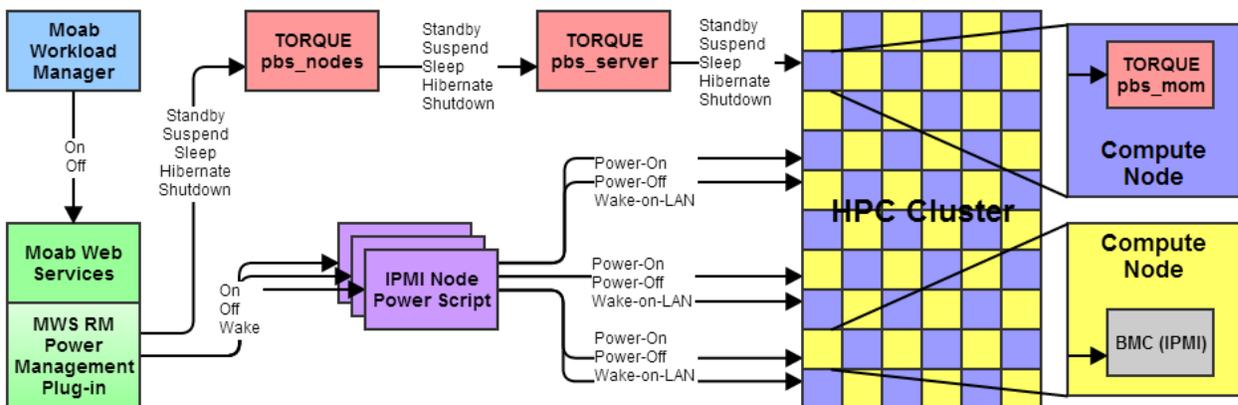

The MWS RM power management plug-in runs the multi-threaded Power Query script for sets of compute nodes which obtain their actual power state through IPMI, or more specifically, a hardware vendor's IPMI implementation (e.g., Dell DRAC, HP iLO, etc), which the RM plug-in saves. It also runs the TORQUE `pbsnodes` command to obtain the low-power or no-power states that may have been set via TORQUE earlier (`pbs_server` retains knowledge of any previous command to set a node's power state to one of the low-power or no-power states).

Note it is quite possible for IPMI to report `off` and TORQUE to report `hibernate` or `shutdown`, both of which indicate a compute node has no power, and for IPMI to report `on` and TORQUE to report `standby` or `suspend`, both of which indicate a compute node is in a low-power state from which it can be quickly awakened. It is also possible for IPMI to report `on` and TORQUE to report `hibernate` or `shutdown`, which can indicate a booting node that has not yet started the TORQUE `pbs_mom` daemon or a node hibernating or shutting down that has not yet powered off. The MWS plug-in's power management logic reconciles the IPMI and TORQUE reports to produce a single `on` or `off` understood by Moab, which it passes to MWS.

When Moab queries MWS for the current state information of compute nodes at the start of a scheduling cycle/iteration, MWS passes all node information including the binary power on/off Moab understands and the TORQUE node state, at which point Moab has the information it needs to perform green policy-based automated power management.

The diagram below illustrates Moab+MWS power state control interactions.

When Moab detects a condition that requires changing the power state of a compute node, usually as a result of green policies, it performs the appropriate `on` or `off` command as a system job that sends the command to MWS with a list of the host names of compute nodes that should enter an appropriate power state.

MWS interacts with the appropriate MWS RM power management plug-in for each compute node and passes it the `on` or `off` command. For the `off` command, the plug-in examines its configuration of what `off` means and passes the configured standby, suspend, hibernate, or shutdown command to the TORQUE `pbsnodes` command, or passes the configured `off` command to the Node Power script.

If the RM plug-in executes the TORQUE `pbsnodes` command for the configured power state and requested list of compute node host names, it sends the command to the `pbs_server`, which passes the command to each compute node's `pbs_mom` daemon. The `pbs_mom` executes software to place the node into the requested state. The `pbs_server` daemon keeps the requested state in a file for each compute node, which it passes on to the MWS RM power management plug-in as part of a node update report.

**i** In clusters where there is a TORQUE `pbs_server` and `pbs_mom` on the same machine, the administrator should set the **POWERPOLICY** to **STATIC** on this node, because the `pbs_server` should not be powered down. If the `pbs_server` is powered down, Moab will be unable to get cluster query updates from all `pbs_moms` managed by that that `pbs_server`.

On all TORQUE nodes where `pbs_moms` are running, the `pbs_mom` must be configured to auto-start after being rebooted. If the `pbs_mom` isn't auto-started, the `pbs_server` will not be able to determine when it has been powered up and entered an idle state, and therefore won't have the ability to inform Moab on a cluster query the node is idle. Refer to [Startup/Shutdown service script for TORQUE/Moab \(OPTIONAL\)](#) on page 2836 for Torque/Moab for details on how to have the `pbs_mom` auto-start on boot.

When the RM plug-in executes the Node Power script for the configured `off` power state and requested list of compute node host names, the script executes its IPMI `on` command (whatever the administrator configured in the script) that tells the node's BMC to power off the node.

When the RM plug-in receives the `on` command from Moab via MWS, it checks the internal power state of each compute node in the requested list of compute node host names. If the internal power state is standby or suspend, the script executes its IPMI `wake` command (whatever the administrator configured in the script) that tells the node's BMC to bump the node into the active running state; otherwise, the script executes its IPMI `off` command (whatever the administrator configured in the script) that tells the node's BMC to power on the node.

**i** Some operating systems require the Wake-on-LAN bit to be enabled using a tool like `ethtool`. Also, Wake-on-LAN packets may be blocked by the router, but not always.

In this manner, the MWS RM power management plug-in queries the actual power state of individual compute nodes and returns to Moab the simple binary on/off state it understands for scheduling jobs to compute nodes. Likewise, Moab controls the actual power state of individual compute nodes using only its simple binary on/off command. This method of simple command and simple job-scheduling-ability state enables Moab to remain scalable and responsive for automatic power management control using green policies.

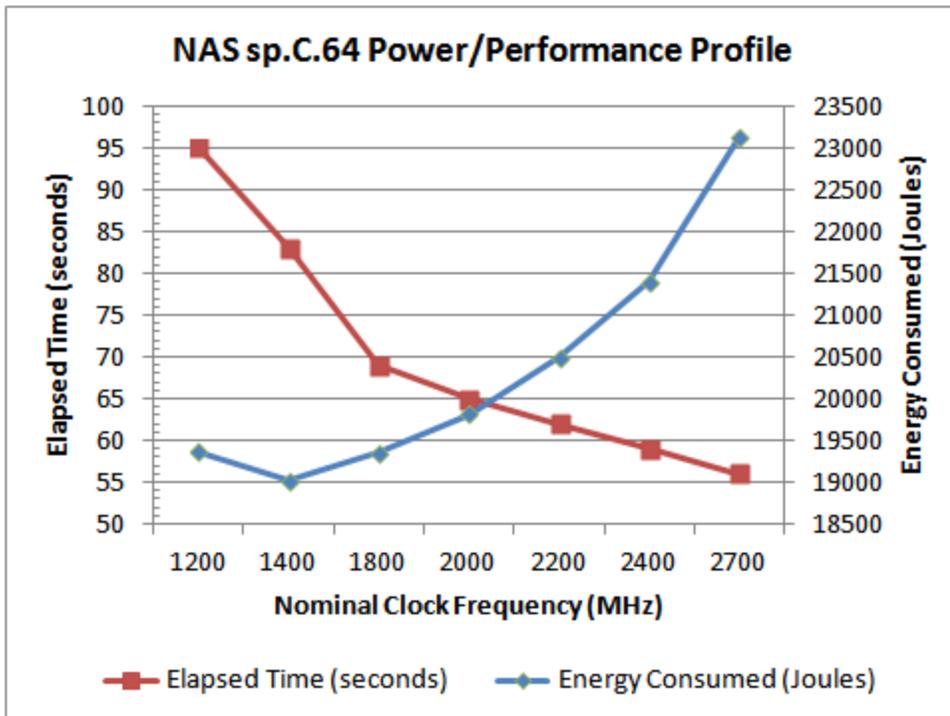

## Active Node Power Management

Moab 8.0 and TORQUE 5.0 introduce support for active node power management; that is, the management of energy consumption while a compute node is running a job, which the new CPU Clock Frequency Control feature provides.

The amount of energy consumption savings achievable through the CPU Clock Frequency Control feature is application-dependent. For example, memory, I/O, and/or network-bound applications, especially memory-bound applications, can often drop the clock frequency of their compute nodes' processors and still have the same execution time even though the compute nodes consume less power. Several studies have shown common power savings of 18-20% and one study showed one application saving 30% on power consumption, all of which translate directly into operational cost savings.

### Power/Performance Profiling

To determine whether a lower clock frequency will produce energy consumption savings, applications must be profiled; that is, a job running a particular application with the same or equivalent data must be run at different clock frequencies while measuring the energy consumption of the job's compute node. Each pair of frequency/energy consumption data points are plotted in a chart to show the application's power performance profile. The charts below are an example of two such profiles for two NAS benchmark HPC applications.

The intersection of the two lines has no meaning as each line has its own vertical scale, either on the left or the right as noted!

Note both applications do not consume the least energy (vertical dashed green line) when running at the lowest clock frequency, which demonstrate the importance of profiling applications to determine the nominal clock frequency at which energy consumption is the lowest. The charts amply illustrate why a simplistic policy of using the lowest clock frequency is not the best policy when a site's objective is the least energy consumption possible.

If the least energy consumption is not a site's primary objective, but running jobs in a manner that balances energy consumption and job execution time, a power/performance profile chart is very useful to determine the clock frequency that meets a balanced objective. For example, the vertical dashed purple line on the right chart shows that running the `bt.C.64` application at 1800 MHz has an increase in energy consumption of ~1% over the minimal energy consumption possible (vertical dashed green line) but results in a ~10% drop in execution time; a possibly very good trade-off!

Obviously, if a site's primary objective is to complete a job as fast as possible but do so saving energy where possible, profiling memory-bound and other bound applications can clearly show the lowest clock frequency at which the application takes longer to execute. The site would then institute a policy that the application should run at the next highest frequency to fulfill the twin objectives of job performance and energy consumption minimization.

For more information about the CPU clock frequency job submission option, see [CPUCLOCK resource manager extension](#) of [msub -l](#).

### *Job Templates*

Most users will not care or want to know about clock frequency control, so administrators can use a job template to specify the CPU clock frequency at which a particular recurring job should execute. A clock frequency specified on a job template overrides a clock frequency given on the job submission command line or inside a job script file with TORQUE PBS commands. This order of precedence allows an administrator to control clock frequency for commonly used applications and jobs based on site policies and objectives.

For more information about using a CPU clock frequency job submission option in job templates, see the [CPUCLOCK job template extension attribute](#).

## Idle node power management

Moab has so-called green policies that together configure Moab to manage and maintain a pool of idle nodes in an active running state so it can immediately schedule jobs to them. When Moab does so and diminishes the pool's idle compute node quantity, it powers on compute nodes by performing an `on` command for nodes in a powered-down state (actually, in a low-power or no-power state) to bring them on-line in order to replenish the pool of idle nodes up to its configured size. When jobs end and the idle node exceed the configured idle node pool size and there are no jobs to run on the now-idle nodes, Moab will power off excess idle nodes by performing an `off` command. In this manner, Moab achieves a site's power management and energy consumption objectives through the configured green policies.

See the Moab-only Method Architecture diagram above to see the color-coded compute nodes in the diagram's cluster illustrating Moab's green idle node pool management. The green nodes represent nodes running jobs, the yellow nodes are idle nodes in a green pool of size 12, and the gray nodes represent `off` nodes. Note Moab does not know what actual power state `off` means; what it means will

be based on command customization inside Moab-only method scripts or Moab+MWS plug-in configuration information.

In order to perform green policy management of an idle node pool, Moab must first be configured to use either the Moab-only or the Moab+MWS method of power management. It is *best practice* to configure power management first and test its configuration before configuring green policies. Thus, if power management is misconfigured, an administrator will know it is the power management configuration and/or scripts and not the green computing policies that are incorrect. If the manual power management commands for the configured power management method work, green computing will work using the configured power management method. For information on how to configure each power management method in Moab, see [Enabling green computing on page 736](#).

## Green Policy Configuration

There are several green policies that affect how Moab performs green idle node pool management using automated power management operations. The policies are configured in the same manner regardless of the power management method used, whether Moab-only or Moab+MWS. The other sections of this chapter describe how to configure green policies that manage the idle node pool for site energy management objectives.

- [pbsnodes on page 2705](#)

## How-to's

### Deploying Adaptive Computing IPMI scripts

#### Context

If you want to enable green computing on your system using the Adaptive Computing supplied IPMI reference scripts, follow the steps here. The IPMI scripts provided are meant as a reference for you to configure the solution to your environment, but can also be used as-is.

#### Prerequisites

- OpenIPMI and ipmitool must be installed and working.
- All nodes must have the same IPMI username and password.
- You must know the IPMI host names and/or IPMI IP addresses of your nodes.
- Python must be installed. The provided IPMI scripts were developed using Python 2.6.5.
- You must identify your Moab home directory. These instructions assume the default Moab home directory of `/opt/moab`.
- You must identify your Moab tools directory. These instructions assume the default Moab tools directory of `/opt/moab/tools`.

## To deploy the Adaptive Computing IPMI scripts

1. Edit the `/opt/moab/tools/ipmi/config.py` script:
  - a. Set **self.ipmiuser** to the IPMI username for your nodes.
  - b. Set **self.ipmipass** to the location of the IPMI password file (`/opt/moab/passfile.txt` by default).

**i** The permissions for the directory and the password file itself should be set so that they can be read only by root or the Moab user running the script.

- c. Set **self.homeDir** to your Moab home directory.
  - d. If desired, change the **self.pollInterval** value. This is the interval, in seconds, between polls from the IPMI monitoring script.
  - e. The **self.ipmifile** value is the name of a temporary file where the cluster query information is stored. You can change this or leave it alone.
  - f. The **self.bmcaddrmap** value is the filename for the Moab node name/IPMI mapping. The file must exist in the Moab home directory and will be created in the next step.
2. Create a `node-bmc.txt` file in the Moab home directory. The file must contain a space-delimited list of Moab node names that map to the IPMI host names or IP address. For Example:

```
node01 node01_ipmi # For all three of these entries, the first value is the
node02 node02_ipmi # node name as Moab knows it. The second value is either
node03 10.1.1.1    # the node IPMI name or IPMI IP address.
```

3. Configure the `moab.cfg` file for green computing as described in [Enabling green computing](#). Use the `ipmi.mon.py` script for the `CLUSTERQUERYURL` and the `ipmi.power.py` script for the `NODEPOWERURL`.
4. Restart Moab and verify green computing is working correctly. If you encounter trouble, see the [Troubleshooting green computing](#) topic for help.

## Choosing which nodes Moab powers on or off

### Context

Moab can use the GREENPOOLPRIORITYF function to determine which nodes to power on or off. The [PRIORITY node allocation policy](#) is used to determine which nodes to allocate workload to. When Moab can no longer allocate workload to available nodes, it begins to power nodes on in the order specified by the GREENPOOLPRIORITYF function.

### To choose which nodes Moab powers on or off

1. Set a GREENPOOLPRIORITYF function to describe which order nodes should be selected for power on/off actions. GREENPOOLPRIORITYF uses the [PRIORITY node allocation policy](#) options and syntax.

```
GREENPOOLPRIORITYF '10*RANDOM'
```

*This tells Moab to randomly choose a node to power on to meet workload demands, and to randomly choose an idle node to power off to meet the [MAXGREENSTANDBYPOOLSIZE](#) goal.*

### To choose which nodes Moab allocates jobs to

1. Set a PRIORITY node allocation policy that uses power as the major factor. This causes Moab to allocate jobs to nodes that are already powered on. When no nodes are available to meet this policy, Moab uses the GREENPOOLPRIORITYF function to turn on nodes that are powered off.

```
NODEALLOCATIONPOLICY PRIORITY
NODECFG[DEFAULT] PRIORITYF='10000*POWER + 10*RANDOM'
```

*The nodes with the highest priority for workload are the nodes that are powered on. After that, Moab randomly allocates workload.*

- [Maximizing scheduling efficiency on page 741](#)

## Enabling green computing

### Context

There are two ways to do green computing in Moab. With just Moab, nodes can be turned on or off. With [MWS](#), however, you can put nodes into several low-power states. The MWS solution is also more scalable. The supported low-power states are:

- Running
- Standby
- Suspend
- Hibernate
- Shutdown

Nodes cannot be moved from one low-power state to another. The node must go from low-power to running, and then to the new low-power state.

### To enable green computing with Moab and MWS

1. Edit `moab.cfg` to use MWS for green computing:
  - a. Configure the [POWERPOLICY](#) attribute of the [NODECFG](#) parameter. The default value is *STATIC*. Set it to *OnDemand*.
  - b. Set the resource manager type as *MWS*
  - c. Set `FLAGS=UserSpaceIsSeparate` for the MWS resource manager.
  - d. Point `BASEURL` to your MWS server.

```
NODECFG [DEFAULT]      POWERPOLICY=OnDemand
RMCFG [mws]            TYPE=MWS
RMCFG [mws]            FLAGS=UserSpaceIsSeparate
RMCFG [mws]            BASEURL=http://localhost:8080/mws
```

2. Configure the MWS [Power Management Plugin on page 1758](#).

### To enable green computing with just Moab

1. Edit `moab.cfg` to enable green computing. There are four things you must configure for basic functionality of green computing:
  - a. Configure the `POWERPOLICY` attribute of the `NODECFG` parameter. The default value is `STATIC`. Set it to `OnDemand`.
  - b. Configure a power provisioning resource manager to be `TYPE=NATIVE` and `RESOURCE_TYPE=PROV`. The resource type of `PROV` means the RM works only with node hardware and not workloads.
  - c. Configure a `CLUSTERQUERYURL` attribute of the power provisioning RM to point to the power query script you'd like to use. Moab uses this script to query the current power state of the nodes. `CLUSTERQUERYURL` is traditionally used as a workload query but is also used by green computing for the node power state query. Adaptive Computing provides a reference [IPMI script](#) you can use.
  - d. Configure a `NODEPOWERURL` attribute of the power provisioning RM to point to the power action script you'd like to use. Moab uses this script to turn nodes on or off. Adaptive Computing provides a reference [IPMI script](#) you can use.

```
NODECFG[DEFAULT] POWERPOLICY=OnDemand
RMCFG[ipmi] TYPE=NATIVE RESOURCE_TYPE=PROV
RMCFG[ipmi] CLUSTERQUERYURL=exec://$TOOLS_DIR/ipmi/ipmi.mon.py
RMCFG[ipmi] NODEPOWERURL=exec://$TOOLS_DIR/ipmi/ipmi.power.py
```

### Sample moab.cfg for green computing

Below is a sample `moab.cfg` configuration file of a green computing setup using the Adaptive Computing IPMI scripts.

```

RMCFG [mws] BASEURL=http://localhost:8080/mws

# We want green policy to work so it allocates jobs to compute nodes already
# powered on and will power on powered-off compute nodes only when there are
# no powered-on compute nodes available. This requires using the PRIORITY
# node allocation policy with a PRIORITYF function that has the POWER variable
# as the greatest contributing factor to the function (1 = powered-on,
# 0 = powered-off).
# If we want all compute nodes to operate under green policy, we can assign
# the PRIORITYF function to the default node configuration, which is easier
# than assigning it to individual compute nodes. If only some compute nodes
# should operate under green policy, then the PRIORITYF function must be
# configured for the individual nodes. Note the POWER variable must be the
# largest factor in the function below; it is assigned the largest multiplier,
# which should be greater than the sum of all other factors! Doing so forces
# Moab to use all eligible powered-on nodes for workload placement before
# powering on any eligible powered-off nodes.

# Enable PRIORITYF functionality
#NODEALLOCATIONPOLICY PRIORITY

# Use a priority function that uses power as the major factor (plus some other
# imaginary factors)
#NODECFG[DEFAULT] PRIORITYF='1000000*POWER + 1000*factor2 + 100*factor3...'
# Use a priority function where power is the only factor.
#NODECFG[DEFAULT] PRIORITYF='10000*POWER'
# Use a priority function that adds some randomness but uses power as the major
# factor.
#NODECFG[DEFAULT] PRIORITYF='10000*POWER + 10*RANDOM'

# Set a priority function that specifies the order nodes should be chosen to power
# up/down. By default, Moab will start at the top of the node list and go down.
# Some
# installations want to rotate power cycles among nodes in a different order.
# The configuration below forces Moab to power on/off random nodes, which
# eventually guarantees all nodes occasionally go through a power cycle.
#GREENPOOLPRIORITYF '10*RANDOM'

# Ensure we are recording power management events
# (powering on and off nodes are recorded as "node modification" events).
#RECORDEVENTLIST +NODEMODIFY

# Set the size of the standby pool. This is the number of idle nodes that will
# be powered on and idle. As the workload changes, Moab turns nodes on
# or off to try to meet this goal.
# Default value is 0
MAXGREENSTANDBYPOOLSIZE 5

# Set the length of time that it takes to power a node on/off. This will be the
# walltime of the system job that performs the power operation and should be the
# maximum expected time. If Moab detects (via the power RM) that the power
# operations have all completed, the system job will finish early.
# Default value is 10 minutes (600)
PARCFG[ALL] NODEPOWEROFFDURATION=600
PARCFG[ALL] NODEPOWERONDURATION=600
# Set the length of time a node should remain idle before it is powered off.
# This prevents Moab from immediately powering off nodes that have just finished
# a job. Increasing this number should decrease power on/off thrashing
# This should be set higher than NODEPOWEROFFDURATION and/or NODEPOWERONDURATION

```

```
NODEIDLEPOWERTHRESHOLD 660
```

```
# If a node fails to power on, we need to remove it from the available nodes so
# Moab won't keep [re-]trying to power it on. Do this by setting a reservation
# on the failed node to give time for manual investigation.
#RMCFG[torque] NODEFAILURERSVPROFILE=failure
#RSVPROFILE[failure] DURATION=3600
```

## Related topics

- [Deploying Adaptive Computing IPMI scripts on page 733](#)

- [Maximizing scheduling efficiency on page 741](#)
- [Troubleshooting green computing on page 742](#)
- [Power Management Plugin on page 1758](#)

## Adjusting green pool size

### Context

The MAXGREENSTANDBYPOOLSIZE parameter allows you to allocate the number of nodes to keep powered on in the standby pool. This is the number of idle nodes that are allowed be powered on and idle. As the workload changes, Moab turns nodes on or off to try to meet this goal. The default value is 0.

### To adjust the green pool size

1. Modify the MAXGREENSTANDBYPOOLSIZE parameter with the number of nodes you want Moab to keep powered on for the standby pool.

```
MAXGREENSTANDBYPOOLSIZE 10
```

*Moab keeps up to 10 idle nodes powered on to be kept on standby.*

### Related topics

- [Maximizing scheduling efficiency on page 741](#)
- [Choosing which nodes Moab powers on or off on page 735](#)

## Handling power-related events

### Context

Power actions are considered [NODEMODIFYURL](#) events and are not recorded by default, but you can configure Moab to include power-related events in the logs. Also, if a node fails to turn on (or off), it's best to associate a reservation on the failed node so that Moab won't keep trying to perform the power action over and over.

## To configure Moab to record power-related events

1. Modify the **RECORDEVENTLIST** parameter.

```
RECORDEVENTLIST +NODEMODIFY
```

*Power-related events are logged to the Moab log file.*

## To put a reservation on a node that fails to perform a power action

1. Configure the **NODEFAILURERSVPROFILE** attribute of **RMCFG** and create an **RSVPROFILE** with a high duration.

```
RMCFG[torque] NODEFAILURERSVPROFILE=failure
RSVPROFILE[failure] DURATION=3600
```

*Nodes that fail to power on or off have a 1-hour reservation placed on them.*

### Related topics

- [RECORDEVENTLIST](#) on page 1026

## Maximizing scheduling efficiency

### Context

When considering whether to power a node on or off, Moab can take into account the amount of time that it takes to power on or power off the node. With this information, Moab can keep an idle node powered on if it knows that workload in the queue will be ready for the node in less time that it takes to power off/power on the node.

Moab can also wait to shut down nodes after they've been idle for a specific amount of time.

### To specify node power on/power off duration

1. Modify the **NODEPOWERONDURATION** and **NODEPOWEROFFDURATION** attributes of **PARCFG** with the maximum amount of time it takes for your nodes to power on/power off. Make sure to use the keyword **ALL** for the resource manager name to avoid cases where Moab won't consider the power on/off duration for a node before making a power action decision.

```
PARCFG[ALL] NODEPOWERONDURATION=2:00
PARCFG[ALL] NODEPOWEROFFDURATION=2:00
```

*If a node goes idle and has to wait for workload, Moab will not power off the node if the workload will be available within 4 minutes or less.*

### To shut down on nodes after they've been idle for a specified time

1. Modify the **NODEIDLEPOWERTHRESHOLD** parameter with the duration (in seconds) you want Moab to wait before shutting down an idle node. The default value is 60 seconds. Increasing the number should decrease power on/off thrashing. This should be set higher than **NODEPOWERONDURATION**

and/or **NODEPOWEROFFDURATION**.

```
NODEIDLEPOWERTHRESHOLD 300
```

*Moab will wait 5 minutes before shutting down a node that has become idle.*

#### Related topics

- [Adjusting green pool size on page 740](#)
- [Choosing which nodes Moab powers on or off on page 735](#)

## Putting idle nodes in power-saving states

### Context

When nodes exceed their idle threshold limits, the default behavior is to turn the nodes off. With the **NODEIDLEPOWERACTION** parameter, you can choose which power-saving state to put idle nodes into. This parameter is configured at the partition level. Configuring it for the **ALL** partition effectively makes it a global parameter.

### To specify what to do with idle nodes

1. Modify the **NODEIDLEPOWERACTION** parameter.

```
NODEIDLEPOWERTHRESHOLD 300
PARCFG[ALL] NODEIDLEPOWERACTION SLEEP
```

*All nodes that are idle for more than 5 minutes are put into a sleep state.*

## Troubleshooting green computing

### Context

If you've enabled green computing and are having trouble, here are some tips that can help you determine the cause of the issues you encounter. These tips are specifically for the [Adaptive Computing supplied IPMI scripts](#), but can be generalized for whatever power management solution you use. Simply substitute your power management system, power query script (as specified by **CLUSTERQUERYURL**), and power action script (as specified by **NODEPOWERURL**) where appropriate.

### Verify your IPMI access

1. Use the `ipmitool` command to verify you have access to the IPMI interface of your nodes. Try getting the current power state of a node. The syntax is `ipmitool -I lan -H <host> -U <IPMI username> -P <IPMI password> chassis power status`.

```
$ ipmitool -I lan -H qt06 -U ADMIN -P ADMIN chassis power status
Chassis Power is off
```

### Verify the power query (CLUSTERQUERYURL) script is working

1. Execute the `ipmi.mon.py` script (should be found in `/<MOABHOMEDIR>/tools/ipmi`) to start the monitor.

```
$ cd /opt/moab/tools/ipmi
$ ./ipmi.mon.py
```

2. Execute the script again. The following is an example of the expected output:

```
$ ./ipmi.mon.py
qt09  GMETRIC[System_Temp]=27 GMETRIC[CPU_Temp]=25 POWER=on State=Unknown
qt08  GMETRIC[System_Temp]=31 GMETRIC[CPU_Temp]=25 POWER=on State=Unknown
qt07  GMETRIC[System_Temp]=30 GMETRIC[CPU_Temp]=29 POWER=on State=Unknown
qt06  GMETRIC[System_Temp]=Disabled GMETRIC[CPU_Temp]=Disabled POWER=off
State=Unknown
```

*If the **POWER** attribute is not present the script is not working correctly.*

### Verify the power action (NODEPOWERURL) script is working

1. Execute the `ipmi.power.py` script (should be found in `/<MOABHOMEDIR>/tools/ipmi`) to see if you can force a node to power on or off. The syntax is `ipmi.power.py <node>,<node>,<node>... [off|on]`

```
$ /opt/moab/tools/ipmi/ipmi.power.py qt06 off
```

*This example is trying to power off a node named qt06.*

2. Verify the machine's power state was changed to what you attempted in the previous step. You can do this remotely via two methods:
  - a. If the [cluster query script](#) is working, you can use that to verify the current power state of the node.
  - b. If you have [IPMI access](#), you can use the `ipmitool` command to verify the current power state of the node.

## Verify the scripts are configured correctly

1. Run the `mdiag -R` command to verify your IPMI resource manager configuration.

```
$ mdiag -R -v
RM[ipmi]      State: Active  Type: NATIVE  ResourceType: PROV
Timeout:      30000.00 ms
Cluster Query URL: exec://$TOOLSDIR/ipmi/ipmi.mon.py
Node Power URL:  exec://$TOOLSDIR/ipmi/ipmi.power.py
Objects Reported: Nodes=3 (0 procs)  Jobs=0
Nodes Reported: 3 (N/A)
Partition:     SHARED
Event Management: (event interface disabled)
RM Performance: AvgTime=0.05s MaxTime=0.06s (176 samples)
RM Languages:  NATIVE
RM Sub-Languages: NATIVE
```

2. Run the `mdiag -G` command to verify that power information is being reported correctly.

```
$ mdiag -G

NodeID      State      Power      Watts      PWatts
qt09        Idle       On          0.00       0.00
qt08        Idle       On          0.00       0.00
qt07        Idle       Off         0.00       0.00
```

## Verify the scripts are running

1. Once green is configured and Moab is running, Moab should start the power query script automatically. Use the `ps` command to verify the script is running.

```
$ ps -ef | grep <CLUSTERQUERYURL script name>
```

*If this command does not show the power query script running then your settings in `moab.cfg` aren't working.*

## Verify Moab can power nodes on or off

1. Use the `mnodectl` command to turn a node on or off. The syntax is `mnodectl -m power=[off|on] <node>`.

```
mnodectl -m power=off qt06
```

*Moab should turn off the node named qt06.*

- a. Moab generates a system job called `poweron-<num>` or `poweroff-<num>` job as shown in [showq](#). The system job calls the `ipmi.power.py` (**NODEPOWERURL**) script to execute the command.
- b. Moab waits until the cluster query reports the correct data. In this case, the `ipmi.power.py` script reports that the power attribute has changed.
- c. Moab does not change the power status based on the power script return code. Rather, Moab completes the system power job when it detects the power attribute has changed as indicated by the cluster query script.

## Object triggers

### About object triggers

Moab triggers are configurable actions that respond to an event occurring on a Moab object. A trigger is attached to an object and consists of both an event that may take place on the object and the action that the trigger will take.

Image 3-9: Trigger attachment

**i** Triggers are a powerful tool. Extreme caution should be taken when using them. They are useful in creating automatic responses to well-understood Moab events; however, by default triggers run as root and do exactly as they are told, meaning they require great thought and consideration to ensure that they act appropriately in response to the event.

### Use case

An administrator wants to create the following setup in Moab:

When a node's temperature exceeds 34°C, Moab reserves it. If the temperature increases to more than 40°C, Moab requeues all jobs on the node. If the node's temperature exceeds 50°C, Moab shuts it down. Moab removes the node's reservation and unsets the variables when the node cools to less than 25°C.

The administrator wants to receive an email whenever any of these events occur. All of this can be configured in Moab using triggers. To see a full example for this use case, see [Node maintenance example](#) on page 773.

## How-to's

## Creating a trigger

## Context

Three methods exist for attaching a trigger to an object:

- Directly to the object via the command line
- Directly to the object via the configuration file
- As part of a template via the configuration file

`<attr>=<val>` pair delimiters, quotation marks, and other elements of the syntax may differ slightly from one method/object combination to another, but creating any trigger follows the same basic format:

```
<attr>=<val>[[{&, }<attr>=<val>] ... ]
```

The beginning of the trigger is set off by the keyword *trigger*. It is followed by a delimited list (typically by commas) of `<attr>=<val>` pairs.

Each method of trigger creation can only be used for certain Moab objects. The following table displays which objects can receive triggers via each method. The links contain examples.

Method	Objects
<b>Command line</b>	job, reservation; a trigger can be attached to any existing object using <a href="#">mschedctl -c</a>
<b>Configuration file</b>	node, reservation, RM, scheduler
<b>Template</b>	job, reservation

Triggers are composed of attributes. Only three are required for each trigger: an [EType](#) (event type), an [AType](#) (action type), and an [Action](#).

Image 3-10: Required trigger attributes

## Required trigger attributes

```
EType=start AType=exec Action="/tmp/report.pl"
```

<b>EType</b>	<b>Event Type - The event that fires the trigger</b>
<b>AType</b>	<b>Action Type - The type of action the trigger will perform</b>
<b>Action</b>	<b>Action - The actual action the trigger will perform</b>

Other attributes exist to further customize triggers. See [Trigger components on page 765](#) for more information.

### To create a Moab trigger

1. Choose an object to which, and a method by which, you will attach the trigger. Use the format and examples described in its corresponding documentation:
  - [Job triggers on page 758](#)
  - [Node triggers on page 759](#)
  - [Reservation triggers on page 761](#)
  - [Resource manager triggers on page 762](#)
  - [Scheduler triggers on page 763](#)

**i** If the trigger is to be attached to a job, you must first enable job triggers (see [Enabling job triggers on page 755](#) for more information.). Please carefully review the warning before doing so.

2. Decide whether to attach the trigger via the command line or configuration file. Verify the correct syntax.
3. Set the **EType** equal to whichever event will launch the trigger if and when it occurs on the object.

Each object has a different lifecycle, so not every event type will occur on every object. For a list of valid **ETypes** for your selected object, see the corresponding object reference page linked in step 1.

- a. To modify the timing of the trigger in any of the following ways, see [Event-modifying trigger components on page 769](#).
  - To set the trigger as rearmable and specify the amount of time the trigger must wait before firing again.
  - To set an amount of time before or after the event that the trigger will fire (See [Offset on page 769](#) for restrictions).
  - To set a specific threshold and the amount of time that the object must meet that threshold before the trigger will fire.
4. Configure the action that the trigger will take when the event happens. To do so, you must set the **AType** to a valid value for your object and specify the action. For instance, to execute a script, set the **AType** to **exec** and the **Action** to the location of the script in quotation marks. Include the name of the object on which the script will run.

```
NODECFG[node01] TRIGGER=EType=fail,AType=exec,Action="node.fail.sh node01"
```

- a. To modify the action in any of the following ways, see [Action-modifying trigger components on page 771](#).
  - To specify environment variables available to the trigger
  - To set a flag on the trigger
    - To attach any stderr output generated by the trigger to the parent object
    - To destroy the trigger if its object ends or cancels
    - To tell Moab to checkpoint the trigger
    - To set the trigger as periodic
    - To pass the object's XML information to the trigger's stdin
    - To set the trigger to reset if its object is modified
    - To set the trigger to fire under the user ID of the object's owner
  - To specify an amount of time that Moab will suspend normal operation to wait for the trigger to execute
  - To allot an amount of time that the trigger will attempt to run before it is marked as unsuccessful and the process, if any exists, is killed
  - Set a maximum number of times that a trigger will attempt to fire before it fails
- b. To give the trigger a name or description, see [Organizational trigger components on page 772](#).
- c. To configure the trigger to set or unset a variable when it fires or to require a variable to fire, see [Setting and receiving trigger variables on page 776](#).

## Creating VM triggers

### Context

Triggers can be attached to virtual machines on the command line using the `mvmctl` command.

## To create a VM trigger via the command line

1. Type the `mvmctl -m trigger=` command to modify a virtual machine. Use `trigger=` to mark the beginning of the trigger configuration.

```
> mvmctl -m trigger=
```

2. Set the `EType` to start. End with a backslash (`\`) and ampersand (`&`).

```
> mvmctl -m trigger=EType=start\&
```

3. Specify the action the trigger should take when the event occurs by setting the `AType` attribute to `changeparam`, `exec`, `internal`, `query`, or `submit`. End with a backslash and ampersand.

```
> mvmctl -m trigger=EType=start\&AType=exec\&
```

4. If the trigger launches when the job reaches a threshold, define the threshold.
5. Use the `Action` attribute to specify the action the trigger will take. Use single quotes.

```
> mvmctl -m trigger=EType=start\&AType=exec\&Action='trig.py $OID $HOSTLIST'
```

6. Configure any desired time-related attributes (The offset time, whether a trigger can fire multiple times, how often, etc.). Insert a comma between the time attribute(s) and the action.

```
> mvmctl -m trigger=EType=start\&AType=exec\&Action='trig.py $OID
$HOSTLIST',Offset=30
```

Moab launches the `trig.py` script 30 seconds after the VM starts.

7. Configure any desired variables. Verify that all attributes are separated by commas.

```
> mvmctl -m trigger=EType=start\&AType=exec\&Action='trig.py $OID
$HOSTLIST',Offset=30,sets=vmStart
```

8. Set any desired flags.
9. Submit the trigger.

## Using a trigger to send email

### Context

Mail triggers can be attached to nodes, jobs, reservations, and the scheduler. The recipient of the email depends on the object to which the trigger is attached. To select different recipient(s) and add flexibility to formatting, send email via a script [using an exec trigger](#).

### To use a trigger to send email

1. For objects that send mail to the primary user, you must configure the Moab administrator email using the [MAILPROGRAM on page 992](#) parameter.
2. Create a trigger on one of the four valid objects listed below, setting the `AType` to [mail](#) and the `Action` to the body of the message inside of quotation marks.

Object	Recipient
<b>Node</b>	The primary user (the first user listed in <a href="#">ADMINCFG[1]</a> , typically root)
<b>Job</b>	The job's owner
<b>Reservation</b>	The primary user
<b>Scheduler</b>	The primary user

- When attaching a mail trigger to all objects of a certain type, use internal variables in the **Action** to add information that is specific to an object, such as the ID, owner, time the event occurred, etc. A variable must be preceded by a dollar sign (\$).

Variable	Description
<b>\$OID</b>	Name of the object to which the trigger is attached
<b>\$OTYPE</b>	The type of object to which the trigger is attached
<b>\$TIME</b>	Time the trigger launched
<b>\$HOSTLIST</b>	Hostlist of the trigger's object (jobs and reservations)
<b>\$OWNER</b>	Owner of the trigger's object (jobs and reservations)
<b>\$USER</b>	User (jobs and reservations)

The variable is replaced with the information described above. For example, the following trigger is configured on all nodes:

```
NODECFG[DEFAULT] EType=fail,AType=mail,Action="node $OID failed at $TIME"
```

*When, for example, node node03 fails, an email is sent to the primary user with a message with the subject line "node node03 started on Sat Aug 18 11:42:00".*

## Using a trigger to execute a script

### Context

Exec triggers launch a program or script when the event occurs. A few examples of what a script might do in response to an event include:

- Execute an external program
- Send a complex email to any desired recipient(s)
- Collect diagnostics

**i** It is important to note that when a script runs via a trigger, Moab forks and performs a direct OS exec, meaning there will be no pre-processing of the command by the shell. In addition, the script runs in a new, reduced environment without the same settings and variables as the environment from which it stemmed. The script must be able to run in the reduced environment.

### To use a trigger to execute a script

1. Create or locate the script and note its location.
2. Create a trigger on the desired object, setting the **AType** to **exec** and the **Action** to location of the script or program.

```
JOBCFG[temp1] TRIGGER=EType=start,AType=exec,Offset=03:00,Action="/tmp/monitor.pl"
```

*Jobs with the temp1 template receive a trigger that executes monitor.pl three minutes after the job starts.*

## Using a trigger to perform internal Moab actions

### To perform internal actions in Moab with a trigger

- Create a trigger on a job, node, or reservation, setting the **AType** to **internal** and the **Action** to one of the following:
  - **node:-:reserve** - reserves the node to which the trigger is attached
  - **job:-:cancel** - cancels the job to which the trigger is attached
  - **reservation:-:cancel** - cancels the reservation to which the trigger is attached

The specified object reserves or cancels itself once the event occurs. See [Internal Action on page 768](#) for examples.

## Requiring an object threshold for trigger execution

### Context

Threshold triggers allow sites to configure triggers to launch based on internal scheduler statistics, such as generic metrics. For example, you might configure a trigger to warn the administrator when the percentage of nodes available is less than 25.

### To configure a threshold trigger

1. Create a trigger. Set its **EType** to *threshold*. Configure the **AType**, **Action**, and **Threshold** attributes' values based on the valid thresholds per object listed in the table found in [Threshold triggers on page 764](#).

```
NODECFG[node04] TRIGGER=EType=threshold,AType=exec,Action="$HOME/hightemp.py
$OID",Threshold=gmetric
```

2. Insert the gmetric name between brackets (such as `gmetric[temp]`). Provide a comparison operator. For valid options, see the [comparison operators table](#).
3. Provide a number or string to match against the threshold.

```
NODECFG[node04] TRIGGER=EType=threshold,AType=exec,Action="$HOME/hightemp.py
$OID",Threshold=gmetric[TEMP]>70,RearmTime=5:00
```

*Moab launches a script that warns the administrator when node04's gmetric temp exceeds 70. Moab rearms the trigger five minutes after it fires.*

## Enabling job triggers

### Context

By default common users cannot create most objects, and as a result, common users also cannot create triggers. The exception, however, is jobs. Because common users can create jobs and triggers generally run as root, additional security is necessary to ensure that not all users can create triggers. For this reason, job triggers are disabled by default.

Because triggers generally run as root, any user given the power to attach triggers has the power to run scripts and commands as root. It is recommended that you only enable job triggers on closed systems in which human users do not have access to directly submit jobs.

To give specific users permission to create job triggers, you must create a QoS, set the *trigger* flag, and add users to it.

### To enable job triggers

1. In the `moab.cfg` file, create a QoS and set the *trigger* flag.

```
QOSCFG[triggerok] QFLAGS=trigger
```

2. Add users to the QoS who should be allowed to add triggers to jobs.

```
USERCFG[joe] QDEF=triggerok
```

User `joe` is added to the *triggerok* QoS, giving him both the power to create job triggers and root access to the machine.

## Modifying a trigger

### Context

You can modify a trigger at any time by updating its settings in the Moab configuration file (`moab.cfg`). This will update most triggers at the beginning of the next Moab iteration; however, modifying template triggers (configured using [RSVPROFILE](#) or [JOBFCFG](#)) will not update the instances of the trigger that were attached to individual reservations or jobs on creation. The modification will only affect the triggers that the template attaches to future objects.

Any trigger with a specified name can be modified using the `mschedctl -m` command in the following format:

```
mschedctl -m trigger: <triggerID><attr1>=<val1><attr2>=<val2>
```

Modifying triggers on the command line does not change their configuration in `moab.cfg`. Except for reservations that are checkpointed, changes made dynamically are lost when Moab restarts.

For example, the procedure below demonstrates how to modify the following trigger so that the offset is 10 minutes instead of 5 and so that Moab will attempt to fire the trigger up to 10 times if it fails. Assume your trigger currently looks like this:

```
NODECFG[DEFAULT] EType=fail,AType=exec,Action="/scripts/node_fail.pl",Name=nodeFailTrig,Offset=00:05:00,MultiFire=TRUE,RearmTime=01:00:00
```

### To modify a trigger

1. Type `mschedctl -m` into the command line and set off the trigger modification with `trigger:<id>`. Use the trigger's assigned ID or specified name to state which trigger will receive the modification.

```
> mschedctl -m trigger:nodeFailTrig
```

2. Type any changing attributes equal to the new value. Separate multiple modifications with a space between each `<attr>=<val>` pair. In this case, set the **Offset** and **MaxRetry** attributes the following way:

```
> mschedctl -m trigger:nodeFailTrig Offset=00:10:00 MaxRetry=10
```

The newly-specified attributes replace the original ones. Trigger `nodeFailTrig` now has an offset of 10 minutes and will try to fire a maximum of 10 times if it fails. The new trigger has the following attributes:

```
EType=fail,AType=exec,Action="/scripts/start_rsv.pl",Name=nodeFailTrig,Offset=00:10:00,MultiFire=TRUE,RearmTime=01:00:00,MaxRetry=10
```

## Viewing a trigger

### Context

Moab provides a list of triggers when you run the [mddiag -T](#) command. You can view a specific trigger by running `mddiag -T` in the following format:

```
mddiag -T [<triggerID>|<objectID>|<triggerName>|<objectType>]
```

### To view a trigger

1. Type `mddiag -T` in the command line.
2. Specify either the trigger ID, the trigger name, the name of the object to which the trigger is attached, or the type of object to which the trigger is attached. For example, if you wanted to view information about a trigger with ID `trigger.34` and name `jobFailTrigger`, which is attached to job `job.493`, you could run any of the following commands:

```
> mdiag -T trigger.34
> mdiag -T job.493
> mdiag -T jobFailTrigger
> mdiag -T job
```

*The output of the first command would provide basic information about `trigger.34`; the second command, information about all triggers attached to `job.493` that the user can access; the third command, basic information about `jobFailTrigger`; and the fourth command, basic information about all triggers attached to jobs that the user can access.*

3. Optional: to view additional information about the trigger, run the same command with the `-v` flag specified after `-T`.

```
> mdiag -T -v job.493
```

This mode outputs information in multiple lines.

4. Optional: to view detailed information about all triggers available to you, use the `mddiag -T -v` command. This outputs all triggers available to the user in a single line for each trigger. It provides additional state information about triggers, including reasons triggers are currently blocked.

```
> mdiag -T -v
```

## Checkpointing a trigger

### Context

Checkpointing is the process of saving state information when Moab is shut down. In general, triggers defined in the `moab.cfg` file are not checkpointed but are recreated when Moab starts. The exception is the [JOB\\_CFG](#) parameter, which attaches triggers to jobs as they are created. There are two cases in which you may want to tell Moab to checkpoint a trigger:

- If a trigger is defined in the `moab.cfg` file but was created at the command line
- When creating a trigger using the [mschedctl on page 264](#) command

## To checkpoint a trigger

1. Locate the trigger to be checkpointed in the `moab.cfg` file, create one on the command line, or modify a trigger dynamically (See [Modifying a trigger on page 756](#) for more information). Attach the *checkpoint* flag using the **FLAGS** attribute. For more information about flags, see [Flags on page 771](#).

```
FLAGS=checkpoint
```

2. If you are working in the configuration file, save the changes. Moab will now checkpoint your trigger.

## References

### Job triggers

For security reasons, job triggers are disabled by default. They must be enabled in order to successfully attach triggers to jobs (See [Enabling job triggers on page 755](#) for more information.).

Triggers attached to jobs follow the same basic rules and formats as attaching them to other objects; however, not all attribute options are valid for each object. Jobs, like other objects, have a unique set of trigger rules. The table below details the methods, options, and other notable details associated with attaching triggers to jobs.

### Creation methods

Method	Format	Example
<b>Command line on job creation:</b> <a href="#">msub -l</a>	<code>msub &lt;jobName&gt; -l 'trig=&lt;trigSpec&gt;'</code> Attributes are delimited by backslash ampersand (\&).	<pre style="border: 1px dashed gray; padding: 5px;">&gt; msub my.job -l 'trig=EType=create\&amp;AType=exec\&amp;Action="/jobs/my_trigger.pl"\&amp;Offset=10:00'</pre>
<b>Command line on existing job:</b> <a href="#">mschedctl -c</a>	<code>mschedctl -c trigger &lt;trigSpec&gt; -o job:&lt;jobID&gt;</code>	<pre style="border: 1px dashed gray; padding: 5px;">&gt; mschedctl -c trigger EType=end,AType=mail,Action="Job moab.54 has ended" -o job:moab.54</pre>
<b>Job template in moab.cfg:</b> <a href="#">JOBCFG</a>	<code>JOBCFG[&lt;templateName&gt;] TRIGGER=&lt;trigSpec&gt;</code>	<pre style="border: 1px dashed gray; padding: 5px;">JOBCFG[vmcreate] TRIGGER=,EType=end,AType=exec,Action="/tmp/jobEnd.sh"</pre>

## Valid event types

- [cancel on page 768](#)
- [checkpoint on page 768](#)
- [create on page 768](#)
- [end on page 768](#)
- [hold on page 769](#)
- [modify on page 769](#)
- [preempt on page 769](#)
- [start on page 769](#)

## Valid action types

- [changeparam](#)
- [exec](#)
- [internal](#)
- [mail](#)

## Mail recipient

The job's owner

See [Using a trigger to send email on page 752](#) for more information.

## Node triggers

Triggers attached to nodes follow the same basic rules and formats as attaching them to other objects; however, not all attribute options are valid for each object. Nodes, like the other objects, have a unique set of trigger rules. The table below details the methods, options, and other notable details that come with attaching triggers to nodes.

### Creation methods

Method	Format	Example
<b>Command line on existing node:</b> <a href="#">mschedctl - c</a>	<code>mschedctl -c trigger &lt;trigSpec&gt; -o node:&lt;nodeID&gt;</code>	<pre>&gt; mschedctl -c trigger EType=fail, AType=exec, Action="/tmp/nodeFailure.sh" -o node:node01</pre>

Method	Format	Example
<b>Node configuration in moab.cfg:</b> <a href="#">NODECFG</a>	NODECFG [<name>] TRIGGER= <trigSpec>	<pre>NODECFG[node04] TRIGGER=EType=threshold,AType=exec,Action="\$HOME/hightemp.py \$OID",Threshold=gmetric[TEMP]&gt;70</pre>

## Valid event types

- [create](#) on page 768
- [discover](#) on page 768
- [end](#) on page 768
- [fail](#) on page 769
- [standing](#) on page 769
- [threshold](#) on page 769

## Valid action types

- [changeparam](#)
- [exec](#)
- [internal](#)
- [mail](#)

## Thresholds

Node threshold settings	
Valid ETypes	threshold
Valid Threshold types	gmetric

## Mail recipient

The user listed first in [ADMINCFG\[1\]](#) (usually root)

See [Using a trigger to send email](#) on page 752 for more information.

## Reservation triggers

Triggers attached to reservations follow the same basic rules and formats as attaching them to other objects; however, not all attribute options are valid for each object. Reservations, like the other objects, have a unique set of trigger rules. The table below details the methods, options, and other notable details that come with attaching triggers to reservations.

### Creation methods

Method	Format	Example
<b>Command line on reservation creation:</b> <a href="#">mrsvctl -T</a>	<code>mrsvctl -c -h &lt;host-list&gt; -T &lt;trigSpec&gt;</code>	<pre>&gt; mrsvctl -c -h node01 -T EType=start,AType=exec, Action="/scripts/node_start.pl"</pre>
<b>Command line on existing reservation:</b> <a href="#">mschedctl -c</a>	<code>mschedctl -c trigger &lt;trigSpec&gt; -o rsv:&lt;rsvID&gt;</code>	<pre>&gt; mschedctl -c trigger EType=modify,AType=mail,Action="Reservation system.4 has been modified" -o rsv:system.4</pre>
<b>Standing reservation configuration in moab.cfg:</b> <a href="#">SRCFG</a>	<code>SRCFG [&lt;name&gt;] TRIGGER= &lt;trigSpec&gt;</code>	<pre>SRCFG[Mail2] TRIGGER=EType=start,Offset=200,AType=exec,Action="/tmp/email.sh"</pre>
<b>Reservation template in moab.cfg:</b> <a href="#">RSVPROFILE</a>	<code>RSVPROFILE [&lt;name&gt;] TRIGGER= &lt;trigSpec&gt;</code>	<pre>RSVPROFILE[rsvtest] TRIGGER=EType=cancel,AType=exec,Action="\$HOME/logdate.pl TEST CANCEL \$VPCHOSTLIST \$OID \$HOSTLIST \$ACTIVE"</pre>

### Valid event types

- [create on page 768](#)
- [end on page 768](#)
- [modify on page 769](#)
- [standing on page 769](#)
- [start on page 769](#)
- [threshold on page 769](#)

## Valid action types

- [cancel](#)
- [changeparam](#)
- [exec](#)
- [internal](#)
- [jobpreempt](#)
- [mail](#)

## Thresholds

Node threshold settings	
Valid ETypes	threshold
Valid Threshold types	usage

## Mail recipient

The owner of the reservation. If the owner is unknown or not a user, the first user listed first in [ADMINCFG](#) (usually `root`).

See [Using a trigger to send email on page 752](#) for more information.

## Resource manager triggers

Triggers attached to the resource manager follow the same basic rules and formats as attaching them to other objects; however, not all attribute options are valid for each object. The resource manager, like other objects, has a unique set of trigger rules. The table below details the methods, options, and other notable details that come with attaching triggers to RMs.

## Creation methods

Method	Format	Example
<b>Command line on existing RM:</b> <a href="#">mschedctl</a> <b>-c</b>	<code>mschedctl -c trigger</code> <code>&lt;trigSpec&gt; -o rm:&lt;rmID&gt;</code>	<pre>&gt; mschedctl -c trigger EType=start,AType=exec,Action="/tmp/rmStart.sh" -o rm:torque</pre>

Method	Format	Example
<b>RM configuration in moab.cfg:</b> <a href="#">RMCFG</a>	RMCFG [<name>] TRIGGER= <trigSpec>	<pre>RMCFG[base] TRIGGER=EType=fail,AType=exec,Action="/opt/moab/tools/diagnose_rm.pl \$OID"</pre>

## Valid event types

- [fail](#) on page 769
- [threshold](#) on page 769

## Valid action types

- [changeparam](#)
- [exec](#)
- [internal](#)

## Scheduler triggers

Triggers attached to the scheduler follow the same basic rules and formats as attaching them to other objects; however, not all attribute options are valid for each object. The scheduler, like the other objects, has a unique set of trigger rules. The table below details the methods, options, and other notable details associated with attaching triggers to the scheduler.

## Creation methods

Method	Format	Example
<b>Command line on existing scheduler:</b> <a href="#">mschedctl -c</a>	mschedctl -c trigger <trigSpec> -o sched:<schedID>	<pre>&gt; mschedctl -c trigger EType=end,AType=exec,Action="/tmp/startRsvs.sh" -o sched:moab</pre>
<b>Scheduler configuration in moab.cfg:</b> <a href="#">SCHEDCFG</a>	SCHEDCFG [<name>] TRIGGER=<trigSpec>	<pre>SCHEDCFG[MyCluster] TRIGGER=EType=fail,AType=mail,Action="scheduler failure detected on \$TIME",RearmTime=15:00</pre>

## Valid event types

- [create on page 768](#)
- [end on page 768](#)
- [fail on page 769](#)
- [modify on page 769](#)
- [standing on page 769](#)
- [start on page 769](#)

## Valid action types

- [changeparam](#)
- [exec](#)
- [internal](#)
- [mail](#)

## Mail recipient

The user listed first in [ADMINCFG](#) (usually `root`)

See [Using a trigger to send email on page 752](#) for more information.

## Threshold triggers

The following table identifies the object event, and usage types with which the threshold event/action type feature works.

Object type	Event Type	Usage types
<b>Node</b>	Threshold	gmetric
<b>Reservation</b>	Threshold	usage

The following table defines each of the usage types:

Usage type	Description
<b>gmetric</b>	Generic performance metrics configured in Moab (See Enabling Generic Metrics for more information).
<b>usage</b>	The percentage of the resource being used (not idle).

The following table defines each of the threshold trigger comparison operators:

Comparison operator	Value
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
==	Equal to

## Examples

*Example 3-150: Reservation usage threshold*

```
SRCFG[res1] TRIGGER=EType=threshold,AType=mail,Action="More than 75% of reservation
res1 is being used",Threshold=usage>75,FailOffset=1:00
```

*When more than 75% of the reservation has been in use for at least a minute, Moab fires a trigger to notify the primary user.*

## Trigger components

### Required trigger components

#### AType

Action type	Description
<b>cancel</b>	Cancels the object
<b>changeparam</b>	Causes Moab to give a parameter to a new value
<b>exec</b>	Launches an external program or script on the command line when the dependencies are fulfilled. See <a href="#">Using a trigger to execute a script on page 754</a> for more information.
<b>internal</b>	Modifies Moab without using the command line. See <a href="#">Using a trigger to perform internal Moab actions on page 754</a> for more information.

Action type	Description
<b>jobpreempt</b>	Indicates the preempt policy to apply to all jobs currently allocated resources assigned to the trigger's parent reservation
<b>mail</b>	Causes Moab to send mail. See <a href="#">Using a trigger to send email on page 752</a> for more information.

## Action

Cancel Action	
<b>Format</b>	NONE
<b>Description</b>	Indicates that Moab should cancel the reservation when the event occurs. No action should be specified.
<b>Example</b>	<pre>Etype=threshold,Threshold=usage&lt;10,FailOffset=1:00,AType=cancel</pre> <p><i>When less than 10% of the reservation has been in use for a minute, Moab cancels it.</i></p>

Changeparam Action	
<b>Format</b>	Action="<STRING>"
<b>Description</b>	Specifies the parameter to change and its new value (using the same syntax and behavior as the <a href="#">changeparam on page 363</a> command)
<b>Example</b>	<pre>Atype=changeparam,Action="JOBPCURGETIME 02:00:00"</pre> <p><i>Moab maintains detailed job information for two hours after a job has completed.</i></p>

Jobpreempt Action	
<b>Format</b>	Action="cancel checkpoint requeue suspend"
<b>Description</b>	Signifies <a href="#">PREEMTPOLICY</a> to apply to jobs that are running on allocated resources

Jobpreempt Action	
<b>Example</b>	<pre>RSVPROFILE [adm1] TRIGGER=EType=start,Offset=-240,AType=jobpreempt,Action="cancel"</pre> <p><i>40 minutes after the reservation adm1 starts, all jobs using the reservation's resources adopt a <b>PREEMTPOLICY</b> of <b>cancel</b>.</i></p>

Mail Action	
<b>Format</b>	Action="<MESSAGE>"
<b>Description</b>	<p>When <b>AType=mail</b>, the <b>Action</b> parameter contains the message body of the email. This can be configured to include certain variables. See <a href="#">Using a trigger to send email on page 752</a> for details.</p> <p>Mail triggers can be configured to launch for node failures, reservation creation or release, scheduler failures, and even job events. In this way, site administrators can keep track of scheduler events through email.</p> <p>The email comes from <i>moabadmin</i>, has a subject of <i>moab update</i>, and has a body of whatever you specified in the <b>Action</b> attribute. The recipient list depends on the type of object the trigger is attached to.</p> <ul style="list-style-type: none"> <li>• <b>Node</b> - The primary user (first listed in <a href="#">ADMINCFG[1]</a>), typically <i>root</i></li> <li>• <b>Scheduler</b> - The primary user</li> <li>• <b>Job</b> - The user who owns the job</li> <li>• <b>Reservation</b> - The primary user</li> </ul>
<b>Example</b>	<pre>NODECFG[DEFAULT] TRIGGER=EType=fail,AType=mail,Action="node \$OID will failed.",Offset=05:00:00</pre> <p><i>This example sends an email to the primary administrator informing him/her that the node (including the node ID) has failed.</i></p>

Exec Action	
<b>Format</b>	Action="<script>"
<b>Description</b>	<p>Exec triggers will launch an external program or script when their dependencies are fulfilled. The following example will submit <i>job.cmd</i> and then execute <i>monitor.pl</i> three minutes after the job is started. See <a href="#">Using a trigger to execute a script on page 754</a> for more information.</p>
<b>Example</b>	<pre>&gt; msub -l trig=EType=start\&amp;AType=exec\&amp;Action="/tmp/monitor.pl" job.cmd\&amp;Offset=03:00</pre>

Internal Action	
<b>Format</b>	Action=" <i>&lt;objectType&gt;</i> ::<cancel reserve>"
<b>Description</b>	<p>A couple different actions are valid depending on what type of object the internal trigger is acting upon. The following list shows the available actions:</p> <ul style="list-style-type: none"> <li>• Reserve a node</li> <li>• Cancel a job</li> <li>• Cancel a reservation</li> </ul> <p>See <a href="#">Using a trigger to perform internal Moab actions on page 754</a> for more information.</p>
<b>Example</b>	<pre>NODECFG[node01] TRIGGER=EType=start,AType=internal,Action="node::-reserve"</pre> <p><i>When node01 starts, it becomes a reservation.</i></p> <pre>&gt; msub moab.3 -l 'trig=EType=fail\&amp;AType=internal\&amp;Action="job::-cancel"</pre> <p><i>If moab.3 fails, Moab cancels it.</i></p> <pre>&gt; mrsvctl -c -a user==joe -h node50 -T EType=start,AType=internal,Action="reservation::-cancel",Offset=10:00</pre> <p><i>User joe's jobs are given a ten-minute window to start, then the reservation cancels.</i></p>

## EType

Event type	Description
<b>cancel</b>	The event is triggered when the parent object is either canceled or deleted.
<b>checkpoint</b>	Triggers fire when the job is checkpointed. <i>checkpoint</i> triggers can only be attached to jobs.
<b>create</b>	Triggers fire when the parent object is created. <i>create</i> triggers can be attached to nodes, jobs, reservations, and the scheduler (when attached to the scheduler, triggers fire when Moab starts).
<b>discover</b>	Triggers fire when the node is loaded from a resource manager and Moab cannot recognize it nor find it in the checkpoint file.
<b>end</b>	Triggers fire when the parent object ends. <i>end</i> triggers can be attached to nodes, jobs, reservations, and the scheduler (when attached to the scheduler, triggers fire when Moab shuts down).

Event type	Description
<b>fail</b>	Triggers fire when the resource manager is in a corrupt or down state for longer than the configured fail time, or when Moab detects a corruption in a node's reservation table. <i>fail</i> triggers can be attached to jobs, nodes, resource managers, and the scheduler.
<b>hold</b>	Triggers fire when the job is put on hold. <i>hold</i> triggers can only be attached to jobs.
<b>modify</b>	Triggers fire when the parent object is modified. <i>modify</i> triggers can be attached to jobs and reservations
<b>preempt</b>	Triggers fire when the job is preempted. <i>preempt</i> triggers can only be attached to jobs.
<b>standing</b>	Triggers fire multiple times based on a certain period. They can be used with <a href="#">Period</a> and <a href="#">Offset</a> attributes. <i>standing</i> triggers can be attached to nodes and the scheduler.
<b>start</b>	Triggers fire when the parent object or Moab starts. <i>start</i> triggers can be attached to jobs, reservations, resource managers, and the scheduler (when Moab starts and at the beginning of Moab's first iteration).
<b>threshold</b>	Triggers fire when a threshold, such as usage or a gmetric comparison, is true. <i>threshold</i> triggers can be attached to nodes and reservations. Triggers with <b>ETypes</b> set to <i>threshold</i> must include the <a href="#">Threshold</a> attribute.

## Event-modifying trigger components

The following trigger attributes modify the event that causes the trigger to fire.

RearmTime	
<b>Possible Values</b>	[[HH:]MM:]SS
<b>Description</b>	The amount of time that must pass before a trigger can fire again. <b>RearmTime</b> is enforced from the trigger event time.
<b>Usage Notes</b>	---

Offset	
<b>Possible Values</b>	[-] [[HH:]MM:]SS

Offset	
<b>Description</b>	The relative time offset from event when trigger can fire
<b>Usage Notes</b>	<ul style="list-style-type: none"> <li>• Only end triggers can have a negative value for <b>Offset</b>.</li> <li>• <b>Offset</b> cannot be used with cancel.</li> </ul>

Period	
<b>Possible Values</b>	<i>Minute, Hour, Day, Week, Month, Infinity</i>
<b>Description</b>	The period at which the trigger will regularly fire
<b>Usage Notes</b>	---

Threshold	
<b>Possible Values</b>	Threshold={<metric>[<metricName>]}{> >= < <= ==}<FLOAT> Where <metric> is one of: <ul style="list-style-type: none"> <li>• <b>gmetric</b></li> <li>• <b>usage</b></li> </ul>
<b>Description</b>	When the object meets, drops below, or increases past the configured <b>Threshold</b> , the trigger will fire.
<b>Usage Notes</b>	Threshold triggers allow sites to configure triggers to launch based on internal scheduler statistics, such as the usage of a reservation.

FailOffset	
<b>Possible Values</b>	[ [HH:]MM:]SS
<b>Description</b>	The time that the threshold condition must exist before the trigger fires
<b>Usage Notes</b>	Use with fail triggers to avoid transient triggers.

## Action-modifying trigger components

Flags	
<b>Possible Values</b>	<p>Flags=&lt;flag&gt;[:&lt;flag&gt;] or Flags=[&lt;flag&gt;][[&lt;flag&gt;]]</p> <p><i>attacherror</i> - If the trigger outputs anything to stderr, Moab attaches it as a message to the trigger object.</p> <p><i>cleanup</i> - If the trigger is still running when the parent object completes or is canceled, Moab kills the trigger.</p> <p><i>checkpoint</i> - Moab always checkpoints this trigger. For more information, see <a href="#">Checkpointing a trigger on page 757</a>.</p> <p><i>objectxmlstdin</i> - Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.</p> <p><i>resetonmodify</i> - The trigger resets if its object is modified, even if <b>RearmTime</b> is not set.</p> <p><i>user</i> - The trigger executes under the user ID of the object's owner. If the parent object is the scheduler, you may explicitly specify the user using the format <code>user+&lt;username&gt;</code>. For example: <code>Flags=user+john</code>.</p>
<b>Description</b>	Specifies various trigger behaviors and actions
<b>Usage Notes</b>	<p>When specifying multiple flags, each flag can be delimited by colons (:) or with square brackets; for example:</p> <p>Flags=[user] [cleanup] or Flags=user:cleanup</p>

BlockTime	
<b>Possible Values</b>	[[HH:]MM:]SS
<b>Description</b>	The amount of time Moab will suspend normal operation to wait for trigger execution to finish
<b>Usage Notes</b>	Use caution; Moab will completely stop normal operation until <b>BlockTime</b> expires.

ExpireTime	
<b>Possible Values</b>	<INTEGER>
<b>Description</b>	The time at which trigger should be terminated if it has not already been activated
<b>Usage Notes</b>	---

Timeout	
<b>Possible Values</b>	[+ -] [[HH:]MM:]SS
<b>Description</b>	The time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed
<b>Usage Notes</b>	---

MaxRetry	
<b>Possible Values</b>	MaxRetry=<INTEGER>
<b>Description</b>	The number of times <b>Action</b> will be attempted before the trigger is designated a failure
<b>Usage Notes</b>	If <b>Action</b> fails, the trigger will restart immediately (up to <b>MaxRetry</b> times). If it fails more than <b>MaxRetry</b> times, the trigger has failed. This restart ignores <b>FailOffset</b> and <b>RearmTime</b> .

## Organizational trigger components

Name	
<b>Possible Values</b>	Name=<STRING>
<b>Description</b>	Name of the trigger
<b>Usage Notes</b>	Because Moab uses its own internal ID to distinguish triggers, the <b>Name</b> need not be unique. Only the first 16 characters of <b>Name</b> are stored by Moab.

Description	
<b>Possible Values</b>	Description=<STRING>
<b>Description</b>	Description of the trigger
<b>Usage Notes</b>	---

## Trigger exit codes

By default Moab considers any non-zero exit code as a failure and marks the trigger as having failed. If a trigger is killed by a signal outside of Moab, Moab treats the signal as the exit code and (in almost all cases) marks the trigger as having failed. Only exec triggers that exit with an exit code of 0 are marked as successful.

## Node maintenance example

### Example scenario

An administrator wants to create the following setup in Moab:

When a node's temperature exceeds 34°C, Moab reserves it. If the temperature increases to more than 40°C, Moab requeues all jobs on the node. If the node's temperature exceeds 50°C, Moab shuts it down. Moab removes the node's reservation and unsets the variables when the node cools to less than 25°C. The administrator wants to receive an email whenever any of these events occur.

The first trigger reserves the node when its reported temperature exceeds 34°C. Note that the gmetric name in the trigger must match the name of the configured gmetric exactly, including its case (See [Enabling Generic Metrics on page 575](#) for more information.).

```
NODECFG[DEFAULT] TRIGGER=Description="ThresholdA",EType=threshold,Threshold=gmetric
[temp]>34,AType=internal,Action="node::-reserve",RearmTime=30,Offset=2:00,Sets=temp_
rsv
```

The administrator wants the trigger to fire any time a node overheats, so it must be rearmable. It also needs to specify that the node must be over 34°C for at least two minutes for Moab to reserve it. If the trigger succeeds, it will set a variable to be received by the next trigger in order to make them sequential.

The administrator wants to know when this trigger has fired, so another trigger will send an email once the first trigger has fired and the `temp_rsv` variable is set. This one does so via a script:

```
NODECFG[DEFAULT] Trigger=Description="Email on
Reservation",EType=start,AType=exec,Action="$TOOLSDDIR/node_temp_emailReserve.pl
$OID",RearmTime=3:00,Requires=temp_rsv
```

The second threshold trigger requeues the node's jobs if the node exceeds 40°C and the `temp_rsv` variable is set. It uses a script to do so. It sets `node_evac` variable when it fires, regardless of whether it succeeds or fails.

```
NODECFG[DEFAULT] Trigger=Description="Threshold B",EType=threshold,Threshold=gmetric
[temp]>40,AType=exec,Action="$TOOLSDDIR/node_evacuate.pl
$OID",RearmTime=3:00,requires=temp_rsv,Sets=node_evac,!node_evac
```

The administrator wants another email to inform him that the node is still overheating and has been evacuated. Another email trigger fires once it receives the `node_evac` variable.

```
NODECFG[DEFAULT] Trigger=Description="Email on
Evacuation",EType=start,AType=exec,Action="$TOOLSDDIR/node_temp_emailEvac.pl
$OID",RearmTime=3:00,Requires=node_evac
```

The third threshold trigger uses a script to shut down the node if the temp gmetric exceeds 50 and the node\_evac variable is set. It sets a node\_shutdown variable to be received by the notification email.

```
NODECFG[DEFAULT TRIGGER=Description="Threshold C",EType=threshold,Threshold=gmetric
[temp]>50,AType=exec,Action="$TOOLSDIR/node_shutdown.pl
$OID",RearmTime=3:00,Requires=node_evac,Sets=node_shutdown

NODECFG[DEFAULT] Trigger=Description="Email on
Shutdown",EType=start,AType=exec,Action="$TOOLSDIR/node_temp_emailShutdown.pl
$OID",RearmTime=3:00,Requires=node_shutdown
```

The final trigger removes the reservation and unsets the variables once the node's temp gmetric is less than 25.

```
NODECFG[DEFAULT] Trigger=Description="Remove
Reservation",EType=threshold,Threshold=gmetric[temp]
<25,AType=exec,Action="opt/moab/bin/mrsvctl -r r:$OID",RearmTime=3:00,Requires=temp_
rsv,unsets=temp_rsv.node_evac.node_shutdown
```

## Environment creation example

### Example scenario

An administrator wants to create the following setup in Moab:

If a user requests an environment, she must have the permission of her two managers and the administrator. If all three approve, then the environment builds. The user is sent email messages informing her of the environment's end date in case she would like an extension. These are sent 7, 3, and 1 days prior to the environment's ending.

The administrator wants to require his and the managers' approval of any modifications the user makes to her environment so that it cannot be extended without consent.

The first trigger requests manager and administrator approval in response to the user's environment request. So in the event of a reservation's creation, a script is used to send messages to the administrator and manager. The internal variable OWNER is used to indicate to the recipients (via the script) which user is requesting the environment.

```
RSVPROFILE[envSetup] TRIGGER=EType=create,AType=exec,Action="envRequest.sh $OWNER"
```

The managers and administrator use an external program to approve or reject the request. On approval, a variable is sent back to Moab (to the reservation specifically). Once all three variables are set, the environment can start. In this example, the variables are called approval1, approval2, and approval3.

```
RSVPROFILE[envSetup]
TRIGGER=EType=start,AType=exec,Action="buildScript",Requires=approval1.approval2.appro
val3
```

As it is configured now, the reservation will continue to reserve the requested resources regardless of whether all three approvals are given. So, in case approval is not given, the next trigger cancels the reservation 7 days after its creation if the three variables are not set.

```
RSVPROFILE [envSetup]
TRIGGER=EType=create,Offset=7:00:00,AType=internal,Action="rsv::-cancel",Requires=!approval1.!approval2.!approval3
```

Every remaining trigger in this series is meant to fire for an approved environment and must require the approval variables. Otherwise these notifications would be sent to users who do not have the environment they requested. The next triggers must be rearmable so that it can fire again if necessary; however, they should be set to just over the amount of time left on the reservation so that it doesn't fire again for the same environment. The notification triggers use the **Offset** attribute to fire at the administrator's requested times (7, 3, and 1 day(s) prior to the environment's end).

```
RSVPROFILE [envSetup] TRIGGER=EType=end,Offset=7:00:00,AType=exec,Action="weekNotification.sh",RearmTime=7:00:00:02,Requires=approval1.approval2.approval3

RSVPROFILE [envSetup] TRIGGER=EType=end,Offset=3:00:00,AType=exec,Action="3dayNotification.sh",RearmTime=3:00:00:02,Requires=approval1.approval2.approval3

RSVPROFILE [envSetup] TRIGGER=EType=end,Offset=1:00:00,AType=exec,Action="dayNotification.sh",RearmTime=1:00:00:02,Requires=approval1.approval2.approval3
```

The next trigger requests administrator and manager approval when the environment is modified. The problem is that the trigger must be rearmable in case of multiple modifications and each time the [RearmTime on page 769](#) is reached, Moab will fire the trigger based on the *first* instance of modification. To resolve this issue, this modification trigger requires a *modify* variable. When the reservation is modified, the *modify* variable is set.

```
RSVPROFILE [envSetup]
TRIGGER=EType=modify,AType=exec,Action="modify.sh",RearmTime=1:00:00,Requires=approval1.approval2.approval3.!modify,Sets=modify
RSVPROFILE [envSetup]
TRIGGER=EType=modify,AType=exec,Action="modificationRequest.sh",RearmTime=5:00,Requires=approval1.approval2.approval3.modify,Unsets=modify
```

The final triggers notify the user of the end of the environment.

```
RSVPROFILE [envSetup]
TRIGGER=EType=end,AType=exec,Action="end.sh",Requires=approval1.approval2.approval3
```

The same trigger is repeated for the **cancelEType** in case the environment ends unexpectedly.

```
RSVPROFILE [envSetup]
TRIGGER=EType=cancel,AType=exec,Action="end.sh",Requires=approval1.approval2.approval3
```

## Trigger variables

### About trigger variables

Trigger variables are pieces of information that pass from trigger to trigger. They allow triggers to fire based on another trigger's behavior, state, and/or output. A variable can be a required condition for a trigger to fire; for instance, a trigger might be set to launch when a reservation starts, but only if it has received a variable from another trigger indicating that a specific node has started first. Variables give

greater flexibility and power to a site administrator who wants to automate certain tasks and system behaviors.

Variables can be used to define under what circumstances the trigger will fire. Many Moab objects have their own variables and each object's variable name space is unique. Triggers can use their own variables or the variables attached to their parent objects. A trigger's variable name space is limited to itself and its parent object. Variables do not have to be unique across all objects.

#### How-to's

- [Setting and receiving trigger variables on page 776](#)
- [Externally injecting variables into job triggers on page 777](#)
- [Exporting variables to parent objects on page 777](#)
- [Requiring variables from generations of parent objects on page 778](#)
- [Requesting name space variables on page 778](#)

#### References

- [Dependency trigger components on page 779](#)
- [Internal variables on page 780](#)

## How-to's

### Setting and receiving trigger variables

#### Context

Following is an example of how comparative dependencies can be expressed when creating a trigger.

#### To set and require variables

1. Create a trigger.

```
EType=start,AType=exec,Action="/tmp/trigger1.sh"
```

2. Use the **Sets** attribute to set a variable if the trigger succeeds. You can precede the variable with "!" to indicate that the variable should be set if the trigger fails. You can specify more than one variable by separating them with a period.

```
AType=exec,Action="/tmp/trigger1.sh",EType=start,Sets=!Var1.Var2
```

*The trigger sets variable Var2 when it succeeds and variable Var1 when it fails.*

3. Set up the recipient trigger(s). Use the **Requires** attribute to receive the variable(s). Note that preceding the variable with "!" means that the variable must not be set in order for the trigger to fire.

```
AType=exec,Action="/tmp/trigger1.sh",EType=start,Sets=!Var1.Var2
AType=exec,Action="/tmp/trigger2.sh",EType=start,Requires=Var1
AType=exec,Action="/tmp/trigger3.sh",EType=start,Requires=Var2
```

*The second trigger will launch if Var1 has been set (the first trigger failed), and the third trigger will launch if Var2 is set (the first trigger succeeded).*

## 4. Refine the requirement with comparisons.

## a. Use the following format:

```
<varID>[:<type>[:<varVal>]]
```

## b. Change &lt;varID&gt; to the variable name.

c. Use any of the comparisons found on the [Trigger variable comparison types on page 779](#) page in place of <type>:

## d. Set the value that the variable will be compared against.

```
AType=exec,Action="/tmp/trigger2.sh",EType=start,Requires=Var1:eq:45
AType=exec,Action="/tmp/trigger3.sh",EType=start,Requires=Var2:ne:failure1
```

*The first trigger fires if Var1 exists and has a value of 45. The second trigger fires if Var2 does not have a string value of failure1.*

## Externally injecting variables into job triggers

### Context

Job triggers are able to see the variables in the job object to which it is attached. This means that, for triggers that are attached to job objects, another method for supplying variables exists. Updating the job object's variables effectively updates the variable for the trigger.

### To externally inject variables into job triggers

Use the `mjobctl -m` command to set a variable to attach to a job.

```
> mjobctl -m var=Flag1=TRUE 1664
```

The variable `Flag1` is set. This will be available to any trigger attached to job 1664.

## Exporting variables to parent objects

### To export variables to parent objects

1. When setting a variable, indicate that the variable is to be exported to the parent object by using a caret (^).

```
AType=exec,Action="/tmp/trigger1.sh",EType=start,Sets=Var1.^Var2
AType=exec,Action="/tmp/trigger2.sh",EType=start,Requires=Var1
AType=exec,Action="/tmp/trigger3.sh",EType=start,Requires=Var2
```

`Var2` is exported to the parent object if the trigger fails. It can be used by job and reservation triggers at the same level or by parent objects.

2. Optional: if running a script, you can set a variable as a string to pass up to the parent object.

a. Set the variable to pass up to the parent object with the caret (^). Use the `exec AType` to run a script.

```
AType=exec,Action="/tmp/trigger.sh",EType=start,Sets=^Var1
```

The trigger sets `Var1` when it completes successfully. Because the trigger launches a script, a string value can be set for `Var1`.

- b. Declare the variable's string value on its own line in the trigger stdout.

```
EXITCODE=15
Var1=linux
```

*Var1 has the value of linux and is passed up to the parent object. This is useful in workflows in which a trigger may depend on the value given by a previous trigger.*

**i** To return multiple variables, simply print out one per line.

## Requiring variables from generations of parent objects

### Context

By default, triggers look for variables to fulfill dependencies in the object to which they are directly attached. If they are attached to a job object, they will also look in the job group, if defined. However, it is not uncommon for objects to have multiple generations of parent objects. If the desired behavior is to search through all parent objects, do the following task.

### To require variables from generations of parent objects

- Set the **Requires** attribute in the trigger to the required variable, preceded by a caret (^).

```
EType=start, AType=exec, Action="/tmp/trigger2.sh", Requires=^Var1
```

*The trigger searches through the parent objects in which it resides for the variable Var1.*

## Requesting name space variables

### To request a name space variable in a trigger

- [Configure the trigger](#). If it is attached to a generic system job, verify that it meets all the generic system job trigger requirements.
- Create an argument list in the **Action** attribute (after the script path and before the closing quotes) and request the desired variable with an asterisk (\*) in place of the name space.

```
...Action="$HOME/myTrig.py $*.IPAddr"...
```

*Each applicable name space variable is added to the argument list in the format <varName>=<val>.*

For instance, the example above would cause the script to run the following way:

```
> myTrig.py vc1.IPAddr=/tmp/dir1 vc2.IPAddr=/tmp/dir2 vc4.IPAddr=/tmp/dir3
```

*Any other arguments provided here without name spaces will not change.*

- Filter which name spaces are passed down to a job trigger by setting **trigns** when you submit the job. Its value is a comma-delimited list of the desired name spaces.

```
msub -l ... -W x="trigns=vc2,vc4"
```

If the new job is applied to the example in step 2, the script's arguments include *vc2.IPAddr* and *vc4.Addr* and exclude *vc1.IPAddr*. The script runs as follows:

```
> myTrig.py vc2.IPAddr=/tmp/dir1 vc4.IPAddr=/tmp/dir2
```

## References

### Dependency trigger components

Sets	
<b>Possible values</b>	' ' delimited string
<b>Description</b>	Variable values this trigger sets upon success or failure
<b>Usage notes</b>	Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the trigger completes and satisfies all its set conditions. Used in conjunction with <a href="#">Requires on page 779</a> to create trigger dependencies.

Unsets	
<b>Possible values</b>	' ' delimited string
<b>Description</b>	Variable this trigger destroys upon success or failure.
<b>Usage notes</b>	Preceding the string with an exclamation mark (!) indicates this variable is unset upon trigger failure. Used in conjunction with <a href="#">Requires on page 779</a> to create trigger dependencies.

Requires	
<b>Possible values</b>	' ' delimited string
<b>Description</b>	Variables this trigger requires to be set or not set before it will fire.
<b>Usage notes</b>	Preceding the string with an exclamation mark (!) indicates this variable must not be set. Preceding the string with a caret (^) indicates that the variable may come from a parent object (See <a href="#">Requiring variables from generations of parent objects on page 778</a> for more information.). Used in conjunction with <a href="#">Sets on page 779</a> to create trigger dependencies.

### Trigger variable comparison types

The following table describes the valid types of comparisons you can use to express the relationship of a trigger variable to its value:

Type	Comparison	Notes
<b>set</b>	is set (exists)	Default
<b>notset</b>	not set (does not exist)	Same as specifying '!' before a variable
<b>eq</b>	equals	
<b>ne</b>	not equal	
<b>gt</b>	greater than	Integer values only
<b>lt</b>	less than	Integer values only
<b>ge</b>	greater than or equal to	Integer values only
<b>le</b>	less than or equal to	Integer values only

### Internal variables

Several internal variables are available for use in trigger scripts. These can be accessed using `$(varName)`.

Internal Variables	
<b>ETYPE</b>	The type of event that signals that the trigger can fire. ETYPE values include cancel, checkpoint, create, end, fail, hold, migrate, preempt, standing, start, and threshold.
<b>OID</b>	The name of the object to which the trigger was attached
<b>OTYPE</b>	The type of object to which the trigger is attached; can be rsv, job, node, vm, or sched
<b>OWNERMAIL</b>	A variable that is populated only if the trigger's parent object has a user associated with it and that user has an email address associated with it
<b>TIME</b>	The time of the trigger launch in the following format: Wed Mar 10 12:35:12 2012
<b>USER</b>	The user (when applicable)

## Object-specific internal variables

Job Variables	
<b>MASTERHOST</b>	The primary node for the job
<b>HOSTLIST</b>	The entire hostlist of the job

Reservation Variables	
<b>HOSTLIST</b>	The entire hostlist for the reservation
<b>OBJECTXML</b>	The XML representation of an object output is the same that is generated by <a href="#">mdiag -r --xml</a>
<b>OS</b>	The operating system on the first node of the reservation
<b>OWNER</b>	The owner of the reservation

Example 3-151: Internal variable example

```
AType=exec,Action="/tmp/trigger.sh $OID $HOSTLIST",EType=start
```

*The object ID (`$OID`) and hostlist (`$HOSTLIST`) will be passed to `/tmp/trigger.sh` as command line arguments when the trigger executes the script. The script can then process this information as needed.*

## Miscellaneous

- [User Feedback Overview](#) on page 781
- [Enabling High Availability Features](#) on page 783
- [Malleable Jobs](#) on page 785
- [Identity Managers](#) on page 786
- [Generic System Jobs](#) on page 790

## User Feedback Overview

The Feedback facility allows a site administrator to provide job performance information to users at job completion time. When a job completes, the program pointed to by the [FEEDBACKPROGRAM](#) parameter is called with a number of command line arguments. The site administrator is responsible for creating a program capable of processing and acting upon the contents of the command line. The command line arguments passed are as follows:

1. job id
2. user name
3. user email
4. final job state
5. QoS requested
6. epoch time job was submitted
7. epoch time job started
8. epoch time job completed
9. job XFactor
10. job wallclock limit
11. processors requested
12. memory requested
13. average per task cpu load
14. maximum per task cpu load
15. average per task memory usage
16. maximum per task memory usage
17. messages associated with the job
18. hostlist (comma-delimited)

For many sites, the feedback script is useful as a means of letting users know the accuracy of their wallclock limit estimate, as well as the CPU efficiency, and memory usage pattern of their job. The feedback script may be used as a mechanism to do any of the following:

- email users regarding statistics of all completed jobs
- email users only when certain criteria are met (such as "Job 14991 has just completed which requested 128 MB of memory per task. During execution, it used 253 MB of memory per task potentially conflicting with other jobs. Please improve your resource usage estimates in future jobs.")
- update system databases
- take system actions based on job completion statistics

Some of these fields may be set to zero if the underlying OS/resource manager does not support the necessary data collection.

*Example 3-152:*

```
FEEDBACKPROGAM /opt/moab/tools/fb.pl
```

## Enabling High Availability Features

**i** Contact Adaptive Computing before attempting to implement any type of high availability.

- [Moab High Availability Overview](#)
  - [Configuring High Availability via a Networked File System](#)
  - [Confirming High Availability on a Networked File System](#)
- [Other High Availability Configuration](#)

### High Availability Overview

High availability allows Moab to run on two different machines: a primary and secondary server. The configuration method to achieve this behavior takes advantage of a networked file system to configure two Moab servers with only one operating at a time.

**i** If you use a shared file system for high availability and Moab is configured to use a database, Moab must be an ODBC build, not SQLite.

When configured to run on a networked file system — any networked file system that supports file locking is supported — the first Moab server that starts locks a particular file. The second Moab server waits on that lock and only begins scheduling when it gains control of the lock on the file. This method achieves near instantaneous turnover between failures and eliminates the need for two Moab servers to synchronize information periodically as the two Moab servers access the same database/checkpoint file.

**i** As Moab uses timestamping in the lock file to implement high availability, the clocks on both servers require synchronization; all machines in a cluster must be synchronized to the same time server.

Moab high availability and TORQUE high availability operate independently of each other. If a job is submitted with `msub` and the primary Moab server is down, `msub` tries to connect to the fallback Moab server. Once the job is given to TORQUE, if TORQUE can't connect to the primary `pbs_server`, it tries to connect to the fallback `pbs_server`. For example:

A job is submitted with `msub`, but Moab is down on `server01`, so `msub` contacts Moab running on `server02`.

A job is submitted with `msub` and Moab hands it off to TORQUE, but `pbs_server` is down on `server01`, so `qsub` contacts `pbs_server` running on `server02`.

When you shut down or restart Moab on both servers, you must run the command twice. A single shutdown (`mschedctl -k`) or restart (`mschedctl -R`) command will go to the primary server and kill it, causing the secondary server to fall back and start operating. To kill the secondary server, resubmit the command.

**i** Do not use anything but a plain simple NFS fileshare that is not used by anybody or anything else (i.e., only Moab can use the fileshare).

**i** Do not use any general-purpose NAS, do not use any parallel file system, and do not use company-wide shared infrastructure to set up Moab high availability using "native" high availability.

## Configuring High Availability on a Networked File System

Because the two Moab servers access the same files, configuration is only required in the `moab.cfg` file. The two hosts that run Moab must be configured with the **SERVER** and **FBSERVER** parameters. File lock is turned on using the **FLAGS=filelockha** flag. Specify the lock file with the **HALOCKFILE** parameter. The following example illustrates a possible configuration:

```
SCHEDCFG [Moab]  SERVER=host1:42559
SCHEDCFG [Moab]  FBSERVER=host2
SCHEDCFG [Moab]  FLAGS=filelockha
SCHEDCFG [Moab]  HALOCKFILE=/opt/moab/.moab_lock
```

Use the **HALOCKUPDATETIME** parameter to specify how frequently the primary server updates the timestamp on the lock file. Use the **HALOCKCHECKTIME** parameter to specify how frequently the secondary server checks the timestamp on the lock file.

```
HALOCKCHECKTIME 9
HALOCKUPDATETIME 3
```

*In the preceding example, the secondary server checks the lock file for updates every 9 seconds. The **HALOCKUPDATETIME** parameter is set to 3 seconds, permitting the primary server three opportunities to update the timestamp for each time the secondary server checks the timestamp on the lock file.*

**i** **FBSERVER** does not take a port number. The primary server's port is used for both the primary server and the fallback server.

## Confirming High Availability on a Networked File System

Administrators can run the `mdiag -S -v` command to view which Moab server is currently scheduling and responding to client requests.

## Other High Availability Configuration

Moab has many features to improve the availability of a cluster beyond the ability to automatically relocate to another execution server. The following table describes some of these features.

Feature	Description
<b>AMCFG[] BACKUPHOST</b>	<p>If using the Moab Accounting Manager, you may enable high availability with the accounting manager by specifying a backup server as in the following example:</p> <pre>AMCFG[mam] BACKUPHOST=headnode2</pre>
<b><u>JOBACNONNODEFAILURE</u></b>	<p>If a node allocated to an active job fails, it is possible for the job to continue running indefinitely even though the output it produces is of no value. Setting this parameter allows the scheduler to automatically preempt these jobs when a node failure is detected, possibly allowing the job to run elsewhere and also allowing other allocated nodes to be used by other jobs.</p>
<b><u>SCHEDCFG[] RECOVERYACTION</u></b>	<p>If a catastrophic failure event occurs (SIGSEGV or SIGILL signal is triggered), Moab can be configured to automatically restart, trap the failure, ignore the failure, or behave in the default manner for the specified signal. These actions are specified using the values <i>RESTART</i>, <i>TRAP</i>, <i>IGNORE</i>, or <i>DIE</i>, as in the following example:</p> <pre>SCHEDCFG[bas] MODE=NORMAL RECOVERYACTION=RESTART</pre>

## Malleable Jobs

Malleable jobs are jobs that can be adjusted in terms of resources and duration required, and which allow the scheduler to maximize job responsiveness by selecting a job's resource shape or footprint prior to job execution. Once a job has started, however, its resource footprint is fixed until job completion.

To enable malleable jobs, the underlying resource manager must support dynamic modification of resource requirements prior to execution (i.e., [TORQUE](#)) and the jobs must be submitted using the [TRL](#) (task request list) resource manager extension string. With the **TRL** attribute specified, Moab will attempt to select a start time and resource footprint to minimize job completion time and maximize overall effective system utilization (i.e.,  $\langle \text{AverageJobEfficiency} \rangle * \langle \text{AverageSystemUtilization} \rangle$ ).

*Example 3-153:*

With the following job submission, Moab will execute the job in one of the following configurations: 1 node for 1 hour, 2 nodes for 30 minutes, or 4 nodes for 15 minutes.

```
> qsub -l nodes=1,trl=1@3600:2@1800:4@900 testjob.cmd
job 72436.orion submitted
```

## Identity Managers

- [Identity Manager Overview](#)
- [Basic Configuration](#)
- [Importing Credential Fairness Policies](#)
- [Identity Manager Data Format](#)
- [Identity Manager Conflicts](#)
- [Refreshing Identity Manager Data](#)

The Moab identity manager interface can be used to coordinate global and local information regarding users, groups, accounts, and classes associated with compute resources. The identity manager interface may also be used to allow Moab to automatically and dynamically create and modify user accounts and credential attributes according to current workload needs.

 Only one identity manager can be configured at a time.

### Identity Manager Overview

Moab allows sites extensive flexibility when it comes to defining credential access, attributes, and relationships. In most cases, use of the [USERCFG](#), [GROUPCFG](#), [ACCOUNTCFG](#), [CLASSCFG](#), and [QOSCFG](#) parameters is adequate to specify the needed configuration. However, in certain cases such as the following, this approach may not be ideal or even adequate:

- Environments with very large user sets
- Environments with very dynamic credential configurations in terms of fairshare targets, priorities, service access constraints, and credential relationships
- Grid environments with external credential mapping information services
- Enterprise environments with fairness policies based on multi-cluster usage

Moab addresses these and similar issues through the use of an identity manager. An identity manager is configured with the [IDCFG](#) parameter and allows Moab to exchange information with an external identity management service. As with Moab resource manager interfaces, this service can be a full commercial package designed for this purpose, or something far simpler such as a web service, text file, or database.

### Basic Configuration

Configuring an identity manager in basic read-only mode can be accomplished by simply setting the **SERVER** attribute. If Moab is to interact with the identity manager in read/write mode, some additional configuration may be required.

BLOCKCREDLIST	
<b>Format</b>	One or more comma-delimited object types from the following list: <i>acct</i> , <i>group</i> , or <i>user</i>
<b>Details</b>	<p>If specified, Moab will block all jobs associated with credentials not explicitly reported in the most recent identity manager update. If the credential appears on subsequent updates, resource access will be immediately restored.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin: 5px 0;"> <p><b>i</b> Jobs will only be blocked if <u>fairshare</u> is enabled. This can be accomplished by setting the <u>FSPOLICY</u> parameter to any value such as in the following example:</p> <pre style="border: 1px dashed #0070C0; padding: 5px; display: inline-block;">FSPOLICY DEDICATEDPS</pre> </div>
<b>Example</b>	<pre>IDCFG[test01] BLOCKCREDLIST=acct,user,groups</pre> <div style="border: 1px dashed #0070C0; padding: 5px; margin: 5px 0;"> <p><i>Moab will block any jobs associated with accounts, users, or groups not in the most recent identity manager update.</i></p> </div>

CREATECRED	
<b>Format</b>	<BOOLEAN> (default is <i>FALSE</i> )
<b>Details</b>	Specifies whether Moab should create credentials reported by the identity manager that have not yet been locally discovered or loaded via the resource manager. By default, Moab will only load information for credentials which have been discovered outside of the identity manager.
<b>Example</b>	<pre>IDCFG[test01] CREATECRED=TRUE</pre> <div style="border: 1px dashed #0070C0; padding: 5px; margin: 5px 0;"> <p><i>Moab will create credentials from test01 that have not been previously loaded.</i></p> </div>

REFRESHPERIOD	
<b>Format</b>	<i>minute</i> , <i>hour</i> , <i>day</i> , or <i>infinity</i> (default is <i>infinity</i> ).
<b>Details</b>	If specified, Moab refreshes identity manager information once every specified iteration. If <i>infinity</i> is specified, the information is updated only at Moab start up.
<b>Example</b>	<pre>IDCFG[test01] REFRESHPERIOD=hour</pre> <div style="border: 1px dashed #0070C0; padding: 5px; margin: 5px 0;"> <p><i>Moab queries the identity manager every hour.</i></p> </div>

RESETCREDLIST	
<b>Format</b>	One or more comma-delimited object types from the following list: <i>acct</i> , <i>group</i> , or <i>user</i> .
<b>Details</b>	If specified, Moab will reset the account access list and fairshare cap and target for all credentials of the specified type(s) regardless of whether they are included in the current info manager report. Moab will then load information for the specified credentials.
<b>Example</b>	<pre>IDCFG[test01] RESETCREDLIST=group</pre> <p><i>Moab will reset the account access list and fairshare target for all groups.</i></p>

SERVER	
<b>Format</b>	<URL>
<b>Details</b>	Specifies the protocol/interface to use to contact the identity manager.
<b>Example</b>	<pre>IDCFG[test01] SERVER=exec://\$HOME/example.pl</pre> <p><i>Moab will use example.pl to communicate with the identity manager.</i></p>

UPDATEREFRESHONFAILURE	
<b>Format</b>	<BOOLEAN> (default is <i>FALSE</i> )
<b>Details</b>	When an <b>IDCFG</b> script fails, it retries almost immediately and continuously until it succeeds. When <b>UPDATEREFRESHONFAILURE</b> is set to <i>TRUE</i> , a failed script does not attempt to rerun immediately, but instead follows the specified <b>REFRESHPERIOD</b> schedule. When set to <i>TRUE</i> , <b>UPDATEREFRESHONFAILURE</b> updates the script execution timestamp, even if the script does not end successfully.
<b>Example</b>	<pre>IDCFG[info] SERVER=exec:///home/tshaw/test/1447/bad_script.pl REFRESHPERIOD=hour UPDATEREFRESHONFAILURE=TRUE</pre>

## Importing Credential Fairness Policies

One common use for an identity manager is to import fairness data from a global external information service. As an example, assume a site needed to coordinate Moab group level fairshare targets with an

allocation database that constrains total allocations available to any given group. To enable this, a configuration like the following might be used:

```
IDCFG[alloc] SERVER=exec://$TOOLS_DIR/idquery.pl
...
```

*The tools/idquery.pl script could be set up to query a local database and report its results to Moab. Each iteration, Moab will then import this information, adjust its internal configuration, and immediately respect the new fairness policies.*

## Identity Manager Data Format

When an identity manager outputs credential information either through an `exec` or file based interface, the data should be organized in the following format:

```
<CREDTYPE>:<CREDID> <ATTR>=<VALUE>
```

where

- `<CREDTYPE>` is one of `user`, `group`, `account`, `class`, or `qos`.
- `<CREDID>` is the name of the credential.
- `<ATTR>` is one of `adminlevel`, `alist`, `chargerate`, [comment](#), [emailaddress](#), `fstarget`, `globalfstarget`, `globalfsusage`, [maxjob](#), [maxmem](#), [maxnode](#), [maxpe](#), [maxproc](#), [maxps](#), [maxwc](#), `plist`, `priority`, `qlist`, or `role`. [Multi-dimensional policies](#) work here as well.
- `<VALUE>` is the value for the specified attribute.

To clear a comment, set its value to `""`; for example: `comment=""`.

*Example 3-154:*

The following output may be generated by an `exec` based identity manager:

```
group:financial fstarget=16.3 alist=project2
group:marketing fstarget=2.5
group:engineering fstarget=36.7
group:dm fstarget=42.5
user:jason adminlevel=3
account:sales maxnode=128 maxjob=8,16
```

The following example limits user `bob` to 8 `matlab` generic resources.

```
user:bob MAXGRES[matlab]=8
```

To specify unlimited use of generic resources, set the value to `-1`.

## Identity Manager Conflicts

When local credential configuration (as specified via `moab.cfg`) conflicts with identity manager configuration, the identity manager value takes precedence and the local values are overwritten.

## Refreshing Identity Manager Data

By default, Moab only loads identity manager information once when it is first started up. If the identity manager data is dynamic, then you may want Moab to periodically update its information. To do this, set the **REFRESHPERIOD** attribute of the **IDCFG** parameter. Legal values are documented in the following table:

Value	Description
<b>minute</b>	Update identity information once per minute
<b>hour</b>	Update identity information once per hour
<b>day</b>	Update identity information once per day
<b>infinity</b>	Update identity information only at start-up (default)

Example 3-155:

```
IDCFG[hq] SERVER=exec://$TOOLS DIR/updatepolicy.sh REFRESHPERIOD=hour
```

 Job credential feasibility is evaluated at job submission and start time.

## Generic System Jobs

Generic system jobs are system jobs with a trigger. They are useful for specifying steps in a workflow.

- [Creating a Generic System Job](#)
  - [The Trigger](#)
- [Workflows Using Job Template Dependencies](#)
  - [Inheriting Resources in Workflows](#)

### Creating a Generic System Job

Generic system jobs are specified via a job template. The template can be selectable and you must use the **GENERICSYSJOB** attribute to let Moab know that this job template describes a generic system job and to specify a trigger, as shown in the following example:

```
JOBCFG[gen]
GENERICSYSJOB=EType=start,AType=exec,Action="$HOME/genericTrig.py",Timeout=5:00
```

## The Trigger

The generic system job's trigger that meets certain criteria. This trigger must have a timeout, an `Atype=Exec`, and the `EType` must equal "start". The timeout of the trigger will be used as the walltime for the job. The trigger will begin when the system job begins and the job will be considered completed when the trigger completes. The job will have the same completion code as the trigger. The walltime on the job template is not applicable in this case since the timeout of the trigger will be the walltime.

If the trigger fails, an error message will be attached to all of the job's parent VCs. You can view this in the `--xml` output of the VC query. The message includes the location of `STDIN`, `STDOUT`, and `STDERR` files. For example:

```

mvcctl -q ALL --xml
<Data>
<vc CREATETIME="1320184350" DESCRIPTION="Moab.1"
  FLAGS="DESTROYOBJECTS, DESTROYWHENEMPTY, HASSTARTED, WORKFLOW"
  JOBS="Moab.1" NAME="vc1" OWNER="user:frank">
<ACL aff="positive" cmp="%=" name="frank" type="USER"></ACL>
<MESSAGES>
<message COUNT="1" CTIME="1320184362"
  DATA="Trigger 10 failed on job Moab.1.setup- STDIN:
/tmp/ByLLl2wv/spool/vm.py.ieWPPS5 STDOUT:
/tmp/ByLLl2wv/spool/vm.py.oDMIXAW STDERR /tmp/ByLLl2wv/spool/vm.py.e2jD5iN"
  EXPIRETIME="1322776362" OWNER="frank" PRIORITY="0"
  TYPE="other" index="0"></message>
</MESSAGES>
<Variables>
<Variable name="VMID">vm1</Variable>
<Variable name="HV">TRUE</Variable>
</Variables>
</vc>
</Data>

```

You can specify other triggers on a generic system job using the **TRIGGER** attribute and delimiting them with semicolons. For example:

```

JOBCFG[gen]  GENERICSYSJOB=<genericSystemJobTriggerSpecs>
JOBCFG[gen]  TRIGGER=<triggerSpecs>;TRIGGER=<triggerSpecs>

```

## Workflows Using Job Template Dependencies

To create workflows, use the following format:

```

JOBCFG[gen]  TEMPLATEDEPEND=AFTERANY:otherTemplate

```

This will create a job based on the template `otherTemplate`. The generic job will run after the `otherTemplate` job has finished. [Afterany](#) in the example means after all other jobs have completed, regardless of success.

## Inheriting Resources in Workflows

The **INHERITRES** flag can be used to cause the same resources in one step of a workflow to be passed to the next step:

```

JOBcfg[gen]   TEMPLATEDEPEND=AFTERANY:otherTemplate
JOBcfg[otherTemplate] INHERITRES=TRUE

```

*This example forces the job based on `otherTemplate` to have the same resource requirements as its parent. When the `otherTemplate` job is finished, the **INHERITRES** flag will cause the parent to run on the same resources as the child.*

The job that finishes first will pass its allocation up.

Any variables on the original job will be passed to the other jobs in the workflow. Variables can be added by other jobs in the workflow via the [sets](#) attribute in the generic system job's trigger. Other triggers must then request that variable name in the command line options.

**i** You will need to set the carat (^) in order for the variable to be sent up to the job group.

If you set the variable, you need to set it in the STDOUT of the trigger script. See the example below:

```

JOBcfg[W1]   GENERICSYSJOB=...,action='$HOME/W1.py $ipaddress' TEMPLATEDEPEND=AFTER:W2
JOBcfg[W2]   TRIGGER=...,action='$HOME/W2.py',sets=^ipaddress

```

*If a variable value is not set in STDOUT, it will be set to **TRUE**.*

To set the variable to a specific value, the `w2.py` script must set the value in its STDOUT:

```

print "ipaddress=10.10.10.1" #This will be parsed by Moab and set as the value of the
"ipaddress" variable

```

#### Example 3-156:

To create a VM with a workflow using job template dependencies and generic system jobs, use the following format:

```

#The job template that is "gate" to the workflow
JOBcfg[CreateVMWithSoftware] TEMPLATEDEPEND=AFTEROK:InstallSoftware SELECT=TRUE

JOBcfg[InstallSoftware]
GENERICSYSJOB=EType=start,AType=exec,Action="$HOME/setupSoftware.py
$IPAddr",Timeout=30:00
JOBcfg[InstallSoftware]   INHERITRES=TRUE
JOBcfg[InstallSoftware]   TEMPLATEDEPEND=AFTEROK:CreateVM

JOBcfg[CreateVM]   GENERICSYSJOB=EType=start,AType=exec,Action=$HOME/installVM.py
$HOSTLIST",Timeout=1:00:00,sets=^IPAddr
JOBcfg[CreateVM]   INHERITRES=TRUE

```

The user will then submit the job requesting what they need in the VM:

```

msub -l walltime=2:00:00,template=CreateVMWithSoftware,nodes=1:ppn=4,mem=1024
ActualWorkload.py

```

*The job will have the `CreateVMWithSoftware` template applied to it and will create the `InstallSoftware` job. The `InstallSoftware` job, because of **INHERITRES**, will have the same resource request (4 procs, 1GB of memory). This job then has its template applied to it which will do the same thing in creating the `CreateVM` job. The `CreateVM` job will then run, the trigger script will return the IP address of the new VM and pass its allocation up to the `InstallSoftware` job. The `InstallSoftware` job will use the `IPAddr` variable to find the VM and install the software. It will then return its resources up to the parent job, which will run the actual workload.*

## Database Configuration

Moab supports connecting to a database via native SQLite3, and it can also connect to other databases using the ODBC driver. These optional external databases store some additional information that the MongoDB database does not and allow you to query them directly using SQL. These databases are slower, however, and only SQLite3, which does not allow external queries, is supported.

The SQLite3 connection is for storing statistics. Consider reviewing the SQLite web page [Appropriate Uses for SQLite](#) for information regarding the suitability of using SQLite3 on your system.

While the ODBC connection is useful for storing statistics, it also stores events, nodes, and jobs. You can further configure Moab to store checkpoint information to a database rather than to the flat text file (`.moab.ck`) if you set the `CHECKPOINTWITHDATABASE` parameter to `TRUE`.

Connecting to an external database makes Moab more searchable, allowing you to run queries for statistics and events rather than using regular expressions to draw the information from the Moab flat files.

- [SQLite3 on page 793](#)
- [Connecting to a MySQL Database with an ODBC Driver on page 794](#)
- [Connecting to a PostgreSQL Database with an ODBC Driver on page 797](#)
- [Connecting to an Oracle Database with an ODBC Driver on page 799](#)
  - [Installing the Oracle Instant Client on page 806](#)
- [Migrating Your Database to Newer Versions of Moab on page 808](#)
- [Importing Statistics from stats/DAY.\\* to the Moab Database on page 815](#)

## SQLite3

Moab supports connecting to a database via native SQLite3. Database installation and configuration occurs automatically during normal Moab installation (`configure`, `make install`). If you did not follow the normal process to install Moab and need to install the database, do the following to manually install and configure Moab database support:

1. Create the database file `moab.db` in your moab home directory by running the following command from the root of your unzipped Moab build directory:
 

```
perl buildutils/install.sqlite3.pl <moab-home-directory>
```

  - Verify that the command worked by running `lib/sqlite3 <moab-home-directory>/moab.db`; at the resulting prompt, type `.tables` and press **ENTER**. You should see several tables such as `mcheckpoint` listed. Exit from this program with the `.quit` command.
  - The `perl buildutils/install.sqlite3.pl <moab-home-directory>` command may fail if your operating system cannot find the SQLite3 libraries. Also, Moab fails if unable to identify the libraries. To temporarily force the libraries to be found, run the following command:
 

```
export LD_LIBRARY_PATH=<location where libraries were copied>
```

2. In the `moab.cfg` file in the `etc/` folder of the home directory, add the following line:

```
USEDATABASE INTERNAL
```

To verify that Moab is running with SQLite3 support, start Moab and run the `mdiag -S -v` command. If there are no database-related error messages displayed, then Moab should be successfully connected to a database.

**i** > `moabd` is a safe and recommended method of starting Moab if things are not installed in their default locations.

## Connecting to a MySQL Database with an ODBC Driver

This documentation shows how to set up and configure Moab to connect to a MySQL database using the MySQL ODBC driver. This document assumes the necessary MySQL and ODBC drivers have already been installed and configured.

To set up and configure Moab to connect to a MySQL database using the MySQL ODBC driver, do the following:

**i** This solution has been tested and works with these versions:

- libmyodbc - 5.1.5
- MySQL 5.1

1. Download and install the ODBC version of Moab. [Install and configure](#) Moab as normal but add the following in the Moab configuration file (`moab.cfg`):

```
USEDATABASE          ODBC
# Turn on stat profiling
USERCFG [DEFAULT]    ENABLEPROFILING=TRUE
GROUPCFG [DEFAULT]   ENABLEPROFILING=TRUE
QOSCFG [DEFAULT]     ENABLEPROFILING=TRUE
CLASSCFG [DEFAULT]   ENABLEPROFILING=TRUE
ACCOUNTCFG [DEFAULT] ENABLEPROFILING=TRUE
NODECFG [DEFAULT]    ENABLEPROFILING=TRUE
```

2. Create the database in MySQL using the MySQL database dump contained in the `moab-db.sql` file. This file is located in the `contrib/sql` directory in the root of the binaries.

- Run the following command:

```
mysql -u root -p < moab-db-mysql-create.sql
```

3. Configure the MySQL and ODBC driver. The `odbcinst.ini` file must be contained in `/etc`.

**i** Run the following command to find the MySQL ODBC client driver. You could also query the `libmyodbc` package that was installed.

```
[root]# updatedb
[root]# locate libmyodbc
```

```
[MySQL]
Description = ODBC for MySQL
Driver = /usr/lib/odbc/libmyodbc.so
```

4. Configure Moab to use the MySQL ODBC driver. Moab uses an ODBC datastore file to connect to MySQL using ODBC. This file must be located in the Moab home directory (`/opt/moab` by default) and be named `dsninfo.dsn`, which is used by Moab. You need to have the following data in both `/etc/odbc.ini` and `$MOABHOMEDIR/dsninfo.dsn`:

```
[ODBC]
Driver = MySQL
USER = <username>
PASSWORD = <password>
Server = localhost
Database = Moab
Port = 3306
```

**i** The user should have read/write privileges on the Moab database.

The preceding example file tells ODBC to use the MySQL driver, username `<username>`, password `<password>`, and to connect to MySQL running on the localhost on port 3306. ODBC uses this information to connect to the database called `Moab`.

5. Test the ODBC to MySQL connection by running the `isql` command, which reads the `/etc/odbc.ini` file:

```

$ isql -v ODBC
+-----+
| Connected! |
| |
| sql-statement |
| help [tablename] |
| quit |
| |
+-----+
SQL> show tables;
+-----+
| Tables_in_Moab |
+-----+
| EventType |
| Events |
| GeneralStats |
| GenericMetrics |
| Moab |
| NodeStats |
| NodeStatsGenericResources |
| ObjectType |
| mcheckpoint |
+-----+
SQLRowCount returns 10
10 rows fetched
SQL>

```

If you encounter any errors using the `isql` command, there was a problem setting up the ODBC to MySQL connection. Try the following debugging steps to resolve the issue:

- a. The `odbcinst.ini` and `odbc.ini` files are usually assumed to be located in `/etc`, but that is not always true. Use the `odbcinst -j` command to determine the assumed location of the files in your configuration.

```

[root#] odbcinst -j
unixODBC 2.2.12
DRIVERS.....: /etc/unixODBC/odbcinst.ini
SYSTEM DATA SOURCES: /etc/unixODBC/odbc.ini
USER DATA SOURCES...: /home/adaptive/.odbc.ini

```

- b. Because `odbcinst.ini` and `odbc.ini` are expected in `/etc/unixODBC`, not `/etc`, move them from `/etc` to `/etc/unixODBC`.
- c. Use the `strace` command to determine where `isql` expects the `odbc.ini` and `odbcinst.ini` files. Note the location in which `isql` expects these files.

```

$ strace isql -v ODBC

```

6. With the ODBC driver configured, the database created, and Moab configured to use the database, start Moab for it to begin storing information in the created database.

 > `moabd` is a safe and recommended method of starting Moab if things are not installed in their default locations.

## Related topics

- [Importing Statistics to the Moab Database](#)

## Connecting to a PostgreSQL Database with an ODBC Driver

This documentation shows how to set up and configure Moab to connect to a PostgreSQL database using the ODBC driver. This document assumes the necessary ODBC drivers have already been installed and configured.

**i** Occasionally vacuuming your PostgreSQL database could improve Moab performance. See the PostgreSQL documentation for information on how to vacuum your database.

To set up and configure Moab to connect to a PostgreSQL database using the ODBC driver, do the following:

**i** This solution has been tested and works with the following file version:

- odbc-postgresql - 1:08.03.0200-1.2

1. Configure the PostgreSQL and ODBC driver. `odbcinst.ini` file must be contained in `/etc`.

**i** Run the following commands to find the PostgreSQL ODBC client driver and setup file. You could also query the `libodbcpsql` package that was installed.

```
[root]# updatedb
[root]# locate psqlodbc
[root]# locate libodbcpsql
```

```
[PostgreSQL]
Description = PostgreSQL ODBC driver
Driver = /usr/lib/odbc/psqlodbc.so
Setup = /usr/lib/odbc/libodbcpsqlS.so
Debug = 0
CommLog = 1
UsageCount = 2
```

2. Configure Moab to use the PostgreSQL ODBC driver. Moab uses an ODBC data source file to connect to PostgreSQL using ODBC. This file must be located in the Moab home directory (`/opt/moab` by default) and be named `dsninfo.dsn`, which is used by Moab. If the following content, which follows the standard ODBC driver file syntax, is not already included in the `/etc/odbc.ini` file, make sure that you include it. Also, include the same content in the `dsninfo.dsn` file.

```
[ODBC]
Driver = PostgreSQL
Description = PostgreSQL Data Source
Servername = localhost
Port = 5432
Protocol = 8.4
Username = postgres
Password = moab
Database = Moab
```

**i** The user should have read/write privileges on the Moab database.

The preceding example file tells ODBC to use the PostgreSQL driver, `postgres` user, `moab` password, and to connect to PostgreSQL running on the localhost on port 5432. ODBC uses this information and connects to the database called `Moab`.

3. Test the ODBC to PostgreSQL connection by running the `isql` command, which reads the `/etc/odbc.ini` file. If connected, you should be able to run the `help` command.

If you encounter any errors using the `isql` command, there was a problem setting up the ODBC to MySQL connection. Try the following debugging steps to resolve the issue:

- a. The `odbcinst.ini` and `odbc.ini` files are usually assumed to be located in `/etc`, but that is not always true. Use the `odbcinst -j` command to determine the assumed location of the files in your configuration.

```
[root#] odbcinst -j
unixODBC 2.2.12
DRIVERS.....: /etc/unixODBC/odbcinst.ini
SYSTEM DATA SOURCES: /etc/unixODBC/odbc.ini
USER DATA SOURCES...: /home/adaptive/.odbc.ini
```

- b. Because `odbcinst.ini` and `odbc.ini` are expected in `/etc/unixODBC`, not `/etc`, move them from `/etc` to `/etc/unixODBC`.
- c. Use the `strace` command to determine where `isql` expects the `odbc.ini` and `odbcinst.ini` files. Note the location in which `isql` expects these files.

```
$ strace isql -v ODBC
```

4. Create the database in PostgreSQL using the `moab-db-postgresql.sh` setup script contained in the `contrib/sql` directory at the root of the binary.
  - Run the script and provide the DB username that will attach to the Moab database (you must supply a DB username or the script will exit). The default admin user is `postgres`, but you can make a new user at this time:

```
> ./moab-db-postgresql.sh postgres
Create db user "postgres" in postgresQL? (y/n)>
```

- The script asks if you want to create the DB user you specified in postgresQL. If the DB user already exists, answer 'n'. Otherwise, the DB user is created and it asks for the new user's password.
  - The script then creates the database "Moab".
  - Finally, as the DB user you provided, the script imports the DB schema from `moab-db-postgresql-create.sql` into the Moab database.
5. Download and install the ODBC version of Moab. [Install and configure](#) Moab as normal but add the following in the Moab configuration file (`moab.cfg`):

```

USEDATABASE          ODBC
# Turn on stat profiling
USERCFG [DEFAULT]    ENABLEPROFILING=TRUE
GROUPCFG [DEFAULT]   ENABLEPROFILING=TRUE
QOSCFG [DEFAULT]     ENABLEPROFILING=TRUE
CLASSCFG [DEFAULT]   ENABLEPROFILING=TRUE
ACCOUNTCFG [DEFAULT] ENABLEPROFILING=TRUE
NODECFG [DEFAULT]    ENABLEPROFILING=TRUE

```

6. With the ODBC driver configured, the database created, and Moab configured to use the database, start Moab for it to begin storing information in the created database.

**i** > moabd is a safe and recommended method of starting Moab if things are not installed in their default locations.

## Connecting to an Oracle Database with an ODBC Driver

### Context

This documentation shows how to set up and configure Moab to connect to an Oracle database using the ODBC driver.

### To connect to an Oracle database with an ODBC driver

1. Install and configure the Oracle Instant Client with ODBC supporting libraries. For instructions, see [Installing the Oracle Instant Client on page 806](#).
2. Open your Moab configuration file (`$MOABHOMEDIR/moab.cfg`) and add the following lines to the end of the file.

```

USEDATABASE ODBC
# Turn on stat profiling
USERCFG [DEFAULT]    ENABLEPROFILING=TRUE
GROUPCFG [DEFAULT]   ENABLEPROFILING=TRUE
QOSCFG [DEFAULT]     ENABLEPROFILING=TRUE
CLASSCFG [DEFAULT]   ENABLEPROFILING=TRUE
ACCOUNTCFG [DEFAULT] ENABLEPROFILING=TRUE
NODECFG [DEFAULT]    ENABLEPROFILING=TRUE

```

3. Configure the Oracle ODBC Driver. The `odbcinst.ini` file must be contained in `/etc`.

```
[root]# vim /etc/odbcinst.ini
```

**i** Run the following command to find the Oracle Instant Client driver. You could also query the Oracle Instant Client package that was installed.

```
[root]# updatedb && locate libsqora
```

Add the following text to the file.

```
[Oracle 11g ODBC driver]
Description      = Oracle ODBC driver for Oracle 11g
Driver          = /usr/lib/oracle/11.2/client64/lib/libsqora.so.11.1
Setup           =
FileUsage       =
CPTimeout       =
CPReuse         =
Driver Logging  = 7

[ODBC]
Trace = Yes
TraceFile = /tmp/odbc.log
ForceTrace = Yes
Pooling = No
DEBUG = 1
```

**i** Driver Logging is set high (level 7) so that you can debug during the installation and configuration process if necessary. You can decrease the setting or remove the directive once you finish the process.

**i** To configure the location of the ODBC log (/tmp/odbc.log), set the TraceFile attribute shown in the example above. See "[unixODBC without the GUI](#)" on the unixODBC website for more information.

4. Because the driver installed in step 1 is a shared library, run `ldd` to verify that it and all of its dependencies are installed and working.

```
[root]# ldd /usr/lib/oracle/11.2/client64/lib/libsqora.so.11.1
linux-vdso.so.1 => (0x00007fff631fff00)
libdl.so.2 => /lib64/libdl.so.2 (0x00007f8afbe83000)
libm.so.6 => /lib64/libm.so.6 (0x00007f8afbbff000)
libpthread.so.0 => /lib64/libpthread.so.0 (0x00007f8afb9e1000)
libnsl.so.1 => /lib64/libnsl.so.1 (0x00007f8afb7c8000)
libclntsh.so.11.1 =>
/usr/lib/oracle/11.2/client64/lib/libclntsh.so.11.1 (0x00007f8af8e59000)
libodbcinst.so.1 => not found
libc.so.6 => /lib64/libc.so.6 (0x00007f8af8ac5000)
/lib64/ld-linux-x86-64.so.2 (0x0000003bdb000000)
libnnz11.so => /usr/lib/oracle/11.2/client64/lib/libnnz11.so
(0x00007f8af86f8000)
libaio.so.1 => /lib64/libaio.so.1 (0x00007f8af84f6000)
```

**i** If the command returns `libodbcinst.so.1 => not found`, create a symbolic link from `/usr/lib64/libodbcinst.so.1` to `/usr/lib64/libodbcinst.so.2`. This is a known Red Hat issue. See [Red Hat Bugzilla](#) for more information.

```
[root]# locate libodbcinst
/usr/local/lib/libodbcinst.so.2

[root]# cd /usr/lib64
[root]# ln -s libodbcinst.so.2 libodbcinst.so.1
```

Rerun `ldd`. It should load `libsqora.so.11.1` without error, as shown in the `ldd` example above.

**i** If the `ldd` command returns a warning like this: "ldd: warning: you do not have execution permission for `/usr/lib/oracle/11.2/client64/lib/libsqora.so.11.1`", run the following command:

```
[root]# chmod 755 /usr/lib/oracle/11.2/client64/lib/lib*
```

Rerun `ldd`. It should load `libsqora.so.11.1` without error, as shown in the `ldd` example above.

5. Configure Moab to use the Oracle ODBC driver. This example assumes that a Moab user exists and has been granted read and write privileges to the MOAB database instance referred to on the [Installing the Oracle Instant Client](#) on page 806 page.

```
[root]# vim $MOABHOMEDIR/dsninfo.dsn
```

Add the following lines the file, but change `ServerName`, `UserName`, and `Password` to suit your own system. `ServerName` is the name of the Oracle database instance. `Username` and `Password` are the credentials used to connect to that instance.

```
[ODBC]
Application Attributes = T
Attributes = W
BatchAutocommitMode = IfAllSuccessful
BindAsFLOAT = F
CloseCursor = F
DisableDPM = F
DisableMTS = T
Driver = Oracle 11g ODBC driver
DSN = ODBC
EXECSchemaOpt =
EXECSyntax = T
Failover = T
FailoverDelay = 10
FailoverRetryCount = 10
FetchBufferSize = 64000
ForceWCHAR = F
Lobs = T
Longs = T
MaxLargeData = 0
MetadataIdDefault = F
QueryTimeout = T
ResultSets = T
ServerName = MOAB
SQLGetData extensions = F
Translation DLL =
Translation Option = 0
DisableRULEHint = T
UserID = moab
Password = moab
StatementCache=F
CacheBufferSize=20
UseOCIDescribeAny=F
MaxTokenSize=8192
```

6. Add the contents of the `dsninfo.dsn` file to `/etc/odbc.ini`. Because the contents of `dsninfo.dsn` are required in both files, use the following command to concatenate the contents of `dsninfo.dsn` to `/etc/odbc.ini`. If the `odbc.ini` file already has content, verify that there are no conflicts.

```
[root]# cat $MOABHOMDIR/dsninfo.dsn >> /etc/odbc.ini
```

7. Create a directory to store the `tnsnames.ora` file you will create in the next step.

```
[root]# mkdir /etc/oracle
```

8. Create the `tnsnames.ora` file. The `ServerName` in `$MOABHOMEDIR/dsninfo.dsn` tells the Oracle ODBC driver what `tnsnames.ora` entry to use (`MOAB`). The `MOAB` `tnsnames` entry tells the Oracle ODBC driver to connect to server `adaptive-oracle` on the local domain (`ac`) on port 1561 using TCP and to connect to the Oracle instance named `MOAB` (The `SID` is the unique name of the instance).

```
[root]# cat >/etc/oracle/tnsnames.ora <<EOL
MOAB =
  (DESCRIPTION =
    (ADDRESS_LIST =
      (ADDRESS = (PROTOCOL = TCP) (HOST = adaptive-oracle) (PORT = 1561))
    )
    (CONNECT_DATA =
      (SID = MOAB)
    )
  )
EOL
```

9. Create a profile script (`oracle-instant-client.sh`) to be invoked by the operating system at startup. This script will set the `ORACLE_HOME`, `TWO_TASK`, and `TNS_ADMIN` environment variables required by Oracle and will amend the `LD_LIBRARY_PATH` to include required Oracle client libraries in the library search path.

```
[root]# cat >/etc/profile.d/oracle-instant-client.sh <<EOL
# Set ORACLE_HOME to the directory where the bin and lib directories are located
for the oracle client
export ORACLE_HOME=/usr/lib/oracle/11.2/client64

# No need to add ORACLE_HOME to the linker search path. oracle-instant-client.conf
in
# /etc/ld.so.conf.d should already contain /usr/lib/oracle/11.2/client64.
# Alternately, you can set it here by uncommenting the following line:
# export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$ORACLE_HOME/lib

# Define the default location where Oracle should look for the server
export TWO_TASK=//adaptive-oracle:1561/listener

# Define where to find the tnsnames.ora file
export TNS_ADMIN=/etc/oracle
EOL
```

10. Source the `oracle-instant-client.sh` script and verify that each environment variable is set correctly.

```
[root]# source /etc/profile.d/oracle-instant-client.sh
[root]# echo $ORACLE_HOME
[root]# echo $LD_LIBRARY_PATH
[root]# echo $TWO_TASK
[root]# echo $TNS_ADMIN
```

11. Modify either the Moab startup script (`/etc/init.d/moab`) – recommended – or the `moabd` script (`/opt/moab/sbin/moabd`) to source `oracle-instant-client.sh`.

- Moab startup script (recommended): the following example suggests a location to source the `oracle-instant-client.sh` script within the Moab startup script.

```
...
# Export all environment variables required by the Oracle Instant Client
. /etc/profile.d/oracle-instant-client.sh

export MOABHOMEDIR=/opt/moab
...
```

- **moabd shell script:** the following example will resemble the moabd script in /opt/moab/sbin. Note that the moabd script is not invoked by the Moab startup script; The Moab startup script invokes the Moab binary (/opt/moab/sbin/moab) by default.

```
#!/bin/sh
#
# Copyright (C) 2012 by Adaptive Computing Enterprises, Inc. All Rights
Reserved.
#
# Export all environment variables required by the Oracle Instant Client
. /etc/profile.d/oracle-instant-client.sh
MOABHOMEDIR="/opt/moab" LD_LIBRARY_PATH="/opt/moab/lib:$LD_LIBRARY_PATH" moab
"$@"
```

## 12. Verify the Oracle ODBC driver is working.

```
isql -v ODBC
+-----+
| Connected!
|
| sql-statement
| help [tablename]
| quit
|
+-----+
```

If you encounter any errors using the `isql` command, there was a problem setting up the ODBC to Oracle connection. Try the following debugging steps to resolve the issue:

- The `odbcinst.ini` and `odbc.ini` files are usually assumed to be located in `/etc`, but that is not always true. Use the `odbcinst -j` command to determine the assumed location of the files in your configuration.

```
[root#] odbcinst -j
unixODBC 2.2.12
DRIVERS.....: /etc/unixODBC/odbcinst.ini
SYSTEM DATA SOURCES: /etc/unixODBC/odbc.ini
USER DATA SOURCES..: /home/adaptive/.odbc.ini
```

- Because `odbcinst.ini` and `odbc.ini` are expected in `/etc/unixODBC`, not `/etc`, move them from `/etc` to `/etc/unixODBC`.
- Use the `strace` command to determine where `isql` expects the `odbc.ini` and `odbcinst.ini` files. Note the location in which `isql` expects these files.

```
$ strace isql -v ODBC
```

- If you have not already done so, create the database tables in Oracle using the `moab-db-oracle-create.sql` script located in the `contrib/sql` directory in the root of the binaries. This example assumes that you are logged into the MOAB database instance (referred to on the [Installing the Oracle Instant Client on page 806](#) page) as Moab user with read and write privileges.

```
SQL> @./contrib/sql/moab-db-oracle-create.sql
```

- Verify that the database schema installed correctly by listing the tables. Your results should look like this:

```
SQL> select table_name from all_tables where owner = 'MOAB';
+-----+
| TABLE_NAME |
+-----+
| TRIGGERS     |
| MOAB        |
| OBJECTTYPE  |
| VCS         |
| EVENTTYPE   |
| JOBHISTORY  |
| MCHECKPOINT |
| NODES       |
| EVENTS      |
| NODESTATSGENERICRESOURCES |
| JOBS        |
| RESERVATIONS |
| GENERICMETRICS |
| REQUESTS    |
| GENERALSTATS |
| NODESTATS   |
+-----+
SQLRowCount returns -1
16 rows fetched
```

#### 15. Restart Moab.

```
[root]# mschedctl -R
```

#### 16. Verify Moab is correctly configured to write to the Oracle database by doing each of the following steps:

##### a. Tail the moab.log file for ODBC errors.

```
# Check the $MOABHOMEDIR/log/moab.log file for ODBC errors. You should see a few hits even if there are no errors.
[root]# tail -f $MOABHOMEDIR/log/moab.log | grep -i odbc
```

##### b. Log in to the Moab Oracle database.

In the first example below, `isql` will search `/etc/odbc.ini` for "[ODBC]". `unixODBC` will then use the Oracle 11g ODBC driver defined in `/etc/odbcinst.ini` to establish a connection. The `ServerName` in `/etc/odbc.ini` tells the Oracle driver to reference the `MOAB` `tnsnames` entry in `/etc/oracle/tnsnames.ora` for connection parameters.

The second example uses `sqlplus` and a connect string to connect.

Try both connection methods.

```
# Log in to Oracle. Try both isql and sqlplus64 clients.
[root]# isql -v ODBC
```

```
[root]# sqlplus64 moab/moab@adaptive-oracle:1561/MOAB
```

##### c. Select some data from one or more of the tables (Nodes, Events, and the like) to verify that data is being stored in the Moab Oracle instance.

```

# sqlplus64 moab/moab@adaptive-oracle:1561/MOAB

## Related topics

- [Installing the Oracle Instant Client on page 806](#)
- [Connecting to a MySQL Database with an ODBC Driver on page 794](#)
- [Connecting to a PostgreSQL Database with an ODBC Driver on page 797](#)
- [Database Configuration on page 793](#)

## Installing the Oracle Instant Client

### Context

The following procedure demonstrates how to install the correct ODBC drivers for your Oracle database. This guide is a prerequisite for the [Connecting to an Oracle Database with an ODBC Driver on page 799](#) task. Each step must be performed as root.

### To install the Oracle Instant Client

1. Go to the "[Install Client Downloads](#)" page on the Oracle website. Choose the link that matches your system type (for instance, Instant Client for Linux x86-64). Choose **Accept License Agreement** at the top of the page and download the following RPM or zip files for your target version (such as 11.2):

 The process of connecting Oracle to Moab Workload Manager has been tested on Oracle Instant Client version 11.2. The process may work with other versions, but they are not supported.

- Basic (oracle-instantclient11.2-basic-11.2.0.4.0-1.x86\_64.rpm)
- SQL Plus (oracle-instantclient11.2-sqlplus-11.2.0.4.0-1.x86\_64.rpm)
- ODBC (oracle-instantclient11.2-odbc-11.2.0.4.0-1.x86\_64.rpm)

2. Install the packages. This example installs the RPMs.

```
[root]# rpm -i ./oracle-instantclient11.2-basic-11.2.0.4.0-1.x86_64.rpm
[root]# rpm -i ./oracle-instantclient11.2-sqlplus-11.2.0.4.0-1.x86_64.rpm
[root]# rpm -i ./oracle-instantclient11.2-odbc-11.2.0.4.0-1.x86_64.rpm
```

3. Create a configuration file in /etc/ld.so.conf.d to add the Oracle client libraries to the LD\_LIBRARY\_PATH.

To confirm where the RPMs installed the libraries, run `rpm -qlp <rpmFileName>`.

```
[root]# cat >/etc/ld.so.conf.d/oracle-instant-client.conf <<EOL
/usr/lib/oracle/11.2/client64/lib
EOL
```

**i** If you installed Oracle Instant Client from a repository, run `repoquery -ql <rpmName>` instead.

Rebuild the LD\_LIBRARY\_PATH.

```
[root]# ldconfig
```

4. Connect to the database using `sqlplus`. If you used RPMs to install the client, the 32-bit and 64-bit clients are already in your PATH.

```
[root]# sqlplus64 moab/moab@adaptive-oracle:1561/MOAB
SQL*Plus: Release 11.2.0.4.0 Production on Mon Sep 30 14:35:10 2013
Copyright (c) 1982, 2013, Oracle. All rights reserved.
Connected to:
Oracle Database 11g Release 11.2.0.1.0 - 64bit Production
```

*The 64-bit sqlplus client was used to connect to a 64-bit 11g instance called MOAB, which is hosted on adaptive-oracle.ac*

5. Verify that you are logged in to the correct database.

```
SQL> select name from v$database
2 ;
NAME
-----
MOAB
```

6. Create the database in Oracle using the `moab-db-oracle-create.sh` script located in the `contrib/sql` directory in the root of the binaries.

**i** Useful comments are at the top of the script. Read the comments before running the script.

```
[root]# ./moab-db-oracle-create.sh
```

### 7. Display all of user MOAB's tables.

```
SQL> select table_name from all_tables where owner = 'MOAB';

TABLE_NAME
-----
TRIGGERS
MOAB
OBJECTTYPE
VCS
EVENTTYPE
JOBHISTORY
MCHECKPOINT
NODES
EVENTS
NODESTATSGENERICRESOURCES
JOBS
RESERVATIONS
GENERICMETRICS
REQUESTS
GENERALSTATS
NODESTATS

16 rows selected.
SQL>
```

### 8. Generate a script to describe all of user MOAB's tables. Cut and paste the following into a terminal that is *not* logged in to SQLPlus.

```
[root]# cat > /tmp/generateDescribe.sql <<EOL
SET HEADING OFF
SET FEEDBACK OFF
SET ECHO OFF
SET PAGESIZE 0
SPOOL /tmp/describeAllUserTables.sql
select 'desc '||owner||'.'||table_name||';' from all_tables where owner = 'MOAB';
SPOOL OFF
EOL
```

### 9. Run describeAllUserTables.sql.

```
[root]# SQL> start /tmp/describeAllUserTables.sql
```

## Migrating Your Database to Newer Versions of Moab

Sometimes when upgrading from an older version of Moab to a newer version, you must update your database schema. If the schema Moab expects to operate against is different from the actual schema of the database Moab is connected to, Moab might not be able to use the database properly and data might be lost.

When upgrading the Moab database schema from an old version, you must perform each version upgrade in order. You cannot skip versions. For example, to migrate from version 6.1 to version 7.5, you must follow the steps in [Migrating from Moab 6.1 to Moab 7.0 on page 810](#), [Migrating from Moab 7.0 to](#)

[Moab 7.1 on page 810](#), [Migrating from Moab 7.1 to Moab 7.2 on page 810](#), [Migrating from Moab 7.2 to Moab 7.2.6 on page 809](#), then [Migrating from Moab 7.2.6 to Moab 7.5 on page 809](#), and so on.

**i** If you are upgrading your database to the 7.5 schema from 7.2.x where "x" is 5 or lower, you must complete the instructions for the following two sections in order:

- [Migrating from Moab 7.2 to Moab 7.2.6 on page 809](#)
- [Migrating from Moab 7.2.6 to Moab 7.5 on page 809](#).

## Migrating from Moab 7.5 to Moab 8.0

In Moab Workload Manager 8.0, column names that have become reserved words in newer versions of MySQL, PostgreSQL, and Oracle were renamed to eliminate the need to quote column names in SQL statements. Also, a few additional columns were added to existing tables to support Moab's Green feature. To upgrade your database with these changes, use the `moab-db-<database>-upgrade8_0.sql` file located in the `contrib/sql` directory in the root of the binaries. For example, to migrate your MySQL database from the 7.5 (or later) schema, run the following:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade8_0.sql
```

*The database name is usually "Moab".*

Similar migration scripts exist for Oracle and PostgreSQL.

## Migrating from Moab 7.2.6 to Moab 7.5

In Moab Workload Manager 7.5, column names that are reserved words in databases supported by Adaptive Computing were renamed to eliminate the need to quote column names in SQL statements. To upgrade your database with these changes, use the `moab-db-<database>-upgrade7_5.sql` file located in the `contrib/sql` directory in the root of the binaries. For example, to migrate your MySQL database from the 7.2.6 (or later) schema, run the following:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade7_5.sql
```

*The database name is usually "Moab".*

Similar migration scripts exist for Oracle and PostgreSQL.

## Migrating from Moab 7.2 to Moab 7.2.6

In Moab Workload Manager 7.2.6, several columns were extended and the primary key on the Triggers table changed. To upgrade your database with these changes, use the `moab-db-<database>-upgrade7_2_6.sql` file located in the `contrib/sql` directory in the root of the binaries. For example, to migrate your MySQL database from the 7.2.x (pre-7.2.6) schema to the 7.2.6 schema, run the following:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade7_2_6.sql
```

*The database name is usually "Moab".*

Similar migration scripts exist for Oracle and PostgreSQL.

**i** The 7.2.6 database upgrade is compatible with all earlier versions of 7.2.

## Migrating from Moab 7.1 to Moab 7.2

In Moab 7.2, several events in the event table related to the Accounting Manager were renamed. To upgrade your database with these changes, use the `moab-db-<database>-upgrade7_2.sql` file located in the `contrib/sql` directory in the root of the binaries. For example, to migrate your MySQL database from the 7.1 schema to the 7.2 schema, run the following:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade7_2.sql
```

*The database name is usually "Moab".*

Similar migration scripts exist for Oracle and PostgreSQL.

## Migrating from Moab 7.0 to Moab 7.1

In Moab 7.1, Offset was renamed TriggerOffset in the Triggers table. To upgrade your database with these changes, use the `moab-db-<database>-upgrade7_1.sql` file located in the root of the binaries. For example, to migrate your MySQL database from the 7.0 schema to the 7.1 schema, run the following:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade7_1.sql
```

*The database name is usually "Moab".*

Similar migration scripts exist for Oracle and PostgreSQL.

## Migrating from Moab 6.1 to Moab 7.0

In Moab 7.0, the Moab table has been removed from the database, and MoabInfo and JobHistory tables have been added to it. To upgrade your database with these changes, use the `moab-db-mysql-upgrade6_1.sql` file located in the `contrib/sql` directory in the root of the binaries. This is done by running the following command:

```
[root@]# mysql -u root -D <database name> -p < moab-db-mysql-upgrade6_1.sql
```

*The database name is usually "Moab".*

Your MySQL database is updated for Moab 7.0.

## Migrating from Moab 6.0 to Moab 6.1

An Events table has been added to the database in Moab 6.1. Update the `contrib/sql/moab-db.sql` file with the following table:

```
CREATE TABLE Events (
  ID INTEGER,
  ObjectType INTEGER,
  EventType INTEGER,
  EventTime INTEGER UNSIGNED,
  ObjectName VARCHAR(64),
  Name VARCHAR(64),
  Description TEXT,
  PRIMARY KEY (ID)
);
```

Use the `mdiag -e --xml` command in the following format to query the events table.

```
mdiag -e [-w <starttime>|<endtime>|<eventtypes>|<oidlist>|<eidlist>|<objectlist>] --xml
```

The table is then displayed with all specified events configured with the [RECORDEVENTLIST](#) parameter.

**i** If the command could return a large of data, redirect the output. `mdiag -e --xml > outputfile`

## Migrating from Moab 5.4 to Moab 6.0

The ODBC database schema has been updated for Moab 6.0. When updating Moab to version 6.0, the changes below must be applied to the database for database functionality to work. Below are the SQL statements required to update the schema for Moab 6.0.

**i** These changes are only necessary for an ODBC database. An SQLite database does not require an update.

```
ALTER TABLE Events ADD COLUMN Name VARCHAR(64);
ALTER TABLE Events MODIFY Description TEXT;
```

```
CREATE TABLE Nodes (
  ID VARCHAR(64),
  State VARCHAR(64),
  OperatingSystem VARCHAR(64),
  ConfiguredProcessors INTEGER UNSIGNED,
  AvailableProcessors INTEGER UNSIGNED,
  ConfiguredMemory INTEGER UNSIGNED,
  AvailableMemory INTEGER UNSIGNED,
  Architecture VARCHAR(64),
  AvailGres VARCHAR(64),
  ConfigGres VARCHAR(64),
  AvailClasses VARCHAR(64),
  ConfigClasses VARCHAR(64),
  ChargeRate DOUBLE,
  DynamicPriority DOUBLE,
  EnableProfiling INTEGER UNSIGNED,
  Features VARCHAR(64),
  GMetric VARCHAR(64),
  HopCount INTEGER UNSIGNED,
  HypervisorType VARCHAR(64),
  IsDeleted INTEGER UNSIGNED,
  IsDynamic INTEGER UNSIGNED,
  JobList VARCHAR(64),
  LastUpdateTime INTEGER UNSIGNED,
  LoadAvg DOUBLE,
  MaxLoad DOUBLE,
  MaxJob INTEGER UNSIGNED,
  MaxJobPerUser INTEGER UNSIGNED,
  MaxProc INTEGER UNSIGNED,
  MaxProcPerUser INTEGER UNSIGNED,
  OldMessages VARCHAR(64),
  NetworkAddress VARCHAR(64),
  NodeSubstate VARCHAR(64),
  Operations VARCHAR(64),
  OSList VARCHAR(64),
  Owner VARCHAR(64),
  ResOvercommitFactor VARCHAR(64),
  Partition VARCHAR(64),
  PowerIsEnabled INTEGER UNSIGNED,
  PowerPolicy VARCHAR(64),
  PowerSelectState VARCHAR(64),
  PowerState VARCHAR(64),
  Priority INTEGER UNSIGNED,
  PriorityFunction VARCHAR(64),
  ProcessorSpeed INTEGER UNSIGNED,
  ProvisioningData VARCHAR(64),
  AvailableDisk INTEGER UNSIGNED,
  AvailableSwap INTEGER UNSIGNED,
  ConfiguredDisk INTEGER UNSIGNED,

## Importing Statistics from stats/DAY.\* to the Moab Database

The contrib/stat\_converter folder contains the files to build mstat\_converter, an executable that reads file-based statistics in a Moab stats directory and dumps them into a database. It also reads the Moab checkpoint file (.moab.ck) and dumps that to the database as well. It uses the \$MOABHOMEDIR/moab.cfg file to connect to the appropriate database and reads the statistics files from \$MOABHOMEDIR/stats.

To run, execute the program mstat\_converter with no arguments.

The statistics converter program does not clear the database before converting. However, if there are statistics in the database and the statistics files from the same period, the converter overwrites the database information with the information from the statistics files.

## Accelerators

Moab can integrate with the TORQUE resource manager to discover, report, schedule, and submit workload to various accelerator architectures (such as NVIDIA GPUs or Intel® Xeon Phi™ co-processor architecture) for parallel processing. See the topics below for specific information.

- [Scheduling GPUs](#)
  - [Using GPUs with NUMA](#)
  - [NVIDIA GPUs](#)

- [GPU Metrics](#)
- [Configuring Intel® Xeon Phi™ Co-processor Architecture](#)
  - [Intel® Xeon Phi™ Co-processor Metrics](#)

## Scheduling GPUs

In TORQUE 2.5.4 and later, users can request GPUs on a node at job submission by specifying a nodes resource request, using the `qsub -l` option. The number of GPUs a node has must be specified in the nodes file. The GPU is then reported in the output of `pbsnodes`:

```
napali
state = free
np = 2
ntype = cluster
status = rectime=1288888871,varattr=,jobs=,state=free,netload=1606207294,gres=tom:!/home/dbeer/dev/scripts/dynamic_
resc.sh,loadave=0.10,ncpus=2,physmem=3091140kb,availmem=32788032348kb,
totmem=34653576492kb,idletime=4983,nusers=3,nsessions=14,sessions=3136 1805 2380 2428
1161 3174 3184
3191 3209 3228 3272 3333 20560 32371,uname=Linux napali 2.6.32-25-generic #45-Ubuntu
SMP Sat Oct 16 19:52:42
UTC 2010 x86_64,opsys=linux
mom_service_port = 15002
mom_manager_port = 15003
gpus = 1
```

The `$PBS_GPUFILE` has been created to include GPU awareness. The GPU appears as a separate line in `$PBS_GPUFILE` and follows this syntax:

```
<hostname>-gpu<index>
```

If a job were submitted to run on a server called "napali" (the submit command would look something like: `qsub test.sh -l nodes=1:ppn=2:gpus=1`), the `$PBS_GPUFILE` would contain:

```
napali-gpu0
```

It is left up to the job's owner to make sure that the job executes properly on the GPU. By default, TORQUE treats GPUs exactly the same as `ppn` (which corresponds to CPUs).

## Using GPUs with NUMA

The `pbs_server` requires awareness of how the MOM is reporting nodes since there is only one MOM daemon and multiple MOM nodes. Configure the `server_priv/nodes` file with the `num_node_boards` and `numa_gpu_node_str` attributes. The attribute `num_node_boards` tells `pbs_server` how many NUMA nodes are reported by the MOM. If each NUMA node has the same number of GPUs, add the total

number of GPUs to the nodes file. Following is an example of how to configure the nodes file with `num_node_boards`:

```
numahost gpus=12 num_node_boards=6
```

This line in the nodes file tells `pbs_server` there is a host named `numahost` and that it has 12 GPUs and 6 nodes. The `pbs_server` divides the value of GPUs (12) by the value for `num_node_boards` (6) and determines there are 2 GPUs per NUMA node.

In this example, the NUMA system is uniform in its configuration of GPUs per node board, but a system does not have to be configured with the same number of GPUs per node board. For systems with non-uniform GPU distributions, use the attribute `numa_gpu_node_str` to let `pbs_server` know where GPUs are located in the cluster.

If there are equal numbers of GPUs on each NUMA node, you can specify them with a string. For example, if there are 3 NUMA nodes and the first has 0 GPUs, the second has 3, and the third has 5, you would add this to the nodes file entry:

```
numa_gpu_node_str=0,3,5
```

In this configuration, `pbs_server` knows it has three MOM nodes and the nodes have 0, 3s, and 5 GPUs respectively. Note that the attribute `gpus` is not used. The `gpus` attribute is ignored because the number of GPUs per node is specifically given.

In TORQUE 3.0.2 or later, `qsub` supports the mapping of `-l gpus=X` to `-l gres=gpus:X`. This allows users who are using NUMA systems to make requests such as `-l ncpus=20,gpus=5` ( or `-l ncpus=20:gpus=5`) indicating they are not concerned with the GPUs in relation to the NUMA nodes they request; they only want a total of 20 cores and 5 GPUs.

## NVIDIA GPUs

The `pbs_mom` file can now query for GPU hardware information and report status to the `pbs_server`. `gpustatus` will appear in `pbsnodes` output. New commands allow for setting GPU modes and for resetting GPU ECC error counts.

 This feature is only available in TORQUE 2.5.6, 3.0.2, and later.

 This document assumes that you have installed the NVIDIA CUDA ToolKit and the NVIDIA development drivers on a compute node with an NVIDIA GPU. (Both can be downloaded from <http://developer.nvidia.com/category/zone/cuda-zone>).

You will want to download the latest version if you run into problems compiling.

If the `pbs_server` does not have GPUs, it only needs to be configured with `--enable-nvidia-gpus`. All other systems that have NVIDIA GPUs will need:

- `--enable-nvidia-gpus`
- `--with-nvml-include=DIR` (include path for `nvml.h`)

 `nvml.h` is only found in the NVIDIA CUDA ToolKit.

- `--with-nvml-lib=DIR` (\*lib path for `libnvidia-ml`)

Systems that have NVIDIA GPUs require the following:

Server

```
./configure --with-debug --enable-nvidia-gpus
```

Compute nodes (with NVIDIA GPUs)

```
./configure --with-debug --enable-nvidia-gpus --with-nvml-lib=/usr/lib64 --with-nvml-include=/cuda/NVML
```

If all of the compute nodes have the same hardware and software configuration, you can choose to compile on one compute node and then run `make packages`.

```
> make packages
Building ./torque-package-clients-linux-x86_64.sh ...
Building ./torque-package-mom-linux-x86_64.sh ...
Building ./torque-package-server-linux-x86_64.sh ...
Building ./torque-package-gui-linux-x86_64.sh ...
Building ./torque-package-devel-linux-x86_64.sh ...
Done.
```

The package files are self-extracting packages that can be copied and executed on your production machines. (Use `--help` for options.)

 When updating, it is good practice to stop the `pbs_server` and make a backup of the TORQUE home directory. You will also want to backup the output of `qmgr -c 'p s'`. The update will only overwrite the binaries.

 If you move GPU cards to different slots, you must restart `pbs_server` in order for TORQUE to recognize the drivers as the same ones in different locations rather than 2 new, additional drivers.

For further details, see these topics:

- [TORQUE configuration on page 818](#)
- [GPU modes for NVIDIA 260.x driver on page 819](#)
- [GPU Modes for NVIDIA 270.x driver on page 819](#)
- [gpu\\_status on page 820](#)
- [New NVIDIA GPU support on page 820](#)

## TORQUE configuration

There are three configuration (`./configure`) options available for use with Nvidia GPGPUs:

- `--enable-nvidia-gpus`
- `--with-nvml-lib=DIR`
- `--with-nvml-include=DIR`

`--enable-nvidia-gpus` is used to enable the new features for the Nvidia GPGPUs. By default, the `pbs_moms` use the `nvidia_smi` command to interface with the Nvidia GPUs.

```
./configure --enable-nvidia-gpus
```

To use the NVML (NVIDIA Management Library) API instead of `nvidia-smi`, configure TORQUE using `--with-nvml-lib=DIR` and `--with-nvml-include=DIR`. These commands specify the location of the `libnvidia-ml` library and the location of the `nvml.h` include file.

```
./configure --with-nvml-lib=/usr/lib
--with-nvml-include=/usr/local/cuda/Tools/NVML
server_priv/nodes:
node001 gpus=1
node002 gpus=4
...
pbsnodes -a
node001
...
    gpus = 1
...
```

By default, when TORQUE is configured with `--enable-nvidia-gpus` the `$TORQUE_HOME/nodes` file is automatically updated with the correct GPU count for each MOM node. See the TORQUE documentation on [ggpumode](#) for additional information.

## GPU modes for NVIDIA 260.x driver

- 0 – Default - Shared mode available for multiple processes
- 1 – Exclusive - Only one COMPUTE thread is allowed to run on the GPU
- 2 – Prohibited - No COMPUTE contexts are allowed to run on the GPU

## GPU Modes for NVIDIA 270.x driver

- 0 – Default - Shared mode available for multiple processes
- 1 – Exclusive Thread - Only one COMPUTE thread is allowed to run on the GPU (v260 exclusive)
- 2 – Prohibited - No COMPUTE contexts are allowed to run on the GPU
- 3 – Exclusive Process - Only one COMPUTE process is allowed to run on the GPU

## gpu\_status

```

root@gpu:~# pbsnodes gpu
gpu
...
  gpus = 2
  gpu status = gpu[1]=gpu_id=0:6:0;gpu_product_name=Tesla
  C2050;gpu_display=Disabled;gpu_pci_device_id=6D110DE;gpu_pci_location_id=0:6:0;
  gpu_fan_speed=54 %;gpu_memory_total=2687 Mb;gpu_memory_used=74

```

## New NVIDIA GPU support

qsub allows specifying required compute mode when requesting GPUs. If no GPU mode is requested, it will default to "exclusive" for Nvidia driver version 260 or "exclusive\_thread" for NVIDIA driver version 270 and above.

- qsub -l nodes=1:ppn=1:gpus=1
- qsub -l nodes=1:gpus=1
- qsub -l nodes=1:gpus=1:exclusive\_thread
- qsub -l nodes=1:gpus=1:exclusive\_process
- qsub -l nodes=1:gpus=1:reseterr
- qsub -l nodes=1:gpus=1:reseterr:exclusive\_thread (exclusive\_thread:reseterr)
- qsub -l nodes=1:gpus=1:reseterr:exclusive\_process

## GPU Metrics

GPU metrics can be collected for nodes that:

- Have one or more GPUs.
- Run TORQUE 2.5.x or later.
- Use NVIDIA drivers v260.x or v270.x.

GPU metric tracking must be enabled in `moab.cfg`:

```
RMCFG[torque] flags=RECORDGPUMETRICS
```

**i** There is one GPU metric for all GPU devices within a node (`gpu_timestamp`) and nine GPU metrics for each GPU device within a node. If the maximum GPU devices within a node is 4, you must increase the `MAXGMETRIC` value in `moab.cfg` by  $(\text{maxgpudevices} \times \text{gpumetrics}) + 1$ . In this case, the formula is  $(4 \times 9) + 1 = 37$ , so whatever the `MAXGMETRIC` value is, it must be increased by 37. This way, when enabling GPU metrics recording, Moab has enough GMETRIC types to accommodate the GPU metrics.

## GPU Metrics Map

The GPU metric names map is as follows (where *X* is the GPU number):

Metric name as returned by pbsnodes	GMETRIC name as stored in Moab	Metric output
<b>timestamp</b>	gpu_timestamp <div style="border: 1px solid black; padding: 5px; margin-top: 5px;"> <b>i</b> The <code>gpu_timestamp</code> metric is global to all GPUs on the node and indicates the last time the driver collected information on the GPUs.           </div>	The time data was collected in epoch time
<b>gpu_fan_speed</b>	gpuX_fan	The current fan speed as a percentage
<b>gpu_memory_total</b>	gpuX_mem	The total GPU memory in megabytes
<b>gpu_memory_used</b>	gpuX_usedmem	The total used GPU memory in megabytes
<b>gpu_utilization</b>	gpuX_util	The GPU capability currently in use as a percentage
<b>gpu_memory_utilization</b>	gpuX_memutil	The GPU memory currently in use as a percentage
<b>gpu_ecc_mode</b>	gpuX_ecc	Whether ECC is enabled or disabled
<b>gpu_single_bit_ecc_errors</b>	gpuX_ecc1err	The total number of EEC single-bit errors since the last counter reset

Metric name as returned by pbsnodes	GMETRIC name as stored in Moab	Metric output
<b>gpu_double_bit_ecc_errors</b>	gpuX_ecc2err	The total number of EEC double-bit errors since the last counter reset
<b>gpu_temperature</b>	gpuX_temp	The GPU current temperature in Celsius

Example 3-157: GPU example

## Intel® Xeon Phi™ Coprocessor Configuration

### Intel Many-Integrated Cores (MIC) architecture configuration

If you use an Intel Many-Integrated Cores (MIC) architecture-based product (e.g., Intel Xeon Phi™) in your cluster for parallel processing, you must configure TORQUE to detect them.

#### Prerequisites

- TORQUE 4.2 or later
- If you set up TORQUE using auto-detection and intend to get the MIC-based device status report, you must build pbs\_mom on a system that has the lower-level API libraries for the MIC-based device(s) installed. Additionally, every MOM built with `--enable-mics` and running on a compute node must already have the lower-level API libraries installed on the node. Note that the library is called `coi_host`. You must obtain the API libraries from [Intel](#).

## Setup Options

There are two ways to configure MIC-based devices with TORQUE: (1) manually and (2) by auto-detection.

### Manual configuration

- Add `mics=X` to the [nodes file](#) for the appropriate nodes.

```
napali np=12 mics=2
```

### Auto-detect

When you use auto-detection, `pbs_mom` discovers the MIC-based devices and reports them to `pbs_server`.

- At build time, add `--enable-mics` to the configure line.

```
./configure --enable-mics <other configure options>
```

## Validating the configuration

### TORQUE

## Job submission

### Syntax

Example 3-161: Request MIC-based device(s) in qsub

```
qsub .... -l nodes=X:mics=Y
```

*Because these resources are delimited with a colon, this command requests a job with X nodes and Y mics per task. If you run the same command and delimit the resources with a comma (qsub .... -l nodes=X,mics=Y), you request a job with X nodes and Y mics per job.*

### qstat -f

Example 3-162: qstat -f output

```
Job Id: 5271.napali
Job_Name = STDIN
Job_Owner = dbeer@napali
job_state = Q
queue = batch
server = napali
Checkpoint = u
ctime = Fri Sep 14 08:56:33 2012
Error_Path = napali:/home/dbeer/dev/private-torque/trunk/STDIN.e5271
Hold_Types = n
Join_Path = oe
Keep_Files = n
Mail_Points = a
mtime = Fri Sep 14 08:56:33 2012
Output_Path = napali:/home/dbeer/dev/private-torque/trunk/STDIN.o5271
Priority = 0
qtime = Fri Sep 14 08:56:33 2012
Rerunable = True
Resource_List.nodect = 1
Resource_List.nodes = 1:mics=1
substate = 10
Variable_List = PBS_O_QUEUE=batch,PBS_O_HOME=/home/dbeer,
                PBS_O_LOGNAME=dbeer,
                PBS_O_PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/b
                in:/usr/games,PBS_O_MAIL=/var/mail/dbeer,PBS_O_SHELL=/bin/bash,
                PBS_O_LANG=en_US.UTF-8,
                PBS_O_SUBMIT_FILTER=/usr/local/sbin/torque_submitfilter,
                PBS_O_WORKDIR=/home/dbeer/dev/private-torque/trunk,PBS_O_HOST=napali,
                PBS_O_SERVER=napali
euser = dbeer
egroup = company
queue_rank = 3
queue_type = E
etime = Fri Sep 14 08:56:33 2012
submit_args = -l nodes=1:mics=1
fault_tolerant = False
job_radix = 0
submit_host = napali
```

## checkjob -v

Example 3-163: checkjob -v output

```

dthompson@mahalo:~/dev/moab-test/trunk$ checkjob -v 2
job 2 (RM job '2.mahalo')

AName: STDIN
State: Idle
Creds: user:dthompson group:dthompson class:batch
WallTime: 00:00:00 of 1:00:00
SubmitTime: Thu Sep 13 17:06:06
(Time Queued Total: 00:00:24 Eligible: 00:00:02)

TemplateSets: DEFAULT
Total Requested Tasks: 1

Req[0] TaskCount: 1 Partition: ALL
Dedicated Resources Per Task: PROCS: 1 MICS: 1

...

```

## Intel® Xeon Phi™ Co-processor Metrics

Intel Many-Integrated Cores (MIC) architecture-based device (e.g., Intel Xeon Phi™) metrics can be collected for nodes that:

- Have one or more MIC-based devices.
- Run TORQUE 4.2.x or later.
- Run Moab 7.2 or later.

MIC-based device metric tracking must be enabled in `moab.cfg`:

```

RMCFG[torque] flags=RECORDMICMETRICS

```

**i** There are 11 metrics for each MIC-based device within a node. If the maximum MIC-based devices within a node is 4, you must increase the `MAXGMETRIC` value in `moab.cfg` by  $(maxmicdevices \times micmetrics)$ . In this case, the formula is  $(4 \times 11) = 44$ , so whatever the `MAXGMETRIC` value is, it must be increased by 44. This way, when enabling MIC-based device metrics recording, Moab has enough GMETRIC types to accommodate the additional metrics.

## MIC-based Metrics Map

The MIC-based metric names map is as follows (where *X* is the MIC-based device number):

Metric name as returned by pbsnodes	GMETRIC name as stored in Moab	Metric output
mic_id	micX_mic_id	The ID of the MIC-based device
num_cores	micX_num_cores	The number of cores in the MIC-based device
num_threads	micX_num_threads	The number of hardware threads on the MIC-based device
physmem	micX_physmem	The total physical memory in the MIC-based device
free_physmem	micX_free_physmem	The available physical memory in the MIC-based device
swap	micX_swap	The total swap space on the MIC-based device
free_swap	micX_free_swap	The unused swap space on the MIC-based device
max_frequency	micX_max_frequency	The maximum frequency speed of any core in the MIC-based device
isa	micX_isa	The hardware interface type of the MIC-based device
load	micX_load	The total current load of the MIC-based device
normalized_load	micX_normalized_load	The normalized load of the MIC-based device (total load divided by number of cores in the MIC-based device)

## Preemption

### About preemption

Sites possess workloads of varying importance, and users may want to run jobs with higher priorities before jobs with lower priorities. This can be done by using preemption. Preemption is simply the process by which a higher-priority job can take the place of a lower-priority job. You can also use preemption for optimistic scheduling and development job support.

This section explains how to configure and use preemption. [Simple example of preemption on page 848](#) offers a basic introduction and contains examples to help you get started using preemption. The other sections offer more explanation and information about what you can do with preemption and contain some best practices that will help you avoid the need for troubleshooting in the future.

While this section does not explain every possible preemption configuration, it does prescribe the best practices for setting up and using preemption with your system. It is recommended that you follow the established instructions contained in this section.

 Preemption does not work with dynamic provisioning.

 Neither *SPANEVENLY* nor *DELAY* values of the `NODESETPLUS` parameter will work with multi-req jobs or preemption.

 Do not allow preemption with interactive jobs unless `PREEMTPOLICY` is set to *CANCEL*. (For more information, see [Canceling jobs with preemption on page 830](#).)

Tasks associated with preemption:

The following sections include information about each type of preemption, their different usage benefits, and any configurations and settings needed to use them.

- [Canceling jobs with preemption on page 830](#)
- [Checkpointing jobs with preemption on page 833](#)
- [Requeueing jobs with preemption on page 834](#)
- [Suspending jobs with preemption on page 837](#)
- [Using owner preemption on page 840](#)
- [Using QoS preemption on page 844](#)

Preemption references:

These sections contain information that you can use as references for the preemption tasks.

- [Manual preemption commands on page 845](#)
- [Preemption flags on page 846](#)
- [PREEMTPOLICY types on page 848](#)
- [Simple example of preemption on page 848](#)
- [Testing and troubleshooting preemption on page 852](#)

## How-to's

### Canceling jobs with preemption

#### Context

**CANCEL** is one of the [PREEMTPOLICY](#) types (for more information, see [PREEMTPOLICY types on page 848](#)). The **CANCEL** attribute cancels active jobs, regardless of any **JOBFLAGS** (such as **REQUEUEABLE** or **SUSPENDABLE**). (For more information, see [Job Flags on page 145](#).)

For information about **PREEMPTEE** and **PREEMPTOR** flags, see [Preemption flags on page 846](#)

**i** You should not allow preemption with interactive jobs unless **PREEMTPOLICY** is set to **CANCEL**.

The following outlines some benefits of using **CANCEL** and also lists some things you should be aware of if you choose to use it.

#### Advantages:

This attribute is the easiest to configure and use.

#### Cautions:

Canceled jobs are not automatically restarted or requeued. Users must resubmit canceled jobs.

### To preempt jobs using CANCEL

1. Make the following configurations to the `moab.cfg` file:
  - a. Set **GUARANTEEDPREEMPTION** to **TRUE**. (This causes Moab to lock **PREEMPTOR** jobs until **JOBRETRYTIME** expires.)
  - b. Make sure that **JOBNODEMATCHPOLICY** is *not* set to **EXACTNODE**, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
  - c. Set **PREEMTPOLICY** to **CANCEL** (for more information, see [PREEMTPOLICY types on page 848](#)).
  - d. Make sure that the **PREEMPTEE** job has a lower priority than the **PREEMPTOR** job (for more information, see [Preemption flags on page 846](#)).

For example:

```
GUARANTEEDPREEMPTION TRUE
PREEMTPOLICY CANCEL

QOSCFG[test1] QFLAGS=PREEMPTEE MEMBERULIST=john PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=10000
```

2. Submit a job to the preemptee QoS (`test1`). For example:

```
[john@g06]# echo sleep 600 | msub -l walltime=600 -l qos=test1 -l procs=128
```

(Optional) Examine the following output for showq:

```
Moab.7
[john@g06]# showq

active jobs-----
JOBID      USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.7     john       Running    128        00:01:59    Thu Nov 10 12:28:44

1 active job      128 of 128 processors in use by local jobs (100.00%)
                    2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 eligible jobs

blocked jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 blocked jobs

Total job: 1
```

3. Now submit a job to the preemptor QoS (test2). For example:

```
[john@g06]$ echo sleep 120 | msub -l procs=128,walltime=120 -l qos=test2
```

(Optional) Examine the following output for showq:

```
Moab.8
[john@g06]# showq

active jobs-----
JOBID      USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.7     john       Canceled  128        00:01:56    Thu Nov 10 12:28:44
Moab.8     john       Running    128        00:02:00    Thu Nov 10 12:28:48

2 active jobs 128 of 128 processors in use by local jobs (100.00%)
                    2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 eligible jobs

blocked jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 blocked jobs

Total jobs: 2
```

*Note that test1 is canceled when test2 is submitted.*

(Optional) Examine the checkjob outputs for these two jobs:

```
[john@g06]$ checkjob Moab.9
job Moab.9

State: Removed
Completion Code: -1 Time: Thu Nov 10 12:28:48
Creds: user:john group:john qos:test1

## Checkpointing jobs with preemption

### Context

*CHECKPOINT* is one of the [PREEMTPOLICY](#) types (for more information, see [PREEMTPOLICY types on page 848](#)). For systems that allow checkpointing, the *CHECKPOINT* attribute allows a job to save its current state and either terminate or continue running. A checkpointed job may restart at any time and resume execution from its most recent checkpoint.

You can tune checkpointing behavior on a per-resource manager-basis by setting the *CHECKPOINTSIG* and *CHECKPOINTTIMEOUT* attributes of the [RMCFG](#) parameter.

For information about *PREEMPTTEE* and *PREEMPTOR* flags, see [Preemption flags on page 846](#)

The following outlines some benefits of using *CHECKPOINT* and also lists some things you should be aware of if you choose to use it.

#### Advantages:

This attribute allows you to restart a job from its last checkpoint.

#### Cautions:

Jobs tend to take longer to complete when you use *CHECKPOINT*.

## To preempt jobs using CHECKPOINT

Make the following configurations to the `moab.cfg` file:

1. Set [GUARANTEEDPREEMPTION](#) to *TRUE*. (This causes Moab to lock *PREEMPTOR* jobs until [JOBRETRYTIME](#) expires.) (This locks the job on a node and keeps trying to preempt.)
2. Make sure that [JOBNODEMATCHPOLICY](#) is *not* set to *EXACTNODE*, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
3. Set [PREEMTPOLICY](#) to *CHECKPOINT* (for more information, see [PREEMTPOLICY types on page 848](#)).
4. Make sure that the *PREEMPTTEE* job has a lower priority than the *PREEMPTOR* job (for more information, see [Preemption flags on page 846](#)).

For example:

```

GUARANTEEDPREEMPTION TRUE
PREEMTPOLICY CHECKPOINT

QOSCFG[test1] QFLAGS=PREEMPTTEE MEMBERULIST=john PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=10000

```

- [About preemption](#) on page 828
- [PREEMTPOLICY types](#) on page 848
- [Testing and troubleshooting preemption](#) on page 852

## Requeueing jobs with preemption

### Context

*REQUEUE* is one of the [PREEMTPOLICY](#) types (for more information, see [PREEMTPOLICY types on page 848](#)). The *REQUEUE* value terminates active jobs and returns them to the job queue in an idle state.

For information about *PREEMPTTEE* and *PREEMPTOR* flags, see [Preemption flags on page 846](#)

The following outlines some benefits of using *REQUEUE* and also lists some things you should be aware of if you choose to use it.

#### Advantages:

- Jobs are automatically resubmitted into the job queue.

#### Cautions:

- A job gets resubmitted in the job queue at the same priority it had when Moab originally started it (i.e., the job does not jump ahead in the queue).
- Jobs start over from the beginning.

You must mark a job as *RESTARTABLE* if you want it to requeue. If you do not, the job will be canceled when it is preempted.

If supported by the resource manager, you can set the *RESTARTABLE* job flag when submitting the job by using the `msub -r` option. Otherwise, use the [JOBFLAGS](#) attribute of the associated class or QoS credential, as in this example:

```
CLASSCFG[low] JOBFLAGS=RESTARTABLE
```

For more information, see [Job Flags on page 145](#).

## To preempt jobs using REQUEUE

1. Make the following configurations to the `moab.cfg` file:
  - a. Set [GUARANTEEDPREEMPTION](#) to *TRUE*. (This causes Moab to lock *PREEMPTOR* jobs until [JOBRETRYTIME](#) expires.)

- b. Make sure that **JOBNODEMATCHPOLICY** is *not* set to **EXACTNODE**, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
- c. Set **PREEMTPOLICY** to **REQUEUE** (for more information, see [PREEMTPOLICY types on page 848](#)).
- d. Make sure that the **PREEMPTEE** job has a lower priority than the **PREEMPTOR** job (for more information, see [Preemption flags on page 846](#)).

For example:

```

GUARANTEEDPREEMPTION TRUE
PREEMTPOLICY REQUEUE

QOSCFG[test1] QFLAGS=PREEMPTEE JOBFLAGS=RESTARTABLE MEMBERULIST=john PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=10000
    
```

2. Submit a job to the preemptee QoS (test1). For example:

```
[john@g06]# echo sleep 600 | msub -l walltime=600 -l qos=test1 -l procs=128
```

(Optional) Examine the following output for showq:

```

Moab.1
[john@g06]# showq

active jobs-----
JOBID      USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.1     john       Running    128        00:09:59   Wed Nov 9 15:56:33

1 active job      128 of 128 processors in use by local jobs (100.00%)
                   2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUETIME

0 eligible jobs

blocked jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUETIME

0 blocked jobs

Total job: 1
    
```

3. Now submit a job to the preemptor QoS (test2). For example:

```
[john@g06]# echo sleep 600 | msub -l walltime=600 -l qos=test2 -l procs=128
```

(Optional) Examine the following output for showq and checkjob:

```

Moab.2
[john@g06]# showq

active jobs-----
JOBID      USERNAME      STATE      PROCS      REMAINING      STARTTIME
Moab.2     john          Running    128        00:09:59       Wed Nov 9 15:56:47

1 active job 128 of 128 processors in use by local jobs (100.00%)
  2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME      STATE      PROCS      WCLIMIT        QUEUE TIME
Moab.1     john          Idle       128        00:10:00       Wed Nov 9 15:56:33

1 eligible job

blocked jobs-----
JOBID      USERNAME      STATE      PROCS      WCLIMIT        QUEUE TIME

0 blocked jobs

Total jobs: 2

```

```

[john@g06]# checkjob Moab.2
job Moab.2

State: Running
Creds: user:john group:john qos:test2
WallTime: 00:02:04 of 00:10:00

- [About preemption on page 828](#)

- [PREEMTPOLICY types on page 848](#)
- [Testing and troubleshooting preemption on page 852](#)

## Suspending jobs with preemption

### Context

**SUSPEND** is one of the **PREEMTPOLICY** types (for more information, see [PREEMTPOLICY types on page 848](#)). The **SUSPEND** attribute causes active jobs to stop executing, but to remain in memory on the allocated compute nodes.

For information about **PREEMPTTEE** and **PREEMPTOR** flags, see [Preemption flags on page 846](#)

The following outlines some benefits of using **SUSPEND** and also lists some things you should be aware of if you choose to use it.

#### Advantages:

- The job remains in memory on the allocated compute nodes.
- Using **SUSPEND** frees up processor resources.
- The job can restart where it left off before it was suspended.

#### Cautions:

- There is a possibility that having multiple suspended jobs on a compute node will crash the swap.
- Moab tracks only *requested* memory of active jobs (not *used* memory). The swap can crash if the job uses a lot of memory and Moab starts other jobs.
- Suspended jobs do not relinquish their licenses.

You must mark a job as **SUSPENDABLE** if you want it to suspend. If you do not, the job will be requeued or canceled when it is preempted.

If supported by the resource manager, you can set the job **SUSPENDABLE** flag when submitting the job by using the `msub -r` option. Otherwise, use the **JOBFLAGS** attribute of the associated class or QoS credential, as in this example:

```
CLASSCFG[low] JOBFLAGS=SUSPENDABLE
```

For more information, see [Job Flags on page 145](#).

### To preempt jobs using SUSPEND

When you use **SUSPEND**, you must increase your **JOBRETRYTIME**. By default, **JOBRETRYTIME** is set to 60 seconds, but when you use **SUSPEND**, it is recommended that you increase the time to 300 seconds (5 minutes).

1. Make the following configurations to the `moab.cfg` file:
  - a. Set **GUARANTEEDPREEMPTION** to **TRUE**. (This causes Moab to lock **PREEMPTOR** jobs until **JOBRETRYTIME** expires.)
  - b. Make sure that **JOBNODEMATCHPOLICY** is *not* set to **EXACTNODE**, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
  - c. Set **PREEMTPOLICY** to **SUSPEND** (for more information, see [PREEMTPOLICY types on page 848](#)).
  - d. For the **PREEMPTEE** job, set **JOBFLAGS=RESTARTABLE,SUSPENDABLE**.
  - e. Make sure that the **PREEMPTEE** job has a lower priority than the **PREEMPTOR** job (for more information, see [Preemption flags on page 846](#)).

For example:

```

GUARANTEEDPREEMPTION TRUE
PREEMTPOLICY SUSPEND

QOSCFG[test1] QFLAGS=PREEMPTEE JOBFLAGS=RESTARTABLE,SUSPENDABLE MEMBERULIST=john
PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=10000

```

2. Submit a job to the preemptee QoS (`test1`). For example:

```
[john@g06]$ echo sleep 120 | msub -l procs=128,walltime=120 -l qos=test1
```

(Optional) Examine the output for `showq`:

```

Moab.7
[john@g06]# showq

active jobs-----
JOBID      USERNAME    STATE      PROCS      REMAINING    STARTTIME
Moab.7     john        Running    128        00:01:59     Thu Nov 10 12:28:44

1 active job      128 of 128 processors in use by local jobs (100.00%)
                   2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME    STATE      PROCS      WCLIMIT      QUEUE TIME

0 eligible jobs

blocked jobs-----
JOBID      USERNAME    STATE      PROCS      WCLIMIT      QUEUE TIME

0 blocked jobs

Total job: 1

```

3. Now submit a job to the preemptor QoS (`test2`). For example:

```
[john@g06]$ echo sleep 120 | msub -l procs=128,walltime=120 -l qos=test2
```

(Optional) Examine the output for showq:

```
Moab.8
[john@g06]# showq

active jobs-----
JOBID      USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.7     john       Suspended  128        00:01:56   Thu Nov 10 12:28:44
Moab.8     john       Running    128        00:02:00   Thu Nov 10 12:28:48

2 active jobs 128 of 128 processors in use by local jobs (100.00%)
      2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 eligible jobs

blocked jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
0 blocked jobs

Total jobs: 2
```

*Note that when a job is suspended, it stays in the output of showq. This is normal behavior for a suspended job. Moab should only suspend a job once.*

4. (Optional) Examine the checkjob outputs for these two jobs.

```
[john@g06]$ checkjob Moab.9
job Moab.9

State: Suspended

Reservation 'Moab.10' (-00:00:07 -> 00:01:53 Duration: 00:02:00)
```

**i** Occasionally, Moab will keep a job from restarting, holding it in a suspended state for a long period of time, if it thinks the job cannot restart. For example, if a job could write to I/O before it was suspended, and now it cannot, Moab would realize the job is unable to start and would leave it in a suspended state.

- [Checkpointing jobs with preemption on page 833](#)
- [Queueing jobs with preemption on page 834](#)
- [Canceling jobs with preemption on page 830](#)
- [Preemption flags on page 846](#)
- [About preemption on page 828](#)
- [PREEMTPOLICY types on page 848](#)
- [Testing and troubleshooting preemption on page 852](#)

## Using owner preemption

### Context

Owner preemption allows jobs submitted by a reservation owner to preempt jobs submitted by other users (for more information, see [Configuring and Managing Reservations on page 460](#)).

Owner preemption is enabled with the [OWNERPREEMPT](#) reservation flag.

For information about [PREEMPTEE](#) and [PREEMPTOR](#) flags, see [Preemption flags on page 846](#)

## To enable owner preemption

1. Make the following configurations to the `moab.cfg` file:

- a. Set **GUARANTEEDPREEMPTION** to *TRUE*. (This causes Moab to lock *PREEMPTOR* jobs until JOBRETRYTIME expires.)
- b. Make sure that **JOBNODEMATCHPOLICY** is *not* set to *EXACTNODE*, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
- c. Set the **PREEMTPOLICY** type (for more information, see [PREEMTPOLICY types on page 848](#)).
- d. Set the **OWNERPREEMPT** flag.

**i** Optionally, if you want the owner preemption to override any PREEMPTMINTIME settings for *PREEMPTEE* jobs, you can set the OWNERPREEMPTIGNOREMINTIME flag as well.

e. Specify an owner.

**i** If the non-owner job does not have a *RESTARTABLE* or *REQUEUEABLE* flag set, the job will cancel.

For example:

```

GUARANTEEDPREEMPTION TRUE
PREEMTPOLICY <policy>

SRCFG[myrez] FLAGS=OWNERPREEMPT HOSTLIST=node01
SRCFG[myrez] OWNER=USER:john
SRCFG[myrez] USERLIST=jane,john PERIOD=INFINITY

QOSCFG[test1] QFLAGS=PREEMPTEE JOBFLAGS=restartable MEMBERULIST=john PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=10000

```

2. Submit a job to a user who is not the owner (in this example, jane).

```
[jane@g06]$ echo sleep 600 | msub -l walltime=600 -l procs=64
```

(Optional) Examine the following output for `showq` and `checkjob` for jane's job:

```

Moab.1
[jane@g06]$ showq

active jobs-----
JOBID      USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.1     jane      Running    64          00:09:57    Mon Nov 14 12:07:52

1 active job      64 of 64 processors in use by local jobs (100.00%)
                   1 of 1 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME

0 eligible jobs

blocked jobs-----
JOBID      USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME

0 blocked jobs

Total job: 1
    
```

```

root@g06]# checkjob Moab.1
job Moab.1

State: Running
Creds: user:jane group:jane
WallTime: 00:01:02 of 00:10:00
SubmitTime: Mon Nov 14 12:07:52
(Time Queued Total: 00:00:00 Eligible: 00:00:00)

StartTime: Mon Nov 14 12:07:52
Total Requested Tasks: 64

Req[0] TaskCount: 64 Partition: FLEXlm
NodeCount: 1

Allocated Nodes:
[node01:64]

IWD: /opt/native
SubmitDir: /opt/native

## Using QoS preemption

### Context

This section breaks down how to configure the `moab.cfg` file to set up preemption with QoS. Using QoS, you can specify preemption rules and control access to preemption privileges by using the `QFLAGS PREEMPT` and `PREEMPTOR` credentials. For information about the `PREEMPT` and `PREEMPTOR` flags, see [Preemption flags on page 846](#).

QoS-based preemption only occurs when the following three conditions are satisfied:

- The preemptor job has the `PREEMPTOR` attribute set.
- The preemptee job has the `PREEMPT` attribute set.
- The preemptor job has a higher priority than the preemptee job.

### To configure `moab.cfg` for QoS preemption

1. Set `GUARANTEEDPREEMPTION` to `TRUE`. (This causes Moab to lock `PREEMPTOR` jobs until `JOBRETRYTIME` expires.)

2. Make sure that [JOBNODEMATCHPOLICY](#) is *not* set to [EXACTNODE](#), which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
3. If it is not already, set [NODEACCESSPOLICY](#) to [SHARED](#).
4. Set the [PREEMPTPOLICY](#) policy type (for more information, see [PREEMPTPOLICY types on page 848](#)).
5. Set up [QFLAGS](#) to mark jobs as [PREEMPTTEE](#) (a lower-priority job that can be preempted by a higher-priority job), or as [PREEMPTOR](#) (a higher-priority job that can preempt a lower-priority job). As in the example:

```
QOSCFG[test1] QFLAGS=PREEMPTTEE MEMBERULIST=<user> PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=<user> PRIORITY=10000
```

For more information, see [Preemption flags on page 846](#).

6. Make sure that the [PREEMPTTEE](#) job has a lower priority than the [PREEMPTOR](#) job. As in the example:

```
QOSCFG[test1] QFLAGS=PREEMPTTEE MEMBERULIST=<user> PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=<user> PRIORITY=10000
```

For example:

```
GUARANTEEDPREEMPTION TRUE
PREEMPTPOLICY <policy>

QOSCFG[test1] QFLAGS=PREEMPTTEE MEMBERULIST=<user> PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=<user> PRIORITY=10000
```

## References

### Manual preemption commands

You can use the [mjobctl](#) command to manually preempt jobs. The command can modify a job's execution state in the following ways:

Action	Flag	Details
Cancel	-c	Terminate job; remove from queue
Checkpoint	-C	Terminate and checkpoint job leaving job in queue
Requeue	-R	Terminate job; leave in queue
Resume	-r	Resume suspended job
Start (execute)	-x	Start idle job
Suspend	-s	Suspend active job

In general, users are allowed to suspend or terminate jobs they own. Administrators are allowed to suspend, terminate, resume, and execute any queued jobs.

## Preemption flags

Using QoS, you can specify preemption rules and control access to preemption privileges. This allows you to increase system throughput, improve job response time for specific classes of jobs, or enable various political policies. You enable all policies by specifying some QoS credentials with the [QFLAGS](#) *PREEMPT*, and others with *PREEMPTOR*.

PREEMPT	
<b>Description</b>	Indicates that the job can be preempted by a higher-priority job.
<b>Use</b>	Use for lower-priority jobs that can be preempted.
<b>Notes</b>	<div style="border: 1px solid #0056b3; border-radius: 10px; padding: 10px; background-color: #e6f2ff;">  This may delay some node actions. When reprovisioning, the system job may expire before the provision action occurs; while the action will still occur, the job will not show it.                 </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px;">QOSCFG[test1] QFLAGS=PREEMPT MEMBERULIST=&lt;user&gt; PRIORITY=100</pre>

PREEMPTOR	
<b>Description</b>	Indicates that the job should take priority and preempt any <i>PREEMPTEE</i> jobs.
<b>Use</b>	Use for jobs that need to take precedence over lower-priority jobs.
<b>Notes</b>	<p><b>i</b> <i>PREEMPTOR</i> jobs, either queued or running, must have a higher priority than <i>PREEMPTEE</i> jobs.</p> <p>When you configure job as a <i>PREEMPTOR</i>, you should also increase its priority (for details, see <a href="#">PREEMPTPRIOJOBSELECTWEIGHT</a> and <a href="#">PREEMPTRIMEWEIGHT</a>).</p>
<b>Example</b>	<code>QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=&lt;user&gt; PRIORITY=10000</code>

## Additional preemptor and preemptee information

**i** Preemptor priority plays a big role in preemption. Generally, you should assign the preemptor job a higher priority value than any other queued jobs so that it will move to (or near to) the top of the eligible queue.

You can set the [RESERVATIONPOLICY](#) parameter to *NEVER*. With this configuration, preemptee jobs can start whenever idle resources become available. These jobs will be allowed to run until a preemptor job arrives, at which point the preemptee jobs are preempted, freeing the resource. This configuration allows near immediate resource access for the preemptor jobs. Using this approach, a cluster can maintain near 100% system utilization while still delivering excellent turnaround time to the most important jobs.

In environments where job checkpointing or job suspension incur significant overhead, you might want to constrain the rate at which job preemption is allowed. You can use the [JOBPREEMPTMINACTIVETIME](#) parameter to throttle job preemption. In essence, this parameter prevents a newly started or newly resumed job from being eligible for preemption until it has executed for a specified amount of time. Conversely, you can exclude jobs from preemption after they have run for a certain amount of time by using the [JOBPREEMPTMAXACTIVETIME](#) parameter.

- [Manual preemption commands](#) on page 845
- [PREEMTPOLICY types](#) on page 848
- [Testing and troubleshooting preemption](#) on page 852

## PREEMTPOLICY types

You can use the [PREEMTPOLICY](#) parameter to control how the scheduler preempts a job. This parameter enforces preemption using one of the following methods:

PREEMTPOLICY type	Description
<b>SUSPEND</b>	Causes active jobs to stop executing, but to remain in memory on the allocated compute nodes.
<b>CHECKPOINT</b>	Saves the current job state and either terminates or continues running the job. A checkpointed job may restart at any time and resume execution from its most recent checkpoint.
<b>REQUEUE</b>	Terminates active jobs and returns them to the job queue in an idle state.
<b>CANCEL</b>	Cancels active jobs.

Each of these methods varies in the level of disruption to the job, *SUSPEND* being the least disruptive and *CANCEL* being the most disruptive.

Moab uses preemption escalation to free up resources. So for example, if the **PREEMTPOLICY** is set to *SUSPEND*, Moab uses this method if it is available; however, Moab will escalate it to something potentially more disruptive if necessary to preempt and free up resources.

## Simple example of preemption

This section illustrates the process of setting up preemption on your system from beginning to end and contains examples of what actions to take and what you should see as you go.

### Example scenario

For this basic setup example, we will have a user who can submit to either a "test1" or "test2" QoS. This example will use a *QUEUE* preemption type.

We will go through three parts to set up this preemption:

- Configuring the `moab.cfg` file
- Submitting a job to the *PREEMPT* QoS
- Submitting a job to the *PREEMPTOR* QoS

Okay, let's get started!

## Configuring moab.cfg

First, you will need to make some configurations to the `moab.cfg` file.

1. Set **GUARANTEEDPREEMPTION** to *TRUE*. (This causes Moab to lock *PREEMPTOR* jobs until **JOBRETRYTIME** expires.)
2. Make sure that **JOBNODEMATCHPOLICY** is *not* set to *EXACTNODE*, which is not currently supported for preemption (for more information, see [Testing and troubleshooting preemption on page 852](#)).
3. Set the **PREEMTPOLICY** type. In this example, **PREEMTPOLICY** is set to *QUEUE*. For more information, see [PREEMTPOLICY types on page 848](#).
4. Set up **QFLAGS** to mark jobs as *PREEMPT* (a lower-priority job that can be preempted by a higher-priority job), or as *PREEMPTOR* (a higher-priority job that can preempt a lower-priority job). For more information, see [Preemption flags on page 846](#).

**i** For this example, we also set **JOBFLAGS=RESTARTABLE** (because this example uses *QUEUE*). For more information, see [Queueing jobs with preemption on page 834](#).

5. Make sure that the *PREEMPT* job has a lower priority than the *PREEMPTOR* job.

Here is an example of how that would all look in a `moab.cfg` file (text marked **red** for emphasis).

```
GUARANTEEDPREEMPTION TRUE
#should not be JOBNODEMATCHPOLICY EXACTNODE as it causes problems when starting jobs

PREEMTPOLICY QUEUE

QOSCFG[test1] QFLAGS=PREEMPT JOBFLAGS=RESTARTABLE MEMBERULIST=john PRIORITY=100
QOSCFG[test2] QFLAGS=PREEMPTOR MEMBERULIST=john PRIORITY=1000
```

Now you can submit a job to the preemptee QoS (*test1*).

## Submitting a job to the preemptee QoS

Let's submit a job to the preemptee QoS (*test1*), requesting all processor cores in the cluster:

```
[john@g06]# echo sleep 600 | msub -l walltime=600 -l qos=test1 -l procs=128
```

Take a look at the `showq` and `checkjob` output:

```
Moab.1
[john@g06]# showq

active jobs-----
JOBID      USERNAME    STATE      PROCS      REMAINING    STARTTIME
Moab.1     john        Running    128        00:09:59     Wed Nov 9 15:56:33

1 active job      128 of 128 processors in use by local jobs (100.00%)
2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID      USERNAME    STATE      PROCS      WCLIMIT      QUEUE TIME
0 eligible jobs

blocked jobs-----
JOBID      USERNAME    STATE      PROCS      WCLIMIT      QUEUE TIME
0 blocked jobs

Total job: 1
```

```
[john@g06]# checkjob Moab.1
job Moab.1

State: Running
Creds: user:john group:john qos:test1
WallTime: 00:00:00 of 00:10:00
SubmitTime: Wed Nov 9 15:56:33
(Time Queued Total: 00:00:00 Eligible: 00:00:00)

StartTime: Wed Nov 9 15:56:33
Total Requested Tasks: 128

Req[0] TaskCount: 128 Partition: licenses

Allocated Nodes:
node[01-02]*64

IWD: /opt/native/
SubmitDir: /opt/native/
Executable: /opt/native/spool/moab.job.zOyf1N

StartCount: 1
Flags: RESTARTABLE,PREEMPTEE,GLOBALQUEUE,PROCSPECIFIED
Attr: PREEMPTEE
StartPriority: 100
Reservation 'Moab.1' (-00:00:03 -> 00:09:57 Duration: 00:10:00)
```

## Submitting a job to the preemptor QoS

Now we will submit a preemptor QoS job (*test2*) to preempt the first job (*test1*):

```
[john@g06]# echo sleep 600 | msub -l walltime=600 -l qos=test2 -l procs=128
```

Examine the following output for `showq` and `checkjob`:

```

Moab.2
[john@g06]# showq

active jobs-----
JOBID   USERNAME   STATE      PROCS      REMAINING   STARTTIME
Moab.2   john       Running    128        00:09:59   Wed Nov 9 15:56:47

1 active job 128 of 128 processors in use by local jobs (100.00%)
  2 of 2 nodes active (100.00%)

eligible jobs-----
JOBID   USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME
Moab.1   john       Idle       128        00:10:00   Wed Nov 9 15:56:33

1 eligible job

blocked jobs-----
JOBID   USERNAME   STATE      PROCS      WCLIMIT     QUEUE TIME

0 blocked jobs

Total jobs: 2

```

*Note that the preemptor job (Moab.2) moved to **Running**, while the preemptee job (Moab.1) was requested.*

```

[john@g06]# checkjob Moab.2
job Moab.2

State: Running
Creds: user:john group:john qos:test2
WallTime: 00:02:04 of 00:10:00
SubmitTime: Wed Nov 9 15:56:46
(Time Queued Total: 00:00:01 Eligible: 00:00:00)

StartTime: Wed Nov 9 15:56:47
Total Requested Tasks: 128

Req[0] TaskCount: 128 Partition: licenses
NodeCount: 2

Allocated Nodes:
node[01-02]*64

IWD: /opt/native/
SubmitDir: /opt/native/
Executable: /opt/native/spool/moab.job.ELoX5Q

StartCount: 1
Flags: HASPREEMPTED, PREEMPTOR, GLOBALQUEUE, PROCSPECIFIED
StartPriority: 10000
Reservation 'Moab.2' (-00:02:21 -> 00:07:39 Duration: 00:10:00)

```

*Note the flag, **HASPREEMPTED**. **HASPREEMPTED** is set when the **PREEMPTOR** job has preempted the **PREEMPTEE** job. Also note that the preemptor job priority plays a very big role in preemption. Generally, you should assign the preemptor a higher priority than any other queued jobs so that it will move to (or near to) the top of the eligible queue.*

## Testing and troubleshooting preemption

There are multiple steps associated with setting up a working preemption policy. With preemption, issues arise because it appears that Moab is not allowing preemptor jobs to preempt preemptee jobs in the right way. To diagnose this, use the following checklist:

Verify that preemptor jobs are marked with the <i>PREEMPTOR</i> flag. (Verify with <a href="#">checkjob &lt;JOBID&gt;   grep Flags</a> .)
Verify that preemptee jobs are marked with the <i>PREEMPTEE</i> flag. (Verify with <a href="#">checkjob &lt;JOBID&gt;   grep Flags</a> .)
Verify that the start priority of the preemptor job is higher than the priority of the preemptee job. (Verify with <a href="#">checkjob &lt;JOBID&gt;   grep Priority</a> .)
Verify that the resources allocated to the preemptee job match those requested by the preemptor job.
Verify that the preemptor job is within the 32-preemptee limit.
Verify that there are no policies preventing preemption from occurring. (Verify with <a href="#">checkjob -v -n &lt;NODEID&gt; &lt;JOBID&gt;</a> .)
Verify that the <a href="#">PREEMTPOLICY</a> parameter is properly set. (See <a href="#">PREEMTPOLICY types</a> on page 848.)
Verify that the preemptee job is properly marked as restartable, suspendable, or checkpointable. (Verify with <a href="#">checkjob &lt;JOBID&gt;   grep Flags</a> .)
Verify that <a href="#">GUARANTEEDPREEMPTION</a> is set to <i>TRUE</i> .
Verify that <a href="#">JOBNODEMATCHPOLICY</a> is <i>not</i> set to <i>EXACTNODE</i> . Moab does not currently consider <i>EXACTNODE</i> when it handles preemption, resulting in unexpected behavior when <i>EXACTNODE</i> is set in an environment with preemption.
Verify that <a href="#">NODEACCESSPOLICY</a> is <i>not</i> set to <i>SINGLEUSER</i> . ( <i>SHARED</i> is recommended.)
Verify that <a href="#">BACKFILLPOLICY</a> is set to <i>FIRSTFIT</i> .
Verify that the resource manager is properly responding to preemption requests. (Use <a href="#">mdiag -R</a> .)

If there is a resource manager level race condition, verify that Moab is properly holding target resources. (Verify with [mdiag -S](#) and set [RESERVATIONRETRYTIME](#) if needed.)

## Job templates

### About job templates

A Moab job template is a set of pre-configured settings, attributes, and resources that Moab applies to jobs that match certain criteria or to which you manually apply it. They perform three primary functions:

1. They generically match and categorize jobs.
2. They set arbitrary default or forced attributes for certain jobs.
3. They generate workflows that create and maintain user-requested services in a cloud environment.

You can use job templates in many aspects of scheduling [Peer-Based Grid](#) usage policies. Job templates are defined using the [JOB\\_CFG on page 975](#) configuration parameter.

Two methods exist for applying job templates to jobs. You can use the [JOBMATCHCFG on page 978](#) parameter to mark a template that contains the criteria a job must meet for eligibility and another template as the one to be applied to the job if it is eligible. This allows you to automate the use of templates. For example, to force all interactive jobs to run on a certain set of nodes, you can set one template (the criteria template) to have the *interactive* flag, then give the other template the desired host list. You can also apply a template directly to a job at submission if that ability is enabled for that template.

## How-to's

### Creating job templates

#### Context

Job templates are created in the Moab configure file using the [JOB\\_CFG](#) on page 975 parameter.

#### To create a job template

1. Open `moab.cfg`. Add the **JOB\_CFG** parameter and give the new job template a unique name.

```
JOB_CFG[newtemplate]
```

2. Configure any desired attributes (see [Job template extension attributes](#) on page 858.). Some of the important attributes include:

- [FLAGS](#) on page 860 - Lets you specify any job flags that should be applied.

```
JOB_CFG[newtemplate] FLAGS=SUSPENDABLE
```

*When Moab applies `newtemplate` to a job, the job is marked as suspendable.*

- [SELECT](#) on page 866 - Lets you apply the template directly at job submission.

```
JOB_CFG[newtemplate] FLAGS=SUSPENDABLE SELECT=TRUE
```

*When you submit a job via `msub`, you can specify that your job has `newtemplate` applied to it. When Moab applies the template to a job, that job is marked as suspendable.*

- [TEMPLATEDPEND](#) on page 868 - Lets you create dependencies when you create a job template workflow (see [Creating workflows with job templates](#) on page 857.).

```
JOBCFG[newtemplate] FLAGS=SUSPENDABLE SELECT=TRUE TEMPLATEDEPEND=AFTER:job1.pre
```

*When Moab applies `newtemplate` to a job, the job cannot run until job `job1.pre` has finished running; the job is also marked as suspendable. You can specify that Moab apply this template to a job as you submit it.*

3. If you want to automate job template application, see [Applying templates based on job attributes on page 855](#) for instructions. If you want to apply the template manually on job submission, see [Requesting job templates directly on page 856](#) for instructions.

## Viewing job templates

### Context

You can view a job template by running the `mdiag -j` command.

### To view a job template

- Run the `mdiag -j` command with the `policy` flag. Moab returns a list of job templates configured in `moab.cfg`.

```
> mdiag -j --flags=policy --blocking
```

## Applying templates based on job attributes

### Context

The [JOBMATCHCFG on page 978](#) parameter allows you to establish relationships between a number of job templates. [JMAX](#) and [JMIN](#) function as filters to determine whether a job is eligible for a subsequent template to be applied to the job. If a job is eligible, [JDEF](#) and [JSET](#) templates apply attributes to the job. See [Job template extension attributes on page 858](#) for more information about the [JOBMATCHCFG](#) attributes. The table on that page indicates which job template types are compatible with which job template extension attributes.

**i** [JSETs](#) and [JDEFs](#) have only been tested using `msub` as the job submission command.

### To apply a job template based on job attributes

1. In the Moab configuration file, create a job template with a set of criteria that a job must meet in order for Moab to apply the template. In the following example, Moab will apply a template to all interactive jobs, so the first template sets the `interactive` flag.

```
JOBCFG[inter.min] FLAGS=interactive
```

2. Create the job template that Moab should apply to the job if it meets the requirements set in the first template. In this example, Moab ignores all configured policies, so the second template sets the *ignpolicies* flag.

```
JOBCFG[inter.set] FLAGS=ignpolicies
```

3. Use the **JOBMATCHCFG** parameter and its **JMAX** or **JMIN** (specify the template specifying maximum or minimum requirements) and **JDEF** or **JSET** (specify the template to be applied) attributes to demonstrate the relationship between the two templates (See [Job template matching attributes on page 870](#) for more information.). In this case, all interactive jobs ignore policies; in other words, if a submitted job has at least the *inter.min* template settings, Moab applies the *inter.set* template settings to the job.

```
JOBMATCHCFG[interactive] JMIN=inter.min JSET=inter.set
```

*Moab applies the inter.set template to all jobs with the interactive flag set, causing them to ignore Moab's configured policies.*

4. To control which job template is applied to a job that matches multiple templates, use **FLAGS=BREAK**. Job templates are processed in the order they are listed in the configuration file and using the **BREAK** flag causes Moab to stop evaluating **JOBMATCHCFG** entries that occur after the current match.

```
JOBMATCHCFG[small] JMIN=small.min JMAX=small.max JSET.set=small.set FLAGS=BREAK
JOBMATCHCFG[large] JMIN=large.min JMAX=large.max JSET=large.set
```

*In this case, the large template would not be applied when a job matches both the small and large templates. The small template matches first, and because of **FLAGS=BREAK**, Moab stops evaluating further **JOBMATCHCFG** entries for the job.*

## Related topics

- [Requesting job templates directly on page 856](#)
- [Job template examples on page 870](#)

## Requesting job templates directly

### Context

When a job template has its [SELECT on page 866](#) attribute set to **TRUE**, you can request that template directly on job submission.

### To directly request job templates

1. Set the **SELECT** attribute on the template in `moab.cfg`.

```
JOBCFG[medium.set] NODESET=ONEOF:FEATURE:fast,slow SELECT=true
```

2. Submit a job with a resource list (`msub -l`), requesting the template using the format `template=<templateName>`.

```
> msub -l template=medium.set
```

Moab creates a job with the *medium.set* job template created in step 1.

**i** Attributes set in the template are evaluated as if they were part of the job submission. They are still subject to all of the same ACLs and policies.

### Related topics

- [Applying templates based on job attributes on page 855](#)

## Creating workflows with job templates

### Context

Moab can create workflows from individual jobs using job templates.

### To build a workflow with job templates

1. Create the jobs in the workflow using the [JOBCFG on page 975](#) parameter (See [Creating job templates on page 854](#) for more information.). It might be useful to add the [PURGEONSUCCESSONLY on page 149](#) flag to your setup or destroy jobs; it will allow you to restart the jobs easily if they fail. Specify the order in which they should run with the [TEMPLATEDEPEND on page 868](#) attribute. Please see the [Job dependency syntax table](#) for a list of valid dependency options.

```
JOBCFG[setup.pre]   TASKS=2 WCLIMIT=00:01:00 SELECT=TRUE
EXEC=/usr/tools/setup.pre.sh
JOBCFG[setup.pre2]  TEMPLATEDEPEND=AFTER:setup.pre SELECT=TRUE
EXEC=/nfs/tools/setup.pre2.sh
JOBCFG[engineering] TEMPLATEDEPEND=AFTER:setup.pre2
```

*When Moab applies the engineering template to a qualifying job, the job will not run until template job setup.pre and then setup.pre2 are created from the specified EXEC strings and finish running.*

**i** The Moab naming convention for jobs created with job templates is `<moabId>.<templateName>`. By default, when Moab submits jobs to only one resource manager, the job IDs are synchronized with the resource manager's job IDs. You can use the parameter [USEMOABJOBID on page 1067](#) so that a template-created job is easily associated with its parent job (such as `moab.1.moab.1.setup.pre`).

2. Create the job template that will act as the criteria a job must meet for Moab to apply the *engineering* template. In this situation, the job must be submitted with the account name *engineering*.

```
JOBCFG[engineering.match] ACCOUNT=engineering
```

3. Create the [JOBMATCHCFG on page 978](#) configuration to tell Moab that when a job matches the *engineering.match* template, it should apply the *engineering* template.

```
JOBMATCHCFG[engineering.job] JMIN=engineering.match JSET=engineering
```

## Job template extension attributes

When creating a job template, you can use any attribute acceptable within the [WIKI](#) workload query data format. In addition, job templates can use any of the extension attributes in the following table. Note that the Template type (**JMIN**, **JMAX**, **JDEF**, **JSET**) row indicates compatibility with the associated attribute (See [Applying templates based on job attributes on page 855](#) for more information.).

**i** Attributes set in a template are evaluated as if they were part of the original job submission. Their jobs are still subject to all the same ACLs and policies.

ACCOUNT	
<b>Format</b>	<ACCOUNT>[,<ACCOUNT>]...
<b>Template type</b>	<b>JMIN</b> <b>JDEF</b> <b>JSET</b>
<b>Description</b>	Account credentials associated with job. This is used for job template matching.
<b>Example</b>	<pre> JOBCFG[public] FLAGS=preemptee JOBCFG[public.min] ACCOUNT=public_acct JOBMATCHCFG[public] JMIN=public.min JSET=public                     </pre>

CLASS	
<b>Format</b>	<CLASS>[,<CLASS>]...
<b>Template type</b>	<b>JMIN</b> <b>JDEF</b> <b>JSET</b>
<b>Description</b>	Class credentials associated with job. This is used for job template matching.
<b>Example</b>	<pre> JOBCFG[night] FLAGS=preemptor JOBCFG[night.min] CLASS=night_class JOBMATCHCFG[night] JMIN=night.min JSET=night                     </pre>

CPUCLOCK	
<b>Format</b>	<STRING>
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JSET</b>
<b>Description</b>	CPU clock frequency for all CPUs of a job. For more information, see <a href="#">CPUCLOCK on page 621</a> . The job template extension overrides the job script.
<b>Example</b>	<pre> JOBCFG[slow] SELECT=TRUE cpuclock=1400 JOBCFG[fast] SELECT=TRUE cpuclock=3200  JOBCFG[cpu.min] CPUCLOCK=1000 JOBCFG[cpu.max] CPUCLOCK=2000 JOBCFG[cpu.set] CPUCLOCK=1500  JOBMATCHCFG[cpu] JMIN=cpu.min JMAX=cpu.max JSET=cpu.set </pre>

CPULIMIT	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JDEF</b> <b>JSET</b>
<b>Description</b>	Maximum amount of CPU time used by all processes in the job.
<b>Example</b>	<pre> JOBCFG[job.min] CPULIMIT=1:00:00:00 JOBCFG[job.max] CPULIMIT=2:00:00:00 </pre>

DESCRIPTION	
<b>Format</b>	<STRING>
<b>Template type</b>	<b>JMAX</b> <b>JDEF</b>
<b>Description</b>	Description of the job. When you run the <a href="#">checkjob</a> command, the description appears as Reason.
<b>Example</b>	<pre> JOBCFG[webdb] DESCRIPTION="Template job" </pre>

DPROCS	
<b>Format</b>	<INTEGER>
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JSET</b>
<b>Description</b>	Number of processors dedicated per task. The default is 1.
<b>Example</b>	<pre>JOBCFG [job.min] DPROCS=2 JOBCFG [job.max] DPROCS=4</pre>

EXEC	
<b>Format</b>	<STRING>
<b>Template type</b>	<b>JSET</b>
<b>Description</b>	Specifies what the job runs, regardless of what the user set.
<b>Example</b>	<pre>JOBCFG [setup.pre] EXEC=nfs/tools/setup.pre.sh</pre>

FLAGS	
<b>Format</b>	<JOBFLAG>[,<JOBFLAG>]...
<b>Template type</b>	<b>JMIN</b> <b>JDEF</b> <b>JSET</b>
<b>Description</b>	One or more legal <a href="#">job flag</a> values.
<b>Example</b>	<pre>JOBCFG [webdb] FLAGS=NORMSTART</pre>

GNAME	
<b>Format</b>	<STRING>

GNAME	
<b>Template type</b>	JDEF JSET
<b>Description</b>	Group credential associated with job.
<b>Example</b>	<pre>JOBCFG[webserv] GNAME=service</pre> <p> For matching the group, see the <a href="#">GROUP</a> attribute.</p>

GRES	
<b>Format</b>	<genericResource>[:<COUNT>][,<genericResource>[:<COUNT>]]...
<b>Template type</b>	JMAX JDEF
<b>Description</b>	Consumable generic attributes associated with individual nodes or the special pseudo-node <a href="#">global</a> , which provides shared cluster (floating) consumable resources. Use the <a href="#">NODECFG</a> parameter to configure such resources.
<b>Example</b>	<pre>JOBCFG[gres.set] GRES=abacus:2</pre> <p><i>In this example, the gres.set template applies two Abaqus licenses per task to a matched job.</i></p>

GROUP	
<b>Format</b>	<GROUP>[,<GROUP>]...
<b>Template type</b>	JMIN
<b>Description</b>	Group credentials associated with job. This is used for job template matching.
<b>Example</b>	<pre>JOBCFG[webserv] GROUP=service</pre> <p> For information about setting the group, see the <a href="#">GNAME</a> attribute.</p>

MEM	
<b>Format</b>	<INTEGER>
<b>Template type</b>	JMIN JMAX JDEF JSET
<b>Description</b>	Maximum amount of physical memory per task used by the job in megabytes. You can optionally specify other units with your integer (300kb or 2gb, for example). See <a href="#">Requesting resources on page 2586</a> for more information.
<b>Example</b>	<pre>JOBCFG[smalljobs] MEM=25</pre>

NODEACCESSPOLICY	
<b>Format</b>	One of the following: <a href="#">SHARED</a> , <a href="#">SHAREDONLY</a> , <a href="#">SINGLEJOB</a> , <a href="#">SINGLETASK</a> , <a href="#">SINGLEUSER</a> , or <a href="#">UNIQUEUSER</a>
<b>Template type</b>	JDEF JSET
<b>Description</b>	Specifies how node resources will be shared by a job. See the <a href="#">Node Access Policies on page 403</a> for more information.
<b>Example</b>	<pre>JOBCFG[serverapp] NODEACCESSPOLICY=SINGLEJOB</pre>

NODERANGE	
<b>Format</b>	<MIN>[,<MAX>]
<b>Template type</b>	JMAX JDEF
<b>Description</b>	Minimum and maximum nodes allowed to be allocated to job.
<b>Example</b>	<pre>JOBCFG[vizserver] NODERANGE=1,16</pre>

NODES	
<b>Format</b>	<INTEGER>
<b>Template type</b>	JMIN JMAX JSET
<b>Description</b>	Number of nodes required by the job. The default is 1. See <a href="#">Node Definition</a> for more information.
<b>Example</b>	<pre>JOBCFG[job.min] NODES=2 JOBCFG[job.max] NODES=4</pre>

NODESET	
<b>Format</b>	<STRING>
<b>Template type</b>	JSET
<b>Description</b>	See <a href="#">Node Set Overview on page 514</a> for more information.
<b>Example</b>	<pre>JOBCFG[medium.set] NODESET=ONEOF:FEATURE:fast,slow</pre>

PARTITION	
<b>Format</b>	<PARTITION>[:<PARTITION>]...
<b>Template type</b>	JMIN JDEF JSET
<b>Description</b>	Specifies the partition (or partitions) in which a job must run.
<b>Example</b>	<pre>JOBCFG[meis] PARTITION=math:geology</pre>

PREF	
<b>Format</b>	<FEATURE>[,<FEATURE>]...
<b>Template type</b>	JDEF JSET
<b>Description</b>	Specifies which node features are preferred by the job and should be allocated if available. See <a href="#">PREF</a> for more information.
<b>Example</b>	<code>JOBCFG [meis] PREF=bigmem</code>

PRIORITY	
<b>Format</b>	<INTEGER>
<b>Template type</b>	JMAX JDEF
<b>Description</b>	Relative job priority.  <div style="border: 1px solid #0056b3; padding: 5px; background-color: #e6f2ff;">  <b>PRIORITY</b> works only as a default setting and not as an override (<b>JSET</b>) setting.         </div>
<b>Example</b>	<code>JOBCFG [meis] PRIORITY=25000</code>

PROCRANGE	
<b>Format</b>	<MIN>[,<MAX>]
<b>Template type</b>	JDEF JSET
<b>Description</b>	Minimum and maximum processors allowed to be allocated to job.
<b>Example</b>	<code>JOBCFG [meis] PROCRANGE=2, 64</code>

QOS	
<b>Format</b>	<QOS>[,<QOS>]...
<b>Template type</b>	JMIN JDEF JSET
<b>Description</b>	QoS credentials associated with job. This is used for job template matching.
<b>Example</b>	<pre>JOBCFG[admin] RFEATURES=bigmem JOBCFG[admin.min] QOS=admin_qos JOBMATCHCFG[admin] JMIN=admin.min JSET=admin</pre>

RARCH	
<b>Format</b>	<STRING>
<b>Template type</b>	JSET
<b>Description</b>	Architecture required by job.
<b>Example</b>	<pre>JOBCFG[servapp] RARCH=i386</pre>

RFEATURES	
<b>Format</b>	<FEATURE>[,<FEATURE>]...
<b>Template type</b>	JMIN JDEF JSET
<b>Description</b>	List of features required by job.
<b>Example</b>	<pre>JOBCFG[servapp] RFEATURES=fast, bigmem</pre>

RM	
<b>Format</b>	<STRING>
<b>Template type</b>	JDEF JSET
<b>Description</b>	Destination resource manager to be associated with job.
<b>Example</b>	<code>JOBCFG[webdb] RM=slurm</code>

ROPSYS	
<b>Format</b>	<STRING>
<b>Template type</b>	JDEF JSET
<b>Description</b>	Operating system required by job.
<b>Example</b>	<code>JOBCFG[test.set] ROPSYS=windows</code>

SELECT	
<b>Format</b>	<BOOLEAN> : TRUE   FALSE
<b>Description</b>	Job template can be directly requested by job at submission.
<b>Example</b>	<code>JOBCFG[servapp] SELECT=TRUE</code>

SOFTWARE	
<b>Format</b>	<RESTYPE>[+ :}<COUNT>][@<TIMEFRAME>]
<b>Template type</b>	JDEF JSET

SOFTWARE	
<b>Description</b>	Indicates generic resources required by the job. See <a href="#">SOFTWARE</a> for more information.
<b>Example</b>	<pre>JOBCFG[servapp] SOFTWARE=matlab:2</pre>

SYSTEMJOBTYPE	
<b>Template type</b>	<b>JMIN</b>
<b>Description</b>	System job type (ex. vmcreate).
<b>Example</b>	<pre>JOBCFG[vmcreate.min] SYSTEMJOBTYPE=vmcreate JOBCFG[vmcreate.set] TRIGGER=atype=reserve,action="00:05:00",etype=end JOBMATCHCFG[vmcreate] JMIN=vmcreate.min JSET=vmcreate.set</pre>

TASKS	
<b>Format</b>	<INTEGER>
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JSET</b>
<b>Description</b>	Number of tasks required by job. The default is 1. See <a href="#">Task Definition</a> for more information.
<b>Example</b>	<pre>JOBCFG[job.min] TASKS=4 JOBCFG[job.max] TASKS=8</pre>

TASKPERNODE	
<b>Format</b>	<INTEGER>
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JDEF</b>

TASKPERNODE	
<b>Description</b>	Exact number of tasks required per node. The default is 0. <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; margin-top: 10px;">  <b>TASKPERNODE</b> works only as a default setting and not as an override (<b>JSET</b>) setting.                 </div>
<b>Example</b>	<pre> JOB_CFG[job.min] TASKPERNODE=2 JOB_CFG[job.max] TASKPERNODE=4                     </pre>

TEMPLATEDEPEND	
<b>Format</b>	<TYPE>:<TEMPLATE_NAME>
<b>Description</b>	Create another job from the <TEMPLATE_NAME> job template, on which any jobs using this template will depend. This is used for dynamically creating workflows. See <a href="#">Job Dependencies</a> for more information.
<b>Example</b>	<pre> JOB_CFG[engineering] TEMPLATEDEPEND=AFTER:setup.pre JOB_CFG[setup.pre] SELECT=TRUE EXEC=/tools/setup.pre.sh                     </pre>

UNAME	
<b>Format</b>	<STRING>
<b>Default</b>	<b>JDEF</b> <b>JSET</b>
<b>Description</b>	User credential associated with job.
<b>Example</b>	<pre> JOB_CFG[webserv] UNAME=service                     </pre> <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; margin-top: 10px;">  For matching the user, see the <a href="#">USER</a> attribute.                 </div>

USER	
<b>Format</b>	<USER>[,<USER>]...

USER	
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b>
<b>Description</b>	User credentials associated with job.
<b>Example</b>	<pre>JOBCFG[webserv] USER=service</pre> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 5px;">  For setting the user, see the <a href="#">UNAME</a> attribute.         </div>

VARIABLE	
<b>Format</b>	<NAME>[:<VAL>]
<b>Template type</b>	<b>JMIN</b> <b>JSET</b>
<b>Description</b>	Variables attached to the job template.
<b>Example</b>	<pre>JOBCFG[this] VARIABLE=var1:1 VARIABLE=var2:1</pre> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 5px;">  Variables are set upon successful completion of the job.         </div>

WCLIMIT	
<b>Format</b>	[[HH:]MM:]SS
<b>Template type</b>	<b>JMIN</b> <b>JMAX</b> <b>JDEF</b> <b>JSET</b>
<b>Description</b>	Walltime required by job. The default is 8640000 (100 days).
<b>Example</b>	<pre>JOBCFG[job.min] WCLIMIT=2:00:00 JOBCFG[job.max] WCLIMIT=12:00:00</pre>

## Job template matching attributes

The **JOBMATCHCFG** on page 978 parameter allows you to establish relationships between a number of job templates. The table in [Job template extension attributes on page 858](#) indicates which job template types are compatible with which job template extension attributes. The following types of templates can be specified with the **JOBMATCHCFG** parameter:

Attribute	Description
<b>JMAX</b>	<p>A potential job is rejected if it has matching attributes set or has resource requests that exceed those specified in this template.</p> <div style="border: 1px solid #005596; padding: 5px; margin-top: 10px;"> <p> For <b>JMAX</b>, a job template can specify only positive non-zero numbers as maximum limits for generic resources. If a job requests a generic resource that is not limited by the template, then the template can still be used.</p> </div>
<b>JMIN</b>	A potential job is rejected if it does not have matching attributes set or has resource requests that do not meet or exceed those specified in this template.
<b>JDEF</b>	A matching job has the specified attributes set as defaults but all values can be overridden by the user if the matching attribute is explicitly set at job submission time.
<b>JSET</b>	A matching job has the specified attributes forced to these values and these values override any values specified by the submitter at job submission time.
<b>JSTAT</b>	A matching job has its usage statistics reported into this template.

## Job template examples

Job templates can be used for a wide range of purposes including enabling automated learning, setting up custom application environments, imposing special account constraints, and applying group default settings. The following examples highlight some of these uses:

*Example 3-164: Setting up application-specific environments*

```
JOBCFG[xxx] EXEC=*app* JOBPROLOG=/usr/local/appprolog.x
```

**Example 3-165: Applying job preferences and defaults**

```

JOBCFG[xxx] CLASS=appq EXEC=*app* PREF=clearspeed
NODEALLOCATIONPOLICY PRIORITY
NODECFG[DEFAULT] PRIORITYF=5.0*PREF

```

**Example 3-166: Applying resource constraints to fuzzy collections**

In the following example, a job template match is set up. Using the [JOBMATCHCFG on page 978](#) parameter, Moab is configured to apply all attributes of the *inter.set* job template to all jobs that match the constraints of the *inter.min* job template. In this example, all interactive jobs are assigned the *ignpolicies* flag that allows them to ignore active, idle, system, and partition level policies. Interactive jobs are also locked into the test standing reservation and thus only allowed to run on the associated nodes.

```

# limit all users to a total of two non-interactive jobs
USERCFG[DEFAULT] MAXJOB=2
SRCFG[test] DESCRIPTION="compute pool for interactive and short duration jobs"
SRCFG[test] JOBATTRLIST=INTERACTIVE
SRCFG[test] MAXTIME=1:00:00
SRCFG[test] HOSTLIST=R:atl[16-63]
JOBCFG[inter.min] FLAGS=interactive

## Moab Workload Manager for Grids

[Cluster Consolidation and Sovereign Grids](#) is a video tutorial of a session offered at Moab Con that offers further details for understanding cluster consolidation and sovereign grids.

Moab Grid Scheduler allows sites to establish relationships among multiple clusters. There are three types of relationships you can implement within the grid: (1) centralized management, (2) hierarchal management, and (3) localized management. These relationships provide access to additional resources, improve load-balancing, provide single system images, and offer other benefits. The grid interface is flexible allowing sites to establish the needed relationship.

  - [Grid Relationships](#)
  - [Hierarchal Management](#)
  - [Local Management](#)

- [Submitting Jobs to the Grid](#)
- [Viewing Jobs and Resources](#)

## Grid Overview

A grid enables you to exchange workload and resource status information and to distribute jobs and data among clusters in an established relationship. In addition, you can use resource reservations to mask reported resources, coordinate requests for consumable resources, and quality of service guarantees.

In a grid, some servers running Moab are a source for jobs (that is, where users, portals, and other systems submit jobs), while other servers running Moab are a destination for these jobs (that is, where the jobs execute). Thus, jobs originate from a source server and move to a destination server. For a source server to make an intelligent decision, though, resource availability information must flow from a destination server to that source server.

Because you can manage workload on both the source and destination side of a grid relationship, you have a high degree of control over exactly when, how, and where to execute workload.

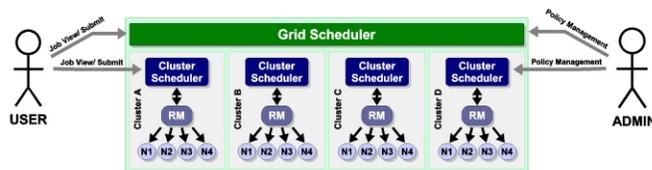

## Grid Benefits

Moab's peer-to-peer capabilities can be used for multiple purposes, including any of the following:

- manage access to external shared resources
- enable cluster monitoring information services
- enable massive-scalability clusters
- enable distributed grid computing

Of these, the most common use is the creation of grids to join multiple centrally managed, partially autonomous, or fully autonomous clusters. The purpose of this section is to highlight the most common uses of grid technology and provide references to sections which further detail their configuration and management. Other sections cover the standard aspects of grid creation including configuring [peer relationships](#), enabling [data staging](#), [credential management](#), [usage policies](#), and other factors.

Image 3-11: Jobs submitted to grid scheduler then cluster schedulers

## Management-Scalability

Much like a massive-scalability cluster, a massive-scalability grid allows organizations to overcome scalability limitations in resource managers, networks, message passing libraries, security middleware, file systems, and other forms of software and hardware infrastructure. Moab does this by allowing a single large set of resources to be broken into multiple smaller, more manageable clusters, and then

virtually re-assembling them using Moab. Moab becomes responsible for integrating the seams between the clusters and presenting a single-system image back to the end-users, administrators, and managers.

 Jobs cannot span clusters.

## Resource Access

In some cases, the primary motivation for creating a grid is to aggregate resources of different types into a single system. This aggregation allows for multi-step jobs to run a portion of the job on one architecture, and a portion on another.

A common example of a multi-architecture parameter-sweep job would be a batch regression test suite which requires a portion of the tests running on Redhat 7.2, a portion on SUSE 9.1, a portion on Myrinet nodes, and a portion on Infiniband nodes. While it would be very difficult to create and manage a single cluster which simultaneously provided all of these configurations, Moab can be used to create and manage a single grid which spans multiple clusters as needed.

## Load-Balancing

While grids often have additional motivations, it is rare to have a grid created where increased total system utilization is not an objective. By aggregating the total pool of jobs requesting resources and increasing the pool of resources available to each job, Moab is able to improve overall system utilization, sometimes significantly. The biggest difficulty in managing multiple clusters is preventing inter-cluster policies and the cost of migration from overwhelming the benefits of decreased fragmentation losses. Even though remote resources may be available for immediate usage, migration costs can occur in the form of credential, job, or data staging and impose a noticeable loss in responsiveness on grid workload.

Moab provides tools to allow these costs to be monitored and managed and both cluster and grid level performance to be reported.

## Single System Image (SSI)

Another common benefit of grids is the simplicity associated with a single system image-based resource pool. This simplicity generally increases productivity for end-users, administrators, and managers.

An SSI environment tends to increase the efficiency of end-users by minimizing human errors associated with porting a request from a known system to a less known system. Additionally, the single point of access grid reduces human overhead associated with monitoring and managing workload within multiple independent systems.

For system administrators, a single system image can reduce overhead, training time, and diagnostic time associated with managing a cluster. Furthermore, with Moab's peer-to-peer technology, no additional software layer is required to enable the grid and no new tools must be learned. No additional layers means no additional failure points, and that is good for everyone involved.

Managers benefit from SSI by being able to pursue organization mission objectives globally in a more coordinated and unified manner. They are also able to monitor progress toward those objectives and effectiveness of resources in general.

## High Availability

A final benefit of grids is their ability to decrease the impact of failures. Grids add another layer of high availability to the cluster-level high availability. For some organizations, this benefit is a primary motivation, pulling together additional resources to allow workload to continue to be processed even in the event that some nodes, or even an entire cluster, become unavailable. Whether the resource unavailability is based on node failures, network failures, systems middleware, systems maintenance, or other factors, a properly configured grid can reroute priority workload throughout the grid to execute on other compatible resources.

With grids, there are a number of important factors in high availability that should be considered:

- enabling highly available job submission/job management interfaces
- avoiding network failures with redundant routes to compute resources
- handling partial failures
- dynamically restarting failed jobs

## Grid Relationships

There are three types of relationships you can implement within the grid:

- [Centralized Management \(Master/Slave\)](#)
- [Centralized/Localized Management \(Hierarchal\)](#)
- [Localized Management \(Peer-to-Peer\)](#)

### Centralized Management (Master/Slave)

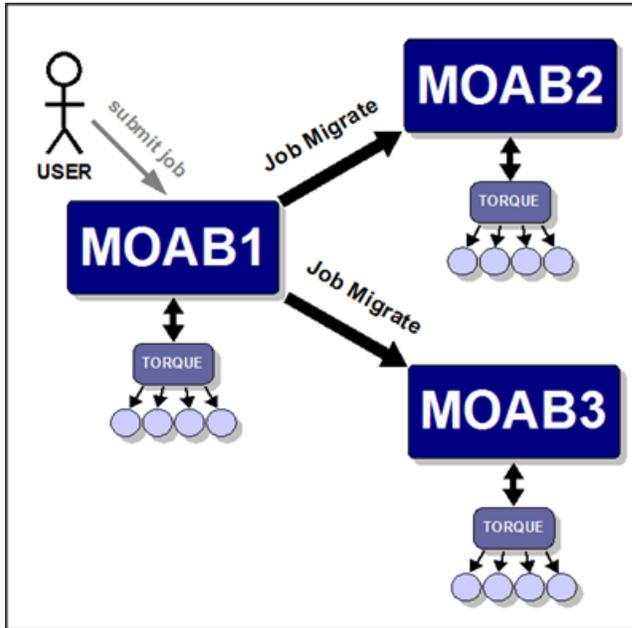

The centralized management model (master/slave) allows users to submit jobs to a centralized source server running Moab. The source Moab server obtains full resource information from all clusters and makes intelligent scheduling decisions across all clusters. Jobs (and [data](#) when configured to do so) are distributed to the remote clusters as needed. The centralized management model is recommended for intra-organization grid environments when cluster autonomy is not as necessary.

In the centralized management (master-slave) configuration, roles are clear. In other configurations, individual Moab servers may simultaneously act as sources to some clusters and destinations to others or as both a source and a destination to another cluster.

#### Example of the Centralized Management (Master/Slave) Model

XYZ Research has three clusters - MOAB1, MOAB2, and MOAB3--running Moab and the [TORQUE](#) resource manager. They would like to submit jobs at a single location (cluster MOAB1) and have the jobs run on whichever cluster can provide the best responsiveness.

The desired behavior is essentially a *master-slave* relationship. MOAB1 is the central, or master, cluster. On MOAB1, resource managers point to the local TORQUE resource manager and to the Moab servers on cluster MOAB2 and cluster MOAB3. The Moab servers on MOAB2 and MOAB3 are configured to trust cluster MOAB1 and to execute in slave mode.

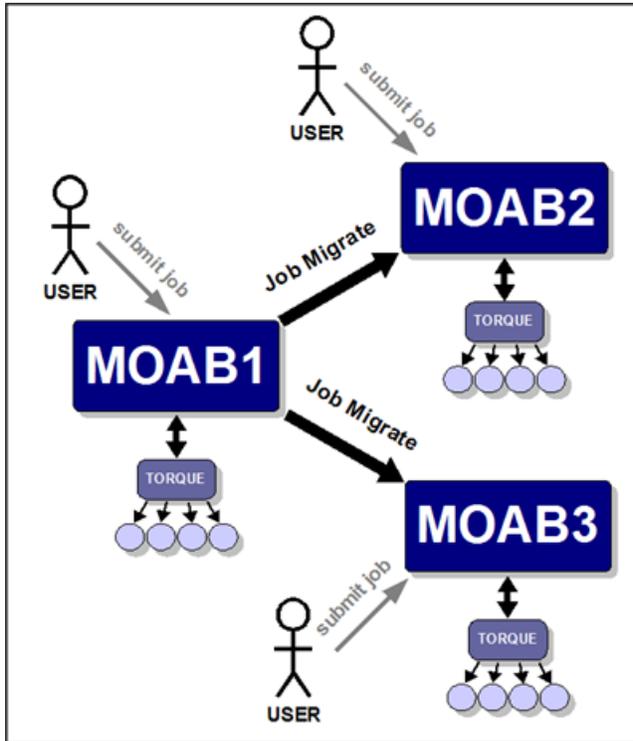

With this configuration, XYZ Research may submit jobs to the master Moab server running on cluster MOAB1 and may, as stated earlier, submit jobs from the slave nodes as well. However, only the master Moab server may schedule jobs. For example, cluster MOAB2 and cluster MOAB3 cannot schedule a job, but they can accept a job and retain it in an idle state until the master directs it to run.

**i** You can turn off job submission on slave nodes by setting the [DISABLESLAVEJOBSUBMIT](#) on page 945 parameter to *TRUE*.

The master Moab server obtains full resource information from all three clusters and makes intelligent scheduling decisions and distributes jobs (and [data](#) when configured to do so) to the remote clusters. The Moab servers running on clusters MOAB2 and MOAB3 are destinations behaving like a local resource manager. The Moab server running on MOAB1 is a source, loading and using this resource information.

## Centralized/Localized Management (Hierarchal)

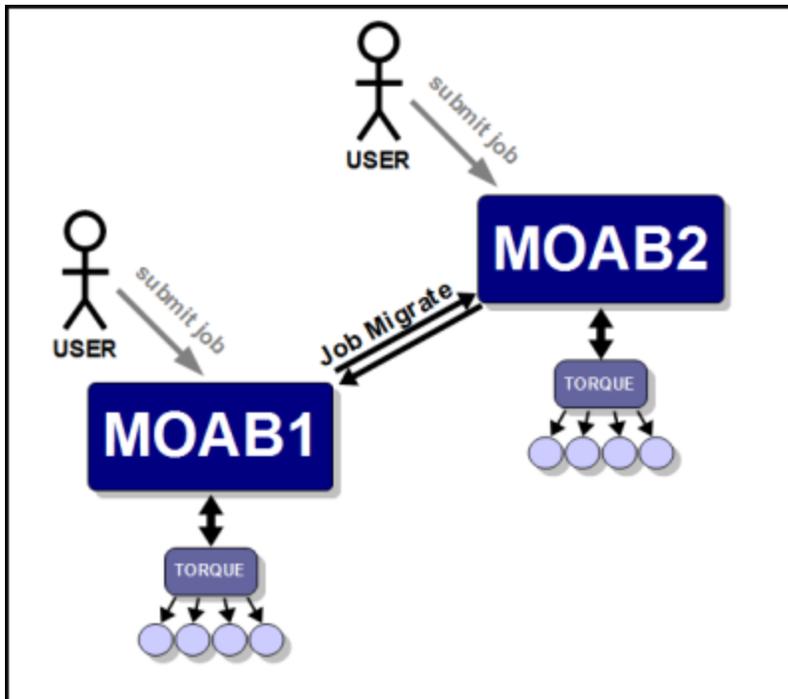

As with the centralized management model (master/slave), the hierarchal model allows users to submit jobs to a centralized source server running Moab. However, in the hierarchal model, clusters retain sovereignty, allowing local job scheduling. Thus, if communication between the source and destination clusters is interrupted, the destination cluster(s) can still run jobs locally.

In the hierarchal model, the source Moab server obtains full resource information from all clusters and makes intelligent scheduling decisions across all clusters. As needed, jobs and data are distributed to the remote clusters. Or, if preferred, a destination cluster may also serve as its own source; however, a destination cluster may not serve as a source to another destination cluster. The centralized management model is recommended for intra-organization grid environments when cluster autonomy and/or local management is necessary.

### Localized Management (Peer-to-Peer)

The localized management (peer-to-peer) model allows you to submit jobs on one cluster and schedule the jobs on the other cluster (it currently works with two clusters). For example, a job may be submitted on MOAB1 and run on MOAB2. Jobs can also migrate in the opposite direction (that is, from MOAB2 to MOAB1). The source servers running Moab obtain full resource information from both clusters and make intelligent scheduling decisions across both clusters. Jobs (and [data](#) when configured to do so) are migrated to other clusters as needed.

**i** Jobs will not migrate indefinitely. The localized management model limits them to one migration.

This model allows clusters to retain their autonomy while still allowing jobs to run on either cluster. No central location for job submission is needed, and you do not need to submit jobs from different nodes based on resource needs. You can submit a job from any location and it is either migrated to nodes on the least utilized cluster or the cluster requested in the job submission. This model is recommended for grids in an inter-organization grid environment.

## Submitting Jobs to the Grid

In any peer-to-peer or grid environment where jobs must be migrated between clusters, use the Moab `msub` command. Once a job has been submitted to Moab using `msub`, Moab identifies potential destinations and migrates the job to the destination cluster.

Using Moab's `msub` job submission command, jobs may be submitted using PBS or LSF command file syntax and be run on any cluster using any of the resource managers. For example, a PBS job script may be submitted using `msub` and depending on availability, Moab may translate a subset of the job's directives and execute it on an LSF cluster.

**i** Moab can only stage/migrate jobs between resource managers (in between clusters) that have been submitted using the `msub` command. If jobs are submitted directly to a low-level resource manager, such as PBS, Moab will still be able to schedule them but only on resources directly managed by the resource manager to which they were submitted.

### Example 1

A small pharmaceutical company, BioGen, runs two clusters in a centralized relationship. The slave is an older IBM cluster running Loadleveler, while the master manages the slave and also directly manages a large Linux cluster running TORQUE. A new user familiar with LSF has multiple LSF job scripts he would like to continue using. To enable this, the administrators make a symbolic link between the Moab `msub` client and the file `bsub`. The user begins submitting his jobs via `bsub` and, according to availability, the jobs run on either the Loadleveler or TORQUE clusters.

**Example 2**

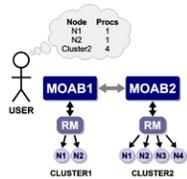

A research lab wants to use spare cycles on its four clusters, each of which is running a local resource manager. In addition to providing better site-wide load balancing, the goal is to also provide some of its users with single point access to all compute resources. Various researchers have made it clear that this new multi-cluster load balancing must not impose any changes on users who are currently using these clusters by submitting jobs locally to each cluster.

In this example, the scheduler mode of the destination clusters should be set to *NORMAL* rather than *SLAVE*. In *SLAVE* mode, Moab makes no local decisions - it simply follows the directions of remote trusted peers. In *NORMAL* mode, each Moab is fully autonomous, scheduling all local workload and coordinating with remote peers when and how to schedule migrated jobs.

From the perspective of a local cluster user, no new behaviors are seen. Remote jobs are migrated in from time to time, but to the user each job looks as if it were locally submitted. The user continues to submit, view, and manage jobs as before, using existing local jobs scripts.

## Viewing Jobs and Resources

By default, each destination Moab server will report all compute nodes it finds back to the source Moab server. These reported nodes appear within the source Moab as local nodes each within a partition associated with the resource manager reporting them. If a source resource manager was named `slave1`, all nodes reported by it would be associated with the `slave1partition`. Users and administrators communicating with the source Moab via [Moab Cluster Manager](#), [Moab Access Portal](#), or standard Moab command line tools would be able to view and analyze all reported nodes.

**i** The grid view will be displayed if either the source or the destination server is configured with grid view.

For job information, the default behavior is to only report to the source Moab information regarding jobs that originated at the source. If information about other jobs is desired, this can be configured as shown in the [Workload Submission and Control](#) section.

- [Resource Control and Access](#)

## Grid Configuration Basics

- [Peer Configuration Overview](#)
- [Initial Configuration](#)
- [Viewing Jobs From Other Peers](#)

### Peer Configuration Overview

In the simplest case, establishing a peer relationship can be accomplished with as few as two configuration lines: one line to indicate how to contact the peer and one line to indicate how to authenticate the server. However, data migration issues, credential mapping, and usage policies must often be addressed in order to make a peer-based grid effective.

To address these issues Moab provides facilities to control how peers inter-operate, enabling full autonomy over both client and server ends of the peer relationship.

### Initial Configuration

At a minimum, only two parameters must be specified to establish a peer relationship: [RMCFG on page 1035](#) and [CLIENTCFG\[<X>\] on page 937](#). **RMCFG** allows a site to specify interface information directing Moab on how to contact and inter-operate with the peer. For peer interfaces, a few guidelines must be followed with the **RMCFG** parameter:

- the **TYPE** attribute of the peer must be set to *moab*
- the **SERVER** attribute must point to the host and user interface port of the remote Moab server
- the *name* of the resource manager should match the name of the remote peer cluster as specified with the [SCHEDCFG on page 1039](#) parameter in the peer `moab.cfg`.

```
# moab.cfg on MoabServer01
SCHEDCFG[MoabServer01] MODE=NORMAL SERVER=hpc-01:41111
RMCFG[MoabServer02]     TYPE=moab   SERVER=hpc-02:40559
...
```

Configuring the **CLIENTCFG** parameter is mandatory. When specifying the **CLIENTCFG** parameter for peers, the following guidelines must be followed:

- the **CLIENTCFG** parameter must be specified in the `moab-private.cfg` file on both peers
- an **RM:** prefix is required before the peer's name
- if using default secret key based security, the value of the **KEY** attribute must match the **KEY** value set on the corresponding remote peer
- the **AUTH** attribute must be set to *admin1* in the `moab-private.cfg` on the destination Moab

```
# moab-private.cfg on MoabServer01
CLIENTCFG[RM:MoabServer02] KEY=3esfv0=32re2-tdbne
....
```

```
# moab-private.cfg on MoabServer02
CLIENTCFG[RM:MoabServer01] KEY=3esfv0=32re2-tdbne AUTH=admin1
...
```

## Centralized Grid Management (Master/Slave)

### Master Configuration

The process of setting up the master configuration is the same as setting up a [source Moab configuration](#). The master/slave relationship is configured in each `moab.cfg` on the slave.

```
# moab.cfg on Master
SCHEDCFG[master] SERVER=master:42559 MODE=NORMAL
...
```

```
# moab-private.cfg on Master
CLIENTCFG[RM:slave1] KEY=3esfv0=32re2-tdbne
...
```

### Slave Configuration

The slave's relationship with the master is determined by the **MODE**. Setting **MODE** to **SLAVE** notifies the master to take control of starting jobs on the slave. The master starts the jobs on the slave. In **SLAVE** mode, jobs can be submitted locally to the slave, but are not seen or started by the master. When a job is submitted locally to the slave the job is locked into the cluster and cannot migrate to other clusters.

```
# moab.cfg on Slave
SCHEDCFG[slave1] SERVER=slave1:42559 MODE=SLAVE
...
```

```
# moab-private.cfg on Slave
CLIENTCFG[RM:master] KEY=3esfv0=32re2-tdbne AUTH=admin1
...
```

## Hierarchical Grid Management

- [Configuring a Peer Server \(Source\)](#)
  - [Simple Hierarchical Grid](#)

## Configuring a Peer Server (Source)

Peer relationships are enabled by creating and configuring a [resource manager](#) interface using the [RMCFG](#) parameter. This interface defines how a given Moab will load resource and workload information and enforce its scheduling decisions. In non-peer cases, the [RMCFG](#) parameter points to a resource manager such as TORQUE, LSF, or SGE. However, if the [TYPE](#) attribute is set to *moab*, the [RMCFG](#) parameter can be used to configure and manage a peer relationship.

## Simple Hierarchal Grid

The first step to create a new peer relationship is to configure an interface to a destination Moab server. In the following example, cluster C1 is configured to be able to *see* and *use* resources from two other clusters.

```
SCHEDCFG [C1]  MODE=NORMAL  SERVER=head.C1.xyz.com:41111
RMCFG [C2]    TYPE=moab    SERVER=head.C2.xyz.com:40559
RMCFG [C3]    TYPE=moab    SERVER=head.C3.xyz.com:40559
...
```

*C1 allows a global view of the underlying clusters. From C1, jobs can be viewed and modified. C2 and C3 act as separate scheduling entities that can receive jobs from C1. C1 migrates jobs to C2 and C3 based on available resources and policies of C1. Jobs migrated to C2 and C3 are scheduled according to the policies on C2 and C3.*

In this case, one [RMCFG](#) parameter is all that is required to configure each peer relationship if standard secret key based authentication is being used and a shared default secret key exists between the source and destination Moabs. However, if peer relationships with multiple clusters are to be established and a per-peer secret key is to be used (highly recommended), then a [CLIENTCFG](#) parameter must be specified for the authentication mechanism. Because the secret key must be kept secure, it must be specified in the `moab-private.cfg` file. For the current example, a per-peer secret key could be set up by creating the following `moab-private.cfg` file on the C1 cluster.

```
CLIENTCFG [RM:C2]  KEY=fastclu3t3r
CLIENTCFG [RM:C3]  KEY=14436aaa
```

**i** The key specified can be any alphanumeric value and can be locally generated or made up. The only critical aspect is that the keys specified on each end of the peer relationship match.

Additional information can be found in the [Grid Security](#) section which provides detailed information on designing, configuring, and troubleshooting peer security.

Continuing with the example, the initial source side configuration is now complete. On the destination clusters, C2 and C3, the first step is to configure authentication. If a shared default secret key exists between all three clusters, then configuration is complete and the clusters are ready to communicate. If per-peer secret keys are used (recommended), then it will be necessary to create matching `moab-private.cfg` files on each of the destination clusters. With this example, the following files would be required on C2 and C3 respectively:

```
CLIENTCFG [RM:C1]  KEY=fastclu3t3r  AUTH=admin1
```

```
CLIENTCFG [RM:C1]  KEY=14436aaa  AUTH=admin1
```

Once peer security is established, a final optional step would be to configure scheduling behavior on the destination clusters. By default, each destination cluster accepts jobs from each trusted peer. However, it will also be fully autonomous, accepting and scheduling locally submitted jobs and enforcing its own local policies and optimizations. If this is the desired behavior, then configuration is complete.

In the current example, with no destination side scheduling configuration, jobs submitted to cluster C1 can run locally, on cluster C2 or on cluster C3. However, the established configuration does not necessarily enforce a strict master-slave relationship because each destination cluster (C2 and C3) has complete autonomy over how, when, and where it schedules both local and remote jobs. Each cluster can potentially receive jobs that are locally submitted and can also receive jobs from other source Moab servers. See [Slave Mode](#) for more information on setting up a master-slave grid.

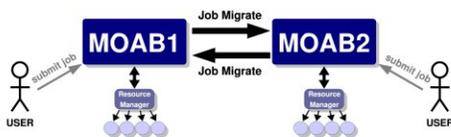

Further, each destination cluster will accept any and all jobs migrated to it from a trusted peer without limitations on who can run, when and where they can run, or how many resources they can use. If this behavior is either too restrictive or not restrictive enough, then destination side configuration will be required.

## Localized Grid Management

- [Enabling Bi-Directional Job Flow](#)
  - [True Peer-to-Peer Grid](#)

### Enabling Bi-Directional Job Flow

Image 3-12: Bi-directional peer-to-peer setup

For each peer interface, an [RMCFG on page 1035](#) parameter is only required for the server (or source side of the interface). If two peers are to share jobs in both directions, the relationship is considered to be bi-directional.

### True Peer-to-Peer Grid

Previous examples involved grid masters that coordinated the activities of the grid and made it so direct contact between peers was not required. However, if preferred, the master is not required and individual clusters can interface directly with each other in a true peer manner. This configuration is highlighted in the following example:

```
# Cluster A
SCHEDCFG[clusterA] MODE=NORMAL SERVER=clusterA
RMCFG[clusterA] TYPE=pbs
RMCFG[clusterB] TYPE=moab SERVER=clusterB:40559
CLIENTCFG[RM:clusterB] AUTH=admin1 KEY=banana16
```

```
# Cluster B
SCHEDCFG[clusterB] MODE=NORMAL SERVER=clusterB
RMCFG[clusterB] TYPE=pbs
RMCFG[clusterA] TYPE=moab SERVER=clusterA:40559
CLIENTCFG[RM:clusterA] AUTH=admin1 KEY=banana16
```

**i** If you are using Moab Accounting Manager, the *Start* action is not supported as a non-blocking accounting action in Peer-to-Peer grids. You will need to include *Start* as a blocking action. For example:

```
AMCFG[mam] BLOCKINGACTIONS=Start
```

## Resource Control and Access

- [Controlling Resource Information](#)
  - [Direct Node View](#)
  - [Mapped Node View](#)
  - [Managing Queue Visibility over the Grid](#)
- [Managing Resources with Grid Sandboxes](#)
  - [Controlling Access on a Per Cluster Basis](#)
  - [Access Control Lists/Granting Access to Local Jobs](#)

### Controlling Resource Information

In a Moab peer-to-peer grid, resources can be viewed in one of two models:

- [Direct](#) - nodes are reported to remote clusters exactly as they appear in the local cluster
- [Mapped](#) - nodes are reported as individual nodes, but node names are mapped to a unique name when imported into the remote cluster

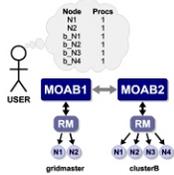

#### Direct Node View

Direct node import is the default resource information mode. No additional configuration is required to enable this mode.

#### Mapped Node View

In this mode, nodes are reported just as they appear locally by the exporting cluster. However, on the importing cluster side, Moab maps the specified node names using the resource manager [object map](#). In an object map, node mapping is specified using the `node` keyword as in the following example:

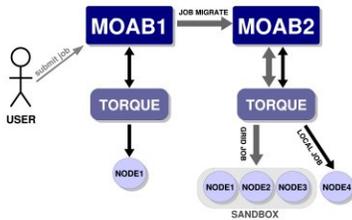

```
SCHEDCFG[gridmaster] MODE=NORMAL
RMCFG[clusterB] TYPE=moab OMAP=file://$HOME/clusterb.omap.dat
...
node:b_*,*
```

In this example, all nodes reported by *clusterB* have the string *b\_* prepended to prevent node name space conflicts with nodes from other clusters. For example, if cluster *clusterB* reported the nodes *node01*, *node02*, and *node03*, cluster *gridmaster* would report them as *b\_node01*, *b\_node02*, and *b\_node03*.

See [object mapping](#) for more information on creating an object map file.

## Managing Resources with Grid Sandboxes

A cluster may wish to participate in a grid but may desire to dedicate only a set amount of resources to external grid workload or may only want certain peers to have access to particular sets of resources. With Moab, this can be achieved by way of a grid sandbox which must be configured at the destination cluster. Grid sandboxes can both constrain external resource access and limit which resources are reported to other peers. This allows a cluster to only report a defined subset of its total resources to source peers and restricts peer workload to the sandbox. The sandbox can be set aside for peer use exclusively, or can allow local workload to also run inside of it. Through the use of multiple, possibly overlapping grid sandboxes, a site may fully control resource availability on a per peer basis.

A grid sandbox is created by configuring a [standing reservation](#) on a destination peer and then specifying the *ALLOWGRID* flag on that reservation. This flag tells the Moab destination peer to treat the standing reservation as a grid sandbox, and, by default, only the resources in the sandbox are visible to grid peers. Also, the sandbox only allows workload from other peers to run on the contained resources.

**Example 3-171: Dedicated Grid Sandbox**

```

SRCFG[sandbox1] PERIOD=INFINITY HOSTLIST=node01,node02,node03
SRCFG[sandbox1] CLUSTERLIST=ALL FLAGS=ALLOWGRID
...

```

*The standing reservation `sandbox1` creates a grid sandbox which always exists and contains the nodes `node01`, `node02`, and `node03`. This sandbox will only allow grid workload to run within it by default. This means that the scheduler will not consider the boxed resources for local workload.*

Grid sandboxes inherit all of the same power and flexibility that standing reservations have. See [Managing Reservations](#) for additional information.

**i** The flag `ALLOWGRID` marks the reservation as a grid sandbox and as such, it precludes grid jobs from running anywhere else. However, it does *not* enable access to the reserved resources. The `CLUSTERLIST` attribute in the above example enables access to all remote jobs.

## Controlling Access on a Per Cluster Basis

Often clusters may wish to control which peers are allowed to use certain sandboxes. For example, Cluster A may have a special contract with Cluster B and will let overflow workload from Cluster B run on 60% of its resources. A third peer in the grid, Cluster C, doesn't have the same contractual agreement, and is only allowed 10% of Cluster A at any given time. Thus two separate sandboxes must be made to accommodate the different policies.

```

SRCFG[sandbox1] PERIOD=INFINITY HOSTLIST=node01,node02,node03,node04,node05
SRCFG[sandbox1] FLAGS=ALLOWGRID CLUSTERLIST=ClusterB
SRCFG[sandbox2] PERIOD=INFINITY HOSTLIST=node06 FLAGS=ALLOWGRID
SRCFG[sandbox2] CLUSTERLIST=ClusterB,ClusterC,ClusterD USERLIST=ALL
...

```

*This example configuration illustrates how cluster A could set up their sandboxes to follow a more complicated policy. In this policy, `sandbox1` provides exclusive access to nodes 1 through 5 to jobs coming from peer ClusterB by including `CLUSTERLIST=ClusterB` in the definition. Reservation `sandbox2` provides shared access to `node6` to local jobs and to jobs from clusters B, C, and D through use of the `CLUSTERLIST` and `USERLIST` attributes.*

With this setup, the following policies are enforced:

- local jobs may see all nodes and run anywhere except nodes 1 through 5
- jobs from cluster B may see and run only on nodes 1 through 6
- jobs from clusters C and D may see and run only on node 6

As shown in the example above, sandboxes can be shared across multiple peers by listing all sharing peers in the `CLUSTERLIST` attribute (comma delimited).

## Access Control Lists/Granting Access to Local Jobs

It is not always desirable to have the grid sandbox reserve resources for grid consumption, exclusively. Many clusters may want to use the grid sandbox when local workload is high and demand from the grid is relatively low. Clusters may also wish to further restrict what kind of grid workload can run in a sandbox. This fine-grained control can be achieved by attaching access control lists (ACLs) to grid sandboxes.

Since sandboxes are basically special standing reservations, the syntax and rules for specifying an ACL is identical to those found in [Managing Reservations](#).

### Example

```
SRCFG[sandbox2] PERIOD=INFINITY HOSTLIST=node04,node05,node06
SRCFG[sandbox2] FLAGS=ALLOWGRID QOSLIST=high GROUPLIST=engineer
...
```

*A cluster decides to dedicate resources to a sandbox, but wishes local workload to also run within it. An additional ACL is then associated with the definition. The reservation `sandbox2` takes advantage of this feature by allowing local jobs running with a QOS of `high`, or under the group `engineer`, to also run on the sandboxed nodes `node04`, `node05`, and `node06`.*

## Workload Submission and Control

- [Controlling Peer Workload Information](#)
- [Determining Resource Availability](#)

### Controlling Peer Workload Information

By default, a peer is only responsible for workload that is submitted via that particular peer. This means that when a source peer communicates with destination peers it only receives information about workload it sent to those destination peers. If desired, the destination peers can send information about *all* of its workload: both jobs originating locally and remotely. This is called *local workload exporting*. This may help simplify administration of different clusters by centralizing monitoring and management of jobs at one peer.

To implement local workload exporting, use the `LOCALWORKLOADEXPORT` resource manager flag. For example:

```
RMCFG[ClusterA.INBOUND] FLAGS=LOCALWORKLOADEXPORT # source peer
...
```

*This example shows the configuration on a destination peer (ClusterB) that exports its local and remote workload to the source peer (ClusterA).*

**i** LOCALWORDKLOADEXPORT does not need to be configured in master/slave grids.

### Related topics

- [Job Start Time Estimates](#)

## Reservations in the Grid

In some environments, globally-shared resources may need to be managed to guarantee the full environment required by a particular job. Resources such as networks, storage systems, and license managers may be used only by batch workload but this workload may be distributed among multiple independent clusters. Consequently, the jobs from one cluster may utilize resources required by jobs

from another. Without a method of coordinating the needs of the various cluster schedulers, resource reservations will not be respected by other clusters and will be of only limited value.

Using the centralized model, Moab allows the importing and exporting of reservations from one peer server to another. With this capability, a source peer can be set up for the shared resource to act as a clearinghouse for other Moab cluster schedulers. This source peer Moab server reports configured and available resource state and in essence possesses a global view of resource reservations for all clusters for the associated resource.

To allow the destination peer to export reservation information to the source Moab, the [RMCFG on page 1035](#) lines for all client resource managers must include the flag *RSVEXPORT*. The source Moab should be configured with a resource manager interface to the destination peer and include both the *RSVEXPORT* and *RSVIMPORT* flags. For the destination peer, *RSVEXPORT* indicates that it should *push* information about newly created reservations to the source Moab, while the *RSVIMPORT* flag indicates that the source Moab server should import and locally enforce reservations detected on the destination peer server.

## Grid Usage Policies

- [Grid Usage Policy Overview](#)
- [Peer Job Resource Limits](#)
- [Usage Limits via Peer Credentials](#)
- [Using General Policies in a Grid Environment](#)
  - [Source Cluster Policies](#)

### Grid Usage Policy Overview

Moab allows extensive control over how peers interact. These controls allow the following:

- Limiting which remote users, group, and accounts can utilize local compute resources
- Limiting the total quantity of local resources made available to remote jobs at any given time
- Limiting remote resource access to a specific subset of resources
- Limiting timeframes during which local resources will be made available to remote jobs
- Limiting the types of remote jobs which will be allowed to execute

### Peer Job Resource Limits

Both source and destination peers can limit the types of jobs they will allow in terms of resources requested, services provided, job duration, applications used, etc using Moab's job template feature. Using this method, one or more job profiles can be created on either the source or destination side, and Moab can be configured to allow or reject jobs based on whether or not the jobs meet the specified job profiles.

When using the **ALLOWJOBLIST** and **REJECTJOBLIST** attributes, the following rules apply:

- All jobs that meet the job templates listed by **ALLOWJOBLIST** are allowed.
- All jobs that do not meet **ALLOWJOBLIST** job templates and which do meet **REJECTJOBLIST** job templates are rejected.
- All jobs that meet no job templates in either list are allowed.

## Usage Limits via Peer Credentials

With peer interfaces, destination clusters willing to accept remote jobs can [map](#) these jobs onto a select subset of users, accounts, QoSs, and queues. With the ability to lock these jobs into certain credentials comes the ability to apply any arbitrary credential constraints, priority adjustments, and resource limitations normally available within cluster management. Specifically, the following can be accomplished:

- limit number of active jobs simultaneously allowed
- limit quantity of allocated compute resources simultaneously allowed
- adjust job priority
- control access to specific scheduling features (deadlines, reservations, preemption, etc)
- adjust fairshare targets
- limit resource access

## Using General Policies in a Grid Environment

While Moab does provide a number of unique grid-based policies for use in a grid environment, the vast majority of available management tools come from the transparent application of cluster policies. Cluster-level policies such as [job prioritization](#), [node allocation](#), [fairshare](#), [usage limits](#), [reservations](#), [preemption](#), and allocation management all just work and can be applied in a grid in exactly the same manner.

The one key concept to understand is that in a centralized based grid, these policies apply across the entire grid; in a peer-based grid, these policies apply only to local workload and resources.

## Source Cluster Policies

In many cases, organizations are interested in treating jobs differently based on their point of origin. This can be accomplished by assigning and/or keying off of a unique credential associated with the remote workload. For example, a site may wish to constrain jobs from a remote cluster to only a portion of the total available cluster cycles. This could be accomplished using usage limits, fairshare targets, fairshare caps, reservations, or allocation management based policies.

The examples below show three different approaches for constraining remote resource access.

**Example 3-172: Constraining Remote Resource Access via Fairshare Caps**

```
# define peer relationship and map all incoming jobs to orion account
RMCFG[orion.INBOUND] SET.JOB=orion.set
JOBCFG[orion.set] ACCOUNT=orion
# configure basic fairshare for 7 one day intervals
FSPOLICY DEDICATEDPS
FSINTERVAL 24:00:00
FSDEPTH 7
FSUSERWEIGHT 100
# use fairshare cap to limit jobs from orion to 10% of cycles
ACCOUNTCFG[orion] FSCAP=10%
```

**Example 3-173: Constraining Remote Resource Access via Fairshare Targets and Preemption**

```
# define peer relationship and map all incoming jobs to orion account RMCFG
[orion.INBOUND] SET.JOB=orion.set
JOBCFG[orion.set] ACCOUNT=orion
# local cluster can preempt jobs from orion
USERCFG[DEFAULT] JOBFLAGS=PREEMPTOR
PREEMTPOLICY CANCEL
# configure basic fairshare for 7 one day intervals
FSPOLICY DEDICATEDPS
FSINTERVAL 24:00:00
FSDEPTH 7
FSUSERWEIGHT 100
# decrease priority of remote jobs and force jobs exceeding 10% usage to be
preemptible
ACCOUNTCFG[orion] FSTARGET=10-
ENABLEFSVIOLATIONPREEMPTION TRUE
```

**Example 3-174: Constraining Remote Resource Access via Priority and Usage Limits**

```
# define peer relationship and map all incoming jobs to orion account RMCFG
[orion.INBOUND] SET.JOB=orion.set
JOBCFG[orion.set] QOS=orion
USERCFG[DEFAULT] QDEF=orion
# local cluster can preempt jobs from orion
USERCFG[DEFAULT] JOBFLAGS=PREEMPTOR
PREEMTPOLICY CANCEL
# adjust remote jobs to have reduced priority
QOSCFG[orion] PRIORITY=-1000
# allow remote jobs to use up to 64 procs without being preemptible and up to 96 as
preemtees
QOSCFG[orion] MAXPROC=64,96
ENABLESPVIOLATIONPREEMPTION TRUE
```

## Grid Scheduling Policies

- [Peer-to-Peer Resource Affinity Overview](#)
- [Peer Allocation Policies](#)
- [Per-partition Scheduling](#)

## Peer-to-Peer Resource Affinity Overview

The concept of resource affinity stems from a number of facts:

- Certain compute architectures are able to execute certain compute jobs more effectively than others.
- From a given location, staging jobs to various clusters may require more expensive allocations, more data and network resources, and more use of system services.
- Certain compute resources are owned by external organizations and should be used sparingly.

Regardless of the reason, Moab servers allow the use of peer resource affinity to guide jobs to the clusters that make the best fit according to a number of criteria.

At a high level, this is accomplished by creating a number of job templates and associating the profiles with different peers with varying impacts on estimated execution time and peer affinity.

## Peer Allocation Policies

A direct way to assign a peer allocation algorithm is with the [PARALLOCATIONPOLICY](#) parameter. Legal values are listed in the following table:

Value	Description
<b>FirstStart</b>	Allocates resources from the eligible peer that can start the job the soonest.
<b>LoadBalance</b>	Allocates resources from the eligible peer with the most available resources; measured in tasks (balances workload distribution across potential peers).
<b>LoadBalanceP</b>	Allocates resources from the eligible peer with the most available resources; measured in percent of configured resources (balances workload distribution across potential peers).
<b>Random</b>	Allocates partitions in a random order each iteration. In general, all the jobs scheduled within the same iteration receive the same randomized list of partitions. This means the randomization happens between iterations and not within the same iteration. One iteration Moab might start with partition X and the next it might start with partition Y.
<b>RoundRobin</b>	Allocates resources from the eligible peer that has been least recently allocated.

The `mdiag -t -v` command can be used to view current calculated partition priority values.

## Per-partition Scheduling

Per-partition scheduling can be enabled by adding the following lines to `moab.cfg`:

```
PERPARTITIONSCHEDULING TRUE
JOBMIGRATEPOLICY JUSTINTIME
```

To use per-partition scheduling, you must configure fairshare trees where particular users have higher priorities on one partition, and other users have higher priorities on a different partition.

**i** Do not set the [USEANYPARTITIONPRIO](#) parameter if you use per-partition scheduling. Doing so causes Moab to schedule jobs to the first partition listed, even if nodes from another partition will be available sooner.

## Grid Credential Management

- [Peer User Credential Management Overview](#)
- [Credential Mapping Files](#)

### Peer Credential Management Overview

Moab provides a number of credential management features that allow sites to control which local users can utilize remote resources and which remote users can utilize local resources and under what conditions this access is granted.

### Peer Credential Mapping

If two peers share a common user space (a given user has the same login on both clusters), then there is often no need to enable credential mapping. When users, groups, classes, QoS's, and accounts are not the same from one peer to another, Moab allows a site to specify an Object Map URL. This URL contains simple one to one or expression based mapping for credentials and other objects. Using the [RMCFG](#) parameter's **OMAP** attribute, a site can tell Moab where to find these mappings. The object map uses the following format:

```
<OBJECTTYPE>:<SOURCE_OBJECTID>,<DESTINATION_OBJECTID>
```

where *<SOURCE\_OBJECT>* can be a particular username or an asterisk (\*) which is a wildcard matching all credentials of the specified type which have not already been matched.

The object map file can be used to translate the following:

Keyword	Objects
<b>account</b>	accounts/projects
<b>class</b>	classes/queues
<b>file</b>	files/directories
<b>group</b>	groups

Keyword	Objects
<b>node</b>	nodes
<b>qos</b>	QoS
<b>user</b>	users

The following `moab.cfg` and `omap.dat` files demonstrate a sample credential mapping.

```
SCHEDCFG[master1] MODE=normal
RMCFG[slave1] OMAP=file:///opt/moab/omap.dat
...
```

```
user:joe,jsmith
user:steve,sjohnson
group:test,staff
class:batch,serial
user:*,grid
```

In this example, a job that is being migrated from cluster *master1* to the peer *slave1* will have its credentials mapped according to the contents of the `omap.dat` file. In this case, a job submitted by user *joe* on *master1* will be executed under the user account *jsmith* on peer *slave1*. Any credential that is not found in the mapping file will be passed to the peer as submitted. In the case of the user credential, all users other than *joe* and *steve* will be remapped to the user *grid* due to the wildcard matching.

Because the **OMAP** attribute is specified as a URL, multiple methods can be used to obtain the mapping information. In addition to the file protocol shown in the example above, `exec` may be used.

Note that there is no need to use the credential mapping facility to map all credentials. In some cases, a common user space exists but it is used to map all classes/queues on the source side to a single queue on the destination side. Likewise, for utilization tracking purposes, it may be desirable to map all source account credentials to a single cluster-wide account.

## Source and Destination Side Credential Mapping

Credential mapping can be implemented on the source cluster, destination cluster, or both. A source cluster may want to map all user names for all outgoing jobs to the name *generaluser* for security purposes, and a destination cluster may want to remap all incoming jobs from this particular user to the username *cluster2* and the QoS *grid*.

## Preventing User Space Collisions

In some cases, a cluster may receive jobs from two independent clusters where grid wide username distinctiveness is not guaranteed. In this case, credential mapping can be used to ensure the uniqueness of each name. With credential mapping files, this can be accomplished using the `<DESTINATION_CREDENTIAL>` wildcard asterisk (\*) character. If specified, this character will be replaced with the exact `<SOURCE_CREDENTIAL>` when generating the destination credential string. For example, consider the following configuration:

```
SCHEDCFG[master1] MODE=normal
RMCFG[slave1] OMAP=file:///opt/moab/omap.dat  FLAGS=client
...
```

```
user:*,cl_*
group:*,*_grid
account:*,temp_*
```

This configuration will remap the usernames of all jobs coming in from the peer *slave1*. The username *john* will be remapped to *c1\_john*, the group *staff* will be remapped to *staff\_grid* and the account *demo* will be remapped to *temp\_demo*.

## Grid Data Management

This method of data staging has been deprecated in Moab Workload Manager 8.0.0 and will be removed from the product in a future release. See [About data staging on page 901](#) for information about the new method of staging data.

- [Grid Data Management Overview](#)
- [Configuring Peer Data Staging](#)
- [Peer-to-Peer SCP Key Authentication](#)
- [Diagnostics](#)

### \_Grid Data Management Overview

Moab provides a highly generalized data manager interface that can allow both simple and advanced data management services to be used to migrate data amongst peer clusters. Using a flexible script interface, services such as *scp*, *NFS*, and *gridftp* can be used to address data staging needs. This feature enables a Moab peer to push job data to a destination Moab peer.

### \_Configuring Peer Data Staging

Moab offers a simple, automatic configuration, as well as advanced configuration options. At a high level, configuring data staging across a peer-to-peer relationship consists of configuring one or more storage managers, associating them with the appropriate peer resource managers, and then specifying data requirements at the local level—when the job is submitted.

To use the data staging features, you must specify the `--with-grid` option at `./configure` time. After properly configuring data staging, you can submit a job to the peer with any user who has SSH keys set up and Moab will automatically or implicitly stage back the standard out and standard error files created by the job. Files can be implicitly staged in or out before a job runs by using the [mstagein](#) or [mstageout](#) options of [msub](#).

## Simple Configuration

Moab automatically does most of the data staging configuration based on a simplified set of parameters (most common defaults) in the configuration file (`moab.cfg`).

Do the following to configure peer data staging:

1. Configure at least two Moab clusters to work in a grid. Please refer to information throughout [Moab Workload Manager for Grids](#) for help on configuring Moab clusters to work together as peers in a grid.
2. [Set up SSH keys](#) so that users on the source grid peer can SSH to destination peers without the need for a password.
3. Make necessary changes to the `moab.cfg` file of the source grid peer to activate data staging, which involves creating a new data resource manager definition within Moab. The resource manager provides data staging services to existing peers in the grid. By defining the data resource manager within the `moab.cfg`, Moab automatically sets up all of the necessary data staging auxiliary scripts.

Use the following syntax for defining a data resource manager:

```
RMCFG[<RMName>] TYPE=NATIVE RESOURCETYPE=STORAGE
VARIABLES=DATASPACEUSER=<DataSpaceUser>,DATASPACE=DIR=<DataSpaceDir>
SERVER=<DataServer>
```

- `<RMName>`: Name of the RM (defined as a storage RM type by `RESOURCETYPE=STORAGE`).
- `<DataSpaceUser>`: User used to SSH into `<DataServer>` to determine available space in `<DataSpaceDir>`. Moab runs a command similar to the following:  

```
ssh <DataServer> -l <DataSpaceUser> df <DataSpaceDir>
```
- `<DataSpaceDir>`: Directory where staged data is stored.
- `<DataServer>`: Name of the server where `<DataSpaceDir>` is located.

Define the following URLs:

```
RMCFG[data] CLUSTERQUERYURL=exec://$TOOLSDIR/cluster.query.dstage.pl
RMCFG[data] SYSTEMMODIFYURL=exec://$TOOLSDIR/system.modify.dstage.pl
RMCFG[data] SYSTEMQUERYURL=exec://$TOOLSDIR/system.query.dstage.pl
RMCFG[data] RMINITIALIZEURL=exec://$TOOLSDIR/setup.config.pl
```

4. Associate the data resource manager with a peer resource manager.

```
RMCFG[remote_data] TYPE=NATIVE RESOURCETYPE=STORAGE
VARIABLES=DATASPACEUSER=datauser,DATASPACE=DIR=/tmp SERVER=clusterhead
RMCFG[remote_cluster] TYPE=MOAB SERVER=clusterhead:42559 DATARM=remote_data
```

5. Restart Moab to finalize changes. You can use the [mschedctl -R](#) command to cause Moab to automatically restart and load the changes.

When restarting, Moab recognizes the added configuration and runs a Perl script in the Moab tool directory that configures the external scripts (also found in the tools directory) that Moab uses to perform data staging. You can view the data staging configuration by looking at the `config.dstage.pl` file in `$MOABHOMEDIR/etc`.

## Advanced Configuration

If you need a more customized data staging setup, contact your account representative.

### Peer-to-Peer SCP Key Authentication

In order to use scp as the data staging protocol, we will need to create SSH keys which allow users to copy files between the two peers, without the need for passwords. For example, if *UserA* is present on the source peer, and his counterpart is *UserB* on the destination peer, then *UserA* will need to create an SSH key and configure *UserB* to allow password-less copying. This will enable *UserA* to copy files to and from the destination peer using Moab's data staging capabilities.

Another common scenario is that several users present on the source peer are mapped to a single user on the destination peer. In this case, each user on the source peer will need to create keys and set them up with the user at the destination peer. Below are steps that can be used to setup SSH keys among two (or more) peers:

**i** These instructions were written for [OpenSSH version 3.6](#) and might not work correctly for older versions.

#### Generate SSH Key on Source Peer

As the user who will be submitting jobs on the source peer, run the following command:

```
ssh-keygen -t rsa
```

You will be prompted to give an optional key. Just hit return and ignore this or other settings. When finished, this command will create two files `id_rsa` and `id_rsa.pub` located inside the user's `~/.ssh/` directory.

#### Copy the Public SSH Key to the Destination Peer

Transfer the newly created public key (`id_rsa.pub`) to the destination peer:

```
scp ~/.ssh/id_rsa.pub ${DESTPEERHOST}:~
```

#### Disable Strict SSH Checking on Source Peer (Optional)

By appending the following to your `~/.ssh/config` file you can disable SSH prompts which ask to add new hosts to the "known hosts file." (These prompts can often cause problems with data staging functionality.) Note that the `${DESTPEERHOST}` should be the name of the host machine running the destination peer:

```
Host ${DESTPEERHOST}
  CheckHostIP no
  StrictHostKeyChecking no
  BatchMode yes
```

#### Configure Destination Peer User

Now, log in to the destination peer as the destination user and set up the newly created public key to be trusted:

**i** The number of bytes transferred for each file is currently not used.

```
> checknode -v scp://keche//tmp/
node scp://keche//tmp/
State:      Idle (in current state for 00:00:13)
Configured Resources: DISK: 578G
Utilized Resources: DISK: 316G
Dedicated Resources: ---
  MTBF(longterm):  INFINITY  MTBF(24h):  INFINITY
Active Data Staging Operations:
  job      native.2 complete (1 bytes transferred)
(/home/brian/stage.txt)
  job      native.3 pending (1 bytes) (/home/brian/stage.txt)
Dedicated Storage Manager Disk Usage:  0 of 592235 MB
Cluster Query URL:  exec://$TOOLS DIR/grid/cluster.query.dstage.pl
Partition:  SHARED Rack/Slot:  ---
Flags:      rmdetected
RM[data]:   TYPE=NATIVE
EffNodeAccessPolicy: SHARED
Total Time: 00:12:15  Up: 00:12:15 (100.00%)  Active: 00:00:00 (0.00%)
Reservations:  ---
```

- **mdiag -n**: Displays the state of the storage node.

```
> mdiag -n
compute node summary
Name                State  Procs   Memory      Opsys
compute1            Idle   4:4     3006:3006   linux
compute2            Down   0:4     3006:3006   linux
scp://keche//tmp/   Idle   0:0     0:0         -
-----            ---    4:8     6012:6012   -----
Total Nodes: 3 (Active: 0 Idle: 2 Down: 1)
```

- **checkjob -v**: Displays the status of the staging request.

**i** The remaining time and size of the file information is currently not used. The information should only be used to see file locations and whether the file has been staged or not.

```
> checkjob -v jobid
...
Stage-In Requirements:
  localhost:/home/brian/stage.txt => keche://tmp/staged.txt  size:0B
status:[NONE]  remaining:00:00:01
  Transfer URL: file:///home/brian/stage.txt,ssh://keche/tmp/staged.txt
...
```

To ensure that SCP key authentication is properly configured, the following conditions must be met:

- Moab is running as root.
- You are able to issue the following command as the root user without being prompted for a password:

```
su - <DATASPACEUSER> -c "/usr/bin/ssh <destination host> -l <DATASPACEUSER> 'df
-k //tmp/ 2>&1 || echo FAILED'"
```

- You can SSH *<destination host>* without a password.

- The `dataSpaceLocalUser` and `dataSpaceMappedUser` variables in your `/opt/moab/etc/config.dstage.pl` script are set to the same username you assigned through `<DATASPACEUSER>`.

## Grid Security

### Secret Key Based Server Authentication

Secret key based security is required in order for the grid to work. It is enabled in the `moab-private.cfg` file. Configuration of `moab-private.cfg` is covered throughout the grid configuration documentation, as well as in [Appendix E: Security](#).

## Grid Diagnostics and Validation

- [Peer Management Overview](#)
- [Peer Diagnostic Overview](#)

### Peer Management Overview

- Use `mdiag -R` to view interface health and performance/usage statistics.
- Use `mrmctl` to enable/disable peer interfaces.
- Use `mrmctl -m` to dynamically modify/configure peer interfaces.

### Peer Diagnostic Overview

- Use `mdiag -R` to diagnose general RM interfaces.
- Use `mdiag -S` to diagnose general scheduler health.
- Use `mdiag -R -V job <RMID>` to diagnose peer-to-peer job migration.

```
> mdiag -R -V job peer1
```

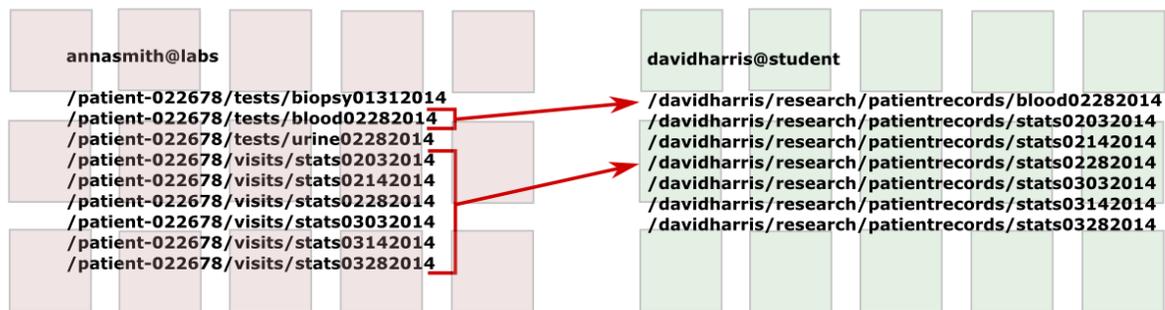

- Use `mdiag -R -V data <RMID>` to diagnose peer-to-peer data staging.
- Use `mdiag -R -V cred <RMID>` to diagnose peer-to-peer credential mapping.

# Data staging

## About data staging

Sometimes you might need a job to process data that resides at another site. With the proper configuration, you can submit your job with the requirement that it copies data from the external site to yours and, if needed, copy the job's resulting data out to the external site for its owner to use. Data staging is an out-of-band method of moving data without reserving compute nodes or other resources for it.

In the example below, which will appear throughout the chapter, a university researcher needs the results of tests done at a hospital. User  `davidharris`  on the  `student`  server of the university submits a job called  `Moab . 1`  that requires several files stored by user  `annasmith`  on the research server of the hospital.  `davidharris`  submitted  `Moab . 1`  with certain options in place that instruct Moab to copy the files to the  `/student/davidharris/research/patientrecords/`  directory on the  `student`  server prior to starting the job.

Moab currently supports the following data staging use cases: 1) Staging data to or from a shared file system, 2) Staging data to or from local node storage on a single compute node, and 3) Staging data to or from a shared file system on an unspecified cluster – resolved at job migration – in a grid configuration.

Before you can submit data staging jobs, you must configure certain generic metrics in your partitions, job templates, and the data staging submit filter for data staging scheduling, throttling, and policies.

Moab uses Linux file transfer utilities to stage the data and includes data staging reference scripts that support the  `scp`  and  `rsync`  Linux file transfer utilities. The scripts will work for standard installations, but you can customize the script to support data staging to and from an external staging server, the Moab server itself, or a local compute node, depending on your implementation. You can also customize your own script for other file transfer utilities, such as  `Aspera` .

Once you configure your system to support data staging, you can begin creating data staging jobs by attaching the  `--stagein` ,  `--stageinfile` ,  `--stageinsize` ,  `--stageout` ,  `--stageoutfile` , and  `--stageoutsize`  options to your  `msub`  commands. See [Staging data on page 299](#) for more information.

## How-to's

The following topics describe how to stage data in different Moab environments.

- [Configuring the SSH keys for the data staging transfer script on page 903](#)

## How-to's

### Configuring the SSH keys for the data staging transfer script

#### Context

For data staging to work correctly, you must configure SSH keys to allow the data staging scripts to run without passphrases. In the sample data staging server configuration shown in the image below, davidharris on the student server stages data from the source server student to the destination server labs. The computation occurs on the labs server before Moab stages the output data from labs back to student. The image below demonstrates the SSH connections necessary and how you should configure your SSH keys.

### Data staging server configuration

For more details on generating keys, see the [ssh-keygen man page](#) and "[SSH login without password](#)".

## To configure the SSH keys for the data staging transfer script

1. Generate a new SSH key on the Moab server (`university`) if one does not already exist. To do so, run each of the following steps.

- a. Run `ssh-keygen` to generate a public and private rsa key pair.

```
[davidharris@university]$ ssh-keygen
```

- b. Enter the name of the file where you want to store the key, or you can accept the default location.

```
/home/davidharris/.ssh/id_rsa
```

- c. When prompted for a passphrase, leave it blank and press **Enter**. Repeat when prompted to retype passphrase.

2. Install the public key on the source and destination hosts. Note that in this example the source host is `student` and the destination host is `labs`.

- a. Copy the `university` public key to `student`. Answer **yes** to continue connecting.

```
[davidharris@university]$ ssh-copy-id -i ~/.ssh/id_rsa.pub student
```

- b. Copy the `university` public key to `labs`. Answer **yes** to continue connecting.

```
[davidharris@university]$ ssh-copy-id -i ~/.ssh/id_rsa.pub labs
```

The next two steps generate a key-pair for each node. It is acceptable to generate a single key-pair and install it on each node. It does not matter where the key-pair is generated, so long as it is compatible with the SSH client/server.

3. Generate a key pair on the source host (`student`) and install the public key generated to the destination host (`labs`). When prompted for a passphrase, leave it blank and press **Enter**. Repeat when prompted to retype passphrase.

```
[davidharris@student]$ ssh-keygen
[davidharris@student]$ ssh-copy-id -i ~/.ssh/id_rsa.pub labs
```

4. Generate a key pair on the destination host (`labs`) and install the public key generated to the source host (`student`). When prompted for a passphrase, leave it blank and press **Enter**. Repeat when prompted to retype passphrase.

```
[davidharris@labs]$ ssh-keygen
[davidharris@labs]$ ssh-copy-id -i ~/.ssh/id_rsa.pub student
```

5. Ensure that each user who will run data staging jobs has read and write permissions on each source and destination server.

6. Test the configuration. To do so:

- a. Install the modules required to run the data staging scripts. `python-paramiko` is required for data staging, but `python-mock` is only required if you intend to run the unit test.

```
> yum install python-paramiko python-mock
```

- b. Transfer a file from the source host to the destination host to verify that the keys work for the users configured. To do so, run `/opt/moab/tools/data-staging/ds_move_scp --test=<source>%<destination>` if you use `scp` or `/opt/moab/tools/data-staging/ds_move_rsync --test=<source>%<destination>` script if you use `rsync`. `<source>%<destination>` is configured the same way as the `--stagein` and `--stageout` options for `msub`; for help configuring your source and destination, see [Staging a file or directory on page 299](#).

```
[davidharris@university]$ /opt/moab/tools/data-staging/ds_move_rsync --test=davidharris@student:/tmp/test%davidharris@labs:/tmp
```

- c. In the same way, transfer a file from the destination host to the source host to verify that the keys work for the users configured.

```
[davidharris@university]$ /opt/moab/tools/data-staging/ds_move_rsync --test=davidharris@labs:/tmp/test%davidharris@student:/test_processed
```

## Configuring data staging

### Context

You must modify your Moab configuration to enable data staging. In addition to the configuration steps described below, you might also consider customizing the configuration (including the associated scripts) to meet your site's specific needs.

For advanced configuration steps and options, see [Configuring data staging with advanced options on page 920](#).

### To configure data staging

1. Verify that your firewall and network are correctly configured to allow the scripts to operate as designed.
2. If you have not already done so, install the modules required to run the data staging scripts. `python-paramiko` is required for data staging, but `python-mock` is only required if you intend to run the unit test.

```
> yum install python-paramiko python-mock
```

3. If you have not already, follow the instructions found in [Configuring the SSH keys for the data staging transfer script on page 903](#).
4. Ensure that the data staging scripts are installed on your system. To do so, list the contents of the `/opt/moab/tools/data-staging` directory. You should see the data staging README file, reference scripts, and other related files.

```
> ls -l /opt/moab/tools/data-staging
```

You can copy and modify the reference scripts and configuration files to meet your specific needs. See the README file packaged in the `data-staging` directory for information about modifying these files.

5. Open your `moab.cfg` file for editing and do each of the following tasks:
  - a. Configure the data staging `msub` filter, located in `/opt/moab/tools/data-staging` by default, as a client-side filter. See [Applying the msub submit filter on page 303](#) for more information.

```
SUBMITFILTER /opt/moab/tools/data-staging/ds_filter
```

The data staging filter checks the `msub` argument syntax to verify that the arguments make sense and are consistent; attempts a dry run connection via SSH and the file transfer utility to ensure that keys exist for the user on the necessary systems; and attempts to determine the size of the data that will be transferred.

You can customize the script to meet your specific needs; the file contains detailed comments illustrating its default behavior to facilitate its modification. If you replace or modify the submit filter, it is your responsibility to ensure that the same functionality described in the paragraph above is present in your filter.

Note that this filter has the `DEFAULT_TEMPLATE` name which should match the name of the master data staging template in `moab.cfg`. For more information, see [Configuring data staging with advanced options on page 920](#).

- b. Set the data staging bandwidth gmetric (`DATASTAGINGBANDWIDTH_MBITS_PER_SEC`) on each partition associated with an RM to the rate at which its network to be used for data staging transfers data in megabits per second (see [Per-Partition Settings on page 497](#) for more information). Moab will use the specified rate and the data staging size specified at job submission (see [Stage in or out file size on page 301](#) for more information) to determine how long staging the data will take and to schedule the job as soon after data staging completes as possible.

#### Example 3-175: Non-grid

```
RMCFG[torque] Type=pbs
PARCFG[torque] GMETRIC[DATASTAGINGBANDWIDTH_MBITS_PER_SEC]=58
```

*Partition `torque` has a transfer rate of 58 megabits per second. Moab uses the rate when it estimates the time it will take to stage data in and determine when to schedule the job that will use the data.*

#### Example 3-176: Grid

```
RMCFG[m1] type=Moab
PARCFG[m1] GMETRIC[DATASTAGINGBANDWIDTH_MBITS_PER_SEC]=100
```

*Partition `m1` has a transfer rate of 100 megabits per second. Moab uses the rate when it estimates the time it will take to stage data in and determine when to schedule the job that will use the data.*

- c. Set the bandwidth generic resource on all nodes to limit the total number of concurrent data staging jobs in your system.

```
NODECFG[GLOBAL] GRES=bandwidth:10
```

*Data staging jobs can use up to 10 units of bandwidth on the system. You can specify the number of units consumed by each data staging job when you configure the data staging job templates.*

- 6. Install the msub client filter on all client submission hosts.

- [About data staging on page 901](#)

## Staging data to or from a shared file system

Context

In the most common data staging use case, the cluster utilizes a shared file system between all compute nodes. This type of data staging makes data stored outside of the cluster available to a job that will run on any set of nodes in the cluster. At the time of submission, you must specify where Moab will obtain the data with a username, host name, and path to a file or directory and where on the shared file system Moab will store the data. After the job runs, you can also copy data from the shared file system back to a remote file system.

Image 3-13: Data staging to or from a shared file system

## To stage data to or from a shared file system

1. If you have not already done so, configure your SSH keys and `moab.cfg` to support data staging. See [Configuring the SSH keys for the data staging transfer script on page 903](#) and [Configuring data staging on page 905](#) for more information.
2. Create your job templates for data staging jobs in `moab.cfg`. The templates in the example below create a compute job that stages data in before it starts and stages data out when it completes. For more information about creating job templates, see [About job templates on page 853](#).
  - a. Create a selectable master template, called `ds` in the example below, that creates a stage in and stage out system job. This name should match the `DEFAULT_TEMPLATE` value in `ds_config.py`. See [Configuring data staging with advanced options on page 920](#) for more information.
  - b. For the data staging in job template, called `dsin` in the example below, specify that it will create a data staging job by setting `DATASTAGINGJOB` to `TRUE`. Note that the name of this job template must match the name of the data stage in job template referenced in the master template.
  - c. Set the bandwidth `GRES` to the amount of bandwidth a single stage in job should use. This indicates how many of the bandwidth units specified with `NODECFG[GLOBAL]` in [Configuring data staging on page 905](#) a data staging job with this template should consume.
  - d. Add `FLAGS=GRESONLY` to indicate that this data staging job does not require any compute resources.
  - e. Create a trigger that executes the `ds_move_scp`, `ds_move_rsync`, or [ds move multiplex](#) script, depending on which file transfer utility you use. Set the `attacherror`, `objectxmlstdin`, and `user` `FLAGS` to attach any trigger stderr as a message to the job, pass the job XML to the script, and indicate that the script should run as the job's user, respectively.

**i** If you use the `rsync` protocol, you can configure your data staging jobs to report the actual number of bytes transferred and the total data size to be transferred. To do so, use the `Sets` attribute to `^BYTES_IN.^DATA_SIZE_IN` for stage in jobs and `^BYTES_OUT.^DATA_SIZE_OUT` for stage out jobs. For example, a stage in trigger would look like the following:

```
JOBCFG[dsin]
TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_move_rsync --stagein",Flags=objectxmlstdin:user:attacherror,Sets=^BYTES_IN.^DATA_SIZE_IN
```

A stage out trigger would look like the following:

```
JOBCFG[dsout]
TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_move_rsync --stageout",Flags=objectxmlstdin:user:attacherror,Sets=^BYTES_OUT.^DATA_SIZE_OUT
```

These variables show up as events if you set your `WIKIEVENTS` parameter to `TRUE`.

- f. Create the stage out job, called `dsout` in the example below, by repeating steps 2b - 2e in a new template. In the example below, this template is called `dsout`. Note that the name of this job

template must match the name of the data stage out job template referenced in the data staging master template.

```

JOBCFG[ds]      TEMPLATEDEPEND=AFTEROK:dsin  TEMPLATEDEPEND=BEFORE:dsout
SELECT=TRUE

JOBCFG[dsin]   DATASTAGINGSYSJOB=TRUE
JOBCFG[dsin]   GRES=bandwidth:2
JOBCFG[dsin]   FLAGS=GRESONLY
JOBCFG[dsin]   TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_rsync --stagein",Flags=attacherror:objectxmlstdin:user

JOBCFG[dsout]  DATASTAGINGSYSJOB=TRUE
JOBCFG[dsout]  GRES=bandwidth:1
JOBCFG[dsout]  FLAGS=GRESONLY
JOBCFG[dsout]  TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_rsync --stageout",Flags=attacherror:objectxmlstdin:user

```

3. Create the job using `msub`, adding resources and specifying a script as you normally would. Then configure Moab to stage the data for it. To do so:

- a. At the end of the command, use the `--stagein/--stageout` option and/or `--stageinfile/--stageoutfile` option.
  - The `--stagein/--stageout` option lets you specify a single file or directory to stage in or out. You must set the option equal to `<source>%<destination>`, where `<source>` and `<destination>` are both `[<user>@]<host>:/<path>/[<fileName>]`. See [Staging a file or directory on page 299](#) for format and details.

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

```
> msub --stagein=annasmith@labs:/patient-
022678/%davidharris@university:/davidharris/research/patientrecords
<jobScript>
```

*Moab copies the /patient-022678 directory from the hospital's labs server to the university cluster where the job will run prior to job start.*

- The `--stageinfile/--stageoutfile` option lets you specify a file that contains the file and/or directory name(s) to stage in or out. You must set the option equal to `<path>/<fileName>` of the file. The file must contain at least one line with this format: `<source>%<destination>`, where both `<source>` and `<destination>` are `[<user>@]<host>:/<path>/[<fileName>]`. See [Staging multiple files or directories on page 300](#) for more information.

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

```
> msub --stageinfile=/davidharris/research/recordlist <jobScript>
```

*Moab copies all files specified in the /davidharris/research/recordlist file to the cluster where the job will run prior to job start.*

```
/davidharris/research/recordlist:
```

```
annasmith@labs:/patient-
022678/tests/blood02282014%davidharris@university:/davidharris/research/patie
ntrecords/blood02282014
annasmith@labs:/patient-
022678/visits/stats02032014%davidharris@university:/davidharris/research/pati
entrecords/stats02032014
annasmith@labs:/patient-
022678/visits/stats02142014%davidharris@university:/davidharris/research/pati
entrecords/stats02142014
annasmith@labs:/patient-
022678/visits/stats02282014%davidharris@university:/davidharris/research/pati
entrecords/stats02282014
annasmith@labs:/patient-
022678/visits/stats03032014%davidharris@university:/davidharris/research/pati
entrecords/stats03032014
annasmith@labs:/patient-
022678/visits/stats03142014%davidharris@university:/davidharris/research/pati
entrecords/stats03142014
annasmith@labs:/patient-
022678/visits/stats03282014%davidharris@university:/davidharris/research/pati
entrecords/stats03282014
```

*Moab copies the seven patient record files from the hospital's labs server to the university cluster where the job will run prior to job start.*

- b. The `--stageinsize/--stageoutsize` option lets you specify the estimated size of the files and/or directories to help Moab more quickly and accurately calculate the amount of time it will take to stage the data and therefore schedule your job correctly. If you are staging data out, then setting `--stageoutsize` is required. If you provide an integer, Moab will assume the number is in megabytes. To change the unit, add another suffix. See [Stage in or out file size on page 301](#) for more information.

```
> msub --stageinfile=/davidharris/research/recordlist --stageinsize=100
<jobScript>
```

*Moab copies the /davidharris/research/recordlist file, which is approximately 100 megabytes, from the biology node to the host where the job will run prior to job start.*

4. To see the status, errors, and other details associated with your data staging job, run `checkjob -v`. See "[checkjob](#)" for details.

## Staging data to or from a shared file system in a grid

### Context

You can stage data in an environment where multiple instances of Moab run in a grid configuration. For this type of data staging, each cluster utilizes a shared file system with all compute nodes. This type of data staging will make data available to a job that will run on a set of nodes in one of the clusters in the grid. You must specify where the remote data can be obtained with a username, host name, and path to a file or directory and where on the shared storage Moab will store the data. The remote data source location is known at job submission time, but you must use the `$CLUSTERHOST` placeholder for the host name of the data transfer server on which the job will be scheduled. After the job runs, you can also copy data from the cluster shared file system to a remote file system.

Note that you cannot stage data to or from a local compute node with its own local storage in a grid environment.

Image 3-14: Data staging in a grid

## To stage data to or from a shared file system in a grid

1. If you have not already done so, configure your SSH keys and `moab.cfg` to support data staging. See [Configuring the SSH keys for the data staging transfer script on page 903](#) and [Configuring data staging on page 905](#) for more information.
2. Create your job templates for data staging jobs in `moab.cfg`. The templates in the example below create a compute job that stages data in before it starts and stages data out when it completes. For more information about creating job templates, see [About job templates on page 853](#).
  - a. Create a selectable master template, called `ds` in the example below, that creates a stage in and stage out system job. This name should match the `DEFAULT_TEMPLATE` value in `ds_config.py`. For more information, see [Configuring data staging with advanced options on page 920](#).
  - b. For the data staging in job template, called `dsin` in the example below, specify that it will create a data staging job by setting `DATASTAGINGJOB` to `TRUE`. Note that the name of this job template must match the name of the data stage in job template referenced in the master template.
  - c. Set the staging job template bandwidth `GRES` to the amount of bandwidth a single stage in job should use. This indicates how many of the bandwidth units specified with `NODECFG[GLOBAL]` in [Configuring data staging on page 905](#) a data staging job with this template should consume.
  - d. Set `JOBMIGRATEPOLICY` to `JUSTINTIME`.
  - e. Add `FLAGS=GRESONLY` to indicate that this data staging job does not require any compute resources.
  - f. Create a trigger that executes the `ds_move_scp`, `ds_move_rsync`, or `ds_move_multiplex` script, depending on which file transfer utility you use. Set the `attacherror`, `objectxmlstdin`, and `user` `FLAGS` to attach any trigger stderr as a message to the job, pass the job XML to the script, and indicate that the script should run as the job's user, respectively.

**i** If you use the `rsync` protocol, you can configure your data staging jobs to report the actual number of bytes transferred and the total data size to be transferred. To do so, use the `Sets` attribute to `^BYTES_IN.^DATA_SIZE_IN` for stage in jobs and `^BYTES_OUT.^DATA_SIZE_OUT` for stage out jobs. For example, a stage in trigger would look like the following:

```
JOBCFG[dsin]
TRIGGER=EType=start, AType=exec, Action="/opt/moab/tools/data-staging/ds_move_rsync --stagein", Flags=objectxmlstdin:user:attacherror, Sets=^BYTES_IN.^DATA_SIZE_IN
```

A stage out trigger would look like the following:

```
JOBCFG[dsout]
TRIGGER=EType=start, AType=exec, Action="/opt/moab/tools/data-staging/ds_move_rsync --stageout", Flags=objectxmlstdin:user:attacherror, Sets=^BYTES_OUT.^DATA_SIZE_OUT
```

These variables show up as events if you set your `WIKIEVENTS` parameter to `TRUE`.

- g. Create the stage out job, called `dsout` in the example below, by repeating steps 2b - 2f in a new template. In the example below, this template is called `dsout`. Note that the name of this job template must match the name of the data stage out job template referenced in the master template.

```

JOBCFG[ds]      TEMPLATEDEPEND=AFTEROK:dsin  TEMPLATEDEPEND=BEFORE:dsout
SELECT=TRUE

JOBCFG[dsin]   DATASTAGINGSYSJOB=TRUE
JOBCFG[dsin]   GRES=bandwidth:2
JOBCFG[dsin]   FLAGS=GRESONLY
JOBCFG[dsin]   TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_rsync --stagein",Flags=attacherror:objectxmlstdin:user

JOBCFG[dsout]  DATASTAGINGSYSJOB=TRUE
JOBCFG[dsout]  FLAGS=GRESONLY
JOBCFG[dsout]  INHERITRES=TRUE
JOBCFG[dsout]  TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_rsync --stageout",Flags=attacherror:objectxmlstdin:user

```

3. Create the job using `msub`, adding resources and specifying a script as you normally would. Then configure Moab to stage the data for it. To do so:

- a. At the end of the command, use the `--stagein/--stageout` option and/or `--stageinfile/--stageoutfile` option.

- The `--stagein/--stageout` option lets you specify a single file or directory to stage in or out. You must set the option equal to `<source>%<destination>`, where `<source>` and `<destination>` are both `[<user>@] <host>:/<path>/[<fileName>]`. See [Staging a file or directory on page 299](#) for format and details.

Note that if you do not know the cluster where the job will run but want the data staged to the same location, you can use the `$CLUSTERHOST` variable in place of a host. If you choose to use the `$CLUSTERHOST` variable, you must first customize the `ds_config.py` file. For more information, see [Configuring the \\$CLUSTERHOST variable on page 915](#).

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

```
> msub ... --stagein=annasmith@labs:/patient-022678/%\${CLUSTERHOST}/davidharris/research/patientrecords <jobScript>
```

*Moab copies the /patient-022678 directory from the hospital's labs server to the cluster where the job will run prior to job start.*

- The `--stageinfile/--stageoutfile` option lets you specify a file that contains the file(s) and directory(-ies) to stage in or out. You must set the option equal to `<path>/<fileName>` of the file. The file must contain at least one line with this format: `[<user>@] <host>:/<path>[<fileName>]`. See [Staging multiple files or directories on page 300](#) for more information.

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

```
> msub ... --stageinfile=/davidharris/research/recordlist <jobScript>
```

*Moab copies all files specified in the /davidharris/research/recordlist file to the cluster where the job will run prior to job start.*

```
/davidharris/research/recordlist:
```

```
annasmith@labs:/patient-022678/tests/blood02282014%$CLUSTERHOST:/davidharris/research/patientrecords/blood02282014
annasmith@labs:/patient-022678/visits/stats02032014%$CLUSTERHOST:/davidharris/research/patientrecords/stats02032014
annasmith@labs:/patient-022678/visits/stats02142014%$CLUSTERHOST:/davidharris/research/patientrecords/stats02142014
annasmith@labs:/patient-022678/visits/stats02282014%$CLUSTERHOST:/davidharris/research/patientrecords/stats02282014
annasmith@labs:/patient-022678/visits/stats03032014%$CLUSTERHOST:/davidharris/research/patientrecords/stats03032014
annasmith@labs:/patient-022678/visits/stats03142014%$CLUSTERHOST:/davidharris/research/patientrecords/stats03142014
annasmith@labs:/patient-022678/visits/stats03282014%$CLUSTERHOST:/davidharris/research/patientrecords/stats03282014
```

*Moab copies the seven patient record files from the hospital's labs server to the cluster where the job will run prior to job start.*

- b. The `--stageinsize/--stageoutsize` option lets you specify the estimated size of the files and/or directories to help Moab more quickly and accurately calculate the amount of time it will take to stage the data and therefore schedule your job correctly. If you used the `$CLUSTERHOST` variable to stage in, then setting `--stageinsize` is required. `--stageoutsize` is always required for staging data out. If you provide an integer, Moab will assume the number is in megabytes. To change the unit, add another suffix. See [Stage in or out file size on page 301](#) for more information.

```
> msub ... --stageinfile=/davidharris/research/recordlist --stageinsize=100 <jobScript>
```

*Moab copies the /davidharris/research/recordlist file, which is approximately 100 megabytes, from the biology node to the host where the job will run prior to job start.*

4. To see the status, errors, and other details associated with your data staging job, run `checkjob -v`. See "[checkjob](#)" for details.

## Configuring the \$CLUSTERHOST variable

### Context

When you submit a data staging job in a grid environment, you can use the `$CLUSTERHOST` variable instead of specifying a destination if you do not know the cluster where the job will run but want the data staged to the same location. Before the variable will work correctly, you must first configure it by customizing the `ds_config.py` script to match your unique system.

#### Use case

In a grid with three clusters, you have a partition named `master` where you want all data staged to a host named `gridheadNAS`; a partition named `csdept` where you want all data staged to a host named `fs001.cs.example.edu`; and a partition named `lab` where you want all data staged to a host named `bigfilesystem`.

## To configure the \$CLUSTERHOST variable

1. Open the `ds_config.py` file for modification. It is located in `/opt/moab/tools/data-staging/` by default.

```
[moab]$ vi /opt/moab/tools/data-staging/ds_config.py
```

2. Locate the `PARTITION_TO_HOST` parameter.

```
...
PARTITION_TO_HOST = {"partition_1_name": "cluster_1_staging_hostname",
                    "partition_2_name": "cluster_2_staging_hostname",
                    "partition_3_name": "cluster_3_staging_hostname"}
...
```

3. Replace the partition names and associated cluster hostnames with those that match your system. For the use case provided above, you would customize it the following way:

```
...
PARTITION_TO_HOST = {"master": "gridheadNAS",
                    "csdept": "fs001.cs.example.edu",
                    "lab": "bigfilesystem"}
...
```

## Staging data to or from a compute node

### Context

You can stage data to or from a local compute node in an environment where each node on the cluster has local storage. This type of data staging will make data stored outside the cluster available to a job that will run on a single node in the cluster. You must specify the username, host name, and path to a file or directory and a location on the compute node where Moab will store the data. You will supply the remote data source location at job submission time, but you must use the `$JOBHOST` placeholder for the name of the compute node. After the job runs, you can also copy data from the local file system to a remote file system.

Image 3-15: Data staging to or from a local compute node

Before staging data to or from a local compute node, please follow the procedure in [Configuring data staging on page 905](#).

### To stage data to or from a local compute node

1. If you have not already done so, configure your SSH keys and `moab.cfg` to support data staging. See [Configuring the SSH keys for the data staging transfer script on page 903](#) and [Configuring data staging on page 905](#) for more information.
2. Create your job templates for data staging jobs in `moab.cfg`. The templates in the example below create a compute job that stages data in before it starts and stages data out when it completes. For more information about creating job templates, see [About job templates on page 853](#).
  - a. Create a selectable master template, called `ds` in the example below, that creates a stage in and stage out system job. This name should match the `DEFAULT_TEMPLATE` value in `ds_config.py`.

For more information, see [Configuring data staging with advanced options on page 920](#).

- b. For the data staging in job template, called `dsin` in the example below, specify that it will create a data staging job by setting **DATASTAGINGJOB** to *TRUE*. Note that the name of this job template must match the name of the data stage in job template referenced in the master template.
- c. Set the staging job template bandwidth **GRES** to the amount of bandwidth a single stage in job should use. This indicates how many of the bandwidth units specified with **NODECFG** [GLOBAL] in [Configuring data staging on page 905](#) a data staging job with this template should consume.
- d. For local node data staging it is important that the data staging job has the entire node to itself. To prevent Moab from scheduling another job on the node at the same time as the data staging job, set the **NODEACCESSPOLICY** to *SINGLEJOB* in the staging job template.
- e. Add **INHERITRES=TRUE** to reserve the compute node for the data staging job to prevent other compute jobs from using the node at the same time and creating input, output, and disk conflicts with the data staging job.
- f. Create a trigger that executes the `ds_move_scp`, `ds_move_rsync`, or `ds_move_multiplex` script, depending on which file transfer utility you use. Set the *attacherror*, *objectxmlstdin*, and *user* **FLAGS** to attach any trigger stderr as a message to the job, pass the job XML to the script, and indicate that the script should run as the job's user, respectively.

**i** If you use the rsync protocol, you can configure your data staging jobs to report the actual number of bytes transferred and the total data size to be transferred. To do so, use the **Sets** attribute to `^BYTES_IN.^DATA_SIZE_IN` for stage in jobs and `^BYTES_OUT.^DATA_SIZE_OUT` for stage out jobs. For example, a stage in trigger would look like the following:

```

JOBCFG[dsin]
TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_
move_rsync --stagein",Flags=objectxmlstdin:user:attacherror,Sets=^BYTES_
IN.^DATA_SIZE_IN

```

A stage out trigger would look like the following:

```

JOBCFG[dsout]
TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_
move_rsync --stageout",Flags=objectxmlstdin:user:attacherror,Sets=^BYTES_
OUT.^DATA_SIZE_OUT

```

These variables show up as events if you set your **WIKIEVENTS** parameter to *TRUE*.

- g. Create the stage out job, called `dsout` in the example below, by repeating steps 2b - 2f in a new template. In the example below, this template is called `dsout`. Note that the name of this job template must match the name of the data stage out job template referenced in the data staging master template.

```

JOBCFG[ds]      TEMPLATEDEPEND=AFTEROK:dsin  TEMPLATEDEPEND=BEFORE:dsout
SELECT=TRUE

JOBCFG[dsin]    DATASTAGINGSYSJOB=TRUE
JOBCFG[dsin]    GRES=bandwidth:2
JOBCFG[dsin]    NODEACCESSPOLICY=SINGLEJOB
JOBCFG[dsin]    INHERITRES=TRUE
JOBCFG[dsin]    TRIGGER=EType=start, AType=exec, Action="/opt/moab/tools/data-
staging/ds_move_rsync --stagein", Flags=attacherror:objectxmlstdin:user

JOBCFG[dsout]   DATASTAGINGSYSJOB=TRUE
JOBCFG[dsout]   GRES=bandwidth:1
JOBCFG[dsout]   NODEACCESSPOLICY=SINGLEJOB
JOBCFG[dsout]   INHERITRES=TRUE
JOBCFG[dsout]   TRIGGER=EType=start, AType=exec, Action="/opt/moab/tools/data-
staging/ds_move_rsync --stageout", Flags=attacherror:objectxmlstdin:user

```

3. Create the job using `msub`, adding resources and specifying a script as you normally would. Then configure Moab to stage the data for it. To do so:

- a. If the compute job does not use all of the node's processors, Moab could schedule another job on the node at the same time. If you did not set **NODEACCESSPOLICY** to **SINGLEJOB** in your `moab.cfg`, set the policy for this job by adding `-l naccesspolicy=singlejob` to your `msub` command.

```
> msub -l naccesspolicy=singlejob... <jobScript>
```

- b. At the end of the command, use the `--stagein/--stageout` option and/or `--stageinfile/--stageoutfile` option.
  - The `--stagein/--stageout` option lets you specify a single file or directory to stage in or out. You must set the option equal to `<source>%<destination>`, where `<source>` and `<destination>` are both `[<user>@]<host>:/<path>/[<fileName>]`. See [Staging a file or directory on page 299](#) for format and details.

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

If you do not know the host where the job will run but want the data staged to the same location, you can use the `$JOBHOST` variable in place of a host.

```
> msub --stagein=annasmith@labs:/patient-022678/%$JOBHOST:/davidharris/research/patientrecords <jobScript>
```

*Moab copies the /patient-022678 directory from the hospital's labs server to the node where the job will run prior to job start.*

- The `--stageinfile/--stageoutfile` option lets you specify a file that contains the file and directory name(s) to stage in or out. You must set the option equal to `<path>/<fileName>%` of the file. The file must contain at least one line with this format: `<source>%<destination>`, where `<source>` and `<destination>` are both `[<user>@]<host>:/<path>/[<fileName>]`. See [Staging multiple files or directories on page 300](#) for more information.

**i** If the destination partition is down or does not have configured resources, the data staging workflow submission will fail.

```
> msub --stageinfile=/davidharris/research/recordlist <jobScript>
```

*Moab copies all files specified in the /davidharris/research/recordlist file to the host where the job will run prior to job start.*

```
/davidharris/research/recordlist:
```

```
annasmith@labs:/patient-
022678/tests/blood02282014%$JOBHOST:/davidharris/research/patientrecords/blood
02282014
annasmith@labs:/patient-
022678/visits/stats02032014%$JOBHOST:/davidharris/research/patientrecords/stat
s02032014
annasmith@labs:/patient-
022678/visits/stats02142014%$JOBHOST:/davidharris/research/patientrecords/stat
s02142014
annasmith@labs:/patient-
022678/visits/stats02282014%$JOBHOST:/davidharris/research/patientrecords/stat
s02282014
annasmith@labs:/patient-
022678/visits/stats03032014%$JOBHOST:/davidharris/research/patientrecords/stat
s03032014
annasmith@labs:/patient-
022678/visits/stats03142014%$JOBHOST:/davidharris/research/patientrecords/stat
s03142014
annasmith@labs:/patient-
022678/visits/stats03282014%$JOBHOST:/davidharris/research/patientrecords/stat
s03282014
```

*Moab copies the seven patient record files from the hospital's labs server to the host where the job will run prior to job start.*

- c. The `--stageinsize/--stageoutsize` option lets you specify the estimated size of the files and/or directories to help Moab more quickly and accurately calculate the amount of time it will take to stage the data and therefore schedule your job correctly. If you used the `$JOBHOST` variable to stage in, then setting `--stageinsize` is required. `--stageoutsize` is always required for staging data out. If you provide an integer, Moab will assume the number is in megabytes. To change the unit, add another suffix. See [Stage in or out file size on page 301](#) for more information.

```
> msub --stageinfile=/davidharris/research/recordlist --stageinsize=100
<jobScript>
```

*Moab copies the /davidharris/research/recordlist file, which is approximately 100 megabytes, from the biology node to the host where the job will run prior to job start.*

4. To see the status, errors, and other details associated with your data staging job, run `checkjob -v`. See "[checkjob](#)" for details.

**i** Your `checkjob` output may include a warning that says "req 1 RM (internal) does not match job destination RM". You can safely ignore this message.

## Configuring data staging with advanced options

### Using a different default template name

When you submit a data staging job, a data staging job template is attached to the job automatically. In the reference script configuration, the default template name is `ds`. This is the template that will be attached to the compute job by the client `msub` filter.

If you would like to change the name of the default template that is automatically attached, you should change the value of `DEFAULT_TEMPLATE` in the `ds_config.py` file installed on all client submit hosts. This name must match the master data staging template name specified in the Moab configuration file.

#### To configure the `DEFAULT_TEMPLATE` variable

1. Open the `ds_config.py` file for modification. It is located in `/opt/moab/tools/data-staging/` by default.

```
[moab]$ vi /opt/moab/tools/data-staging/ds_config.py
```

2. Locate the `DEFAULT_PARTITION` parameter.

```
...
DEFAULT_TEMPLATE = "ds"
...
```

3. Replace the template name with the one specified in the Moab configuration file.

```
ds_config.py
...
DEFAULT_TEMPLATE = "datastaging"
...

moab.cfg
...
JOBCFG[datastaging] TEMPLATEDEPEND=...
```

4. Make these changes on all client submit hosts.

### Supporting multiple file transfer script utilities in a grid on a per-partition basis

If you want a different transfer script to run based on which partition the job is submitted to, you can configure a multiplexer script that will switch execution to various other scripts based on the partition.

## To support multiple file transfer script utilities in a grid on a per-partition basis

1. Configure the trigger in your job templates in `moab.cfg` to run `ds_move_multiplex` instead of `ds_move_rsync` or `ds_move_scp`.
2. Configure the `PARTITION_TO_SCRIPT` variable in `ds_config.py` to provide a mapping from each partition to the desired script to run.
  - a. Open the `ds_config.py` file for modification. It is located in `/opt/moab/tools/data-staging/` by default.

```
[moab]$ vi /opt/moab/tools/data-staging/ds_config.py
```

- b. Locate the `PARTITION_TO_SCRIPT` parameter.

```
...
PARTITION_TO_SCRIPT =
{"partition_1_name": "/opt/moab/tools/data-staging/ds_move_rsync",
 "partition_2_name": "/opt/moab/tools/data-staging/ds_move_scp",
 "partition_3_name": "/opt/moab/tools/data-staging/ds_move_rsync"}
...
```

- c. Replace the `partition_*_names` with partitions that exist in your configuration. After each partition, specify the script that you want to execute for that partition.

## Receiving notification at the completion of the data staging job

If you want explicit notification in case of failure of the stage out job, add an additional trigger to the `dsout` job template which will send email notification to the job's submitter. For more information, see [Using a trigger to send email on page 752](#).

```
JOBCFG[dsout]  DATASTAGINGSYSJOB=TRUE
JOBCFG[dsout]  GRES=bandwidth:1
JOBCFG[dsout]  FLAGS=GRESONLY
JOBCFG[dsout]  TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_
move_rsync --stageout",Flags=attacherror:objectxmlstdin:user
JOBCFG[dsout]  TRIGGER=EType=fail,AType=mail,Action="Your (stageout) data staging job
$OID failed."
```

The first trigger listed in the template configuration should be the `exec` trigger. Add the email trigger and any other triggers after the `exec` trigger. You can modify the email trigger to run at completion rather than at failure. You can also add this type of trigger to stage in jobs.

## Adding a non-default template via `msub`

You can have multiple data staging template workflows defined in the `moab.cfg`. The submit filter is configured to add only one of them by default. If you wish to use one of the other available templates, you can do so by using the `-l template=TEMPLATENAME` option in the `msub` command:

Given the following `moab.cfg`:

```
#Default data staging template:
JOBCFG[ds]      TEMPLATEDEPEND=AFTEROK:dsin TEMPLATEDEPEND=BEFORE:dsout SELECT=TRUE
JOBCFG[dsin]   DATASTAGINGSYSJOB=TRUE
JOBCFG[dsin]   GRES=bandwidth:2
JOBCFG[dsin]   FLAGS=GRESONLY
JOBCFG[dsin]   TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_
move_rsync --stagein",Flags=attacherror:objectxmlstdin:user

JOBCFG[dsout]  DATASTAGINGSYSJOB=TRUE
JOBCFG[dsout]  GRES=bandwidth:1
JOBCFG[dsout]  FLAGS=GRESONLY
JOBCFG[dsout]  TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-staging/ds_
move_rsync --stageout",Flags=attacherror:objectxmlstdin:user

#experimental data staging template:
JOBCFG[dscustom] TEMPLATEDEPEND=AFTEROK:dscustomin
TEMPLATEDPEND=BEFORE:dscustomout SELECT=TRUE
JOBCFG[dscustomin] DATASTAGINGSYSJOB=TRUE
JOBCFG[dscustomin] GRES=bandwidth:2
JOBCFG[dscustomin] FLAGS=GRESONLY
JOBCFG[dscustomin] TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_custom --stagein",Flags=attacherror:objectxmlstdin:user

JOBCFG[dscustomout] DATASTAGINGSYSJOB=TRUE
JOBCFG[dscustomout] GRES=bandwidth:1
JOBCFG[dscustomout] FLAGS=GRESONLY
JOBCFG[dscustomout] TRIGGER=EType=start,AType=exec,Action="/opt/moab/tools/data-
staging/ds_move_custom --stageout",Flags=attacherror:objectxmlstdin:user
```

The user could submit a job using the custom data staging template with the following command:

```
[moab]$ msub -l template=dscustom ...
```

## Using msub to return all the job IDs in the workflow at submission time

By default, `msub` will print the job ID to stdout at the time of submission. If you would like to have `msub` print all of the jobs that are created as part of the data staging workflow template, you can use the `msub --workflowjobids` option to show all the job IDs at submission time:

```
$ echo sleep 60 | msub -l walltime=15 --workflowjobids
MoabA.3.dsin MoabA.3 MoabA.3.dsout
```

This could be useful if you are writing scripts to do your own workflows and you need to programmatically capture the data stage out job name for use in your workflow.

# Appendices

## Appendix A: Moab Parameters

See the [Parameters Overview](#) in the Moab Admin Manual for further information about specifying parameters.

Index: [A](#) [B](#) [C](#) [D](#) [E](#) [F](#) [G](#) [H](#) [I](#) [J](#) [K](#) [L](#) [M](#) [N](#) [O](#) [P](#) [Q](#) [R](#) [S](#) [T](#) [U](#) [V](#) [W](#) [X](#) [Y](#) [Z](#)

ACCOUNTCFG[<ACCOUNTID>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">General Credential Flags</a> , <b>CHARGERATE</b> , <a href="#">PRIORITY</a> , <a href="#">ENABLEPROFILING</a> , <a href="#">MEMBERULIST</a> , <b>PLIST</b> , <b>QDEF</b> , <b>QLIST</b> , <a href="#">usage limit</a> , or a <a href="#">fairness usage limit</a> specification ( <a href="#">FSCAP</a> , <a href="#">FSTARGET</a> , and <a href="#">FSWEIGHT</a> ).
<b>Default</b>	---
<b>Description</b>	Specifies account specific attributes. See the <a href="#">account</a> overview for general information and the <a href="#">job flag overview</a> for a description of legal flag values.
<b>Example</b>	<pre>ACCOUNTCFG[projectX] MAXJOB=50 QDEF=highprio</pre> <p><i>Up to 50 jobs submitted under the account ID projectX will be allowed to execute simultaneously and will be assigned the QOS highprio by default.</i></p>

ACCOUNTINGINTERFACEURL	
<b>Format</b>	<URL> where protocol can be one of <b>exec</b> or <b>file</b>
<b>Default</b>	---
<b>Description</b>	Specifies the interface to use for real-time export of Moab accounting/auditing information. See <a href="#">Exporting Events in Real-Time</a> for more information.
<b>Example</b>	<pre>ACCOUNTINGINTERFACEURL exec:/// \$TOOLS DIR/dumpacc.pl</pre>

ACCOUNTWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the priority weight to be applied to the specified account priority. See <a href="#">Credential (CRED) Factor</a> .
<b>Example</b>	<pre>ACCOUNTWEIGHT 100</pre>

ADMIN <sub>1</sub> , ADMIN <sub>2</sub> , ADMIN <sub>3</sub>	
<b>Format</b>	Space-delimited list of user names
<b>Default</b>	<i>root</i>
<b>Description</b>	Deprecated. Use <a href="#">ADMINCFG</a> . Users listed under the parameter <b>ADMIN<sub>i</sub></b> are allowed to perform any scheduling function. They have full control over the scheduler and access to all data. The first user listed in the <b>ADMIN<sub>i</sub></b> user list is considered to be the 'primary admin' and is the ID under which Moab must be started and run. Valid values include user names or the keyword 'ALL'. Again, these parameters are deprecated; use <a href="#">ADMINCFG</a> .
<b>Example</b>	<pre>ADMIN1 moabuser steve scott jenny</pre> <i>All users listed have full access to Moab control commands and Moab data. Moab must be started by and run under the <b>moabuser</b> user id since <b>moabuser</b> is the primary admin.</i>

ADMINCFG[X]	
<b>Format</b>	One or more <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <b>ENABLEPROXY</b> , <b>USERS</b> , <b>GROUPS</b> , <b>SERVICES</b> , or <b>NAME</b>
<b>Default</b>	---
<b>Description</b>	Allows a site to configure which services and users belong to a particular level of administration. <b>Note:</b> The first user listed in the <b>ADMINCFG[1]</b> users list is considered to be the primary admin. The option <b>USERS=ALL</b> is allowed. The groups list adds the groups' users as if they were listed individually as <b>USERS</b> . To prevent Moab from assigning a primary user from the first group listed, you must specify a primary user first using the <b>USERS</b> attribute, then list the desired groups.
<b>Example</b>	<pre>ADMINCFG[1] USERS=root, john ADMINCFG[1] GROUPS=admin ADMINCFG[1] SERVICES=ALL ADMINCFG[1] NAME=batchadmin ADMINCFG[3] USERS=bob, carol, smoore ADMINCFG[3] GROUPS=science, math ADMINCFG[3] SERVICES=mjobctl, mcredctl, runjob ADMINCFG[3] NAME=helpdesk</pre> <p><i>Members of the <b>batchadmin</b> admin role and members of the <b>admin</b> group are allowed to run all commands. Members of the <b>helpdesk</b> role and <b>science</b> and <b>math</b> groups are allowed to run <b>mjobctl</b>. They are also able to view and modify credential objects (i.e. users, groups, accounts, etc.) See the <a href="#">security overview</a> for more details.</i></p> <pre>ADMINCFG[4] USERS=ALL SERVICES=checknode</pre> <p><i>All users can execute <b>mdiag -n</b> or <b>checknode</b> to get information on any node.</i></p>

AGGREGATENODEACTIONS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	<p>Consolidates queued node actions into as few actions as possible to reduce communication burden with resource manager. Node actions are queued until the <a href="#">AGGREGATENODEACTIONSTIME</a> setting.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> This may delay some node actions. When reprovisioning, the system job may expire before the provision action occurs; while the action will still occur, the job will not show it.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-bottom: 5px;"> <pre>AGGREGATENODEACTIONS TRUE</pre> </div> <div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-left: 20px;"> <p><i>Queues node actions together when possible.</i></p> </div>

AGGREGATENODEACTIONSTIME	
<b>Format</b>	<SECONDS>
<b>Default</b>	60
<b>Description</b>	<p>The delay time for the <a href="#">AGGREGATENODEACTIONS</a> parameter to aggregate requests before sending job batches.</p>
<b>Example</b>	<div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-bottom: 5px;"> <pre>AGGREGATENODEACTIONSTIME 120</pre> </div> <div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-left: 20px;"> <p><i>Sets the <b>AGGREGATENODEACTIONS</b> delay to two minutes.</i></p> </div>

ALLOWMULTIREQNODEUSE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	By default Moab does not allow different requirements on the same job to occupy the same node. For example, if a job is submitted with <code>nodes=2:ppn=8+4:fast:ppn=16</code> , it's possible that some of the tasks requested could overlap onto the same node. This parameter instructs Moab to allow overlapping the same node, or not. This parameter also applies to the various <code>-w</code> clauses of an <a href="#">mshow -a on page 272</a> command.
<b>Example</b>	<pre>ALLOWMULTIREQNODEUSE TRUE</pre>

ALLOWROOTJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether batch jobs from the root user (UID=0) are allowed to be executed. <b>Note:</b> The resource manager must also support root jobs.
<b>Example</b>	<pre>ALLOWROOTJOBS TRUE</pre> <i>Jobs from the root user can execute.</i>

ALLOWVMMIGRATION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Enables Moab to migrate VMs.
<b>Example</b>	<pre>ALLOWVMMIGRATION TRUE</pre>

ALWAYSEVALUATEALLJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	When scheduling priority jobs, Moab stops scheduling when it encounters the first job that cannot run and cannot get a reservation. <b>ALWAYSEVALUATEALLJOBS</b> directs Moab to continue scheduling until all priority jobs (jobs that do not violate any limits) are evaluated.
<b>Example</b>	<pre>ALWAYSEVALUATEALLJOBS TRUE</pre>

AMCFG	
<b>Format</b>	One or more key-value pairs as described in the Allocation Manager Configuration Overview.
<b>Default</b>	---
<b>Description</b>	Specifies the interface and policy configuration for the scheduler-allocation manager interface. Described in detail in the Allocation Manager Configuration Overview.
<b>Example</b>	<pre>AMCFG[mam] SERVER=mam://master.ufl.edu STARTFAILUREACTION=HOLD TIMEOUT=15</pre>

APPLICATIONLIST	
<b>Format</b>	Space-delimited list of generic resources.
<b>Default</b>	---
<b>Description</b>	Specifies which generic resources represent actual applications on the cluster/grid. See <a href="#">Managing Consumable Generic Resources</a> for more information.
<b>Example</b>	<pre>NODECFG[node01] GRES=calclab:1,powerhouse:1 RCSOFTWARE=calclab:1,powerhouse:1 NODECFG[node02] GRES=calclab:1,powerhouse:1 RCSOFTWARE=calclab:1,powerhouse:1 APPLICATIONLIST calclab,powerhouse</pre> <p><i>The generic resources <b>calclab</b> and <b>powerhouse</b> will now be recognized and treated as application software.</i></p>

ARRAYJOBPARLOCK	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , all sub jobs of an array are locked to a single partition. The default behavior when scheduling array sub jobs is to span the jobs across partitions when possible. The <a href="#">ARRAYJOBPARLOCK</a> job flag can be used to specify partition locking at submit time. The <a href="#">ARRAYJOBPARSPAN</a> job flag overrides this parameter.
<b>Example</b>	<pre>ARRAYJOBPARLOCK TRUE</pre>

ASSIGNVLANFEATURES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	When set to <i>TRUE</i> , this forces all VMs to be contained in VLANs.
<b>Example</b>	<pre>ASSIGNVLANFEATURES TRUE</pre>

ATTRATTRWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>0</i>
<b>Description</b>	Specifies the priority weight to be applied to jobs with the specified job attribute. See <a href="#">Attribute (ATTR) Factor</a> .
<b>Example</b>	<pre>ATTRATTRWEIGHT 100</pre>

ATTRGRESWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight to be applied to jobs requesting the specified <a href="#">generic resource</a> . See <a href="#">Attribute (ATTR) Factor</a> .
<b>Example</b>	<pre>ATTRGRESWEIGHT 200</pre>

ATTRSTATEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight to be applied to jobs with the specified job state. See <a href="#">Attribute (ATTR) Factor</a> .
<b>Example</b>	<pre>ATTRSTATEWEIGHT 200</pre>

ATTRWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the priority component weight to be applied to the ATTR subcomponents. See <a href="#">Attribute (ATTR) Factor</a> .
<b>Example</b>	<pre>ATTRWEIGHT 2 ATTRSTATEWEIGHT 200</pre>

BACKFILLDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (no limit)
<b>Description</b>	Specifies the number of idle jobs to evaluate for backfill. The backfill algorithm will evaluate the top <X> priority jobs for scheduling. By default, all jobs are evaluated.
<b>Example</b>	<pre>BACKFILLDEPTH 128</pre> <p><i>Evaluate only the top 128 highest priority idle jobs for consideration for backfill.</i></p>

BACKFILLPOLICY	
<b>Format</b>	One of <i>FIRSTFIT</i> or <i>NONE</i>
<b>Default</b>	<i>FIRSTFIT</i>
<b>Description</b>	Specifies which backfill <a href="#">algorithm</a> will be used. See <a href="#">Configuring Backfill</a> for more information.
<b>Example</b>	<pre>BACKFILLPOLICY NONE</pre>

BFCHUNKDURATION	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0 (chunking disabled)
<b>Description</b>	Specifies the duration during which freed resources will be aggregated for use by larger jobs. Used in conjunction with <a href="#">BFCHUNKSIZE on page 932</a> . See <a href="#">Configuring Backfill</a> for more information.
<b>Example</b>	<pre>BFCHUNKDURATION 00:05:00 BFCHUNKSIZE 4</pre> <p><i>Aggregate backfillable resources for up to 5 minutes, making resources available only to jobs of size 4 or larger.</i></p>

BFCHUNKSIZE	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (chunking disabled)
<b>Description</b>	Specifies the minimum job size which can utilize chunked resources. Used in conjunction with <a href="#">BFCHUNKDURATION</a> on page 931. See <a href="#">Configuring Backfill</a> for more information.
<b>Example</b>	<pre>BFCHUNKDURATION 00:05:00 BFCHUNKSIZE      4</pre> <p><i>Aggregate backfillable resources for up to 5 minutes, making resources available only to jobs of size 4 or larger.</i></p>

BFMINVIRTUALWALLTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	Specifies the minimum job wallclock time for virtual scaling (optimistic-like backfilling.) Any job with a wallclock time less than this setting will <i>not</i> be virtually scaled. The value specified relates to a job's original walltime and not its virtually-scaled walltime.
<b>Example</b>	<pre>BFMINVIRTUALWALLTIME 00:01:30</pre>

BFPRIORITYPOLICY	
<b>Format</b>	One of <i>RANDOM</i> , <i>DURATION</i> , or <i>HWDURATION</i>
<b>Default</b>	---
<b>Description</b>	Specifies policy to use when prioritizing backfill jobs for <a href="#">preemption</a>
<b>Example</b>	<pre>BFPRIORITYPOLICY DURATION</pre> <p><i>Use length of job in determining which backfill job to preempt.</i></p>

BFVIRTUALWALLTIMECONFLICTPOLICY	
<b>Format</b>	One of the following: <i>PREEMPT</i>
<b>Default</b>	---
<b>Description</b>	Specifies how to handle scheduling conflicts when a virtually scaled job "expands" to its original wallclock time. This occurs when the job is within one scheduling iteration - <a href="#">RMPOLLINTERVAL on page 1036</a> - of its virtually scaled wallclock time expiring.
<b>Example</b>	<pre>BFVIRTUALWALLTIMECONFLICTPOLICY PREEMPT</pre>

BFVIRTUALWALLTIMESCALINGFACTOR	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (virtual scaling disabled)
<b>Description</b>	Specifies the factor by which eligible jobs' wallclock time is virtually scaled (optimistic-like backfilling).
<b>Example</b>	<pre>BFVIRTUALWALLTIMESCALINGFACTOR .4</pre>

BYPASSCAP	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the max weighted value allowed from the bypass count subfactor when determining a job's priority (see <a href="#">Priority Factors</a> for more information).
<b>Example</b>	<pre>BYPASSWEIGHT 5000 BYPASSCAP 30000</pre>

BYPASSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight to be applied to a job's backfill bypass count when determining a job's priority (see <a href="#">Priority Factors</a> for more information).
<b>Example</b>	<pre>BYPASSWEIGHT 5000</pre>

CHECKPOINTDIR	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the directory for temporary job checkpoint files (usually of the form <code>jobid.cp</code> ). This is <i>not</i> the directory for Moab's checkpoint file ( <code>.moab.ck</code> ).
<b>Example</b>	<pre>CHECKPOINTDIR /tmp/moabcheckpoint</pre>

CHECKPOINTEXPIRATIONTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS or <i>UNLIMITED</i>
<b>Default</b>	<i>3,000,000 seconds</i>
<b>Description</b>	Specifies how 'stale' checkpoint data can be before it is ignored and purged.
<b>Example</b>	<pre>CHECKPOINTEXPIRATIONTIME 1:00:00:00</pre> <p><i>Expire checkpoint data which has been stale for over 1 day.</i></p>

CHECKPOINTFILE	
<b>Format</b>	<STRING>
<b>Default</b>	<i>moab.ck</i>
<b>Description</b>	Name (absolute or relative) of the Moab checkpoint file.
<b>Example</b>	<pre>CHECKPOINTFILE /var/adm/moab/moab.ck</pre> <p><i>Maintain the Moab checkpoint file in the file specified.</i></p>

CHECKPOINTINTERVAL	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	<i>00:05:00</i>
<b>Description</b>	<p>Time between automatic Moab checkpoints.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p><b>i</b> If <b>RMPOLLINTERVAL</b> on page 1036 does not specify both a minimum and maximum poll time, Moab will ignore <b>CHECKPOINTINTERVAL</b> and checkpoint every iteration.</p> </div>
<b>Example</b>	<pre>CHECKPOINTINTERVAL 00:15:00</pre> <p><i>Moab should checkpoint state information every 15 minutes.</i></p>

CHECKPOINTWITHDATABASE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , Moab stores checkpoint information to a database rather than to the <code>.moab.ck</code> flat text file.
<b>Example</b>	<pre>CHECKPOINTWITHDATABASE TRUE</pre>

CHECKSUSPENDEDJOBPRIORITY	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	Prevents Moab from starting a job on any node containing a suspended job of higher priority.
<b>Example</b>	<pre>CHECKSUSPENDEDJOBPRIORITY FALSE</pre>

CHILDSTDERRCHECK	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , child processes Moab executes are considered failed if their standard error stream contains the text "ERROR".
<b>Example</b>	<pre>CHILDSTDERRCHECK TRUE</pre>

CLASSCFG[<CLASSID>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">General Credential Flags</a> , <a href="#">DEFAULT.ATTR</a> , <a href="#">DEFAULT.DISK</a> , <a href="#">DEFAULT.FEATURES</a> , <a href="#">DEFAULT.GRES</a> , <a href="#">DEFAULT.MEM</a> , <a href="#">DEFAULT.NODE</a> , <a href="#">DEFAULT.NODESET</a> , <a href="#">DEFAULT.PROC</a> , <a href="#">ENABLEPROFILING</a> , <a href="#">EXCL.FEATURES</a> , <a href="#">EXCLUDEUSERLIST</a> , <a href="#">HOSTLIST</a> , <a href="#">JOBPILOG</a> , <a href="#">JOBPROLOG</a> , <a href="#">MAXPROCERNODE</a> , <a href="#">MAX.NODE</a> , <a href="#">MAX.PROC</a> , <a href="#">MAX.WCLIMIT</a> , <a href="#">MIN.NODE</a> , <a href="#">MIN.PROC</a> , <a href="#">MIN.TPN</a> , <a href="#">MIN.WCLIMIT</a> , <a href="#">PARTITION</a> , <a href="#">PRIORITY</a> , <a href="#">PRIORITYF</a> , <a href="#">QDEF</a> , <a href="#">QLIST</a> , <a href="#">REQ.FEATURES</a> , <a href="#">REQUIREDACCOUNTLIST</a> , <a href="#">REQUIREDUSERLIST</a> , <a href="#">RESFAILPOLICY</a> , <a href="#">SYSPRIO</a> , <a href="#">WCOVERRUN</a> , <a href="#">usage limit</a> , or <a href="#">fairshare usage limit</a> specification.
<b>Default</b>	---
<b>Description</b>	Specifies class specific attributes (see <a href="#">Credential Overview</a> for details).
<b>Example</b>	<pre>CLASSCFG[batch] MAXJOB=50 QDEF=highprio</pre> <i>Up to 50 jobs submitted to the class batch will be allowed to execute simultaneously and will be assigned the QOS highprio by default.</i>

CLASSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the weight to be applied to the class priority of each job (see <a href="#">Credential (CRED) Factor</a> and <a href="#">credential priority</a> ).
<b>Example</b>	<pre>CLASSWEIGHT 10</pre>

CLIENTCFG[<X>]	
<b>Format</b>	One or more of <ATTR>-<VALUE> pairs where <X> indicates the specified peer and <ATTR> is one of the following: <b>AUTH</b> , <b>AUTHCMD</b> , <b>AUTHTYPE</b> , <b>HOST</b> , <b>KEY</b> , or <b>DEFAULTSUBMITPARTITION</b> .
<b>Default</b>	---
<b>Description</b>	Specifies the shared secret key and authentication method which Moab will use to communicate with the named peer daemon. See <a href="#">Security Overview</a> for more information. <b>Note:</b> The <b>AUTHTYPE</b> and <b>KEY</b> attributes of this parameter may only be specified in the <code>moab-private.cfg</code> config file.
<b>Example</b>	<pre>CLIENTCFG[silverB] KEY=apple7 AUTH=admin1</pre> <p><i>Moab will use the session key <b>apple7</b> for peer authentication and for encrypting and decrypting messages sent from <code>silverB</code>. Also, client connections from this interface will be authorized at an <b>admin 1</b> level.</i></p>

CLIENTMAXCONNECTIONS	
<b>Format</b>	<INTEGER>
<b>Default</b>	128
<b>Description</b>	Changes the maximum number of connections that can simultaneously connect to Moab. The value can be increased during runtime, but it cannot be decreased. The value cannot be reduced below the default value of 128.
<b>Example</b>	<pre>CLIENTMAXCONNECTIONS 256</pre> <p><i>Doubles the maximum number of connections.</i></p>

CLIENTMAXPRIMARYRETRY	
<b>Format</b>	<INTEGER> or <i>INFINITY</i>
<b>Default</b>	1
<b>Description</b>	Specifies how many times the client command will attempt to retry its connection to the primary server if Moab is not available.
<b>Example</b>	<pre>CLIENTMAXPRIMARYRETRY 5 CLIENTMAXPRIMARYRETRYTIMEOUT 1000</pre> <p><i>The client command will attempt to retry its connection to the primary server 5 times with 1 second intervals before giving up. <b>Note:</b> If <i>INFINITY</i> is specified, Moab will attempt 2,140,000,000 times.</i></p>

CLIENTMAXPRIMARYRETRYTIMEOUT	
<b>Format</b>	<INTEGER> (milliseconds)
<b>Default</b>	2000
<b>Description</b>	Specifies how much time to wait until the client command will attempt to retry its connection to the primary server if Moab is not available.
<b>Example</b>	<pre>CLIENTMAXPRIMARYRETRY 3 CLIENTMAXPRIMARYRETRYTIMEOUT 500</pre> <p><i>The client command will attempt to retry its connection to the primary server 3 times with .5 second intervals before giving up.</i></p>

CLIENTTIMEOUT	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>00:00:30</code>
<b>Description</b>	Time which Moab client commands will wait for a response from the Moab server. See <a href="#">Client Configuration</a> for more information. <b>Note:</b> May also be specified as an environment variable.
<b>Example</b>	<pre>CLIENTTIMEOUT 00:15:00</pre> <p><i>Moab clients will wait up to 15 minutes for a response from the server before timing out.</i></p>

CREDDISCOVERY	
<b>Format</b>	<code>TRUE</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	Specifies that Moab should create otherwise unknown credentials when it discovers them in the statistics files.
<b>Example</b>	<pre>CREDDISCOVERY TRUE</pre>

CREDWEIGHT	
<b>Format</b>	<code>&lt;INTEGER&gt;</code>
<b>Default</b>	<code>1</code>
<b>Description</b>	Specifies the credential component weight associated with the <a href="#">credential priority</a> . See <a href="#">Credential (CRED) Factor</a> for more information.
<b>Example</b>	<pre>CREDWEIGHT 2</pre>

DATASTAGEHOLDTYPE	
<b>Format</b>	Any <a href="#">Job Hold</a> type
<b>Default</b>	<i>DEFER</i>
<b>Description</b>	Specifies what to do if a job's data staging operations fail.
<b>Example</b>	<code>DATASTAGEHOLDTYPE BATCH</code>

DEADLINEPOLICY	
<b>Format</b>	One of <i>CANCEL</i> , <i>HOLD</i> , <i>IGNORE</i> , or <i>RETRY</i>
<b>Default</b>	<i>NONE</i>
<b>Description</b>	Specifies what to do when a requested deadline cannot be reached (see <a href="#">Job Deadlines</a> ).
<b>Example</b>	<code>DEADLINEPOLICY IGNORE</code>

DEFAULTCLASSLIST	
<b>Format</b>	Space-delimited list of one or more <i>&lt;STRING&gt;</i> s.
<b>Default</b>	---
<b>Description</b>	Specifies the default classes supported on each node for RM systems which do not provide this information.
<b>Example</b>	<code>DEFAULTCLASSLIST serial parallel</code>

DEFAULTSUBMITPARTITION	
<b>Format</b>	See parameter <a href="#">CLIENTCFG[]</a> .
<b>Default</b>	---
<b>Description</b>	If a user submits a job using <a href="#">msub</a> which does not specify host, feature, or partition constraints, then the <a href="#">msub</a> client will insert the specified default submit partition into the newly submitted job as a hard requirement.
<b>Example</b>	<pre>CLIENTCFG[DEFAULT] DEFAULTSUBMITPARTITION=partition1</pre>

DEFERCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	24
<b>Description</b>	Specifies the number of times a job can be deferred before it will be placed in batch hold.
<b>Example</b>	<pre>DEFERCOUNT 12</pre>

DEFERSTARTCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the number of times a job will be allowed to fail in its start attempts before being deferred. <b>JOBRETRYTIME</b> overrides <b>DEFERSTARTCOUNT</b> ; <b>DEFERSTARTCOUNT</b> only begins when the <b>JOBRETRYTIME</b> window elapses. <b>Note:</b> A job's startcount will increase each time a start request is made to the resource manager regardless of whether or not this request succeeded. This means start count increases if job starts fail or if jobs are started and then rejected by the resource manager. (For related information, see <a href="#">Reservation Policies</a> , <a href="#">DEFERTIME</a> , <a href="#">RESERVATIONRETRYTIME</a> , <a href="#">NODEFAILURERESERVETIME</a> , <a href="#">JOBRETRYTIME</a> , and <a href="#">GUARANTEEDPREEMPTION</a> .)
<b>Example</b>	<pre>DEFERSTARTCOUNT 3</pre>

DEFERTIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>1:00:00</code>
<b>Description</b>	Specifies the amount of time a job will be held in the deferred state before being released back to the Idle job queue. <b>Note:</b> A job's defer time will be restarted if Moab is restarted. (For related information, see <a href="#">Reservation Policies</a> , <a href="#">DEFERSTARTCOUNT</a> , <a href="#">RESERVATIONRETRYTIME</a> , <a href="#">NODEFAILURERESERVETIME</a> , <a href="#">JOBRETRYTIME</a> , and <a href="#">GUARANTEEDPREEMPTION</a> .)
<b>Example</b>	<pre>DEFERTIME 0:05:00</pre>

DELETESTAGEOUTFILES	
<b>Format</b>	<code>&lt;BOOLEAN&gt;</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	Specifies whether the scheduler should delete explicitly specified stageout files after they are successfully staged. By default, such files are not deleted but are left on the nodes where the job ran.
<b>Example</b>	<pre>DELETESTAGEOUTFILES TRUE Example of an explicit stageout request msub x=MSTAGEOUT:ssh://source_node/tmp/file,file:///results_folder job.cmd</pre> <p><i>With this parameter set to <b>TRUE</b>, /tmp/file on source_node is deleted after it is copied to the specified destination ( file:///results_folder). If the parameter is not set, or if it is set to <b>FALSE</b>, /tmp/file remains on source_node after the job terminates.</i></p>

DEPENDFAILUREPOLICY	
<b>Format</b>	<i>HOLD</i> or <i>CANCEL</i>
<b>Default</b>	<i>HOLD</i>
<b>Description</b>	Specifies what happens to a job if its dependencies cannot be fulfilled; that is, what happens when a job depends on another job to complete successfully but the other job fails.
<b>Example</b>	<pre>DEPENDFAILUREPOLICY CANCEL</pre> <p><i>If job A is submitted with depend=afterok:B and job B fails, job A is canceled.</i></p>

DIRECTORYSERVER	
<b>Format</b>	<HOST>[:<PORT>]
<b>Default</b>	---
<b>Description</b>	Specifies the interface for the directory server.
<b>Example</b>	<pre>DIRECTORYSERVER calli3.icluster.org:4702</pre>

DISABLEEXCHLIST	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If the resource manager rejects a job and the value is set to <i>TRUE</i> , then the node is not added to the job's exclude host list.
<b>Example</b>	<pre>DISABLEEXCHLIST TRUE</pre>

DISABLEINTERACTIVEJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>Disallows interactive jobs submitted with <a href="#">msub -I</a>.</p> <p><b>Note:</b> It is possible for users to submit interactive jobs directly to a resource manager, which can bypass the <b>DISABLEINTERACTIVEJOBS</b> parameter. However, some resource managers (such as TORQUE) will check with Moab before allowing an interactive job.</p>
<b>Example</b>	<pre>DISABLEINTERACTIVEJOBS TRUE</pre>

DISABLEREGEXCACHING	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Turns off regular expression caching. Turning off regular expression caching preserves memory with hostlist reservations and speeds up start time.
<b>Example</b>	<pre>DISABLEREGEXCACHING TRUE</pre>

DISABLEREQUIREDGRESNONE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	When set to <i>TRUE</i> , this causes Moab to reject msub requests that have a gres of "none". <a href="#">ENFORCEGRESACCESS</a> must also be set to TRUE for this feature to work.
<b>Example</b>	<pre>##### moab.cfg ##### ENFORCEGRESACCESS TRUE DISABLEREQUIREDGRESNONE TRUE #####  &gt; msub -A ee -l nodes=1,ttc=5,walltime=600,partition=g02 -l gres=none ERROR: cannot submit job - cannot locate required resource 'none'</pre>

DISABLESAMECREDPREEMPTION	
<b>Format</b>	Comma-delimited list of one or more credentials: <i>ACCT</i> , <i>CLASS</i> , <i>GROUP</i> , <i>QOS</i> , or <i>USER</i>
<b>Default</b>	---
<b>Description</b>	This parameter prevents specified credentials from preempting its own jobs.
<b>Example</b>	<pre>DISABLESAMECREDPREEMPTION QOS,USER</pre>

DISABLESCHEDULING	
<b>Format</b>	< <i>BOOLEAN</i> >
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether or not the scheduler will schedule jobs. If set to <i>TRUE</i> , Moab will continue to update node and job state but will not start, preempt, or otherwise modify jobs. The command <a href="#">mschedctl -r</a> will clear this parameter and resume normal scheduling.
<b>Example</b>	<pre>DISABLESCHEDULING FALSE</pre>

DISABLESLAVEJOBSSUBMIT	
<b>Format</b>	< <i>BOOLEAN</i> >
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	This parameter can be added to the <code>moab.cfg</code> file on a slave Moab server (in a grid configuration) to prevent users from submitting jobs to the master Moab server from the slave Moab server. Some grid configurations allow the user to submit jobs on the slave that are migrated to the master and submitted from the master. Other grid configurations do not allow the jobs to be migrated to the master from the slave, in which case, jobs submitted from the slave remain idle on the slave and never run. This parameter will reject the job submissions on the slave to prevent the submission of jobs that will never run.
<b>Example</b>	<pre>DISABLESLAVEJOBSSUBMIT TRUE example (node04 is a slave and node06 is the master) [test@node04 moab-slurm]\$ echo sleep 100   msub ERROR: cannot submit job from slave</pre>

DISABLETHRESHOLDTRIGGERS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	This makes Moab not fire threshold-based triggers, but will log the intended action to the event logs. Similar to <a href="#">DISABLEVMDECISIONS</a> .
<b>Example</b>	<pre>DISABLETHRESHOLDTRIGGERS TRUE</pre>

DISABLEVMDECISIONS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	This makes Moab not take any automatic decisions with respect to VM's, namely powering on/off nodes and migrating VMs. Intended actions will instead be logged in the event logs. Similar to <a href="#">DISABLETHRESHOLDTRIGGERS</a> .
<b>Example</b>	<pre>DISABLEVMDECISIONS TRUE</pre>

DISKWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight to be applied to the amount of dedicated disk space required per task by a job (in MB).
<b>Example</b>	<pre>RESWEIGHT 10 DISKWEIGHT 100</pre> <p><i>If a job requires 12 tasks and 512 MB per task of dedicated local disk space, Moab will increase the job's priority by <math>10 * 100 * 12 * 512</math></i></p>

DISPLAYFLAGS	
<b>Format</b>	One or more of the following values (space delimited): <i>ACCOUNTCENTRIC</i> , <i>HIDEBLOCKED</i> , <i>HIDEDRAINED</i> , <i>NODECENTRIC</i> , or <i>USEBLOCKING</i>
<b>Default</b>	---
<b>Description</b>	<p>Specifies flags that control how Moab client commands display varied information.</p> <p><i>ACCOUNTCENTRIC</i> will display account information in <a href="#">showq</a>, rather than group information.</p> <p><i>HIDEBLOCKED</i> will prevent <a href="#">showq</a> from listing information about blocked jobs which are not owned by the user if the user is not an admin.</p> <p><i>HIDEDRAINED</i> prevents <a href="#">mdiag -n</a> from displaying nodes and <a href="#">mvmctl -q</a> from displaying VMs in the <a href="#">DRAINED</a> state. An override option of <a href="#">mdiag -n -w nodestate=drained</a> lists only those nodes with a <a href="#">DRAINED</a> state. Similarly, an override option of <a href="#">mvmctl -q -w state=drained</a> lists only those VMs with a <a href="#">DRAINED</a> state.</p> <p><i>NODECENTRIC</i> will display node allocation information instead of processor allocation information in <a href="#">showq</a>.</p> <p><i>USEBLOCKING</i> disables threading for commands that support it; those commands include <a href="#">showq</a>, <a href="#">mdiag -n</a>, and <a href="#">mdiag -j</a>.</p>
<b>Example</b>	<pre>DISPLAYFLAGS NODECENTRIC</pre>

DISPLAYPROXYUSERASUSER	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , Moab shows the proxy users instead of the real user on some queries of system jobs that have proxy users. Commands affected include <a href="#">mjobctl -q diag</a> and <a href="#">checkjob</a> .
<b>Example</b>	<pre>DISPLAYPROXYUSERASUSER TRUE</pre>

DONTCANCELINTERACTIVEHJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , Moab does not cancel interactive jobs that are held.
<b>Example</b>	<code>DONTCANCELINTERACTIVEHJOBS TRUE</code>

DONTENFORCEPEERJOBLIMITS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , only the scheduler that is running the job can cancel the job or enforce other limits.
<b>Example</b>	<code>DONTENFORCEPEERJOBLIMITS TRUE</code>

EMULATIONMODE	
<b>Format</b>	<i>SLURM</i>
<b>Default</b>	---
<b>Description</b>	Specifies whether or not the scheduler will perform the automatic setup of a particular resource manager environment.
<b>Example</b>	<pre>EMULATIONMODE SLURM</pre> <p><i>Moab will perform the automated setup steps as if it were interfacing with a slurm resource manager (automatic QOS creation).</i></p>

ENABLEFAILUREFORPURGEDJOB	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>By default, when a job is purged or removed by the TORQUE resource manager for a walltime violation, the job takes on a state of Completed and a completion code of 0. If <i>TRUE</i>, the job state is set to Removed and has a completion code of 98.</p> <p><b>ENABLEFAILUREFORPURGEDJOB</b> is for the TORQUE resource manager only.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #D9E1F2;"> <p><b>i</b> For <b>ENABLEFAILUREFORPURGEDJOB</b> to return Removed job states, you must reset the TORQUE server attribute <code>keep_completed</code> to 0 in <code>qmgr</code>. See "<a href="#">Queue attributes on page 2626</a>" in the TORQUE Administrator Guide for more information.</p> </div>
<b>Example</b>	<pre>ENABLEFAILUREFORPURGEDJOB TRUE</pre> <p><i>Jobs that are purged or removed by TORQUE are given a state of Removed and a completion code of 98.</i></p>

ENABLEFSVIOLATIONPREEMPTION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If set to <b>TRUE</b> , Moab will allow jobs within the same <a href="#">class/queue</a> to <a href="#">preempt</a> when the preemptee is violating a <a href="#">fairshare</a> target and the preemptor is not.
<b>Example</b>	<pre>ENABLEFSVIOLATIONPREEMPTION TRUE</pre>

ENABLEHIGHTHROUGHPUT	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	<p>Configures Moab so that it will accept <code>msub</code> submissions, start jobs, process triggers, etc., in a manner which minimizes their processing time. The downside is that Moab will return minimal information about these jobs at submit time.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF;"> <p><b>i</b> If <b>ENABLEHIGHTHROUGHPUT</b> is <b>TRUE</b>, you must set <b>NODEALLOCATIONPOLICY</b> on <a href="#">page 999</a> to <b>FIRSTAVAILABLE</b>.</p> </div>
<b>Example</b>	<pre>ENABLEHIGHTHROUGHPUT TRUE</pre> <p><i>Moab can now accept hundreds of jobs per second using msub instead of 20-30.</i></p>

ENABLEJOBARRAYS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	If set to <b>TRUE</b> , job arrays will be enabled .
<b>Example</b>	<pre>ENABLEJOBARRAYS TRUE</pre>

ENABLENEGJOBPRIORITY	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , the scheduler allows job priority value to range from -INFINITY to MMAX_PRIO; otherwise, job priority values are given a lower bound of '1'. For more information, see <a href="#">REJECTNEGPRIOJOBS</a> .
<b>Example</b>	<pre>ENABLENEGJOBPRIORITY TRUE</pre> <p><i>Job priority may range from -INFINITY to MMAX_PRIO.</i></p>

ENABLENODEADDRLOOKUP	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , the scheduler will use the default host name service lookup mechanism (i.e., /etc/hosts, DNS, NIS, etc.) to determine the IP address of the nodes reported by the resource manager. This information is used to correlate information reported by multi-homed hosts.
<b>Example</b>	<pre>ENABLENODEADDRLOOKUP TRUE</pre>

ENABLEPOSUSERPRIORITY	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , the scheduler will allow users to specify positive job priority values which will be honored. In other words, users can specify a priority that falls in the range of -1024 to +1023, inclusive. If set to <i>FALSE</i> (the default), user priority values are given an upper bound of '0' when users request a positive priority. See <a href="#">USERPRIOWEIGHT</a> .
<b>Example</b>	<pre>ENABLEPOSUSERPRIORITY TRUE</pre> <p><i>Users may now specify positive job priorities and have them take effect (e.g. <code>msub -p 100 job.cmd</code>).</i></p>

ENABLESPVIOLATIONPREEMPTION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , Moab will allow jobs within the same <a href="#">class/queue</a> to <a href="#">preempt</a> when the preemptee is violating a <i>soft</i> <a href="#">usage policy</a> and the preemptor is not.
<b>Example</b>	<pre>ENABLESPVIOLATIONPREEMPTION TRUE</pre>

ENABLEVMDESTROY	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If set to <i>TRUE</i> , enables the automatic destruction of a VM when the VM wall time is expired or when the VM is stale and configured to be destroyed (for more information, see <a href="#">VMSTALEACTION</a> ).
<b>Example</b>	<pre>ENABLEVMDESTROY TRUE</pre>

ENFORCEACCOUNTACCESS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether or not Moab will enforce account access constraints without an allocation manager.
<b>Example</b>	<pre>ENFORCEACCOUNTACCESS TRUE</pre>

ENFORCEGRESACCESS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If a user submits a job with a non-existent gres (e.g. in the case of a typo) and <b>ENFORCEGRESACCESS</b> is not set in <code>moab.cfg</code> , or is set to <i>FALSE</i> , then the requested gres will be created (but will not exist on any nodes) and the job will be deferred (similar to <b>ENFORCEACCOUNTACCESS</b> ).
<b>Example</b>	<pre>ENFORCEGRESACCESS TRUE</pre>

EVENTSERVER	
<b>Format</b>	<HOST>[:<PORT>]
<b>Default</b>	---
<b>Description</b>	Specifies the interface for the event server.
<b>Example</b>	<pre>EVENTSERVER calli3.icluster.org:4702</pre>

FEATURENODETYPEHEADER	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the header used to specify node type via node features (i.e. LL features or PBS node attributes).
<b>Example</b>	<pre>FEATURENODETYPEHEADER xnt</pre> <p><i>Moab will interpret all node features with the leading string <b>xnt</b> as a nodetype specification - as used by the allocation manager and other allocation managers, and assign the associated value to the node. i.e., xntFast.</i></p>

FEATUREPARTITIONHEADER	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the header used to specify node partition via node features (i.e. LL features or PBS node attributes).
<b>Example</b>	<pre>FEATUREPARTITIONHEADER xpt</pre> <p><i>Moab will interpret all node features with the leading string <b>xpt</b> as a partition specification and assign the associated value to the node. i.e., xptGold.</i></p>

FEATUREPROCSPEEDHEADER	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the header used to extract node processor speed via node features (i.e., LL features or PBS node attributes). <b>Note:</b> Adding a trailing '\$' character will specify that only features with a trailing number be interpreted. For example, the header 'sp\$' will match 'sp450' but not 'sport'.
<b>Example</b>	<pre>FEATUREPROCSPEEDHEADER xps</pre> <p><i>Moab will interpret all node features with the leading string <b>xps</b> as a processor speed specification and assign the associated value to the node. i.e., xps950.</i></p>

FEATURERACKHEADER	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the header used to extract node rack index via node features (i.e., LL features or PBS node attributes). <b>Note:</b> Adding a trailing '\$' character will specify that only features with a trailing number be interpreted. For example, the header 'rack\$' will match 'rack4' but not 'racket'.
<b>Example</b>	<pre>FEATURERACKHEADER rack</pre> <p><i>Moab will interpret all node features with the leading string <b>rack</b> as a <b>rack</b> index specification and assign the associated value to the node. i.e., rack16.</i></p>

FEATURESLOTHEADER	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the header used to extract node slot index via node features (i.e., LL features or PBS node attributes). <b>Note:</b> Adding a trailing '\$' character will specify that only features with a trailing number be interpreted. For example, the header 'slot\$' will match 'slot12' but not 'slotted'.
<b>Example</b>	<pre>FEATURESLOTHEADER slot</pre> <p><i>Moab will interpret all node features with the leading string <code>slot</code> as a slot index specification and assign the associated value to the node. i.e., slot16.</i></p>

FEEDBACKPROGRAM	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the name of the program to be run at the completion of each job. If not fully qualified, Moab will attempt to locate this program in the 'tools' subdirectory.
<b>Example</b>	<pre>FEEDBACKPROGRAM /var/moab/fb.pl</pre> <p><i>Moab will run the specified program at the completion of each job.</i></p>

FILEREQUESTISJOBCENTRIC	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether a job's file request is a total request for the job or a per task request.
<b>Example</b>	<pre>FILEREQUESTISJOBCENTRIC TRUE</pre> <p><i>Moab will treat file requests as a total request per job.</i></p>

FILTERCMDFILE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	<p>Running the <a href="#">msub</a> command performs the following operations on the submission script:</p> <ul style="list-style-type: none"> <li>• Replace all comments with spaces (excludes Resource Manager directives)</li> <li>• Strip empty lines</li> <li>• Replace \r with \n</li> <li>• Lock job to a PBS resource manager if \$PBS is found in the script</li> </ul> <p>Include the <b>FILTERCMDFILE</b> parameter in the <code>moab.cfg</code> file that resides on the clients.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF;"> <p> <b>FILTERCMDFILE</b> must be <i>FALSE</i> for <a href="#">REJECTDOSSCRIPTS</a> on page 1026 to work correctly.</p> </div>
<b>Example</b>	<pre>FILTERCMDFILE FALSE</pre> <p><i>Running the msub command does not perform the actions detailed earlier.</i></p>

FORCENODEREPROVISION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	<p>When set to <i>TRUE</i>, this config option causes Moab to reprovision a node, even if it is to the same operating system (in essence rewriting the OS).</p>
<b>Example</b>	<pre>FORCENODEREPROVISION TRUE</pre>

FORCERSVSUBTYPE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies that admin reservations must have a <a href="#">subtype</a> associated with them.
<b>Example</b>	<pre>FORCERSVSUBTYPE TRUE</pre> <p><i>Moab will require all admin reservations to include a subtype.</i></p>

FREETIMELOOKAHEADDURATION	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	<i>2 Months</i>
<b>Description</b>	Specifies how far ahead Moab will look when calculating free time on a node.
<b>Example</b>	<pre>FREETIMELOOKAHEADDURATION 7:00:00:00</pre> <p><i>Moab will look <b>1 week</b> ahead when it calculates free time on a node.</i></p>

FSACCOUNTWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>0</i>
<b>Description</b>	Specifies the weight assigned to the account subcomponent of the fairshare component of priority.
<b>Example</b>	<pre>FSACCOUNTWEIGHT 10</pre>

FSCAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum allowed absolute value for a job's total pre-weighted fairshare component.
<b>Example</b>	<pre>FSCAP 10.0</pre> <p><i>Moab will bind a job's pre-weighted fairshare component by the range +/- 10.0.</i></p>

FSCCLASSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to the class subcomponent of the fairshare component of priority.
<b>Example</b>	<pre>FSCCLASSWEIGHT 10</pre>

FSDECAY	
<b>Format</b>	<DOUBLE>
<b>Default</b>	1.0
<b>Description</b>	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing <i>aged</i> usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage. See <a href="#">Fairshare Overview</a> .
<b>Example</b>	<pre>FSPOLICY    DEDICATEDPS FSDECAY     0.8 FSDEPTH     8</pre> <p><i>Moab will apply a decay rate of 0.8 to all fairshare windows.</i></p>

FSDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	8
<b>Description</b>	<b>Note:</b> The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab). See <a href="#">Fairshare Overview</a> .
<b>Example</b>	<code>FSDEPTH 12</code>

FSENABLECAPRIORITY	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Fairshare priority will increase to target and stop.
<b>Example</b>	<code>FSENABLECAPRIORITY TRUE</code>

FSGROUPWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	
<b>Example</b>	<code>FSGROUPWEIGHT 4</code>

FSINTERVAL	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>12:00:00</code>
<b>Description</b>	Specifies the length of each fairshare <a href="#">window</a> .
<b>Example</b>	<pre>FSINTERVAL 12:00:00</pre> <p><i>Track fairshare usage in 12 hour blocks.</i></p>

FSJPUWEIGHT	
<b>Format</b>	<code>&lt;INTEGER&gt;</code>
<b>Default</b>	<code>0</code>
<b>Description</b>	Specifies the fairshare weight assigned to jobs per user.
<b>Example</b>	<pre>FSJPUWEIGHT 10</pre>

FSMOSTSPECIFCLIMIT	
<b>Format</b>	<code>&lt;BOOLEAN&gt;</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	When checking policy usage limits in a fairshare tree, if the most specific policy limit is passed then do not check the same policy again at higher levels in the tree. For example, if a user has a MaxProc policy limit then do not check the MaxProc policy limit on the account for this same user.
<b>Example</b>	<pre>FSMOSTSPECIFCLIMIT TRUE</pre>

FSPOLICY	
<b>Format</b>	<POLICY>[*] where <POLICY> is one of the following: <i>DEDICATEDPS</i> , <i>DEDICATEDPS%</i> , <i>DEDICATEDPES</i> , or <i>UTILIZEDPS</i> .
<b>Default</b>	---
<b>Description</b>	<p>Specifies the unit of tracking fairshare usage. The following options are:</p> <ul style="list-style-type: none"> <li>• <i>DEDICATEDPS</i> (dedicated processor seconds delivered) tracks dedicated processor seconds.</li> <li>• <i>DEDICATEDPS%</i> (dedicated processor seconds available) to specify that <a href="#">percentage based fairshare</a> should be used. See <a href="#">Fairshare Overview</a> and <a href="#">Fairshare Consumption Metrics</a> for more information.</li> <li>• <i>DEDICATEDPES</i> (dedicated processor-equivalent seconds delivered) tracks dedicated processor-equivalent seconds.</li> <li>• <i>UTILIZEDPS</i> (utilized processor seconds delivered) tracks the number of utilized processor seconds.</li> </ul>
<b>Example</b>	<pre>FSPOLICY DEDICATEDPES</pre> <p><i>Moab will track fairshare usage by dedicated processor-equivalent seconds.</i></p>

FSPPUWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the fairshare weight assigned to processors per user.
<b>Example</b>	<pre>FSPPUWEIGHT 10</pre>

FSPSPUWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the fairshare weight assigned to processor-seconds per user.
<b>Example</b>	<code>FSPSPUWEIGHT 10</code>

FSQOSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight assigned to the QOS fairshare subcomponent.
<b>Example</b>	<code>FSQOSWEIGHT 16</code>

FSTARGETISABSOLUTE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether Moab should base fairshare targets off of delivered cycles or up/available cycles.
<b>Example</b>	<code>FSTARGETISABSOLUTE TRUE</code>

FSTREE	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">SHARES</a> or <a href="#">MEMBERLIST</a>
<b>Default</b>	---
<b>Description</b>	Specifies the share tree distribution for job fairshare prioritization (see <a href="#">Hierarchical Share Tree Overview</a> ).
<b>Example</b>	<pre>FSTREE [geo] SHARES=16 MEMBERLIST=geo103,geo313,geo422</pre>

FSTREEACLPOLICY	
<b>Format</b>	<i>OFF, PARENT, or FULL</i>
<b>Default</b>	<i>FULL</i>
<b>Description</b>	Specifies how Moab should interpret credential membership when building the FSTREE (see <a href="#">Hierarchical Share Tree Overview</a> ).
<b>Example</b>	<pre>FSTREEACLPOLICY PARENT</pre> <i>Credentials will be given access to their parent node when applicable.</i>

FSTREEISREQUIRED	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether a job must have an applicable node in the partition's FSTREE in order to execute within that partition (see <a href="#">Hierarchical Share Tree Overview</a> ).
<b>Example</b>	<pre>FSTREEISREQUIRED TRUE</pre> <i>Jobs must have an applicable node in the FSTREE in order to execute.</i>

FSTREEUSERISREQUIRED	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether the user must be given explicit access to a branch in the FSTREE (see <a href="#">Hierarchical Share Tree Overview</a> ).
<b>Example</b>	<pre>FSTREEUSERISREQUIRED TRUE</pre> <p><i>Users must be given explicit access to FSTREE nodes in order to gain access to the FSTREE.</i></p>

FSUSERWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight assigned to the user fairshare subfactor.
<b>Example</b>	<pre>FSUSERWEIGHT 8</pre>

FSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the priority weight assigned to the summation of the fairshare subfactors (see <a href="#">Priority Factor</a> and <a href="#">Fairshare</a> overviews).
<b>Example</b>	<pre>FSWEIGHT 500</pre>

GEVENTCFG[<GEVENT>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is <b>ACTION</b> , <b>ECOUNT</b> , <b>REARM</b> , or <b>SEVERITY</b> . See <a href="#">Responding to Generic Events</a> for details on values you can assign to each attribute.
<b>Default</b>	---
<b>Description</b>	Specifies how the scheduler should behave when various cluster events are detected. See the <a href="#">Generic Events Overview</a> for more information.
<b>Example</b>	<pre>GEVENTCFG[hitemp] ACTION=avoid,record,notify REARM=00:10:00 GEVENT[nodeerror] SEVERITY=3</pre> <p><i>If a hitemp event is detected, Moab adjusts the node allocation policy to minimize the allocation of the node. Moab also sends emails to cluster administrators and reports the event in the Moab event log.</i></p>

GRES CFG[<GRES>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <b>TYPE</b> , <b>PRIVATE</b> , <b>INVERTTASKCOUNT</b> , <a href="#">FEATUREGRES</a> , or <a href="#">STARTDELAY</a>
<b>Default</b>	---
<b>Description</b>	<p>Specifies associations of generic resources into resource groups.</p> <p>When <b>PRIVATE</b> is set to <b>TRUE</b>, Moab puts the requested generic resource on a separate job request.</p> <p>By default a private request is a request with 1 task with X number of generic resources per task. When <b>INVERTTASKCOUNT</b> and <b>PRIVATE</b> are set to <b>TRUE</b>, Moab makes the generic resource's private request a request with X number of tasks with 1 generic resource per task.</p> <p>See <a href="#">12.6 Managing Consumable Generic Resources</a> for more information.</p>
<b>Example</b>	<pre>GRES CFG[scsi1] TYPE=fastio GRES CFG[scsi2] TYPE=fastio GRES CFG[scsi3] TYPE=fastio</pre> <p><i>The generic resources scsi1, scsi2, and scsi3 are all associated with the generic resource type fastio.</i></p>

GRESTOJOBATTR	
<b>Format</b>	Comma delimited list of generic resources
<b>Default</b>	---
<b>Description</b>	The list of generic resources will also be interpreted as JOB features. See <a href="#">Managing Reservations</a> .
<b>Example</b>	<pre>GRESTOJOBATTR matlab,ccs</pre> <p><i>Jobs which request the generic resources <b>matlab</b> or <b>ccs</b> will have a corresponding job attribute assigned to them.</i></p>

GROUPCFG[<GROUPID>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">General Credential Flags</a> , <b>PRIORITY</b> , <a href="#">ENABLEPROFILING</a> , <b>QLIST</b> , <b>QDEF</b> , <b>PLIST</b> , <b>FLAGS</b> , <a href="#">usage limits</a> , or a <a href="#">fairshare usage limit</a> specification.
<b>Default</b>	---
<b>Description</b>	Specifies group specific attributes. See the <a href="#">flag overview</a> for a description of legal flag values.
<b>Example</b>	<pre>GROUPCFG[staff] MAXJOB=50 QDEF=highprio</pre> <p><i>Up to 50 jobs submitted by members of the group staff will be allowed to execute simultaneously and will be assigned the QOS <b>highprio</b> by default.</i></p>

GROUPWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the priority weight assigned to the specified group priority (See <a href="#">Credential (CRED) Factor</a> ).
<b>Example</b>	<pre>GROUPWEIGHT 20</pre>

GUARANTEEDPREEMPTION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	<p>Causes Moab to lock <a href="#">PREEMPTOR</a> jobs until <a href="#">JOBRETRYTIME</a> expires (essentially, waiting for the <a href="#">PREEMPTEE</a> jobs to finish).</p> <p>It may take some time for the <a href="#">PREEMPTEE</a> jobs to clear out. During that time, the <a href="#">PREEMPTOR</a> job might want to look elsewhere to run, which would be disruptive as it might preempt another set of jobs. If you wish it prevent this, it is recommended that you set <b>GUARANTEEDPREEMPTION</b> to <b>TRUE</b>.</p> <p>For related information, see <a href="#">About preemption</a>, <a href="#">Reservation Policies</a>, <a href="#">DEFERSTARTCOUNT</a>, <a href="#">DEFERTIME</a>, <a href="#">RESERVATIONRETRYTIME</a>, <a href="#">NODEFAILURERESERVETIME</a>, and <a href="#">JOBRETRYTIME</a>.</p>
<b>Example</b>	<pre>GUARANTEEDPREEMPTION TRUE</pre>

HALOCKCHECKTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	9
<b>Description</b>	<p>Specifies how frequently the secondary server checks the timestamp on the lock file. See <a href="#">High Availability Overview</a> for more info.</p>
<b>Example</b>	<pre>HALOCKCHECKTIME 00:00:15</pre> <p><i>The Moab fallback server will check the health of the Moab primary server every 15 seconds.</i></p>

HALOCKUPDATETIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	3
<b>Description</b>	Specifies how frequently the primary server checks the timestamp on the lock file. See <a href="#">High Availability Overview</a> for more info.
<b>Example</b>	<pre>HALOCKUPDATETIME 00:00:03</pre> <p><i>The Moab primary server will check the timestamp of the lock file every 3 seconds.</i></p>

HIDEVIRTUALNODES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	Enables VM management; also used to reveal hypervisors.
<b>Example</b>	<pre>HIDEVIRTUALNODES TRANSPARENT</pre>

IDCFG[X]	
<b>Format</b>	One or more of the following attribute/value pairs: <i>BLOCKEDCREDLIST</i> , <a href="#">CREATECRED</a> , <a href="#">CREATECREDURL</a> , <i>REFRESHPERIOD</i> , <i>RESETCREDLIST</i> or <i>SERVER</i> .
<b>Default</b>	---
<b>Description</b>	<p>This parameter enables the <a href="#">identity manager</a> interface allowing credential, policy, and usage information to be shared with an external information service.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; background-color: #E6F2FF;"> <p><b>i</b> Only one identity manager can be configured at a time.</p> </div>
<b>Example</b>	<pre>IDCFG[info] SERVER=exec://dbquery.pl REFRESHPERIOD=hour</pre> <p><i>Moab will refresh credential info every hour using the specified script.</i></p>

IGNOREMDATASTAGING	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	When set to <i>TRUE</i> , Moab will ignore any resource manager specific data staging on a job and assume the resource manager is processing the request. Currently, this only applies to PBS.
<b>Example</b>	<pre>IGNORERMDATASTAGING TRUE</pre>

IGNORECLASSES	
<b>Format</b>	[!]<CLASS>[,<CLASS>]...
<b>Default</b>	---
<b>Description</b>	By default, if using the TORQUE resource manager, jobs from all listed classes are ignored and not scheduled, tracked, or otherwise processed by Moab. If the <b>not</b> (i.e., '!') character is specified, only jobs from listed classes are processed. See the <a href="#">Moab Side-by-Side Analysis</a> for more information.
<b>Example</b>	<pre>IGNORECLASSES dque, batch</pre> <i>Moab will ignore jobs from classes <i>dque</i> and <i>batch</i>.</i>

IGNOREJOBS	
<b>Format</b>	[!]<JOBID>[,<JOBID>]...
<b>Default</b>	---
<b>Description</b>	By default, listed jobs are ignored and not scheduled, tracked, or otherwise processed by Moab. If the <b>not</b> (i.e., '!') character is specified, only listed jobs are processed. See the <a href="#">Moab Side-by-Side Analysis</a> for more information.
<b>Example</b>	<pre>IGNOREJOBS !14221, 14223</pre> <i>Moab will ignore jobs all classes except <i>14221</i> and <i>14223</i>.</i>

IGNORENODES	
<b>Format</b>	<code>[!]&lt;NODE&gt;[,&lt;NODE&gt;]...</code>
<b>Default</b>	---
<b>Description</b>	By default, all listed nodes are ignored and not scheduled, tracked, or otherwise processed by Moab. If the <b>not</b> (i.e., '!') character is specified, only listed nodes are processed. See the <a href="#">Moab Side-by-Side Analysis</a> for more information.
<b>Example</b>	<pre>IGNORENODES !host3,host4</pre> <p><i>Moab will only process nodes <b>host3</b> and <b>host4</b>.</i></p>

IGNOREPREEMPTPRIORITY	
<b>Format</b>	<code>&lt;BOOLEAN&gt;</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	By default, preemptor jobs can only <a href="#">preempt</a> preemptee jobs if the preemptor has a higher job <a href="#">priority</a> than the preemptee. When this parameter is set to true, the priority constraint is removed allowing any preemptor to preempt any preemptees once it reaches the top of the eligible job queue.
<b>Example</b>	<pre>IGNOREPREEMPTPRIORITY TRUE</pre> <p><i>A preemptor job can preempt any preemptee jobs when it is at the top of the eligible job queue.</i></p>

IGNOREUSERS	
<b>Format</b>	<code>[!]&lt;USERNAME&gt;[,&lt;USERNAME&gt;]...</code>
<b>Default</b>	---
<b>Description</b>	By default, if using the TORQUE resource manager, jobs from all listed users are ignored and not scheduled, tracked, or otherwise processed by Moab. If the <b>not</b> (i.e., '!') character is specified, only jobs from listed users are processed. (See the <a href="#">Moab Side-by-Side Analysis</a> for more information.)
<b>Example</b>	<pre>IGNOREUSERS testuser1,annapolis</pre> <p><i>Moab will ignore jobs from users <code>testuser1</code> and <code>annapolis</code>.</i></p>

#INCLUDE	
<b>Format</b>	<code>&lt;STRING&gt;</code>
<b>Default</b>	---
<b>Description</b>	Specifies another file which contains more configuration parameters. If <code>&lt;STRING&gt;</code> is not an absolute path, Moab will search its home directory for the file.
<b>Example</b>	<pre>#INCLUDE moab.acct</pre> <p><i>Moab will process the parameters in <code>moab.acct</code> as well as <code>moab.cfg</code></i></p>

INSTANTSTAGE	
<b>Format</b>	<code>&lt;BOOLEAN&gt;</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	<b>Deprecated.</b> Use <a href="#">JOBMIGRATEPOLICY</a> . Specifies whether Moab should instantly stage jobs to the underlying resource manager when a job is submitted through <a href="#">msub</a> .
<b>Example</b>	<pre>INSTANTSTAGE TRUE</pre>

INVALIDFSTREEMSG	
<b>Format</b>	"<STRING>"
<b>Default</b>	<i>"no valid fstree node found"</i>
<b>Description</b>	Specifies the error message that should be attached to jobs that cannot run because of a fairshare tree configuration violation.
<b>Example</b>	<pre>INVALIDFSTREEMSG "account is invalid for requested partition"</pre>

JOBACTIIONONNODEFAILURE	
<b>Format</b>	<a href="#">CANCEL</a> on page 409, <a href="#">FAIL</a> on page 409, <a href="#">HOLD</a> on page 409, <a href="#">IGNORE</a> on page 409, <a href="#">NOTIFY</a> on page 409, or <a href="#">REQUEUE</a> on page 409
<b>Default</b>	---
<b>Description</b>	<p>Specifies the action to take if Moab detects that a node allocated to an active job has failed (state is <a href="#">down</a>). By default, Moab only reports this information via diagnostic commands. If this parameter is set, Moab will cancel or requeue the active job. See <a href="#">Reallocating Resources When Failures Occur</a> for more information.</p> <p><b>Note:</b> The <i>HOLD</i> value is only applicable when using <a href="#">checkpointing</a>.</p>
<b>Example</b>	<pre>JOBACTIIONONNODEFAILURE REQUEUE</pre> <p><i>Moab will requeue active jobs which have allocated nodes which have failed during the execution of the job.</i></p>

JOBAGGREGATIONTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0
<b>Description</b>	Specifies the minimum amount of time the scheduler should wait after receiving a job event until it should process that event. This parameter allows sites with <i>bursty</i> job submissions to process job events in groups decreasing total job scheduling cycles and allowing the scheduler to make more intelligent choices by aggregating job submissions and choosing between the jobs. See <a href="#">Considerations for Large Clusters</a> .
<b>Example</b>	<pre>JOBAGGREGATIONTIME 00:00:04 RMPOLLINTERVAL 30,30</pre> <p><i>Moab will wait 4 seconds between scheduling cycles when job events have been received and will wait 30 seconds between scheduling cycles otherwise.</i></p>

JOB CFG	
<b>Format</b>	<ATTR>=<VAL> where <ATTR> is one of <a href="#">FLAGS</a> , <a href="#">GRES</a> , <a href="#">NODERANGE</a> , <a href="#">PRIORITYF</a> , <a href="#">PROC RANGE</a> , <a href="#">QOS</a> , <a href="#">RARCH</a> , <a href="#">RFEATURES</a> , <a href="#">ROPSYS</a> , <a href="#">SELECT</a> , or <a href="#">TARGETLOAD</a>
<b>Default</b>	---
<b>Description</b>	<p>Specifies attributes for jobs which satisfy the specified profile. The <b>SELECT</b> attribute allows users to specify the job template by using <a href="#">msub -l template=</a>.</p> <p>The <b>JOB CFG</b> parameter supports the following attributes:  <b>NONE, ACCOUNT, ACTION, AUTOSIZE, CLASS, CPULIMIT, DESCRIPTION, DGRES, FAILUREPOLICY, GROUP, IFLAGS, JOBSRIPT MEM</b> (for <b>MEM=&lt;value&gt;</b>), <b>MEMORY</b> (for <b>MEMORY=\$LEARN</b>), <b>NODEACCESSPOLICY, NODEMOD, PARTITION, PREF, QOS, RESTARTABLE, RM, RMSERVICEJOB, SELECT, SOFTWARE, SRM, TEMPLIMIT, TFLAGS, USER, VMUSAGE, WALLTIME, WORK</b></p> <p>It also supports the following Wiki attributes:  <b>ARGS, DMEM, DDISK, DWAP, ERROR, EXEC, EXITCODE, GATTR, GEVENT, IWD, JNAME, NAME, PARTITIONMASK, PRIORITYF, RDISK, RSWAP, RAGRES, RCGRES, TASKPERNODE, TRIGGER, VARIABLE, NULL</b></p> <p><b>Note:</b> The <i>index</i> to the <b>JOB CFG</b> parameter can either be an admin-chosen <a href="#">job template</a> name or the exact name of job reported by one or more <a href="#">workload</a> queries. See <a href="#">Wiki Attributes</a> and <a href="#">Job Template Extensions</a>.</p>
<b>Example</b>	<pre>JOB CFG[sql] RFEATURES=sqlnode QOS=service</pre> <p><i>When the sql job is detected, it will have the specified default qos and node feature attributes set.</i></p>

JOB CPURGETIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	00:05:00
<b>Description</b>	Specifies the amount of time Moab will preserve detailed information about a completed job (see <a href="#">showq -c</a> and <a href="#">checkjob</a> ).
<b>Example</b>	<pre>JOB CPURGETIME 02:00:00</pre> <p><i>Moab will maintain detailed job information for 2 hours after a job has completed.</i></p>

JOBTRUNCATENLCP	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Specifies whether Moab will store only the first node of the node list for a completed job in the checkpoint file.
<b>Example</b>	<pre>JOBTRUNCATENLCP TRUE</pre> <p><i>JOBTRUNCATENLCP reduces the amount of memory Moab uses to store completed job information.</i></p>

JOBEXTENDSTARTWALLTIME	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	Extends the job walltime when Moab starts the job up to the lesser of the maximum or the next reservation (rounded down to the nearest minute).
<b>Example</b>	<pre>JOBEXTENDSTARTWALLTIME TRUE</pre> <p>Submit job with a minimum wallclock limit and a walltime; for example:</p> <pre>echo sleep 500   msub -A ee -l nodes=5,minwclimit=5:00,walltime=30:00,partition=g02</pre> <p><i>At job start, Moab recognizes the nodes assigned to the specified job and extends the walltime for the job (one time at job start) up to the lesser of the maximum walltime requested or the least amount of time available for any of the nodes until the next reservation on that node.</i></p>

JOBFAILRETRYCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	<p>Specifies the number of times a job is requeued and restarted by Moab if the job fails (if the job itself returns a non-zero exit code). Some types of jobs may succeed if automatically retried several times in short succession. This parameter was created with these types of jobs in mind. Note that the job in question must also be restartable (the job needs to have the "RESTARTABLE" flag set on it) and the RM managing the job must support requeuing and starting completed jobs. If a job fails too many times, and reaches the number of retries given by JobFailRetryCount, then a UserHold is placed on the job and a message is attached to it signifying that the job has a "restart count violation."</p>
<b>Example</b>	<pre>JOBFAILRETRYCOUNT 7</pre> <p><i>Any job with a RESTARTABLE flag is requeued, if it fails, up to 7 times before a UserHold is placed on it.</i></p>

JOBIDWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	<p>Specifies the weight to be applied to the job's id. See <a href="#">Attribute (ATTR) Factor</a>.</p>
<b>Example</b>	<pre>JOBIDWEIGHT -1</pre> <p><i>Later jobs' priority will be negatively affected.</i></p>

JOBMATCHCFG	
<b>Format</b>	<ATTR>=<VAL> where <ATTR> is one of <a href="#">JMIN</a> , <a href="#">JMAX</a> , <a href="#">JDEF</a> , <a href="#">JSET</a> , or <a href="#">JSTAT</a>
<b>Default</b>	---
<b>Description</b>	Specifies the job templates which must be matched and which will be applied in the case of a match.
<b>Example</b>	<pre>JOBMATCHCFG[sql] JMIN=interactive JSTAT=istat</pre>

JOBMAXHOLDTIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	---
<b>Description</b>	Specifies the amount of time a job can be held before it is canceled automatically.
<b>Example</b>	<pre>JOBMAXHOLDTIME 02:00:00</pre> <p><i>Moab will keep jobs in any HOLD state for 2 hours before canceling them.</i></p>

JOBMAXNODECOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1024
<b>Description</b>	Specifies the maximum number of nodes which can be allocated to a job. After changing this parameter, Moab must be restarted. <b>Note:</b> This value cannot exceed either <b>MMAX_NODE</b> or <b>MMAX_TASK_PER_JOB</b> . If larger values are required, these values must also be increased. Moab must be restarted before changes to this command will take effect. The command <code>mdiag -S</code> will indicate if any job node count overflows have occurred. See <a href="#">Consideration for Large Clusters</a> .
<b>Example</b>	<pre>JOBMAXNODECOUNT 4000</pre>

JOBMAXOVERRUN	
<b>Format</b>	[[[DD:]HH:]MM:]SS],[[DD:]HH:]MM:]SS
<b>Default</b>	(no soft limit), <i>10 minutes</i> (hard limit)
<b>Description</b>	<p>Soft and hard limit of the amount of time Moab will allow a job to exceed its wallclock limit before it first sends a mail to the primary admin (soft limit) and then terminates the job (hard limit). See <a href="#">WCVIOLATIONACTION</a> or <a href="#">Usage-based Limits</a>.</p> <div style="border: 1px solid #0070C0; padding: 10px; margin-top: 10px;"> <p><b>i</b> If you run Moab with the TORQUE resource manager, you must set the <b>signwalltime</b> parameter to <i>true</i> in the <code>/var/spool/torque/mom_priv/config</code> file, otherwise the <code>pbs_mom</code> will kill any job that exceeds its walltime. See the <a href="#">TORQUE documentation</a> for more information.</p> </div>
<b>Example</b>	<pre>JOBMAXOVERRUN 15:00,1:00:00</pre> <p><i>Jobs may exceed their wallclock limit by up to 1 hour, but Moab will send an email to the primary administrator when a job exceeds its walltime by 15 minutes.</i></p>

JOBMAXPREEMPTPERITERATION	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (No Limit)
<b>Description</b>	Maximum number of jobs allowed to be preempted per iteration.
<b>Example</b>	<pre>JOBMAXPREEMPTPERITERATION 10</pre>

JOBMAXSTARTPERITERATION	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (No Limit)
<b>Description</b>	Maximum number of jobs allowed to start per <a href="#">iteration</a> .
<b>Example</b>	<pre>JOBMAXSTARTPERITERATION 10</pre>

JOBMAXSTARTTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	-1 (NO LIMIT)
<b>Description</b>	length of time a job is allowed to remain in a 'starting' state. If a 'started' job does not transition to a running state within this amount of time, Moab will cancel the job, believing a system failure has occurred.
<b>Example</b>	<pre>JOBMAXSTARTTIME 2:00:00</pre> <p><i>Jobs may attempt to start for up to 2 hours before being canceled by the scheduler</i></p>

JOBMAXTASKCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	4096
<b>Description</b>	Specifies the total number of tasks allowed per job.
<b>Example</b>	<pre>JOBMAXTASKCOUNT 226000</pre>

JOBMIGRATEPOLICY	
<b>Format</b>	One of the following: <i>IMMEDIATE</i> , <i>JUSTINTIME</i> , or <i>AUTO</i>
<b>Default</b>	<i>AUTO</i>
<b>Description</b>	Upon using the <a href="#">msub</a> command to submit a job, you can allocate the job to immediately ( <i>IMMEDIATE</i> ) migrate to the resource manager, or you can instruct Moab to only migrate the job to the resource manager when it is ready to run ( <i>JUSTINTIME</i> ). Specifying <i>AUTO</i> allows MOAB to determine on a per-job basis whether to use <i>IMMEDIATE</i> or <i>JUSTINTIME</i> .
<b>Example</b>	<pre>JOBMIGRATEPOLICY JUSTINTIME</pre>

JOBNAMEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Specifies the weight to be applied to the job's name if the Name contains an integer. See <a href="#">Attribute (ATTR) Factor</a> .
<b>Example</b>	<pre>JOBNAMEWEIGHT 1</pre>

JOBNODEMATCHPOLICY	
<b>Format</b>	<i>EXACTNODE</i> or <i>EXACTPROC</i>
<b>Default</b>	---
<b>Description</b>	Specifies additional constraints on how compute nodes are to be selected. <i>EXACTNODE</i> indicates that Moab should select as many nodes as requested even if it could pack multiple tasks onto the same node. <i>EXACTPROC</i> indicates that Moab should select only nodes with exactly the number of processors configured as are requested per node even if nodes with excess processors are available.
<b>Example</b>	<pre>JOBNODEMATCHPOLICY EXACTNODE</pre> <p><i>In a PBS/Native job with resource specification nodes=&lt;x&gt;:ppn=&lt;y&gt;, Moab will allocate exactly &lt;y&gt; task on each of &lt;x&gt; distinct nodes.</i></p>

JOBPREEMPTMAXACTIVETIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0
<b>Description</b>	The amount of time in which a job may be eligible for preemption. See <a href="#">Job Preemption</a> .
<b>Example</b>	<pre>JOBPREEMPTMAXACTIVETIME 00:05:00</pre> <p><i>A job is preemptable for the first 5 minutes of its run time.</i></p>

JOBPREEMPTMINACTIVETIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0
<b>Description</b>	The minimum amount of time a job must be active before being considered eligible for preemption. See <a href="#">Job Preemption</a> .
<b>Example</b>	<div style="border: 1px dashed gray; padding: 5px; margin-bottom: 5px;"> JOBPREEMPTMINACTIVETIME 00:05:00 </div> <p><i>A job must execute for <b>5 minutes</b> before Moab will consider it eligible for preemption.</i></p>

JOBPRIOACCRUALPOLICY	
<b>Format</b>	<i>ACCRUE</i> or <i>RESET</i>
<b>Default</b>	<i>ACCRUE</i>
<b>Description</b>	<p>Specifies how Moab should track the dynamic aspects of a job's priority. <i>ACCRUE</i> indicates that the job will accrue queuetime based priority from the time it is submitted unless it violates any of the policies not specified in <a href="#">JOBPRIOEXCEPTIONS</a>. <i>RESET</i> indicates that it will accrue priority from the time it is submitted unless it violates any of the <a href="#">JOBPRIOEXCEPTIONS</a>. However, with <i>RESET</i>, if the job does violate <a href="#">JOBPRIOEXCEPTIONS</a> then its queuetime based priority will be reset to 0.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin: 10px 0;"> <p><b>i</b> <a href="#">JOBPRIOACCRUALPOLICY</a> is a global parameter, but can be configured to work only in <a href="#">QOSCFG</a>:</p> <pre style="border: 1px dashed #0070C0; padding: 5px; display: inline-block;">QOSCFG[arrays] JOBPRIOACCRUALPOLICY=ACCRUE</pre> </div> <p>The following old <a href="#">JOBPRIOACCRUALPOLICY</a> values have been deprecated and should be adjusted to the following values:</p> <ul style="list-style-type: none"> <li>• <a href="#">QUEUEPOLICY</a>= <i>ACCRUE</i> and <a href="#">JOBPRIOEXCEPTIONS</a><i>SOFTPOLICY,HARDPOLICY</i></li> <li>• <a href="#">QUEUEPOLICYRESET</a>= <i>RESET</i> and <a href="#">JOBPRIOEXCEPTIONS</a><i>SOFTPOLICY,HARDPOLICY</i></li> <li>• <a href="#">ALWAYS</a>= <i>ACCRUE</i> and <a href="#">JOBPRIOEXCEPTIONS</a><i>ALL</i></li> <li>• <a href="#">FULLPOLICY</a>= <i>ACCRUE</i> and <a href="#">JOBPRIOEXCEPTIONS</a><i>NONE</i></li> <li>• <a href="#">FULLPOLICYRESET</a>= <i>RESET</i> and <a href="#">JOBPRIOEXCEPTIONS</a><i>NONE</i></li> </ul>
<b>Example</b>	<pre style="border: 1px dashed #0070C0; padding: 5px; display: inline-block;">JOBPRIOACCRUALPOLICY RESET</pre> <p style="border: 1px dashed #0070C0; padding: 5px; margin-top: 10px;"><i>Moab will adjust the job's dynamic priority subcomponents, i.e., <a href="#">QUEUE</a>TIME, <a href="#">XFACTOR</a>, and <a href="#">TARGET</a>QUEUE TIME, etc. each iteration that the job does not violate any <a href="#">JOBPRIOEXCEPTIONS</a>, if it is found in violation, its queuetime will be reset to 0.</i></p>

JOBPRIOEXCEPTIONS	
<b>Format</b>	Comma delimited list of any of the following: <i>DEFER</i> , <i>DEPENDS</i> , <i>SOFTPOLICY</i> , <i>HARDPOLICY</i> , <i>IDLEPOLICY</i> , <i>USERHOLD</i> , <i>BATCHHOLD</i> , and <i>SYSTEMHOLD</i> ( <i>ALL</i> or <i>NONE</i> can also be specified on their own)
<b>Default</b>	<i>NONE</i>
<b>Description</b>	<p>Specifies exceptions for calculating a job's dynamic priority (QUEUE TIME, XFACTOR, TARGETQUEUE TIME). Normally, when a job violates a policy, is placed on hold, or has an unsatisfied dependency, it will not accrue priority. Exceptions can be configured to allow a job to accrue priority in spite of any of these violations. With <i>DEPENDS</i> a job will increase in priority even if there exists an unsatisfied dependency. With <i>SOFTPOLICY</i>, <i>HARDPOLICY</i>, or <i>IDLEPOLICY</i> a job can accrue priority despite violating a specific limit. With <i>DEFER</i>, <i>USERHOLD</i>, <i>BATCHHOLD</i>, or <i>SYSTEMHOLD</i> a job can accrue priority despite being on hold.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> <b>JOBPRIOEXCEPTIONS</b> is a global parameter, but can be configured to work only in <a href="#">QOSCFG</a>:</p> <pre style="border: 1px dashed #ccc; padding: 5px; display: inline-block; margin: 5px 0;">QOSCFG[arrays] JOBPRIOEXCEPTIONS=IDLEPOLICY</pre> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; display: inline-block; margin-bottom: 5px;">JOBPRIOEXCEPTIONS BATCHHOLD, SYSTEMHOLD, DEPENDS</pre> <p style="border: 1px dashed #ccc; padding: 5px; display: inline-block; margin-top: 5px;"><i>Jobs will accrue priority in spite of batchholds, systemholds, or unsatisfied dependencies.</i></p>

JOBPRIOF	
<b>Format</b>	<ATTRIBUTE>[<VALUE>]=<PRIORITY> where <ATTRIBUTE> is one of <b>ATTR</b> , <b>GRES</b> or <b>STATE</b>
<b>Default</b>	---
<b>Description</b>	Specifies attribute priority weights for jobs with specific attributes, generic resource requests, or states. State values must be one of the standard Moab <a href="#">job states</a> . See <a href="#">Attribute-Based Job Prioritization</a> .
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; display: inline-block; margin-bottom: 5px;">JOBPRIOF          STATE[Running]=100  STATE[Suspended]=1000  ATTR[PREEMPTEE]=200 GRES[biocalc]=5 ATTRATTRWEIGHT   1 ATTRSTATEWEIGHT  1</pre> <p style="border: 1px dashed #ccc; padding: 5px; display: inline-block; margin-top: 5px;"><i>Moab will adjust the job's dynamic priority subcomponents.</i></p>

JOBPURGETIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>0</code> (purge immediately if the resource manager does not report the job)
<b>Description</b>	The amount of time Moab will keep a job record which is no longer reported by the resource manager. Useful when using a resource manager which <i>drops</i> information about a job due to internal failures. See <a href="#">JOBPCPURGETIME</a> .
<b>Example</b>	<pre>JOBPURGETIME 00:05:00</pre> <p><i>Moab will maintain a job record for 5 minutes after the last update regarding that object received from the resource manager.</i></p>

JOBREJECTPOLICY	
<b>Format</b>	One or more of <i>CANCEL</i> , <i>HOLD</i> , <i>IGNORE</i> (beta), <i>MAIL</i> , or <i>RETRY</i>
<b>Default</b>	<i>HOLD</i>
<b>Description</b>	Specifies the action to take when the scheduler determines that a job can never run. <i>CANCEL</i> issues a call to the resource manager to cancel the job. <i>HOLD</i> places a <i>batch</i> hold on the job preventing the job from being further evaluated until released by an administrator. ( <b>Note:</b> Administrators can dynamically alter job attributes and possibly <i>fix</i> the job with <a href="#">mjobctl -m</a> .) With <i>IGNORE</i> (currently in beta), the scheduler will allow the job to exist within the resource manager queue but will neither process it nor report it. <a href="#">MAIL</a> will send email to both the admin and the user when rejected jobs are detected. If <i>RETRY</i> is set, then Moab will allow the job to remain idle and will only attempt to start the job when the policy violation is resolved. Any combination of attributes may be specified. See <a href="#">QOSREJECTPOLICY</a> .
<b>Example</b>	<pre>JOBREJECTPOLICY MAIL,CANCEL</pre>

JOBREMOVEENVVARLIST	
<b>Format</b>	Comma-delimited list of strings
<b>Default</b>	---
<b>Description</b>	<p>Moab will remove the specified environment variables from the job's environment before migrating the job to its destination resource manager. This is useful when jobs submit themselves from one cluster to another with the full environment.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;">  This parameter is currently only supported with TORQUE resource managers.                 </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 5px;"> <pre>JOBREMOVEENVVARLIST PBS_SERVER, TZ</pre> </div> <div style="border: 1px dashed #ccc; padding: 10px;"> <p><i>Moab will remove the environment variables <b>PBS_SERVER</b> and <b>TZ</b> before submitting jobs.</i></p> </div>

JOBRETRYTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	00:00:60
<b>Description</b>	<p>Period of time Moab will continue to attempt to start a job which has failed to start due to transient failures or which has successfully started and was then rejected by the resource manager due to transient failures. (For related information, see <a href="#">Reservation Policies</a>, <a href="#">DEFERSTARTCOUNT</a>, <a href="#">DEFERTIME</a>, <a href="#">RESERVATIONRETRYTIME</a>, <a href="#">NODEFAILURERESERVETIME</a>, and <a href="#">GUARANTEEDPREEMPTION</a>.)</p>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 5px;"> <pre>JOBRETRYTIME 00:05:00</pre> </div> <div style="border: 1px dashed #ccc; padding: 10px;"> <p><i>Moab will try for up to <b>5 minutes</b> to restart jobs if the job start has failed due to transient errors.</i></p> </div>

LIMITEDJOBCEP	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether there should be limited job checkpointing (see <a href="#">Consideration for Large Clusters</a> ). With <b>LIMITEDJOBCEP</b> enabled, Moab will only checkpoint a job if it is modified with <a href="#">mjobctl on page 212</a> or if it has been submitted with <a href="#">msub on page 286</a> but has not migrated. In all other cases, Moab does not checkpoint the job and all Moab-specific information (such as messages attached to the job) is lost. No TORQUE-specific information will be lost.
<b>Example</b>	<pre>LIMITEDJOBCEP TRUE</pre> <p><i>Moab will only maintain scheduler checkpoint information for jobs with explicitly modified job attributes. Some minor job performance and usage statistics may be lost.</i></p>

LIMITEDNODECEP	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether there should be limited node checkpointing (see <a href="#">Consideration for Large Clusters</a> ).
<b>Example</b>	<pre>LIMITEDNODECEP TRUE</pre> <p><i>Moab will only maintain scheduler checkpoint information for nodes with explicitly modified job attributes. (some minor node performance and usage statistics may be lost)</i></p>

LOADALLJOB	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether Moab should load, during startup, all non-completed jobs in the checkpoint files regardless of whether or not their corresponding resource managers are active. For example, this allows source peers to continue showing remote jobs in the queue based on checkpointed info, even though the destination peer is offline.
<b>Example</b>	<pre>LOADALLJOB TRUE</pre> <p><i>Moab will load, at startup, all non-completed jobs from all checkpoint files.</i></p>

LOCKFILE	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the path for the lock (pid) file used by Moab.
<b>Example</b>	<pre>LOCKFILE /var/spool/moab/lock</pre>

LOGDIR	
<b>Format</b>	<STRING>
<b>Default</b>	log
<b>Description</b>	Specifies the directory in which log files will be maintained. If specified as a relative path, <b>LOGDIR</b> will be relative to \$(MOABHOMEDIR) See <a href="#">Logging Overview</a> for more information.
<b>Example</b>	<pre>LOGDIR /var/spool/moab</pre> <p><i>Moab will record its log files directly into the /var/spool/moab directory</i></p>

LOGFACILITY	
<b>Format</b>	Colon delimited list of one or more of the following: <i>CORE, SCHED, SOCK, UI, LL, CONFIG, STAT, SIM, STRUCT, FS, CKPT, BANK, RM, PBS, WIKI, ALL</i>
<b>Default</b>	<i>ALL</i>
<b>Description</b>	Specifies which types of events to log (see <a href="#">Logging Overview</a> ).
<b>Example</b>	<pre>LOGFACILITY RM:PBS</pre> <p><i>Moab will log only events involving general resource manager or PBS interface activities.</i></p>

LOGFILE	
<b>Format</b>	<STRING>
<b>Default</b>	<i>moab.log</i>
<b>Description</b>	Name of the Moab log file. This file is maintained in the directory pointed to by <LOGDIR> unless <LOGFILE> is an absolute path (see <a href="#">Logging Overview</a> )
<b>Example</b>	<pre>LOGFILE moab.test.log</pre> <p><i>Log information will be written to the file <i>moab.test.log</i> located in the directory pointed to by the <a href="#">LOGDIR</a> parameter.</i></p>

LOGFILEMAXSIZE	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>10000000</i>
<b>Description</b>	Maximum allowed size (in bytes) of the log file before it will be rolled (see <a href="#">Logging Overview</a> ).
<b>Example</b>	<pre>LOGFILEMAXSIZE 50000000</pre> <p><i>Log files will be rolled when they reach <b>50 MB</b> in size</i></p>

LOGFILEROLLDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	3
<b>Description</b>	Number of old log files to maintain (i.e., when full, moab.log will be renamed moab.log.1, moab.log.1 will be renamed moab.log.2, ...). See <a href="#">Logging Overview</a> .
<b>Example</b>	<pre>LOGFILEROLLDEPTH 5</pre> <p><i>Moab will maintain and roll the last 5 log files.</i></p>

LOGLEVEL	
<b>Format</b>	<INTEGER> (0-9)
<b>Default</b>	0
<b>Description</b>	Specifies the verbosity of Moab logging where 9 is the most verbose ( <b>Note:</b> each logging level is approximately an order of magnitude more verbose than the previous level). See <a href="#">Logging Overview</a> .
<b>Example</b>	<pre>LOGLEVEL 4</pre> <p><i>Moab will write all Moab log messages with a threshold of 4 or lower to the moab.log file.</i></p>

LOGLEVELOVERRIDE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>When this parameter is on, if someone runs a command with <code>--loglevel=&lt;x&gt;</code>, that loglevel, if higher than the current loglevel, is used on the scheduler side for the duration of the command. All logs produced during that time are put into a separate log file (this creates a "gap" in the normal logs). This can be very useful for debugging, but it is recommend that this be used only when diagnosing a specific problem so that users can't affect performance by submitting multiple <code>--loglevel</code> commands.</p> <div style="border: 1px solid #0070c0; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p> This parameter does not work with threaded commands (such as <code>showq</code>, <code>mdiag -n</code>, and <code>mdiag -j</code>).</p> </div>
<b>Example</b>	<code>LOGLEVELOVERRIDE TRUE</code>

LOGPERMISSIONS	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>644</i>
<b>Description</b>	Specifies the octal number that represents read, write, and execute permissions.
<b>Example</b>	<div style="border: 1px dashed #ccc; border-radius: 10px; padding: 10px; background-color: #e6f2ff;"> <p><code>LOGPERMISSIONS 600</code></p> <p><i>Allows the file owner to read and write permissions, but denies rights to the group and others.</i></p> </div>

LOGROLLACTION	
<b>Format</b>	< <i>STRING</i> >
<b>Default</b>	---
<b>Description</b>	Specifies a script to run when the logs roll. The script is run as a trigger and can be viewed using <a href="#">mdiag -T</a> . For example, a script can be specified that always moves the first rolled log file, <code>moab.log.1</code> , to an archive directory for longer term storage.
<b>Example</b>	<pre>LOGROLLACTION /usr/local/tools/logroll.pl</pre>

MAILPROGRAM	
<b>Format</b>	[<Full_Path_To_Mail_Command>   <i>DEFAULT</i>   <i>NONE</i> ][@<DEFAULTMAILDOMAIN>]
<b>Default</b>	<i>NONE</i>
<b>Description</b>	<p>If set to <i>NONE</i>, no mail is sent. If set to <i>DEFAULT</i>, Moab sends mail via the system's default mail program (usually <code>/usr/bin/sendmail</code>). If set to the local path of a mail program, Moab uses the specified mail program to send mail.</p> <p>By default, Moab mail notification is disabled. To enable, you must set <b>MAILPROGRAM</b> to <i>DEFAULT</i> or specify some other locally available mail program. If the <i>default mail domain</i> is set, emails will be routed to this domain unless a per-user domain is specified using the <b>EMAILADDRESS</b> attribute of the <a href="#">USERCFG</a> parameter. If neither of these values is set, Moab uses "<code>@localhost</code>" as the mail domain. See <a href="#">Notify Admins</a>.</p> <p>For jobs, the email address used on the <a href="#">msub -M</a> option overrides all other user email addresses. Additionally, administrators are notified in the case of job violations.</p>
<b>Example</b>	<pre>MAILPROGRAM DEFAULT</pre> <p><i>Moab sends mail via the system's default mail program, /usr/bin/sendmail.</i></p> <pre>MAILPROGRAM /usr/local/bin/sendmail@mydomain.com</pre> <p><i>Moab sends mail via the mail program located at /usr/local/bin/sendmail with default mail domain @mydomain.com</i></p>

MAXGRES	
<b>Format</b>	<INTEGER>
<b>Default</b>	512
<b>Description</b>	Specifies how many generic resources Moab should manage.
<b>Example</b>	<code>MAXGRES 1024</code>

MAXGMETRIC	
<b>Format</b>	<INTEGER>
<b>Default</b>	10
<b>Description</b>	Specifies how many generic metrics Moab should manage.
<b>Example</b>	<code>MAXGMETRIC 20</code>

MAXJOB	
<b>Format</b>	<INTEGER>
<b>Default</b>	4096
<b>Description</b>	<p>Specifies the maximum quantity of jobs for which Moab should allocate memory used for tracking jobs. If Moab is tracking the maximum quantity of jobs specified by this parameter, it rejects subsequent jobs submitted by any user since it has no memory left with which to track newly submitted jobs.</p> <p>If a user submitted a job with the <code>msub</code> command, this rejection behavior requires the user to resubmit the job at a later time after other jobs have completed, which frees memory in which Moab can place later-submitted jobs. If a user submitted a job with the TORQUE <code>qsub</code> command, TORQUE will automatically resubmit the job to Moab until Moab accepts it.</p> <p>The <code>mdiag -S</code> command indicates if any job overflows have occurred.</p> <p>If this parameter's value is changed, it does not go into effect until Moab restarts. Moab reads the parameter only on initial startup and uses its value to allocate the memory it uses to track jobs.</p>
<b>Example</b>	<code>MAXJOB 45000</code>

MAXNODE	
<b>Format</b>	<INTEGER>
<b>Default</b>	5120
<b>Description</b>	Specifies the maximum number of compute nodes supported.
<b>Example</b>	<pre>MAXNODE 10000</pre>

MAXRSVPERNODE	
<b>Format</b>	<INTEGER>
<b>Default</b>	48
<b>Description</b>	<p>Specifies the maximum number of reservations on a node.</p> <p>For large SMP systems (&gt;512 processors/node), Adaptive Computing advises adjusting the value to approximately twice the average sum of admin, standing, and job reservations present.</p> <p>A second number, led by a comma, can also be specified to set a maximum number of reservations for nodes that are part of the SHARED partition.</p> <p>The maximum possible value of <b>MAXRSVPERNODE</b> is 8192 for a global node and 4096 for any other node.</p> <p>Moab must be restarted for any changes to this parameter to take effect. The command <code>mdiag -S</code> indicates whether any node reservation overflows have occurred. See <a href="#">Considerations for Large Clusters</a>.</p> <div style="border: 1px solid red; padding: 5px; margin-top: 10px;">  Do not lower the MAXRSVPERNODE value while there are active jobs in the queue. This can lead to queue instability and certain jobs could become stuck or disconnected from the system.         </div>
<b>Example</b>	<pre>MAXRSVPERNODE 64</pre> <p><i>64 is the maximum number of reservations on a single node.</i></p> <pre>MAXRSVPERNODE 100,7000</pre> <p><i>100 is the maximum number of reservations on a single node, and 7000 is the maximum number of reservations for global nodes.</i></p>

MEMREFRESHINTERVAL	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS   job:&lt;COUNT&gt;</code>
<b>Default</b>	---
<b>Description</b>	Specifies the time interval or total job query count at which Moab will perform garbage collection to free memory associated with resource manager API's which possess memory leaks (i.e., Loadleveler, etc.).
<b>Example</b>	<pre># free memory associated with leaky RM API MEMREFRESHINTERVAL 24:00:00</pre> <p><i>Moab will perform garbage collection once every 24 hours.</i></p>

MEMWEIGHT	
<b>Format</b>	<code>&lt;INTEGER&gt;</code>
<b>Default</b>	0
<b>Description</b>	Specifies the coefficient to be multiplied by a job's MEM (dedicated memory in MB) factor. See <a href="#">Resource Priority Overview</a> .
<b>Example</b>	<pre>RESWEIGHT 10 MEMWEIGHT 1000</pre> <p><i>Each job's priority will be increased by <math>10 * 1000 * \text{&lt;request memory&gt;}</math>.</i></p>

MESSAGEQUEUEADDRESS	
<b>Format</b>	The IP address of the machine on which Moab is generating events.
<b>Default</b>	* (all)
<b>Description</b>	When a user subscribes to the events Moab provides and delivers via zeroMQ, s/he must do so by specifying <code>tcp://&lt;ipAddress&gt;:&lt;port&gt;</code> . <b>MESSAGEQUEUEADDRESS</b> specifies the <code>&lt;ipAddress&gt;</code> , which must match the IP address of the machine on which Moab is installed. To specify the port, see <a href="#">MESSAGEQUEUEPORT on page 996</a> .
<b>Example</b>	<pre>MESSAGEQUEUEADDRESS 10.1.0.10</pre> <p><i>To subscribe to Moab events, users must use <code>tcp://10.1.0.10:&lt;port&gt;</code>.</i></p>

MESSAGEQUEUEPORT	
<b>Format</b>	The port of the machine on which Moab is generating events.
<b>Default</b>	5563
<b>Description</b>	When a user subscribes to the events Moab provides and delivers via zeroMQ, s/he must do so by specifying <code>tcp://&lt;ipAddress&gt;:&lt;port&gt;</code> . <b>MESSAGEQUEUEPORT</b> specifies the <code>&lt;port&gt;</code> , which must match the port of the machine on which Moab is installed. To specify the IP address, see <a href="#">MESSAGEQUEUEADDRESS on page 996</a> .
<b>Example</b>	<pre>MESSAGEQUEUEPORT 1010</pre> <p><i>To subscribe to Moab events, users must use <code>tcp://&lt;ipAddress&gt;:1010</code>.</i></p>

MESSAGEQUEUESECRETKEY	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	<p>Causes Moab to encrypt the events delivered via zeroMQ using the Advanced Encryption Standard (AES) algorithm. Must be a <a href="#">Base64</a>-encoded, 128-bit (16-byte) key. Messages will be encrypted using AES in CBC mode where inputs are padded with PKCS5 padding. The initialization vector is calculated by using an MD5 hash of the key specified in <b>MESSAGEQUEUESECRETKEY</b>.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;">  <b>MESSAGEQUEUESECRETKEY</b> can only be specified in the moab-private.cfg file.                 </div>
<b>Example</b>	<pre>MESSAGEQUEUESECRETKEY 1r6RvfqJa6voezy5wAx0hw==</pre>

MINADMINSTIME	
<b>Format</b>	<INTEGER>
<b>Default</b>	60 seconds
<b>Description</b>	Specifies the minimum time a job will be <a href="#">suspended</a> if suspended by an administrator or by a scheduler policy.
<b>Example</b>	<pre>MINADMINSTIME 00:10:00</pre> <div style="border: 1px dashed #000; padding: 10px; margin-top: 10px;"> <p><i>Each job suspended by administrators or policies will stay in the suspended state for at least 10 minutes.</i></p> </div>

MISSINGDEPENDENCYACTION	
<b>Format</b>	<i>CANCEL, HOLD, or RUN</i>
<b>Default</b>	<i>HOLD</i>
<b>Description</b>	Controls what Moab does with a dependent job when its dependency job cannot be found when Moab evaluates the dependent job for scheduling. This only affects jobs whose dependent job cannot be found.
<b>Example</b>	<pre>MISSINGDEPENDENCYACTION CANCEL</pre> <p><i>Any job that has a dependent job that cannot be found is canceled.</i></p>

MSUBQUERYINTERVAL	
<b>Format</b>	<INTEGER>
<b>Default</b>	5 seconds
<b>Description</b>	<p>Specifies the length of the interval (in seconds) between job queries when using <a href="#">msub -K</a>. Jobs submitted with the -K option query the scheduler every <b>MSUBQUERYINTERVAL</b> seconds until the job is completed.</p> <p><b>MSUBQUERYINTERVAL</b> can exist as an environment variable. Any value in <code>moab.cfg</code> overrides the environment variable.</p> <p><b>Note:</b> If <b>MSUBQUERYINTERVAL</b> is set to 0, the -K option will be disabled. Jobs will still submit correctly, but the client will not continue to check on the job.</p>
<b>Example</b>	<pre>MSUBQUERYINTERVAL 60</pre> <p><i>If a user uses the <a href="#">msub -K</a> command, the client remains open and queries the server every 60 seconds until the job completes.</i></p>

NODEACCESSPOLICY	
<b>Format</b>	One of the following: <a href="#">SHARED</a> , <a href="#">SHAREDONLY</a> , <a href="#">SINGLEJOB</a> , <a href="#">SINGLETASK</a> , <a href="#">SINGLEUSER</a> , or <a href="#">UNIQUEUSER</a>
<b>Default</b>	<b>SHARED</b>
<b>Description</b>	Specifies how node resources will be shared by various tasks (See the <a href="#">Node Access Overview</a> for more information).
<b>Example</b>	<pre>NODEACCESSPOLICY SINGLEUSER</pre> <p>Moab will allow resources on a node to be used by more than one job provided that the jobs are all owned by the same user.</p>

NODEALLOCATIONPOLICY	
<b>Format</b>	One of the following: <a href="#">FIRSTAVAILABLE</a> , <a href="#">LASTAVAILABLE</a> , <a href="#">MINRESOURCE</a> , <a href="#">CPULOAD</a> , <a href="#">LOCAL</a> , <a href="#">CONTIGUOUS</a> , <a href="#">MAXBALANCE</a> , <a href="#">PRIORITY</a> , or <a href="#">PLUGIN</a> .
<b>Default</b>	<i>LASTAVAILABLE</i>
<b>Description</b>	<p>Specifies how Moab should allocate available resources to jobs. See <a href="#">Node Allocation Overview</a> for more information.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; margin-top: 10px;"> <p> If <b>ENABLEHIGHTHROUGHPUT</b> on page 950 is <i>TRUE</i>, you must set <b>NODEALLOCATIONPOLICY</b> to <i>FIRSTAVAILABLE</i>.</p> </div>
<b>Example</b>	<pre>NODEALLOCATIONPOLICY MINRESOURCE</pre> <p><i>Moab will apply the node allocation policy <b>MINRESOURCE</b> to all jobs by default.</i></p>

NODEALLOCRESFAILUREPOLICY	
<b>Format</b>	One of the following: <i>CANCEL, HOLD, IGNORE, MIGRATE, NOTIFY, or REQUEUE</i>
<b>Default</b>	<i>NONE</i>
<b>Description</b>	Specifies how Moab should handle active jobs which experience node failures during execution. See the <a href="#">RESFAILPOLICY</a> resource manager extension or the <a href="#">Node Availability Overview</a> .
<b>Example</b>	<pre>NODEALLOCRESFAILUREPOLICY REQUEUE</pre> <p><i>Moab will requeue jobs which have allocated nodes fail during execution.</i></p>

NODEAVAILABILITYPOLICY	
<b>Format</b>	<POLICY>[:<RESOURCE TYPE>] ... where <POLICY> is one of <b>COMBINED</b> , <b>DEDICATED</b> , or <b>UTILIZED</b> and <RESOURCE TYPE> is one of <i>PROC, MEM, SWAP, or DISK</i>
<b>Default</b>	<b>COMBINED</b>
<b>Description</b>	<p>Specifies how available node resources are reported. Moab uses the following calculations to determine the amount of available resources:</p> <p><b>Dedicated</b>(use what Moab has scheduled to be used): Available = Configured - Dedicated</p> <p><b>Utilized</b>(use what the resource manager is reporting is being used): Available = Configured - Utilized</p> <p><b>Combined</b>(use the larger of dedicated and utilized): Available = Configured - (MAX(Dedicated, Utilized))</p> <p>Moab marks a node as busy when it has no available processors, so <b>NODEAVAILABILITYPOLICY</b>, by affecting how many processors are reported as available, also affects node state. See <a href="#">Node Availability Policies</a> for more information.</p>
<b>Example</b>	<pre>NODEAVAILABILITYPOLICY DEDICATED:PROCS COMBINED:MEM</pre> <p><i>Moab will ignore resource utilization information in locating available processors for jobs but will use both dedicated and utilized memory information in determining memory availability.</i></p>

NODEBUSYSTATEDELAYTIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>0:01:00</code> (one minute)
<b>Description</b>	Length of time Moab will assume busy nodes will remain unavailable for scheduling if a system reservation is not explicitly created for the node.
<b>Example</b>	<pre>NODEBUSYSTATEDELAYTIME 0:30:00</pre> <p><i>Moab will assume busy nodes are not available for scheduling for at least <b>30 minutes</b> from the current time. Thus, these nodes will never be allocated to starting jobs. Also, these nodes will only be available for reservations starting more than <b>30 minutes</b> in the future.</i></p>

NODECATCREDLIST	
<b>Format</b>	<code>&lt;LABEL&gt;=&lt;NODECAT&gt;[,&lt;NODECAT&gt;]...[&lt;LABEL&gt;=&lt;NODECAT&gt;[,&lt;NODECAT&gt;]...]</code> where <code>&lt;LABEL&gt;</code> is any string and <code>&lt;NODECAT&gt;</code> is one of the defined node categories.
<b>Default</b>	---
<b>Description</b>	If specified, Moab will generate node category groupings and each iteration will assign usage of matching resources to pseudo-credentials with a name matching the specified label. See the <a href="#">Node Categorization</a> section of the Admin manual for more information.
<b>Example</b>	<pre>NODECATCREDLIST down=BatchFailure,HardwareFailure,NetworkFailure idle=Idle</pre> <p><i>Moab will create a <b>down</b> user, group, account, class, and QoS and will associate <b>BatchFailure</b>, <b>HardwareFailure</b>, and <b>NetworkFailure</b> resources with these credentials. Additionally, Moab will assign all <b>Idle</b> resources to matching <b>idle</b> credentials.</i></p>

NODECFG[X]	
<b>Format</b>	List of space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">ACCESS</a> , <a href="#">CHARGERATE</a> , <a href="#">FEATURES</a> , <a href="#">FLAGS</a> , <a href="#">GRES</a> , <a href="#">MAXJOB</a> , <a href="#">MAXJOBPERUSER</a> , <a href="#">MAXLOAD</a> , <a href="#">MAXPE</a> , <a href="#">NODEINDEX</a> , <a href="#">NODETYPE</a> , <a href="#">OSLIST</a> , <a href="#">PARTITION</a> , <a href="#">POWERPOLICY</a> on page 560, <a href="#">PRIORITY</a> , <a href="#">PRIORITYF</a> , <a href="#">PROCSPEED</a> , <a href="#">RACK</a> , <a href="#">RADISK</a> , <a href="#">SLOT</a> , <a href="#">SPEED</a> , or <a href="#">TRIGGER</a>
<b>Default</b>	---
<b>Description</b>	Specifies node-specific attributes for the node indicated in the array field. See the <a href="#">General Node Administration Overview</a> for more information.
<b>Example</b>	<pre>NODECFG[nodeA] MAXJOB=2 SPEED=1.2</pre> <p><i>Moab will only allow 2 simultaneous jobs to run on node nodeA and will assign a relative machine speed of 1.2 to this node.</i></p>

NODEDOWNSTATEDELAYTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	-1 (never)
<b>Description</b>	Length of time Moab will assume <a href="#">down</a> , <a href="#">drained</a> (offline), or corrupt nodes will remain unavailable for scheduling if a system reservation is not explicitly created for the node. The default specification of "-1" causes Moab to never create job reservations on down nodes. See <a href="#">Node Availability</a> for more information.
<b>Example</b>	<pre>NODEDOWNSTATEDELAYTIME 0:30:00</pre> <p><i>Moab will assume down, drained, and corrupt nodes are not available for scheduling for at least 30 minutes from the current time. Thus, these nodes will never be allocated to starting jobs. Also, these nodes will only be available for reservations starting more than 30 minutes in the future.</i></p>

NODEDOWNTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	The maximum time a previously reported node remains unreported by a resource manager before the node is considered to be in the <a href="#">down</a> state. This can happen if communication with a resource manager or a peer server is lost for more than the specified length of time, or if there is communication with the resource manager but it fails to report the node status.
<b>Example</b>	<pre>NODEDOWNTIME 10:00</pre> <p><i>If Moab loses communication with the resource manager for more than <b>10 minutes</b>, it sets the state of all nodes belonging to that resource manager to <b>DOWN</b>.</i></p>

NODEDRAINSTATEDELAYTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	<b>3:00:00</b> (three hours)
<b>Description</b>	Length of time Moab will assume <a href="#">drained</a> nodes will remain unavailable for scheduling if a system reservation is not explicitly created for the node. Specifying "-1" will cause Moab to never create job reservations on drained nodes. See <a href="#">Node Availability</a> for more information.
<b>Example</b>	<pre>NODEDRAINSTATEDELAYTIME 0:30:00</pre> <p><i>Moab will assume down, drained, and corrupt nodes are not available for scheduling for at least <b>30 minutes</b> from the current time. Thus, these nodes will never be allocated to starting jobs. Also, these nodes will only be available for reservations starting more than <b>30 minutes</b> in the future.</i></p>

NODEFAILURERESERVETIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>0:05:00</code>
<b>Description</b>	Duration of reservation Moab will place on any node in which it detects a failure from the resource manager (0 indicates no reservation will be placed on the node). See <a href="#">Node Availability</a> for more information. See also <a href="#">RMCFG[] NODEFAILURERSVPROFILE</a> . (For related information, see <a href="#">Reservation Policies</a> , <a href="#">DEFERSTARTCOUNT</a> , <a href="#">DEFERTIME</a> , <a href="#">RESERVATIONRETRYTIME</a> , <a href="#">JOBRETRYTIME</a> , and <a href="#">GUARANTEEDPREEMPTION</a> .)
<b>Example</b>	<pre>NODEFAILURERESERVETIME 10:00</pre> <p><i>Moab will reserve failed nodes for 10 minutes.</i></p>

NODEIDFORMAT	
<b>Format</b>	<code>&lt;STRING&gt;</code>
<b>Default</b>	<code>*\$N*</code>
<b>Description</b>	Specifies how a node id can be processed to extract possible node, rack, slot, and cluster index information. The value of the parameter may include the markers <code>\$C</code> (cluster index), <code>\$N</code> (node index), <code>\$R</code> (rack index), or <code>\$S</code> (slot index) separated by <code>*</code> (asterisk - representing any number of non-numeric characters) or other characters to indicate this encoding. See <a href="#">Node Selection</a> for more information on use of node, rack, and slot indices.
<b>Example</b>	<pre>NODEIDFORMAT *\$R*\$S</pre> <p><i>Moab will extract rack and slot information from the cluster node ids (i.e. tg-13s08).</i></p>

NODEIDLEPOWERACTION	
<b>Format</b>	[STANDBY   SUSPEND   SLEEP   HIBERNATE   SHUTDOWN   OFF]
<b>Default</b>	<i>OFF</i>
<b>Description</b>	Specifies what to do with a node that exceeds the NODEIDLEPOWERTHRESHOLD limit.
<b>Example</b>	<pre>PARCFG[ALL] NODEIDLEPOWERACTION STANDBY</pre> <p><i>Nodes that exceed the NODEIDLEPOWERTHRESHOLD limit are placed in standby.</i></p>

NODEIDLEPOWERTHRESHOLD	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>60 seconds</i>
<b>Description</b>	Specifies how long to allow a node to be idle before performing a power action. Increasing the idle duration prevents power on/off thrashing.
<b>Example</b>	<pre>NODEIDLEPOWERTHRESHOLD 300</pre> <p><i>Moab will wait 5 minutes before performing a power action on a node that has become idle.</i></p>

NODEMAXLOAD	
<b>Format</b>	<DOUBLE>
<b>Default</b>	<i>0.0</i>
<b>Description</b>	Specifies that maximum cpu load on an idle or running node. If the node's load reaches or exceeds this value, Moab will mark the node <u>busy</u> .
<b>Example</b>	<pre>NODEMAXLOAD 0.75</pre> <p><i>Moab will adjust the state of all idle and running nodes with a load &gt;= .75 to the state busy.</i></p>

NODEMEMOVERCOMMITFACTOR	
<b>Format</b>	<DOUBLE>
<b>Default</b>	---
<b>Description</b>	The parameter overcommits available and configured memory and swap on a node by the specified factor (for example: mem/swap * factor). Used to show that the node has more mem and swap than it really does. Only works for PBS RM types.
<b>Example</b>	<pre>NODEMEMOVERCOMMITFACTOR .5</pre> <p><i>Moab will overcommit the memory and swap of the node by a factor of 0.5.</i></p>

NODEPOLLFREQUENCY	
<b>Format</b>	<INTEGER>
<b>Default</b>	0 (Poll Always)
<b>Description</b>	Specifies the number of scheduling iterations between scheduler initiated node manager queries. If set to '-2', Moab will never query the node manager daemons. If set to '-1', Moab will only query on the first iteration. <b>Note:</b> this parameter is most often used with OpenPBS and PBSPro. It is not required when using TORQUE, LoadLeveler, LSF, or SGE as the resource managers.
<b>Example</b>	<pre>NODEPOLLFREQUENCY 5</pre> <p><i>Moab will update node manager based information every 5 scheduling iterations.</i></p>

NODESETATTRIBUTE	
<b>Format</b>	<i>FEATURE</i> or <i>VARATTR</i>
<b>Default</b>	---
<b>Description</b>	Specifies the type of node attribute by which node set boundaries will be established. See <a href="#">Node Set Overview</a> .
<b>Example</b>	<pre>NODESETPOLICY    ONEOF NODESETATTRIBUTE FEATURE</pre> <p><i>Moab will create node sets containing nodes with common features.</i></p>

NODESETDELAY	
<b>Format</b>	<i>[[[DD:]HH:]MM:]SS</i>
<b>Default</b>	<i>0:00:00</i>
<b>Description</b>	<p>Causes Moab to attempt to span a job evenly across nodesets unless doing so delays the job beyond the requested <b>NODESETDELAY</b>.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p><b>i</b> Must use with <b>NODESETPLUS</b> on page 1009 set to <i>SPANEVENLY</i>; if you do not want to use <i>SPANEVENLY</i>, use <b>NODESETISOPTIONAL</b> on page 1008 instead of <b>NODESETDELAY</b>.</p> </div>
<b>Example</b>	<pre>NODESETPLUS SPANEVENLY NODESETDELAY    5:00</pre> <p><i>Moab tries to span the job evenly across nodesets unless doing so delays the job by 5 minutes.</i></p>

NODESETISOPTIONAL	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Specifies whether or not Moab will start a job if a requested node set cannot be satisfied. See <a href="#">Node Set Overview</a> .
<b>Example</b>	<pre>NODESETISOPTIONAL TRUE</pre> <p><i>Moab will not block a job from running if its node set cannot be satisfied.</i></p>

NODESETLIST	
<b>Format</b>	<ATTR>[{:}]<ATTR>[...]
<b>Default</b>	---
<b>Description</b>	Specifies the list of node attribute values which will be considered for establishing node sets. See <a href="#">Node Set Overview</a> .
<b>Example</b>	<pre>NODESETPOLICY      ONEOF NODESETATTRIBUTE   FEATURE NODESETLIST        switchA,switchB</pre> <p><i>Moab will allocate nodes to jobs either using only nodes with the <b>switchA</b> feature or using only nodes with the <b>switchB</b> feature.</i></p>

NODESETPLUS	
<b>Format</b>	<i>DELAY</i> or <i>SPANEVENLY</i>
<b>Default</b>	---
<b>Description</b>	<p>Specifies how Moab distributes jobs among nodesets. See <a href="#">Node Set Overview</a>.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> Neither <i>SPANEVENLY</i> nor <i>DELAY</i> values of the <a href="#">NODESETPLUS</a> parameter will work with multi-req jobs or preemption.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 10px;"> <p>NODESETPLUS SPANEVENLY</p> <p><i>Moab attempts to fit all jobs on a single nodeset or to span them evenly across a number of nodesets, unless doing so would delay a job beyond the requested <a href="#">NODESETDELAY</a>.</i></p> </div> <div style="border: 1px dashed #ccc; padding: 10px;"> <p>NODESETPLUS DELAY</p> <p><i>Moab attempts to schedule the job within a nodeset for the configured <a href="#">NODESETDELAY</a>. If Moab cannot find space for the job to start within <a href="#">NODESETDELAY</a> (Moab considers future workload to determine if space will open up in time and might create a future reservation), then Moab schedules the job and ignores the nodeset requirement.</i></p> </div>

NODESETPOLICY	
<b>Format</b>	<i>ANYOF, FIRSTOF, or ONEOF</i>
<b>Default</b>	---
<b>Description</b>	<p>Specifies how nodes will be allocated to the job from the various node set generated. See <a href="#">Node Set Overview</a>.</p>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 10px;"> <p>NODESETPOLICY ONEOF NODESETATTRIBUTE NETWORK</p> </div> <div style="border: 1px dashed #ccc; padding: 10px;"> <p><i>Moab will create node sets containing nodes with common network interfaces.</i></p> </div>

NODESETPRIORITYTYPE	
<b>Format</b>	one of <i>AFFINITY</i> , <i>BESTFIT</i> , <i>WORSTFIT</i> , or <i>MINLOSS</i>
<b>Default</b>	<i>MINLOSS</i>
<b>Description</b>	Specifies how resource sets will be selected when more than one feasible resource can be found. See <a href="#">Node Set Overview</a> .
<b>Example</b>	<pre>NODESETPRIORITYTYPE BESTFIT NODESETATTRIBUTE    PROC SPEED</pre> <p><i>Moab will select the resource set that most closely matches the set of resources requested.</i></p>

NODESYNCTIME	
<b>Format</b>	<i>[[[DD:]HH:]MM:]SS</i>
<b>Default</b>	<i>00:10:00</i>
<b>Description</b>	Specifies the length of time after which Moab will sync up a node's expected state with an unexpected reported state. <b>IMPORTANT Note:</b> Moab will not start new jobs on a node with an expected state which does not match the state reported by the resource manager.
<b>Example</b>	<pre>NODESYNCTIME 1:00:00</pre>

NODETOJOBATTRMAP	
<b>Format</b>	Comma delimited list of node features
<b>Default</b>	---
<b>Description</b>	Job requesting the listed node features will be assigned a corresponding job attribute. These job attributes can be used to enable <a href="#">reservation access</a> , adjust <a href="#">job priority</a> or enable other capabilities.
<b>Example</b>	<pre>NODETOJOBATTRMAP fast, big</pre> <p><i>Jobs requesting node feature <i>fast</i> or <i>big</i> will be assigned a corresponding job attribute.</i></p>

NODEUNTRACKEDRESDELAYTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0:00:00
<b>Description</b>	<p>Length of time Moab will assume untracked generic resources will remain unavailable for scheduling if a system reservation is not explicitly created for the node.</p> <p>If <b>NODEUNTRACKEDRESDELAYTIME</b> is enabled and there is an untracked resource preventing a job from running, then the job remains in the idle queue instead of being deferred.</p>
<b>Example</b>	<div style="border: 1px dashed gray; padding: 10px;"> <p>NODEUNTRACKEDRESDELAYTIME 0:30:00</p> <p><i>Moab will assume untracked generic resources are not available for scheduling for at least 30 minutes from the current time. Thus, these nodes will never be allocated to starting jobs. Also, these nodes will only be available for reservations starting more than 30 minutes in the future.</i></p> </div>

NODEVMFEATURECHECKTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0:10:00
<b>Description</b>	<p>The length of time between each Moab check on node and VM features. If a running VM requires a feature but the resource manager is no longer reporting that feature on the VM's host node, Moab migrates the VM to a node that has the feature. If no other node has that feature, no migration occurs.</p>
<b>Example</b>	<div style="border: 1px dashed gray; padding: 10px;"> <p>NODEVMFEATURECHECKTIME 10:00</p> <p><i>Moab checks node and VM features every 10 minutes.</i></p> </div>

NODEVMREQATTRCHECKTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	0:10:00

NODEVMREQATTRCHECKTIME	
<b>Description</b>	The length of time between each Moab check on a VM's requested node attributes. If a running VM requires node attributes but the resource manager is no longer reporting requested attributes on the VM's host node, Moab migrates the VM to a node that has the requested attributes. If no other node has the requested attributes, no migration occurs.
<b>Example</b>	<pre>NODEVMREQATTRCHECKTIME 10:00</pre> <p><i>Moab checks requested node attributes of a node running a VM every 10 minutes.</i></p>

NODEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight which will be applied to a job's requested node count before this value is added to the job's cumulative priority. <b>Note:</b> this weight currently only applies when a nodecount is specified by the user job. If the job only specifies tasks or processors, no node factor will be applied to the job's total priority. This will be rectified in future versions.
<b>Example</b>	<pre>NODEWEIGHT 1000</pre>

NOLOCALUSERENV	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If <i>TRUE</i> , specifies that a user's UserID, GroupID, and HomeDirectory are available on the Moab server host.
<b>Example</b>	<pre>NOLOCALUSERENV TRUE</pre>

NOJOBHOLDNORESOURCES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If <i>TRUE</i> , Moab does not place a hold on jobs that don't have feasible resources. For example, suppose there are 20 processors available for ClassA and 50 processors for the entire system. If a job requests 21 or more processors from ClassA, or 51 or more processors from the entire system, Moab idles the job (instead of putting a hold on it) until the resources become available.
<b>Example</b>	<pre>NOJOBHOLDNORESOURCES TRUE</pre>

NOTIFICATIONPROGRAM	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the name of the program to handle all notification call-outs.
<b>Example</b>	<pre>NOTIFICATIONPROGRAM tools/notifyme.pl</pre>

NOWAITPREEMPTION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	Generally when a job is trying to preempt another, it just waits for the original jobs that it chose to preempt to end. If this parameter is on, the preemptor will continue trying to preempt jobs until it can get in.
<b>Example</b>	<pre>NOWAITPREEMPTION TRUE</pre>

OSCREDLLOOKUP	
<b>Format</b>	NEVER
<b>Default</b>	---
<b>Description</b>	<p>Disables all Moab OS credential lookups, including UID, GID, user to group mappings, and any other OS specific information.</p> <p>Setting OSCREDLLOOKUP by itself does not allow job submission; additional configuration is required. When submitting jobs from user accounts that do not exist on the head node (where Moab HPC Suite – Basic Edition and TORQUE are running), you must also set the <a href="#">PROXYJOB SUBMISSION</a> flag in addition to specifying configuration settings in the resource manager configuration file. See the example that follows for information on required resource manager settings.</p>
<b>Example</b>	<pre>OSCREDLLOOKUP NEVER RMCFG[] FLAGS=PROXYJOB SUBMISSION</pre> <p>To allow job submission, in the TORQUE configuration file (<a href="#">torque.cfg</a>):</p> <pre>VALIDATEPATH FALSE</pre> <p>Run the following <a href="#">qmgr</a> directive:</p> <pre>set server disable_server_id_check = True</pre> <p>Restart both Moab HPC Suite – Basic Edition and pbs_server.</p>

PARALLOCATIONPOLICY	
<b>Format</b>	One of <i>BestFit</i> , <i>BestFitP</i> , <i>FirstStart</i> , <i>LoadBalance</i> , <i>LoadBalanceP</i> , <i>Random</i> , or <i>RoundRobin</i>
<b>Default</b>	<i>FirstStart</i>
<b>Description</b>	Specifies the approach to use to allocate resources when more than one eligible partition can be found. See <a href="#">Grid Scheduling Policies</a> for more information.
<b>Example</b>	<pre>PARALLOCATIONPOLICY LOADBALANCE</pre> <p><i>New jobs will be started on the most lightly allocated partition.</i></p>

PARCFG	
<b>Format</b>	<a href="#">NODEPOWEROFFDURATION</a> , <a href="#">NODEPOWERONDURATION</a> , <a href="#">NODEALLOCATIONPOLICY</a> or one or more key-value pairs as described in the <a href="#">Partition Overview</a>
<b>Default</b>	---
<b>Description</b>	Specifies the attributes, policies, and constraints for the given partition.
<b>Example</b>	<pre>PARCFG[oldcluster] MAX.WCLIMIT=12:00:00</pre> <p><i>Moab will not allow jobs to run on the oldcluster partition which has a wallclock limit in excess of 12 hours.</i></p>

PBSACCOUNTINGDIR	
<b>Format</b>	<PATH>
<b>Default</b>	---
<b>Description</b>	When specified, Moab will write out job events in standard PBS/ <a href="#">TORQUE tracejob</a> format to the specified directory using the standard PBS/TORQUE log file naming convention.
<b>Example</b>	<pre>PBSACCOUNTINGDIR /var/spool/torque/sched_logs/</pre> <p><i>Job events will be written to the specified directory (can be consumed by PBS's tracejob command).</i></p>

PERPARTITIONSCHEDULING	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>By default Moab's scheduling routine schedules each job on each partition using the following algorithm:</p> <pre> <i>prioritize</i> <i>foreach (job)</i>     <i>find the partition on which that job should run</i>     <i>schedule job</i> </pre> <p>In this model, a job's priority is the same on each partition as it uses a single global priority. Because a job's priority is the same on every partition, Moab prioritizes the queue once and then schedules the prioritized queue across all partitions.</p> <p>When PERPARTITIONSCHEDULING TRUE is set, the following algorithm is used:</p> <pre> <i>foreach (partition)</i>     <i>prioritize</i>     <i>foreach (job)</i>         <i>schedule job</i> </pre> <p>In this case, each partition may have a unique priority configuration and Moab will re-prioritize the jobs for each partition on the system. Each job is prioritized and scheduled on each partition. See <a href="#">PARCFG on page 1015</a> for more information. Also, note that Moab will order the partitions as they are discovered in the moab.cfg file. Partitions should be explicitly ordered via PARCFG in the moab.cfg file.</p>
<b>Example</b>	<pre> PERPARTITIONSCHEDULING TRUE PARCFG [p1] CONFIGFILE=/opt/moab/etc/p1.cfg PARCFG [p2] CONFIGFILE=/opt/moab/etc/p2.cfg </pre> <p><i>Rather than prioritizing the job queue once, Moab prioritizes the job queue for each partition, p1 and p2 respectively, and schedules each partition in turn using the policies located in their respective configuration files. (See <a href="#">Per-Partition Settings on page 497</a> for more information).</i></p>

PEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the coefficient to be multiplied by a job's PE (processor equivalent) priority factor.
<b>Example</b>	<pre>RESWEIGHT 10 PEWEIGHT 100</pre> <p><i>Each job's priority will be increased by 10 * 100 * its PE factor.</i></p>

PREEMTPOLICY	
<b>Format</b>	one of the following: <a href="#">CANCEL</a> , <a href="#">REQUEUE</a> , <a href="#">SUSPEND</a> , or <a href="#">CHECKPOINT</a>
<b>Default</b>	<i>REQUEUE</i>
<b>Description</b>	Specifies how preemptable jobs will be <a href="#">preempted</a> . <b>Note:</b> If this policy is set to <a href="#">REQUEUE</a> , preemptible jobs should be marked as <i>RESTARTABLE</i> . If this policy is set to <a href="#">SUSPEND</a> , preemptible jobs should be marked as <i>SUSPENDABLE</i> . <b>Note:</b> Moab uses preemption escalation to preempt resources if the specified preemption facility is not applicable. This means if the policy is set to <i>SUSPEND</i> and the job is not <i>SUSPENDABLE</i> , Moab may attempt to requeue or even cancel the job.
<b>Example</b>	<pre>PREEMTPOLICY CHECKPOINT</pre> <p><i>Jobs that are to be preempted will be checkpointed and restarted at a later time.</i></p>

PREEMTPRIOJOBSELECTWEIGHT	
<b>Format</b>	<DOUBLE>
<b>Default</b>	256.0
<b>Description</b>	<p>Determines which jobs to preempt based on size or priority. The higher the value, the more emphasis is placed on the priority of the job, causing the lower priority jobs to be preempted first. The lower the value, the more emphasis is placed on the size of the job, causing the smaller jobs to be preempted first. If set to 0, job priority will be ignored, job size will take precedence and the smallest jobs will be preempted.</p> <p>The special setting of -1 places the emphasis solely on resource utilization. This means that jobs will be preempted in a manner that keeps the resource utilization at the highest level, regardless of job priority or size.</p>
<b>Example</b>	<pre>PREEMTPRIOJOBSELECTWEIGHT 220.5</pre>

PREEMPTRIMEWEIGHT	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0
<b>Description</b>	<p>If set to anything other than 0, a job's remaining time is added into the calculation of which jobs will be preempted. If a positive weight is specified, jobs with a longer remaining time are favored. If a negative weight is specified, jobs with a shorter remaining time are favored.</p>
<b>Example</b>	<pre>PREEMPTRIMEWEIGHT 1.5</pre>

PREEMPTSEARCHDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>unlimited</i>
<b>Description</b>	Specifies how many preemptible jobs will be evaluated as potential targets for serial job preemptors. See <a href="#">Preemption Overview</a> for more information.
<b>Example</b>	<pre>PREEMPTSEARCHDEPTH 8</pre> <p><i>Serial job preemptors will only consider the first 8 feasible preemptee jobs when determining the best action to take.</i></p>

PRIORITYTARGETDURATION	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	Specifies the <i>ideal</i> job duration which will maximize the value of the <a href="#">WALLTIMEWEIGHT</a> priority factor. If specified, this factor will be calculated as the distance from the ideal. Consequently, in most cases, the associated subcomponent weight should be set to a negative value.
<b>Example</b>	<pre>WALLTIMEWEIGHT -2500 PRIORITYTARGETDURATION 1:00:00</pre>

PRIORITYTARGETPROCCOUNT	
<b>Format</b>	<INTEGER>{+ - %}
<b>Default</b>	---
<b>Description</b>	Specifies the ideal job requested proc count which will maximize the value of the <a href="#">PROCWEIGHT</a> priority factor. If specified, this factor will be calculated as the distance from the ideal (proc count - ideal = coefficient of PROCWEIGHT). Consequently, in most cases, the associated subcomponent weight should be set to a negative value.
<b>Example</b>	<pre>PROCWEIGHT -1000 PRIORITYTARGETPROCCOUNT 64</pre>

PROCWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the coefficient to be multiplied by a job's requested processor count priority factor.
<b>Example</b>	<code>PROCWEIGHT 2500</code>

PROFILECOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	600
<b>Description</b>	Specifies the number of statistical profiles to maintain. PROFILECOUNT must be set high enough that at least one day of statistics is maintained. The statistics time window can be determined by measuring PROFILEDURATION * PROFILECOUNT. If <a href="#">PROFILEDURATION</a> is one hour then PROFILECOUNT must be at least 24 so 24 hours worth of statistics are maintained. If PROFILEDURATION is 30:00 then PROFILECOUNT must be set to at least 48. If PROFILECOUNT is not high enough for at least one day of statistics, Moab adjusts it automatically.
<b>Example</b>	<code>PROFILECOUNT 300</code>

PROFILEDURATION	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	00:30:00
<b>Description</b>	Specifies the duration of each statistical profile. The duration cannot be more than 24 hours, and any specified duration must be a factor of 24. For example, factors of 1/4, 1/2, 1, 2, 3, 4, 6, 8, 12, and 24 are acceptable durations.
<b>Example</b>	<code>PROFILEDURATION 24:00:00</code>

PURGETIME	
<b>Format</b>	<code>[[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>0</code>
<b>Description</b>	The amount of time Moab will keep a job or node record for an object no longer reported by the resource manager. Useful when using a resource manager which 'drops' information about a node or job due to internal failures. Note: This parameter is superseded by <a href="#">JOBPURGETIME on page 985</a> .
<b>Example</b>	<pre>PURGETIME 00:05:00</pre> <p><i>Moab will maintain a job or node record for 5 minutes after the last update regarding that object received from the resource manager.</i></p>

PUSHCACHETOWEBSERVICE	
<b>Format</b>	<code>&lt;BOOLEAN&gt;</code>
<b>Default</b>	<code>FALSE</code>
<b>Description</b>	Specifies whether or not you want to send cache objects (nodes, jobs, services, etc.) to Moab Web Services.
<b>Example</b>	<pre>PUSHCACHETOWEBSERVICE TRUE</pre>

QOSCFG[<QOSID>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">General Credential Flags</a> , <b>PRIORITY</b> , <a href="#">ENABLEPROFILING</a> , <b>FSTARGET</b> , <a href="#">JOBPRIOACCRUALPOLICY</a> , <a href="#">JOBPRIOEXCEPTIONS</a> , <a href="#">MEMBERULIST</a> , <b>QTWEIGHT</b> , <b>QTTARGET</b> , <b>XFWEIGHT</b> , <b>XFTARGET</b> , <a href="#">PREEMPTMINTIME</a> , <a href="#">PREEMPTMAXTIME</a> , <a href="#">PREEMPTQTTHRESHOLD</a> , <a href="#">PREEMPTXFTHRESHOLD</a> , <a href="#">PREEMPTTEES</a> , <a href="#">RSVQTTHRESHOLD</a> , <a href="#">RSVXFTHRESHOLD</a> , <a href="#">ACLBLTHRESHOLD</a> , <a href="#">ACLQTTHRESHOLD</a> , <a href="#">ACLXFTHRESHOLD</a> , <b>PLIST</b> , <a href="#">QFLAGS</a> , or a <a href="#">usage limit</a> .
<b>Default</b>	---
<b>Description</b>	Specifies QOS specific attributes. See the <a href="#">flag overview</a> for a description of legal flag values. See the <a href="#">QOS Overview</a> section for further details.
<b>Example</b>	<pre>QOSCFG[commercial] PRIORITY=1000 MAXJOB=4 MAXPROC=80</pre> <p><i>Moab will increase the priority of jobs using QOS commercial, and will allow up to 4 simultaneous QOS commercial jobs with up to 80 total allocated processors.</i></p>

QOSDEFAULTORDER	
<b>Format</b>	Comma-delimited list of QOS names.
<b>Default</b>	---
<b>Description</b>	Sets a global QOS default order for all QOS's which overrides any specific default QOS. If the order is defined as b, a, c and a user has access to c, a and submits a job without requesting a specific QOS, the job is assigned a as the default QOS.
<b>Example</b>	<pre>QOSDEFAULTORDER b,a,c</pre> <p><i>If the job does not have a QOS specified, it is assigned a QOS from the QOSDEFAULTORDER list (if the user has access to one of them).</i></p>

QOSISOPTIONAL	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	An entity's default QOS will be the first QOS specified in the QLIST parameter. When this parameter is set to <i>TRUE</i> the default QOS for the associated credential (user, account, class, etc.) will not be automatically set to the first QOS specified in the QLIST.
<b>Example</b>	<pre>QOSISOPTIONAL TRUE USERCFG[bob] QLIST=high, low</pre> <p><i>Moab will set the QOSList for user bob to <b>high</b> and <b>low</b> but will not set the QDEF. Should bob decide to submit to a particular QOS he will have to do so manually.</i></p>

QOSREJECTPOLICY	
<b>Format</b>	One or more of <i>CANCEL</i> , <i>HOLD</i> , <i>IGNORE</i> , or <i>MAIL</i>
<b>Default</b>	<i>HOLD</i> ( <i>IGNORE</i> for SLURM users)
<b>Description</b>	Specifies the action to take when Moab determines that a job cannot access a requested <a href="#">QoS</a> . <i>CANCEL</i> issues a call to the resource manager to cancel the job. <i>HOLD</i> places a <i>batch</i> hold on the job preventing the job from being further evaluated until released by an administrator. ( <b>Note:</b> Administrators can dynamically alter job attributes and possibly <i>fix</i> the job with <a href="#">mjobctl -m</a> .) With <i>IGNORE</i> , Moab will ignore the QoS request and schedule the job using the default QoS for that job. <i>MAIL</i> will send email to both the admin and the user when QoS request violations are detected. Most combinations of attributes may be specified; however, if both <i>MAIL</i> and <i>IGNORE</i> are specified, Moab will not implement <i>MAIL</i> . Similarly, while <i>CANCEL</i> and <i>HOLD</i> are mutually exclusive, <i>CANCEL</i> will supersede <i>HOLD</i> if both are specified. (see <a href="#">JOBREJECTPOLICY</a> ).
<b>Example</b>	<pre>QOSREJECTPOLICY MAIL, CANCEL</pre>

QOSWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the weight to be applied to the qos priority of each job (see <a href="#">Credential (CRED) Factor</a> ).
<b>Example</b>	<pre>QOSWEIGHT 10</pre>

QUEUETIMECAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum allowed absolute pre-weighted queuetime priority factor.
<b>Example</b>	<pre>QUEUETIMECAP 10000 QUEUETIMEWEIGHT 10</pre> <p><i>A job that has been queued for 40 minutes will have its queuetime priority factor calculated as 'Priority = QUEUETIMEWEIGHT * MIN(10000,40)'.</i></p>

QUEUETIMEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies multiplier applied to a job's queue time (in minutes) to determine the job's queuetime priority factor.
<b>Example</b>	<pre>QUEUETIMEWEIGHT 20</pre> <p><i>A job that has been queued for 4:20:00 will have a queuetime priority factor of 20 * 260.</i></p>

REALTIMEDBOBJECTS	
<b>Format</b>	Comma-delimited list of one or more of the following: <i>JOB</i> , <i>NODE</i> , <i>RSV</i> (reservation), <i>TRIG</i> (trigger), <i>VC</i> (virtual container). You can also specify <i>ALL</i> or <i>NONE</i> .
<b>Default</b>	<i>ALL</i>
<b>Description</b>	Specifies which objects Moab will store in the unixodbc database.
<b>Example</b>	<pre>REALTIMEDBOBJECTS JOB,RSV,TRIG</pre> <p><i>Moab stores jobs, reservations, and triggers in the uxodbc database. It will no longer record real time information about nodes and VCs.</i></p>

RECORDEVENTLIST	
<b>Format</b>	One or more comma (',') or plus ('+') separated events of <a href="#">GEVENT</a> , <a href="#">ALLSCHEDCOMMAND</a> , <a href="#">AMCREATE</a> , <a href="#">AMDELETE</a> , <a href="#">AMEND</a> , <a href="#">AMPAUSE</a> , <a href="#">AMQUOTE</a> , <a href="#">AMRESUME</a> , <a href="#">AMSTART</a> , <a href="#">AMUPDATE</a> , <a href="#">JOBCANCEL</a> , <a href="#">JOBCHECKPOINT</a> , <a href="#">JOBEND</a> , <a href="#">JOBFAILURE</a> , <a href="#">JOBMIGRATE</a> , <a href="#">JOBMODIFY</a> , <a href="#">JOBPREEMPT</a> , <a href="#">JOBREJECT</a> , <a href="#">JOBRESUME</a> , <a href="#">JOBSTART</a> , <a href="#">JOBSUBMIT</a> , <a href="#">NODEDOWN</a> , <a href="#">NODEFAILURE</a> , <a href="#">NODEUP</a> , <a href="#">QOSVIOLATION</a> , <a href="#">RMDOWN</a> , <a href="#">RMPOLLEND</a> , <a href="#">RMPOLLSTART</a> , <a href="#">RMUP</a> , <a href="#">RSVCANCEL</a> , <a href="#">RSVCREATE</a> , <a href="#">RSVEND</a> , <a href="#">RSVMODIFY</a> , <a href="#">RSVSTART</a> , <a href="#">SCHEDCOMMAND</a> , <a href="#">SCHEDCYCLEEND</a> , <a href="#">SCHEDCYCLESTART</a> , <a href="#">SCHEDPAUSE</a> , <a href="#">SCHEDSTART</a> , <a href="#">SCHEDSTOP</a> , <a href="#">VMCREATE</a> , <a href="#">VMDESTROY</a> , <a href="#">VMMIGRATE</a> , <a href="#">VMPOWEROFF</a> , <a href="#">VMPOWERON</a> , or <a href="#">ALL</a>
<b>Default</b>	<a href="#">JOBSTART</a> , <a href="#">JOBCANCEL</a> , <a href="#">JOBEND</a> , <a href="#">JOBFAILURE</a> , <a href="#">SCHEDPAUSE</a> , <a href="#">SCHEDSTART</a> , <a href="#">SCHEDSTOP</a> , <a href="#">TRIGEND</a> , <a href="#">TRIGFAILURE</a> , <a href="#">TRIGSTART</a>
<b>Description</b>	Specifies which events should be recorded in the appropriate event file found in Moab's <code>stats/</code> directory. These events are recorded for both local and remotely staged jobs. (See <a href="#">Event Log Overview</a> ) <b>Note:</b> If a plus character is included in the list, the specified events will be added to the default list; otherwise, the specified list will replace the default list.
<b>Example</b>	<pre>RECORDEVENTLIST JOBSTART, JOBCANCEL, JOBEND</pre> <p><i>When a local and/or remote job starts, is canceled, or ends, the respective event will be recorded.</i></p>

REJECTDOSSCRIPTS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<a href="#">TRUE</a>
<b>Description</b>	Moab rejects DOS-formatted scripts submitted with the <code>msub</code> command. This is useful if you use SLURM as your resource manager, since it does not handle DOS scripts well. For <a href="#">REJECTDOSSCRIPTS</a> to work correctly, <a href="#">FILTERCMDFILE</a> on page 957 must be <a href="#">FALSE</a> . Otherwise, Moab modifies the script instead of rejecting it, leading to job errors.
<b>Example</b>	<pre>REJECTDOSSCRIPTS FALSE</pre> <p><i>Moab does not reject DOS-formatted scripts submitted with <code>msub</code>.</i></p>

REJECTINFEASIBLEJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	If zero feasible nodes are found for a job among the currently available nodes on the cluster, the scheduler rejects the job. See <a href="#">JOBREJECTPOLICY</a> for more information.
<b>Example</b>	<pre>REJECTINFEASIBLEJOBS TRUE JOBREJECTPOLICY MAIL, CANCEL</pre> <p><i>Any job with zero feasible nodes for execution will be rejected.</i></p>

REJECTNEGPRIOJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	If enabled, the scheduler will refuse to start any job with a negative priority. See <a href="#">Job Priority Overview</a> and <a href="#">ENABLENEGJOBPRIORITY</a> for more information.
<b>Example</b>	<pre>ENABLENEGJOBPRIORITY TRUE REJECTNEGPRIOJOBS TRUE</pre> <p><i>Any job with a priority less than zero will be rejected.</i></p>

REMAPCLASS	
<b>Format</b>	<ClassID>
<b>Default</b>	---
<b>Description</b>	<p>Specifies which class/queue will be remapped based on the processors, nodes, and node features requested and the resource limits of each <a href="#">class</a>. See <a href="#">Remap Class Overview</a> for more information.</p> <div style="border: 1px solid #0070C0; border-radius: 5px; padding: 5px; background-color: #D9E1F2;"> <p> In order to use <b>REMAPCLASS</b>, you must specify a <b>DEFAULTCLASS</b>.</p> </div>
<b>Example</b>	<pre>RMCFG[internal]  DEFAULTCLASS=batch REMAPCLASS      batch CLASSCFG[small]  MAX.PROC=2 CLASSCFG[medium] MAX.PROC=16 CLASSCFG[large]  MAX.PROC=1024</pre> <div style="border: 1px dashed #000; padding: 5px; margin-top: 10px;"> <p><i>Class <b>batch</b> will be remapped based on the number of processors requested.</i></p> </div>

REMAPCLASSLIST	
<b>Format</b>	Comma delimited list of class names
<b>Default</b>	---
<b>Description</b>	<p>Specifies the order in which classes will be searched when attempting to <a href="#">remap</a> a class. Only classes included in the list will be searched and Moab will select the first class with matches. <b>Note:</b> If no <b>REMAPCLASSLIST</b> is specified, Moab will search all classes and will search them in the order they are discovered. See <a href="#">Remap Class Overview</a> for more information.</p>
<b>Example</b>	<pre>RMCFG[internal]  DEFAULTCLASS=batch REMAPCLASS      batch REMAPCLASSLIST  short,medium,long</pre> <div style="border: 1px dashed #000; padding: 5px; margin-top: 10px;"> <p><i>Class <b>batch</b> will be re-mapped to one of the listed classes.</i></p> </div>

REMOTEFAILTRANSIENT	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Only applicable to Moab configurations with multiple resource managers able to run jobs (such as in a grid environment). When Moab attempts to migrate a job to one of these resource managers, a remote failure may occur. For example, a destination peer in a grid that has an error accepting a job results in a remote error, and the job is rejected. <b>REMOTEFAILTRANSIENT</b> controls how Moab reacts to remote errors. By default, Moab considers such an error permanent and does not try to migrate the same job to that resource manager again. If <b>REMOTEFAILTRANSIENT</b> is set to <i>TRUE</i> , then Moab considers such an error as transient and will not exclude the erring resource manager in future migration attempts.
<b>Example</b>	<pre>REMOTEFAILTRANSIENT  TRUE</pre>

REMOVETRIGOUTPUTFILES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	When Moab launches external trigger actions, the standard output and error of those trigger actions are redirected to files located in Moab's spool directory. By default, these files are cleaned every 24 hours. (Files older than 24 hours are removed.) If, however, you wish to have Moab immediately remove the spool files after they are no longer needed, set <code>RemoveTrigOutputFiles</code> to <i>TRUE</i> .
<b>Example</b>	<pre>REMOVETRIGOUTPUTFILES  TRUE</pre>

RESCAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum allowed absolute pre-weighted job resource priority factor.
<b>Example</b>	<pre>RESCAP 1000</pre> <p><i>The total resource priority factor component of a job will be bound by +/- 1000</i></p>

RESERVATIONDEPTH[X]	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the number of priority reservations which are allowed in the associated reservation bucket. <b>Note:</b> The array index, X, is the bucket label and can be any string up to 64 characters. This label should be synchronized with the <a href="#">RESERVATIONQOSLIST</a> parameter. See <a href="#">Reservation Policies</a> .
<b>Example</b>	<pre>RESERVATIONDEPTH[bigmem] 4 RESERVATIONQOSLIST[bigmem] special,fast,joshua</pre> <p><i>Jobs with QOS's of special, fast, or joshua can have a cumulative total of up to 4 priority reservations.</i></p>

RESERVATIONPOLICY	
<b>Format</b>	One of the following: <i>CURRENTHIGHEST, HIGHEST, NEVER</i>
<b>Default</b>	<i>CURRENTHIGHEST</i>
<b>Description</b>	Specifies how Moab reservations will be handled. (See also <a href="#">RESERVATIONDEPTH</a> ) See <a href="#">Reservation Policies</a> .
<b>Example</b>	<pre>RESERVATIONPOLICY          CURRENTHIGHEST RESERVATIONDEPTH [DEFAULT] 2</pre> <p><i>Moab will maintain reservations for only the 2 currently highest priority jobs.</i></p>

RESERVATIONQOSLIST[X]	
<b>Format</b>	One or more QOS values or <i>[ALL]</i>
<b>Default</b>	<i>[ALL]</i>
<b>Description</b>	Specifies which QOS credentials have access to the associated reservation bucket. <b>Note:</b> The array index, X, is the bucket label and can be any string up to 64 characters. This label should be synchronized with the <a href="#">RESERVATIONDEPTH</a> parameter. See <a href="#">Reservation Policies</a> .
<b>Example</b>	<pre>RESERVATIONDEPTH [big]    4 RESERVATIONQOSLIST [big] hi, low, med</pre> <p><i>Jobs with QOS's of hi, low, or med can have a cumulative total of up to 4 priority reservations.</i></p>

RESERVATIONRETRYTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	60 seconds
<b>Description</b>	Period of time Moab will continue to attempt to allocate resources to start a job after the time resources should be made available. This parameter takes into account resource manager node state race conditions, nodes with residual high load, network glitches, etc. (For related information, see <a href="#">Reservation Policies</a> , <a href="#">DEFERSTARTCOUNT</a> , <a href="#">DEFERTIME</a> , <a href="#">NODEFAILURERESERVETIME</a> , <a href="#">JOBRETRYTIME</a> , and <a href="#">GUARANTEEDPREEMPTION</a> .)
<b>Example</b>	<pre>RESERVATIONRETRYTIME 00:05:00</pre> <p><i>Moab will try for up to 5 minutes to maintain immediate reservations if the reservations are blocked due to node state, network, or batch system based race conditions.</i></p>

RESOURCELIMITMULTIPLIER[<PARID>]	
<b>Format</b>	<p>&lt;RESOURCE&gt;:&lt;MULTIPLIER&gt;[,...]</p> <p>Where &lt;RESOURCE&gt; is one of the following:  <b>NODE, PROC, JOBPROC, MEM, JOBMEM, SWAP, DISK, or WALLTIME</b></p>
<b>Default</b>	1.0
<b>Description</b>	If set to less than one, then the hard limit will be the specified limit and the soft limit will be the specified limit multiplied by the multiplier. If set to a value greater than one, then the specified limit will be the soft limit and the hard limit will be the specified limit multiplied by the multiplier. See <a href="#">Usage-based Limits</a> .
<b>Example</b>	<pre>RESOURCELIMITMULTIPLIER PROC:1.1, MEM:2.0</pre> <p><i>Sets hard limit for <b>PROC</b> at 1.1 times the <b>PROC</b> soft limit, and the hard limit of <b>MEM</b> to 2.0 times the <b>MEM</b> soft limit.</i></p>

RESOURCELIMITPOLICY	
<b>Format</b>	<p>&lt;RESOURCE&gt;:[&lt;SPOLICY&gt;,&lt;HPOLICY&gt; : [&lt;SACTION&gt;,&lt;HACTION&gt;] [[:&lt;SVIOLATIONTIME&gt;,&lt;HVIOLATIONTIME&gt;]..</p> <p>Where <b>RESOURCE</b> is one of <i>CPUTIME, DISK, JOBMEM, JOBPROC, MEM, MINJOBPROC, NETWORK, PROC, SWAP, or WALLTIME</i></p> <p>where <b>*POLICY</b> is one of <i>ALWAYS, EXTENDEDVIOLATION, or BLOCKEDWORKLOADONLY</i></p> <p>and where <b>*ACTION</b> is one of <i>CANCEL, CHECKPOINT, NOTIFY, REQUEUE, SIGNAL, or SUSPEND.</i></p>
<b>Default</b>	No limit enforcement.
<b>Description</b>	Specifies how the scheduler should handle jobs which utilize more resources than they request. See <a href="#">Usage-based Limits</a> .
<b>Example</b>	<pre>RESOURCELIMITPOLICY MEM:ALWAYS, BLOCKEDWORKLOADONLY:REQUEUE, CANCEL</pre> <p><i>Moab will cancel all jobs which exceed their requested memory limits.</i></p>

RESTARTINTERVAL	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	Causes Moab daemon to recycle/restart when the given interval of time has transpired.
<b>Example</b>	<pre>RESTARTINTERVAL 20:00:00</pre> <p><i>Moab daemon will automatically restart every 20 hours.</i></p>

RESOURCEQUERYDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	3
<b>Description</b>	Maximum number of options which will be returned in response to an <a href="#">mshow -a</a> resource query.
<b>Example</b>	<pre>RESOURCEQUERYDEPTH 1</pre> <p><i>The mshow -a command will return at most 1 valid collection of resources.</i></p>

RESWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	All resource priority components are multiplied by this value before being added to the total job priority. See <a href="#">Job Prioritization</a> .
<b>Example</b>	<pre>RESWEIGHT 5 MEMWEIGHT 10 PROCWEIGHT 100 SWAPWEIGHT 0 RESCAP 2000</pre> <p><i>The job priority resource factor will be calculated as <math>\text{MIN}(2000, 5 * (10 * \text{JobMemory} + 100 * \text{JobProc}))</math>.</i></p>

RMCFG	
<b>Format</b>	One or more key-value pairs as described in the <a href="#">Resource Manager Configuration Overview</a>
<b>Default</b>	---
<b>Description</b>	Specifies the interface and policy configuration for the scheduler-resource manager interface. Described in detail in the <a href="#">Resource Manager Configuration Overview</a> .
<b>Example</b>	<pre>RMCFG[TORQUE3] TYPE=PBS</pre> <p><i>The PBS server will be used for resource management.</i></p>

RMMSGIGNORE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether or not Moab should adjust node state based on generic resource manager failure messages. See <a href="#">Compute node health check on page 2677</a> for more info.
<b>Example</b>	<pre>RMMSGIGNORE TRUE</pre> <p><i>Moab will load and report resource manager failure messages but will not adjust node state as a result of them.</i></p>

RMPOLLINTERVAL	
<b>Format</b>	[<MINPOLLTIME>,<MAXPOLLTIME> where poll time is specified as [[[DD:]HH:]MM:]SS
<b>Default</b>	0,30
<b>Description</b>	<p>Specifies the interval between RM polls. The poll interval will be no less than MINPOLLTIME and no more than MAXPOLLTIME. If you specify a single value, Moab interprets the value as the MAXPOLLTIME with a MINPOLLTIME of 0.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> If you use TORQUE as your resource manager, prevent communication errors by giving <a href="#">tcp_timeout</a> on page 2783 at least twice the value of the Moab <b>RMPOLLINTERVAL</b>.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 10px;"> <pre>RMPOLLINTERVAL 30,45</pre> </div> <p><i>Moab will refresh its resource manager information between a minimum of 30 seconds and a maximum of 45 seconds. Note: This parameter specifies the default global poll interval for all resource managers.</i></p>

RMRETRYTIMECAP	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	1:00:00
<b>Description</b>	<p>Moab attempts to contact RMs that are in state 'corrupt' (not down). If the attempt is unsuccessful, Moab tries again later. If the second attempt is unsuccessful, Moab increases the gap (the gap grows exponentially) between communication attempts. <b>RMRETRYTIMECAP</b> puts a cap on the length between connection attempts.</p>
<b>Example</b>	<div style="border: 1px dashed #ccc; padding: 10px; margin-bottom: 10px;"> <pre>RMRETRYTIMECAP 24:00:00</pre> </div> <p><i>Moab stops increasing the gap between connection attempts once the retry gap reaches 24 hours.</i></p>

RSVLIMITPOLICY	
<b>Format</b>	<i>HARD</i> or <i>SOFT</i>
<b>Default</b>	---
<b>Description</b>	Specifies what limits should be enforced when creating reservations.
<b>Example</b>	<pre>RSVLIMITPOLICY HARD</pre> <p><i>Moab will limit reservation creation based on the <b>HARD</b> limits configured.</i></p>

RSVNODEALLOCATIONPOLICY	
<b>Format</b>	One of the following: <a href="#">FIRSTAVAILABLE</a> , <a href="#">LASTAVAILABLE</a> , <a href="#">MINRESOURCE</a> , <a href="#">CPULOAD</a> , <a href="#">LOCAL</a> , <a href="#">CONTIGUOUS</a> , <a href="#">MAXBALANCE</a> , or <a href="#">PRIORITY</a>
<b>Default</b>	<i>LASTAVAILABLE</i>
<b>Description</b>	Specifies how Moab should allocate available resources to reservations.
<b>Example</b>	<pre>RSVNODEALLOCATIONPOLICY MINRESOURCE</pre> <p><i>Moab will apply the node allocation policy <b>MINRESOURCE</b> to all reservations by default.</i></p>

RSVNODEALLOCATIONPRIORITYF	
<b>Format</b>	User specified algorithm
<b>Default</b>	---
<b>Description</b>	When <a href="#">RSVNODEALLOCATIONPOLICY</a> is set to <i>PRIORITY</i> , this parameter allows you to specify your own priority algorithm. The priority functions available are the same as the <a href="#">node priority functions</a> .
<b>Example</b>	<pre>RSVNODEALLOCATIONPOLICY PRIORITY RSVNODEALLOCATIONPRIORITYF 'SPEED + .01 * AMEM - 10 * JOBCOUNT'</pre>

RSVPROFILE[X]	
<b>Format</b>	<p>One or more of the following:</p> <p><i>Allowed:</i></p> <p><a href="#">TRIGGERACL</a> (<a href="#">ACCOUNTLIST</a>, <a href="#">CLASSLIST</a>, <a href="#">GROUPLIST</a>, <a href="#">MAXTIME</a>, <a href="#">QOSLIST</a>, <a href="#">USERLIST</a>)</p> <p>HostExp ( <a href="#">HOSTLIST</a>)</p> <p>Features (<a href="#">NODEFEATURES</a>)</p> <p><a href="#">FLAGS</a></p> <p><a href="#">TASKCOUNT</a></p> <p><a href="#">RSVACCESSLIST</a></p> <p><b>Note:</b> Lists of more than one ACL value cannot be whitespace delimited. Such lists must be delimited with a comma, pipe, or colon.</p> <p><i>Not allowed:</i></p> <p><a href="#">ACCESS</a></p> <p><a href="#">CHARGEACCOUNT</a></p> <p><a href="#">DAYS</a></p> <p><a href="#">DEPTH</a></p> <p><a href="#">ENDTIME</a></p> <p><a href="#">OWNER</a></p> <p><a href="#">PARTITION</a></p> <p><a href="#">PERIOD</a></p> <p><b>PRIORITY</b></p> <p><a href="#">RESOURCES</a></p> <p><a href="#">STARTTIME</a></p> <p><a href="#">TPN</a></p>
<b>Default</b>	---
<b>Description</b>	Specifies attributes of a reservation profile using syntax similar to that for specifying a standing reservation. See <a href="#">Using Reservation Profiles</a> for details.
<b>Example</b>	<pre style="border: 1px dashed gray; padding: 10px;"> RSVPROFILE[fast] USERLIST=john,steve RSVPROFILE[fast] QOSLIST=high,low RSVPROFILE[fast] TRIGGER=ETYPE=start,OFFSET=5:00,ATYPE=exec,ACTION="/opt/moab/rp.pl"                 </pre> <p style="border: 1px dashed gray; padding: 5px; margin-top: 10px;"><i>Moab will create a reservation profile including trigger and ACL information.</i></p>

RSVSEARCHALGO	
<b>Format</b>	<i>LONG</i> or <i>WIDE</i>
<b>Default</b>	<i>NONE</i>
<b>Description</b>	<p>When Moab is determining when and where a job can run, it either searches for the most resources (<i>WIDE</i>) or the longest range of resources (<i>LONG</i>). In almost all cases, searching for the longest range is ideal and returns the soonest starttime. In some rare cases, however, a particular job may need to search for the most resources. In those cases sites can configure this parameter to prevent the starvation of large jobs that fail to hold onto their reservation starttimes. See the <a href="#">WIDERSVSEARCHALGO</a> job flag.</p> <p>If this parameter is not set, it will be displayed in <code>mschedctl -l</code> as <i>NONE</i> but the algorithm that is used will be <i>LONG</i>.</p>
<b>Example</b>	<pre>RSVSEARCHALGO WIDE</pre>

SCHEDCFG	
<b>Format</b>	List of zero or more space delimited <code>&lt;ATTR&gt;=&lt;VALUE&gt;</code> pairs where <code>&lt;ATTR&gt;</code> is one of the following: <a href="#">FBSERVER</a> , <a href="#">FLAGS</a> , <a href="#">MAXJOBID</a> , <a href="#">MAXRECORDEDCJOBID</a> , <a href="#">MINJOBID</a> , <a href="#">HTTPSERVERPORT</a> , <a href="#">MODE</a> , <a href="#">RECOVERYACTION</a> , <a href="#">SERVER</a> , or <a href="#">TRIGGER</a>
<b>Default</b>	---
<b>Description</b>	<p>Specifies scheduler policy and interface configuration.</p> <div style="border: 1px solid #0056b3; padding: 5px; margin-top: 10px;"> <p><b>i</b> The <b>SERVER</b> attribute can also be set using the environment variable <b>\$MOABSERVER</b>. Using this variable allows you to quickly change the Moab server that client commands will connect to.</p> <pre>&gt; export MOABSERVER=cluster2:12221</pre> </div>
<b>Example</b>	<pre>SCHEDCFG[zylem3] SERVER=geronimo.scc.com:3422 MODE=NORMAL</pre> <p><i>Moab will execute in <b>NORMAL</b> mode on the host <b>geronimo.scc.com</b>.</i></p>

SERVERHOST	
<b>Format</b>	<HOSTNAME>
<b>Default</b>	---
<b>Description</b>	<b>Deprecated.</b> Hostname of machine on which Moab will run. See <a href="#">SCHEDCFG</a> for replacement parameter.
<b>Example</b>	<pre>SERVERHOST geronimo.scc.edu</pre> <p><i>Moab will execute on the host <a href="#">geronimo.scc.edu</a>.</i></p>

SERVERMODE	
<b>Format</b>	One of the following: <a href="#">INTERACTIVE</a> , <a href="#">MONITOR</a> , <i>NORMAL</i> , <i>SIMULATION</i> , or <i>SLAVE</i>
<b>Default</b>	<i>NORMAL</i>
<b>Description</b>	<b>Deprecated.</b> Specifies how Moab interacts with the outside world. See <a href="#">SCHEDCFG</a> for replacement parameter.
<b>Example</b>	<pre>SERVERMODE SIMULATION</pre>

SERVERNAME	
<b>Format</b>	<STRING>
<b>Default</b>	<SERVERHOST>
<b>Description</b>	Specifies the name the scheduler will use to refer to itself in communication with peer daemons. See <a href="#">SCHEDCFG</a> for replacement parameter.
<b>Example</b>	<pre>SERVERNAME moabA</pre>

SERVERPORT	
<b>Format</b>	<INTEGER> (range: 1-64000)
<b>Default</b>	40559
<b>Description</b>	Port on which moab will open its user interface socket. See <a href="#">SCHEDCFG</a> for replacement parameter.
<b>Example</b>	<pre>SERVERPORT 30003</pre> <p><i>Moab will listen for client socket connections on port 30003.</i></p>

SERVERSUBMITFILTER	
<b>Format</b>	<PATH>
<b>Default</b>	---
<b>Description</b>	Specifies the location of a global job submit filter script. When you configure a global job submit filter, Moab executes it on the head node and uses it to filter every job submission it receives. See <a href="#">Server-based submit filter on page 305</a> for more information about job submit filters.
<b>Example</b>	<pre>SERVERSUBMITFILTER /opt/moab/scripts/globalfilter.pl</pre> <p><i>Moab uses /opt/moab/scripts/globalfilter.pl to filter every job submitted to Moab.</i></p>

SERVICEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the service component weight associated with the service factors. See <a href="#">Service (SERV) Factor</a> for more information.
<b>Example</b>	<pre>SERVICEWEIGHT 2</pre>

SHOWMIGRATEDJOBSASIDLE	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	By default, migrated jobs in the grid will show as blocked. This is to prevent jobs from counting against the idle policies of multiple clusters rather than just the cluster to which the job was migrated.
<b>Example</b>	<pre>SHOWMIGRATEDJOBSASIDLE TRUE</pre> <p><i>When set to <b>TRUE</b>, migrated jobs will show as idle and will count against the idle policies of the cluster showing the job as migrated.</i></p>

SIMAUTOSHUTDOWN	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>TRUE</i>
<b>Description</b>	If <i>TRUE</i> , the scheduler will end simulations when the active queue and idle queue become empty.
<b>Example</b>	<pre>SIMAUTOSHUTDOWN TRUE</pre> <p><i>The simulation will end as soon as there are no jobs running and no idle jobs which could run.</i></p>

SIMINITIALQUEUEDEPTH	
<b>Format</b>	<INTEGER>
<b>Default</b>	16
<b>Description</b>	Specifies how many jobs the simulator will initially place in the idle job queue (see Simulation Overview).
<b>Example</b>	<pre>SCHEDCFG[sim1]          MODE=SIMULATION SIMINITIALQUEUEDEPTH    64 SIMJOBSSUBMISSIONPOLICY CONSTANTJOBDEPTH</pre> <p><i>Moab will initially place 64 idle jobs in the queue and, because of the specified queue policy, will attempt to maintain this many jobs in the idle queue throughout the duration of the simulation.</i></p>

SIMJOBSSUBMISSIONPOLICY	
<b>Format</b>	One of the following: <i>NORMAL</i> , <i>CONSTANTJOBDEPTH</i> , <i>CONSTANTPSDEPTH</i> , or <a href="#">REPLAY</a>
<b>Default</b>	<i>CONSTANTJOBDEPTH</i>
<b>Description</b>	Specifies how the simulator will submit new jobs into the idle queue. <i>NORMAL</i> mode causes jobs to be submitted at the time recorded in the workload trace file, <i>CONSTANTJOBDEPTH</i> and <i>CONSTANTPSDEPTH</i> attempt to maintain an idle queue of <a href="#">SIMINITIALQUEUEDEPTH</a> jobs and proc-seconds respectively. <i>REPLAY</i> will force jobs to execute at the exactly the time specified in the simulation job trace file. This mode is most often used to generate detailed profile statistics for analysis in <a href="#">Moab Cluster Manager</a> (see Simulation Overview).
<b>Example</b>	<pre>SIMJOBSSUBMISSIONPOLICY NORMAL</pre> <p><i>Moab will submit jobs with the relative time distribution specified in the workload trace file.</i></p>

SIMPURGEBLOCKEDJOBS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Specifies whether Moab should remove jobs which can never execute (see Simulation Overview).
<b>Example</b>	<pre>SIMPURGEBLOCKEDJOBS FALSE</pre>

SIMMRANDOMDELAY	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the random delay added to the RM command base delay accumulated when making any resource manager call in simulation mode.
<b>Example</b>	<pre>SIMMRANDOMDELAY 5</pre> <p><i>Moab will add a random delay of between 0 and 5 seconds to the simulated time delay of all RM calls.</i></p>

SIMSTARTTIME	
<b>Format</b>	[HH]:MM[:SS]][[_MO[/DD[/YY]]]
<b>Default</b>	---
<b>Description</b>	Specifies the time when the simulation starts.
<b>Example</b>	<pre>SIMSTARTTIME 00:00:00_01/01/00</pre> <p><i>Moab will set its clock to <b>January 1, 2000 at 12:00:00</b> in the morning before starting the simulation</i></p>

SIMSTOPTIME	
<b>Format</b>	<code>[HH[:MM[:SS]]][_MO[/DD[/YY]]]</code>
<b>Default</b>	---
<b>Description</b>	Specifies the time when the simulation should pause.
<b>Example</b>	<pre>SIMSTOPTIME 00:00:00_01/01/04</pre> <p><i>Moab will stop scheduling when its internal simulation time reaches January 1, 2004.</i></p>

SIMWORKLOADTRACEFILE	
<b>Format</b>	<code>&lt;STRING&gt;</code>
<b>Default</b>	<code>Traces/workload.trace</code>
<b>Description</b>	Specifies the file from which moab will obtain job information when running in simulation mode. Moab will attempt to locate the file relative to <code>&lt;MOABHOMEDIR&gt;</code> unless specified as an absolute path. See Simulation Overview and <a href="#">Workload Accounting Records</a> .
<b>Example</b>	<pre>SIMWORKLOADTRACEFILE traces/jobs.2</pre> <p><i>Moab will obtain job traces when running in simulation mode from the <code>&lt;MOABHOMEDIR&gt;/traces/jobs.2</code> file.</i></p>

SPOOLDIR	
<b>Format</b>	<code>&lt;STRING&gt;</code>
<b>Default</b>	---
<b>Description</b>	Specifies the directory for temporary spool files created by Moab while submitting a job to the RM.
<b>Example</b>	<pre>SPOOLDIR /tmp/moab/spool</pre>

SPOOLDIRKEEPTIME	
<b>Format</b>	<INTEGER> (seconds) or [[[DD:]HH:]MM:]SS
<b>Default</b>	---
<b>Description</b>	Specifies the interval to delete spool files and other temporary files that have been left in the spool directory.
<b>Example</b>	<pre>SPOOLDIRKEEPTIME 4:00:00</pre>

SPVIOLATIONWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight to be applied to a job which violates <a href="#">soft</a> usage limit policies (see <a href="#">Service (SERVICE) Component on page 384</a> ).
<b>Example</b>	<pre>SPVIOLATIONWEIGHT 5000</pre>

SRCFG[X]	
<b>Format</b>	<p>One or more of the following &lt;ATTR&gt;=&lt;VALUE&gt; pairs  <a href="#">ACCESS</a>, <a href="#">ACCOUNTLIST</a>, <a href="#">CHARGE</a> on page 467, <a href="#">CHARGEACCOUNT</a>, <a href="#">CHARGEUSER</a>, <a href="#">CLASSLIST</a>,  <a href="#">CLUSTERLIST</a>, <a href="#">COMMENT</a>, <a href="#">DAYS</a>, <a href="#">DEPTH</a>, <a href="#">DISABLE</a>, <a href="#">ENDTIME</a>, <a href="#">FLAGS</a>, <a href="#">GROUPLIST</a>, <a href="#">HOSTLIST</a>,  <a href="#">JOBATTRLIST</a>, <a href="#">MAXTIME</a>, <a href="#">NODEFEATURES</a>, <a href="#">OWNER</a>, <a href="#">PARTITION</a>, <a href="#">PERIOD</a>, <a href="#">PRIORITY</a>, <a href="#">QOSLIST</a>,  <a href="#">REQUIREDTPN</a>, <a href="#">RESOURCES</a>, <a href="#">ROLLBACKOFFSET</a>, <a href="#">RSVACCESSLIST</a>, <a href="#">RSVGROUP</a>, <a href="#">STARTTIME</a>,  <a href="#">TASKCOUNT</a>, <a href="#">TIMELIMIT</a>, <a href="#">TPN</a>, <a href="#">TRIGGER</a>, or <a href="#">USERLIST</a>  <b>Note:</b>HOSTLIST and ACL list values must be comma delimited. For example:  <b>HOSTLIST=nodeA,nodeB</b></p>
<b>Default</b>	---
<b>Description</b>	Specifies attributes of a standing reservation. See <a href="#">Managing Reservations</a> for details.
<b>Example</b>	<pre>SRCFG[fast] STARTTIME=9:00:00 ENDTIME=15:00:00 SRCFG[fast] HOSTLIST=node0[1-4]\$ SRCFG[fast] QOSLIST=high,low</pre> <p><i>Moab will create a standing reservation running from 9:00 AM to 3:00 PM on nodes 1 through 4 accessible by jobs with QOS high or low.</i></p>

STARTCOUNTCAP	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the max weighted value allowed from the startcount subfactor when determining a job's priority (see <a href="#">Priority Factors</a> for more information).
<b>Example</b>	<pre>STARTCOUNTWEIGHT 5000 STARTCOUNTCAP 30000</pre>

STARTCOUNTWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight to be applied to a job's startcount when determining a job's priority (see <a href="#">Priority Factors</a> for more information).
<b>Example</b>	<pre>STARTCOUNTWEIGHT 5000</pre>

STATDIR	
<b>Format</b>	<STRING>
<b>Default</b>	stats
<b>Description</b>	Specifies the directory in which Moab statistics will be maintained.
<b>Example</b>	<pre>STATDIR /var/adm/moab/stats</pre>

STATPROCMAX	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	<p>Specifies the maximum number of processors requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via <code>mschedctl -m</code> or <code>changeparam</code> while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-bottom: 10px;"> <pre>STATPROCMAX      256 STATPROCSTEPCOUNT 4 STATPROCSTEPsize 4</pre> </div> <p><i>Each matrix output will display data in rows for jobs requesting between 4 and 256 processors.</i></p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>i</b> A <b>NONE</b> in services will still allow users to run <a href="#">showq</a> and <a href="#">checkjob</a> on their own jobs.</p> </div>

STATPROCMIN	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	<p>Specifies the minimum number of processors requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;">STATPROCMIN      4 STATPROCSTEPCOUNT 4 STATPROCSTEPsize  4</pre> <p style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"><i>Each matrix output will display data in rows for jobs requesting between 4 and 256 processors.</i></p> <div style="border: 1px solid #0070C0; padding: 5px;"> <p><b>i</b> A NONE in services will still allow users to run <a href="#">showq</a> and <a href="#">checkjob</a> on their own jobs.</p> </div>

STATPROCSTEPCOUNT	
<b>Format</b>	<INTEGER>
<b>Default</b>	5
<b>Description</b>	<p>Specifies the number of rows of processors requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;">STATPROCMIN      4 STATPROCSTEPCOUNT 4 STATPROCSTEPsize  4</pre> <p style="border: 1px dashed #ccc; padding: 5px;"><i>Each matrix output will display data in rows for jobs requesting between 4 and 256 processors.</i></p>

STATPROCSTEPSIZE	
<b>Format</b>	<INTEGER>
<b>Default</b>	4
<b>Description</b>	<p>Specifies the processor count multiplier for rows of processors requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre>STATPROCMIN      4 STATPROCSTEPCOUNT 4 STATPROCSTEPSIZE 4</pre> <p><i>Each matrix output will display data in rows for jobs requesting between 4 and 256 processors.</i></p>

STATTIMEMAX	
<b>Format</b>	[[DD:]HH:]MM:]SS
<b>Default</b>	00:15:00
<b>Description</b>	<p>Specifies the maximum amount of time requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre>STATTIMEMAX      02:08:00 STATTIMESTEPCOUNT 4 STATTIMESTEPSIZE 4</pre> <p><i>Each matrix output will display data in columns for jobs requesting between 2 and 128 minutes.</i></p>

STATTIMEMIN	
<b>Format</b>	<code>[[DD:]HH:]MM:]SS</code>
<b>Default</b>	<code>00:15:00</code>
<b>Description</b>	<p>Specifies the minimum amount of time requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre>STATTIMEMIN      00:02:00 STATTIMESTEPCOUNT  4 STATTIMESTEPSIZE   4</pre> <div style="border: 1px dashed #000; padding: 5px; margin-top: 10px;"> <p><i>Each matrix output will display data in columns for jobs requesting between 2 and 128 minutes.</i></p> </div>

STATTIMESTEPCOUNT	
<b>Format</b>	<code>&lt;INTEGER&gt;</code>
<b>Default</b>	<code>6</code>
<b>Description</b>	<p>Specifies the number of columns of time requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre>STATTIMEMIN      00:02:00 STATTIMESTEPCOUNT  4 STATTIMESTEPSIZE   4</pre> <div style="border: 1px dashed #000; padding: 5px; margin-top: 10px;"> <p><i>Each matrix output will display data in columns for jobs requesting between 2 and 128 minutes.</i></p> </div>

STATTIMESTEPSIZE	
<b>Format</b>	<INTEGER>
<b>Default</b>	4
<b>Description</b>	<p>Specifies the time multiplier for columns of time requested by jobs to be displayed in matrix outputs (as displayed by the <a href="#">showstats -f</a> command).</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> It is recommended that you not change any parameters via 'mschedctl -m' or 'changeparam' while Moab is running. Changing any of the parameters invalidates all past data and will start the collection over.</p> </div>
<b>Example</b>	<pre>STATTIMEMIN      00:02:00 STATTIMESTEPCOUNT 4 STATTIMESTEPSIZE 4</pre> <p><i>Each matrix output will display data in columns for jobs requesting between 2 and 128 minutes.</i></p>

STOPITERATION	
<b>Format</b>	<INTEGER>
<b>Default</b>	-1 (don't stop)
<b>Description</b>	Specifies which scheduling iteration Moab will stop and wait for a command to resume scheduling.
<b>Example</b>	<pre>STOPITERATION 10</pre> <p><i>Moab should stop after iteration 10 of scheduling and wait for administrator commands.</i></p>

STOREJOB SUBMISSION	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	<p>When set to <i>TRUE</i>, specifies that Moab will save a job's submit arguments and script to \$MOABHOMEDIR/stats/jobarchive/jobNumber.</p> <p>If you use TORQUE as your resource manager, you can configure it to store completed job information, and it will store the same information returned by the <code>qstat -f</code> command. For more information, see <a href="#">Job logging on page 2664</a> in the TORQUE documentation.</p>
<b>Example</b>	<pre>STOREJOB SUBMISSION TRUE</pre>

STRICTPROTOCOLCHECK	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>Specifies how Moab reacts to differences in XML protocols when communicating with other Moab peers. If set to <i>TRUE</i>, Moab will reject any communication that does not strictly conform to the expected protocol. If set to <i>FALSE</i> (the default), Moab will not reject XML that has extra or unknown attributes.</p>
<b>Example</b>	<pre>STRICTPROTOCOLCHECK TRUE</pre> <p><i>Moab will reject any XML communication that does not strictly conform to the expected protocol definition.</i></p>

SUBMITENVFILELOCATION	
<b>Format</b>	<i>FILE</i> or <i>PIPE</i>
<b>Default</b>	---
<b>Description</b>	<p>If set to <i>FILE</i>, these behaviors are expected:</p> <ul style="list-style-type: none"> <li>• The environment file is owned by a user with 600 permissions.</li> <li>• Moab writes the environment variables ('\0' delimited) to a random file in Moab's spool directory.</li> <li>• Moab adds the <code>--export-file=&lt;path_to_file&gt;</code> on the sbatch command line.</li> <li>• Moab deletes the file after the job completes.</li> </ul> <p>If set to <i>PIPE</i>, these behaviors are expected:</p> <ul style="list-style-type: none"> <li>• Moab creates a pipe and passes the read end of the pipe's file descriptor to sbatch.</li> <li>• Moab's parent process writes the environment ('\0' delimited) into the write end of the pipe.</li> </ul> <p>Adaptive Computing recommends that you configure this parameter for a more secure environment.</p>
<b>Example</b>	<code>SUBMITENVFILELOCATION PIPE</code>

SUBMITFILTER	
<b>Format</b>	< <i>STRING</i> >
<b>Default</b>	---
<b>Description</b>	Specifies the directory of a given <a href="#">submit filter script</a> .
<b>Example</b>	<code>SUBMITFILTER /home/submitfilter/filter.pl</code>

SUBMITHOSTS	
<b>Format</b>	space delimited list of host names
<b>Default</b>	---
<b>Description</b>	If specified, <b>SUBMITHOSTS</b> specifies an explicit list of hosts where jobs can be submitted.
<b>Example</b>	<code>SUBMITHOSTS hostA hostB</code>

SUSPENDRESOURCES[<PARID>]	
<b>Format</b>	<RESOURCE>[,...] Where <RESOURCE> is one of the following: <i>NODE, PROC, MEM, SWAP, DISK</i>
<b>Default</b>	---
<b>Description</b>	List of resources to dedicate while a job is suspended (available in Moab version 4.5.1 and higher).
<b>Example</b>	<pre>SUSPENDRESOURCES [base] MEM, SWAP, DISK</pre> <p><i>While a job is suspended in partition base, the memory, swap and disk for that job will remain dedicated to the job.</i></p>

SYSCFG	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <b>PRIORITY, FSTARGET, QLIST, QDEF, PLIST, FLAGS</b> , or a <a href="#">fairness policy</a> specification.
<b>Default</b>	---
<b>Description</b>	Specifies system-wide default attributes. See the <a href="#">Attribute/Flag Overview</a> for more information.
<b>Example</b>	<pre>SYSCFG PLIST=Partition1 QDEF=highprio</pre> <p><i>By default, all jobs will have access to partition <b>Partition1</b> and will use the QOS <b>highprio</b>.</i></p>

SWAPWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight assigned to the virtual memory request of a job.
<b>Example</b>	<pre>SWAPWEIGHT 10</pre>

SYSTEMMAXPROCPERJOB	
<b>Format</b>	<INTEGER>
<b>Default</b>	-1 (NO LIMIT)
<b>Description</b>	Specifies the maximum number of processors that can be requested by any single job.
<b>Example</b>	<pre>SYSTEMMAXPROCPERJOB 256</pre> <p><i>Moab will reject jobs requesting more than 256 processors.</i></p>

SYSTEMMAXPROCSECONDPERJOB	
<b>Format</b>	<INTEGER>
<b>Default</b>	-1 (NO LIMIT)
<b>Description</b>	Specifies the maximum number of proc-seconds that can be requested by any single job.
<b>Example</b>	<pre>SYSTEMMAXJOBPROCSECOND 86400</pre> <p><i>Moab will reject jobs requesting more than 86400 procs seconds. i.e, 64 processors * 30 minutes will be rejected, while a 2 processor * 12 hour job will be allowed to run.</i></p>

SYSTEMMAXJOBWALLTIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	-1 (NO LIMIT)
<b>Description</b>	Specifies the maximum amount of wallclock time that can be requested by any single job.
<b>Example</b>	<pre>SYSTEMMAXJOBWALLTIME 1:00:00:00</pre> <p><i>Moab will reject jobs requesting more than 1 day of walltime.</i></p>

TARGETQUEUEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to the time remaining until the queue time is reached.
<b>Example</b>	<code>TARGETQUEUEWEIGHT 10</code>

TARGETWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the weight to be applied to a job's queue time and expansion factor target components (see <a href="#">Job Prioritization</a> ).
<b>Example</b>	<code>TARGETWEIGHT 1000</code>

TARGETXFACTORWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to the distance to the target expansion factor.
<b>Example</b>	<code>TARGETXFACTORWEIGHT 10</code>

TASKDISTRIBUTIONPOLICY	
<b>Format</b>	One of <i>DEFAULT</i> , <i>PACK</i> , <i>RR</i> (round-robin)
<b>Default</b>	---
<b>Description</b>	Specifies how job tasks should be mapped to allocated resources. <i>DEFAULT</i> allows the resource manager to determine how the tasks are placed on the nodes. When <i>PACK</i> is used, a node is filled up with tasks before the next node is used. When <i>RR</i> is used, tasks are cycled through nodes, one task at a time, until there are no more tasks. See <a href="#">Task Distribution Overview</a> for more information.
<b>Example</b>	<pre>TASKDISTRIBUTIONPOLICY DEFAULT</pre> <p><i>Moab should use standard task distribution algorithms.</i></p>

THREADPOOLSIZE	
<b>Format</b>	<INTEGER>
<b>Default</b>	<i>2X number of core processors</i> (MAX: 64)
<b>Description</b>	Governs the number of threads used when processing job scheduling. Scalability and performance may improve with multi-threading; to throttle, limit the number of threads used.
<b>Example</b>	<pre>THREADPOOLSIZE 10</pre>

TOOLSDIR	
<b>Format</b>	<STRING>
<b>Default</b>	<i>tools</i>
<b>Description</b>	Specifies the directory in which Moab tools will be maintained (commonly used in conjunction with <a href="#">Native Resource Managers</a> , and <a href="#">Triggers</a> ).
<b>Example</b>	<pre>TOOLSDIR /var/adm/moab/tools</pre>

TRAPFUNCTION	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the functions to be trapped.
<b>Example</b>	<pre>TRAPFUNCTION UpdateNodeUtilization GetNodeSResTime</pre>

TRAPJOB	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the jobs to be trapped.
<b>Example</b>	<pre>TRAPJOB pros23.0023.0</pre>

TRAPNODE	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the nodes to be trapped.
<b>Example</b>	<pre>TRAPNODE node001 node004 node005</pre>

TRAPRES	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the reservations to be trapped.
<b>Example</b>	<pre>TRAPRES interactive.0.1</pre>

TRIGCHECKTIME	
<b>Format</b>	<INTEGER> (milliseconds)
<b>Default</b>	2000
<b>Description</b>	Each scheduling iteration, Moab will have a period of time where it handles commands and other UI requests. This time period is controlled by <a href="#">RMPOLLINTERVAL</a> . During this time period, known as the UI phase, Moab will periodically evaluate triggers. Usually this only takes a fraction of a second, but if the number of triggers are large it could take up substantially more time (up to several seconds). While Moab is evaluating triggers, it doesn't respond to UI commands. This makes Moab feel sluggish and unresponsive. To remedy this, use the parameter <b>TRIGCHECKTIME</b> . This parameter tells Moab to only spend up to X milliseconds processing triggers during the UI phase. After X milliseconds has gone by, Moab will pause the evaluating of triggers, handle any pending UI events, and then restart the trigger evaluations where it last left off.
<b>Example</b>	<pre>TRIGCHECKTIME 4000</pre>

TRIGEVALLIMIT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Each scheduling iteration, Moab will have a period of time where it handles commands and other UI requests. This time period is controlled by <a href="#">RMPOLLINTERVAL</a> . During this time period, known as the UI phase, Moab will periodically evaluate triggers. The number of times Moab evaluates all triggers in the system is controlled by the <b>TRIGEVALLIMIT</b> parameter. By default, this is set to 1. This means that Moab will evaluate all triggers at most once during the UI phase. Moab will not leave the UI phase and start other scheduling tasks until ALL triggers are evaluated at least one time. If TrigEvalLimit is set to 5, then Moab will wait until all triggers are evaluated five times.
<b>Example</b>	<pre>TRIGEVALLIMIT 3</pre>

UJOBWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Weight assigned by jobs per user. -1 will reduce priority by number of active jobs owned by user.
<b>Example</b>	<pre>UJOBWEIGHT 10</pre>

UMASK	
<b>Format</b>	<INTEGER>
<b>Default</b>	0022 (octal) (produces 0644 permissions)
<b>Description</b>	Specifies the file permission mask to use when creating new fairshare, stats, and event files. See the <code>umask</code> man page for more details.
<b>Example</b>	<pre>UMASK 0127</pre> <i>Create statistics and event files which are 'read-write' by owner and 'read' by group only.</i>

UNSUPPORTEDDEPENDENCIES	
<b>Format</b>	Comma delimited string
<b>Default</b>	---
<b>Description</b>	Specifies <a href="#">dependencies</a> that are not supported and should not be accepted by job submissions. A maximum of 30 dependencies is supported.
<b>Example</b>	<pre># moab.cfg UNSUPPORTEDDEPENDENCIES before,beforeok,beforenotok,on  &gt; msub -l depend=before:105 cmd.sh ERROR: cannot submit job - error in extension string</pre>

UPROCWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Weight assigned by processors per user. -1 will reduce priority by number of active procs owned by user.
<b>Example</b>	<pre>UPROCWEIGHT 10</pre>

USAGECONSUMEDWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to per job processor second consumption.
<b>Example</b>	<pre>USAGECONSUMEDWEIGHT 10</pre>

USAGEEXECUTIONTIMEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight assigned to the total job execution time (measured in seconds since job start). See <a href="#">Preemption Overview</a> .
<b>Example</b>	<code>USAGEEXECUTIONTIMEWEIGHT 10</code>

USAGEPERCENTWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to total requested resources consumed.
<b>Example</b>	<code>USAGEPERCENTWEIGHT 5</code>

USAGEREMAININGWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight assigned to remaining usage.
<b>Example</b>	<code>USAGEREMAININGWEIGHT 10</code>

USAGEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the weight assigned to the percent and total job usage subfactors.
<b>Example</b>	<pre>USAGEWEIGHT 100</pre>

USEANYPARTITIONPRIO	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	<p>The FSTREE data from the first feasible FSTREE will be used when determining a job's start priority, rather than having no FSTREE data considered.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p><b>i</b> Do not set <b>USEANYPARTITIONPRIO</b> if you use per-partition scheduling. Doing so causes to schedule jobs to the first partition listed, even if nodes from another partition will be available sooner.</p> </div>
<b>Example</b>	<pre>USEANYPARTITIONPRIO TRUE</pre>

USECPRSVNODELIST	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Specifies whether Moab should use the checkpointed reservation node list when rebuilding reservations on startup. If this is not used then Moab will use the reservation's specified host expression during rebuilding.
<b>Example</b>	<pre>USECPRSVNODELIST FALSE</pre>

USEDATABASE	
<b>Format</b>	INTERNAL
<b>Default</b>	-
<b>Description</b>	Specifies whether Moab should store profile statistics, checkpoint information, and event information in an integrated database. See <a href="#">Layout of Scheduler Components with Integrated Database Enabled</a> for more information.
<b>Example</b>	<pre>USEDATABASE INTERNAL</pre>

USEJOBREGEX	
<b>Format</b>	BOOLEAN
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether <code>mjobctl</code> supports regular expressions.
<b>Example</b>	<pre>USEJOBREGEX TRUE  [user@linux]\$ mjobctl -c 8[1-3]  job '81' cancelled job '82' cancelled job '83' cancelled</pre>

USEMOABCTIME	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	<p>When Moab finds new jobs on the resource manager, it creates a job inside of Moab for each job in the resource manager. By default, when Moab creates a new job, it uses the time the job was submitted to the resource manager to calculate how long the job has been in the queue (Moab processing time - job creation in resource manager), which is then used in determining the job's priority.</p> <p>In a system where more jobs are submitted to a resource manager than Moab can handle in one iteration, there is the possibility of jobs running out of order. For example, two jobs are both submitted at time 5. The first submitted job is processed first at time 6. So the first job's effective queue duration would be 1 (6-5). On the next iteration, the second job is processed at time 8. So the second job's effective queue duration would be 3 (8-5), indicating that it has been in the queue longer than the other job. Since the later job has a higher effective queue duration it will get a higher priority and could be scheduled to run before earlier submitted jobs.</p> <p>Setting <b>USEMOABCTIME</b> to <i>TRUE</i> tells Moab to use the creation time of the job in Moab rather than the creation time in the resource manager. This corrects the possible problem of having later submitted jobs having higher priorities and starting before earlier submitted jobs.</p>
<b>Example</b>	<code>USEMOABCTIME TRUE</code>

USEMOABJOBID	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	Specifies whether to use the Moab job ID, or the resource manager's job ID.
<b>Example</b>	<code>USEMOABJOBID TRUE</code>

USERCFG[<USERID>]	
<b>Format</b>	List of zero or more space delimited <ATTR>=<VALUE> pairs where <ATTR> is one of the following: <a href="#">General Credential Flags</a> , <b>CDEF</b> , <b>DEFAULT.TPN</b> , <b>DEFAULT.WCLIMIT</b> , <b>EMAILADDRESS</b> , <a href="#">ENABLEPROFILING</a> , <b>FSCAP</b> , <b>FSTARGET</b> , <a href="#">JOBFLAGS</a> , <b>MAX.WCLIMIT</b> , <b>QLIST</b> , <b>QDEF</b> , <b>NOEMAIL</b> , <b>OVERRUN</b> , <b>PLIST</b> , <a href="#">PRIORITY</a> , or a <a href="#">usage limit</a> .
<b>Default</b>	---
<b>Description</b>	Specifies user specific attributes. For general user attribute information, See the <a href="#">Credential Overview</a> . For a description of legal flag values, see <a href="#">flag overview</a> .
<b>Example</b>	<pre>USERCFG[john] MAXJOB=50 QDEF=highprio USERCFG[john] EMAILADDRESS=john@company.com</pre> <p><i>Up to 50 jobs submitted under the user ID john will be allowed to execute simultaneously and will be assigned the QOS highprio.</i></p>

USERPRIOCAP	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Specifies the priority cap to be applied to the user specified job priority factor. Under Moab, only negative user priorities may be specified. See <a href="#">Credential (Service) Factor</a> .
<b>Example</b>	<pre>USERPRIOWEIGHT 10 USERPRIOCAP -10000</pre>

USERPRIOWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight to be applied to the user specified job priority. Under Moab, only negative user priorities may be specified. If this weight is set, users may reduce the priority of some of their jobs to allow other jobs to run earlier. See <a href="#">Credential (Service) Factor</a> and <a href="#">User Selectable Prioritization</a> .
<b>Example</b>	<pre>USERPRIOWEIGHT 10</pre>

USERWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the weight to be applied to the user <a href="#">priority</a> of each job. See <a href="#">Credential (CRED) Factor</a> .
<b>Example</b>	<pre>USERWEIGHT 10</pre>

USESYSLOG	
<b>Format</b>	<BOOLEAN>[<FACILITY>]
<b>Default</b>	<i>FALSE:daemon</i>
<b>Description</b>	Specifies whether or not the scheduler will report key events to the system syslog facility. If the <FACILITY> is specified, Moab will report events to this syslog facility. See <a href="#">Logging Facilities</a> for more information.
<b>Example</b>	<pre>USESYSLOG TRUE:local3</pre> <i>Moab will report key events, commands, and failures to syslog using the local3 facility.</i>

USESYSTEMQUEUETIME	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether or not job prioritization should be based on the time the job has been eligible to run, i.e., idle and meets all fairness policies ( <i>TRUE</i> ) or the time the job has been idle ( <i>FALSE</i> ). See <a href="#">Priority Factors</a> for more info. <b>Note:</b> This parameter has been superseded by the <a href="#">JOBPRIOACCRUALPOLICY</a> parameter.
<b>Example</b>	<pre>USESYSTEMQUEUETIME FALSE</pre> <p><i>The queue time and expansion factor components of a job's priority will be calculated based on the length of time the job has been in the idle state.</i></p>

USEUSERHASH	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Enables searching of the user buffer using the user hash key instead of doing sequential searches of the user buffer.
<b>Example</b>	<pre>USEUSERHASH TRUE</pre>

VMCALCULATELOADBYVMSUM	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	When false, vmmigrate using overcommits uses the CPU load from the node to determine if VM's need to be migrated off the hypervisor. When true, overcommit vmmigrates calculates the total node load using the total sum reported by each VM on the hypervisor.
<b>Example</b>	<pre>VMCALCULATELOADBYVMSUM TRUE</pre>

VMCPURGETIME	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	5:00
<b>Description</b>	<p>When a VM completes, Moab stores it in a completed VM table for the specified amount of time. This prevents it from starting again if an RM reports it late. It also prevents a user from creating a VM with the same ID for a certain amount of time.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p><b>i</b> The VM will remain in the completed VM table for more than the specified amount of time if <b>VMSTALETIME</b> is greater than <b>VMCPURGETIME</b>. Both parameters must expire before Moab will remove the VM from the table.</p> </div>
<b>Example</b>	<div style="border: 1px dashed #000; border-radius: 10px; padding: 10px; margin-bottom: 10px;"> <pre>VMCPURGETIME 10:00</pre> </div> <p><i>Moab holds completed VMs for 10 minutes to prevent a late RM from reporting and restarting it.</i></p>

VMMIGRATETOZERoloadNODES	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Allows VM migrations to occur to and from hypervisors that do not report a CPUload or memory load.
<b>Example</b>	<div style="border: 1px dashed #000; border-radius: 10px; padding: 10px;"> <pre>VMMIGRATETOZERoloadNODES TRUE</pre> </div>

VMMIGRATETHROTTLE	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Sets the maximum allowable 'VM migrate' jobs at any given time.
<b>Example</b>	<pre>VMMIGRATETHROTTLE 20</pre> <p><i>Only 20 VM migrate jobs are allowed in the system at any given time.</i></p>

VMMIGRATIONPOLICY	
<b>Format</b>	<STRING>; values include <i>CONSOLIDATION</i> and <i>OVERCOMMIT</i>
<b>Default</b>	<i>NONE</i>
<b>Description</b>	<p>Choose only one of these values:</p> <ul style="list-style-type: none"> <li>• <i>CONSOLIDATION</i>- If the <i>CONSOLIDATION</i> flag is set, Moab consolidates VMs to allow nodes to go idle. This flag also ensures that no hypervisors are overloaded.</li> <li>• <i>OVERCOMMIT</i>- If the <i>OVERCOMMIT</i> flag is set, VMs to be migrated will be selected from overloaded hypervisors to bring them below the selected thresholds. This flag must be set for the <a href="#">VMOCTHRESHOLD</a> parameter to function.</li> </ul>
<b>Example</b>	<pre>VMMIGRATIONPOLICY OVERCOMMIT</pre>

VMMINOPDELAY	
<b>Format</b>	[HH[:MM[:SS]]
<b>Default</b>	---
<b>Description</b>	The minimum time between automatic VM node operations, such as creating, modifying, and destroying VMs. May prevent thrashing.
<b>Example</b>	<pre>VMMINOPDELAY 30</pre>

VMOCTHRESHOLD	
<b>Format</b>	<i>MEM:&lt;0-1&gt;,PROCS:&lt;0-1&gt;,DISK:&lt;0-1&gt;,SWAP:&lt;0-1&gt;,GMETRIC:&lt;metric&gt;:value</i>
<b>Default</b>	---
<b>Description</b>	Percentage threshold at which Moab begins to migrate virtual machines to other nodes. <a href="#">VMMIGRATIONPOLICY</a> must be set to OVERCOMMIT for this to occur.
<b>Example</b>	<pre> NODECFG[DEFAULT]  VMOCTHRESHOLD=PROC:.7,MEM:.9,GMETRIC:mem_io:6000  # This is the                     default global policy NODECFG[node42]   VMOCTHRESHOLD=PROC:.2,MEM:.1,GMETRIC:mem_io:12000 # This is a                     node-specific policy for node42                 </pre> <p><i>When a node surpasses .7 (70%) load of CPU or .9 (90%) of memory, Moab begins to migrate virtual machines to other nodes. When node42 surpasses .2 (20%) load of CPU or .1 (10%) of memory, Moab begins to migrate virtual machines to other nodes.</i></p>

VMPROVISIONSTATUSREADYVALUE	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Checks a VM for a special value or values (which Moab gets from the resource manager) and, based on the value, tells Moab that a VM was created..
<b>Example</b>	<pre> VMProvisionStatusReadyValue 2 VMProvisionStatusReadyValue 1-4,6,16                 </pre>

VMSARESTATIC	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<i>FALSE</i>
<b>Description</b>	When set to true, informs Moab that it can schedule under the assumption that no VMs will be migrated and no new VMs will be created, and disables Moab from scheduling any VM creations or migrations.
<b>Example</b>	<pre> VMSARESTATIC TRUE                 </pre>

VMSTALEACTION	
<b>Format</b>	One of the following: <i>IGNORE</i> , <i>CANCELTRACKINGJOB</i> , or <i>DESTROY</i>
<b>Default</b>	<i>IGNORE</i>
<b>Description</b>	<p>Specifies the action that is applied to a stale VM, or a VM that the resource manager has not reported to Moab recently (see <a href="#">VMSTALETIME</a>).</p> <ul style="list-style-type: none"> <li>• <i>IGNORE</i> (default) specifies that Moab will take no action.</li> <li>• <i>CANCELTRACKINGJOB</i> specifies that Moab will remove the tracking job for stale VMs, but will not remove the actual VM (not recommended).</li> <li>• <i>DESTROY</i> specifies that Moab destroys stale VMs.</li> </ul> <div style="border: 1px solid #0056b3; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p> If you specify <i>DESTROY</i>, you must also set the <a href="#">ENABLEVMDESTROY</a> parameter to TRUE.</p> </div>
<b>Example</b>	<code>VMSTALEACTION DESTROY</code>

VMSTALETIME	
<b>Format</b>	<code>[[HH:]MM:]SS</code>
<b>Default</b>	<i>10:00</i>
<b>Description</b>	<p>Specifies the amount of time a VM must be unreported by any resource manager before it is considered "stale."</p> <p>To specify what happens with the VM after it has become stale, see <a href="#">VMSTALEACTION</a>.</p>
<b>Example</b>	<code>VMSTALETIME 5:00</code> <div style="border: 1px dashed #ccc; padding: 5px; margin-top: 5px;"> <p><i>5 minutes must pass without a resource manager reporting a VM for it to be considered stale.</i></p> </div>

VMSTORAGEMOUNTDIR	
<b>Format</b>	<PATH>
<b>Default</b>	---
<b>Description</b>	The specified path is used as the default location for storage mounts in all newly created VMs (created via the <a href="#">mvmctl</a> command). This parameter defines the default storage mount directory if one is not specified.
<b>Example</b>	<pre>VMSTORAGEMOUNTDIR /var/spool</pre> <p><i>Moab uses <code>/var/spool</code> as a storage mount directory if a storage directory is not submitted (but additional storage is requested) at VM creation.</i></p>

VMTRACKING	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	When set to <b>TRUE</b> , VMTracking jobs are used to represent VMs in the queue.
<b>Example</b>	<pre>VMTRACKING TRUE</pre>

WALLTIMECAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum total pre-weighted absolute contribution to job priority which can be contributed by the walltime component. This value is specified as an absolute priority value, not as a percent.
<b>Example</b>	<pre>WALLTIMECAP 10000</pre> <p><i>Moab will bound a job's pre-weighted walltime priority component within the range +/- 10000.</i></p>

WALLTIMEWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight to be applied to the amount of walltime requested by a job (in seconds) (see <a href="#">Resource (RES) Factor</a> ).
<b>Example</b>	<pre>RESWEIGHT      10 WALLTIMEWEIGHT 100</pre> <p><i>Increase the priority of longer duration jobs.</i></p>

WCACCURACYCAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum total pre-weighted absolute contribution to job priority which can be contributed by the wallclock accuracy component. This value is specified as an absolute priority value, not as a percent.
<b>Example</b>	<pre>WCACCURACYCAP 10000</pre> <p><i>Moab will bound a job's pre-weighted wallclock accuracy priority component within the range +/- 10000.</i></p>

WCACCURACYWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority weight to be applied to the job's historical user wallclock accuracy (range 0.0 to 1.0) (see <a href="#">Fairshare (FS) Factor</a> ).
<b>Example</b>	<pre>FSWEIGHT      10 WCACCURACYWEIGHT 100</pre> <p><i>Favor jobs with good wallclock accuracies by giving them a priority increase.</i></p>

WCVIOLATIONACTION	
<b>Format</b>	one of <i>CANCEL</i> or <i>PREEMPT</i>
<b>Default</b>	<i>CANCEL</i>
<b>Description</b>	Specifies the action to take when a job exceeds its wallclock limit. If set to <i>CANCEL</i> , the job will be terminated. If set to <i>PREEMPT</i> , the action defined by <a href="#">PREEMPTPOLICY</a> parameter will be taken. See <a href="#">JOBMAXOVERRUN</a> or <a href="#">Usage-based limits</a> .
<b>Example</b>	<pre>WCVIOLATIONACTION  PREEMPT PREEMPTPOLICY      REQUEUE</pre> <p><i>Moab will requeue jobs which exceed their wallclock limit.</i></p>

WEBSERVICESURL	
<b>Format</b>	<URL>
<b>Default</b>	---
<b>Description</b>	If specified, Moab sends data to Moab Web Services (MWS) to be stored in a database. This allows Moab to spend more cycles on scheduling instead of database interaction. The sending occurs via HTTP PUT.
<b>Example</b>	<pre>WEBSERVICESURL http://mws-staging.ac:8080/mws/rm/moab/dump</pre> <p><i>Moab sends data that needs to be stored in a database to the specified URL.</i></p>

WIKIEVENTS	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	When set to true, Moab events are set to native wiki format (ATTR=VALUE pairs) to facilitate easier readability .
<b>Example</b>	<pre>WIKIEVENTS TRUE</pre> <p>Moab events will generate output in the format of the following sample:</p> <pre>09:26:40 1288279600:5 job 58 JOBEND 58 REQUESTEDNC=1 REQUESTEDTC=3 UNAME=wightman GNAME=wightman WCLIMIT=60 STATE=Completed RCLASS=[batch:1] SUBMITTIME=1288279493 RMEMCMP=&gt;= RDISKCMP=&gt;= RFEATURES=[NONE] SYSTEMQUEUEUETIME=1288279493 TASKS=1 FLAGS=RESTARTABLE PARTITION=pbs DPROCS=1 ENDDATE=2140000000 TASKMAP=proxy,GLOBAL SRM=pbs EXITCODE=0 SID=2357 NODEALLOCATIONPOLICY=SHARED EFFECTIVEQUEUEEDURATION=107</pre>

XFACTORCAP	
<b>Format</b>	<DOUBLE>
<b>Default</b>	0 (NO CAP)
<b>Description</b>	Specifies the maximum total pre-weighted absolute contribution to job priority which can be contributed by the expansion factor component. This value is specified as an absolute priority value, not as a percent.
<b>Example</b>	<pre>XFACTORCAP 10000</pre> <p>Moab will bound a job's pre-weighted XFactor priority component within the range +/- 10000.</p>

XFACTORWEIGHT	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the weight to be applied to a job's minimum expansion factor before it is added to the job's cumulative priority.
<b>Example</b>	<pre>XFACTORWEIGHT 1000</pre> <p><i>Moab will multiply a job's XFactor value by 1000 and then add this value to its total priority.</i></p>

XFMINWCLIMIT	
<b>Format</b>	[[[DD:]HH:]MM:]SS
<b>Default</b>	-1 (NO LIMIT)
<b>Description</b>	Specifies the minimum job wallclock limit that will be considered in job expansion factor priority calculations.
<b>Example</b>	<pre>XFMINWCLIMIT 0:01:00</pre> <p><i>Jobs requesting less than 1 minute of wallclock time will be treated as if their wallclock limit was set to 1 minute when determining expansion factor for priority calculations.</i></p>

## Introduction

Moab can dynamically provision compute machines to requested operating systems and power off compute machines when not in use. Moab can intelligently control xCAT and use its advanced system configuration mechanisms to adapt systems to current workload requirements. Moab communicates with xCAT using the Moab Service Manager (MSM). MSM is a translation utility that resides between Moab and xCAT and acts as aggregator and interpreter. The Moab Workload Manager will query MSM, which in turn queries xCAT, about system resources, configurations, images, and metrics. After learning about these resources from MSM, Moab then makes intelligent decisions about the best way to maximize system utilization.

In this model Moab gathers system information from two resource managers. The first is TORQUE, which handles the workload on the system; the second is MSM, which relays information gathered by xCAT. By leveraging these software packages, Moab intelligently adapts clusters to deliver on-site goals.

This document assumes that xCAT has been installed and configured. It describes the process of getting MSM and xCAT communicating, and it offers troubleshooting guidance for basic integration. This document offers a description for how to get Moab communicating with MSM and the final steps in verifying a complete software stack.

## xCAT Configuration Requirements

Observe the following xCAT configuration requirements before installing MSM:

- Configure xCAT normally for your site.
  - Test the following commands to verify proper function:
    - **rpower**
    - **nodeset**
    - **makedhcp**
    - **makedns**
    - **nodestat**
    - **rvitals**
  - If MSM will run on a different machine than the one on which xCAT runs, install the xCAT client packages on that machine, and test the previously listed commands on that machine as well.
  - Configure and test all stateful/stateless images you intend to use.
- Configure xCAT to use either PostgreSQL or MySQL. Note that the default of SQLite may not function properly when MSM drives xCAT.

- PostgreSQL: See [xCATSetupPostgreSQL.pdf](#) for more information.
- MySQL: See [xCAT2.SetupMySQL.pdf](#) for more information.

**i** You must have a valid Moab license file (`moab.lic`) with provisioning and green enabled. For information on acquiring an evaluation license, please contact [info@adaptivecomputing.com](mailto:info@adaptivecomputing.com).

## MSM Installation

- Determine the installation directory (usually `/opt/moab/tools/msm`)
- Untar the MSM tarball into the specified directory (making it the MSM home directory, or `$MSMHOMEDIR`)
- Verify the required Perl modules and version are available

```
> perl -e 'use Storable 2.18'
> perl -MXML::Simple -e 'exit'
> perl -MProc::Daemon -e 'exit'
> perl -MDBD::SQLite -e 'exit'
```

## Integrating MSM and xCAT

Copy the `x_msm` table schema to the xCAT schema directory:

```
> cp $MSMHOMEDIR/contrib/xcat/MSM.pm $XCATROOT/lib/perl/xCAT_schema
```

Restart `xcatd` and check the `x_msm` table is correctly created:

```
> service xcatd restart
```

```
> tabdump x_msm
```

Prepare xCAT images and ensure they provision correctly (see xCAT documentation)

Populate the `x_msm` table with your image definitions:

```
> tabedit x_msm
#flavorname,arch,profile,os,nodeset,features,vmoslist,hvtype,hvgroupname,vmgroupname,comments,disable
"compute","x86_64","compute","centos5.3","netboot","torque",,,,,,
"science","x86","compute","scientific_linux","netboot","torque",,,,,,
```

- **flavorname** - A user specified name for the image and settings; also an xCAT group name, nodes are added to this group when provisioned
- **arch** - Architecture as used by xCAT
- **profile** - Profile as used by xCAT
- **os** - Operating system as used by xCAT
- **nodeset** - One of netboot|install|stelite

- **features** - Names of xCAT groups that identify special hardware features ('torque' and 'paravirt' are special cases)
- **vmoslist** - Note: Not used. List of flavorname's this image may host as VMs (hypervisor images only)
- **hvtype** - Note: Not used. One of esx|xen|kvm (hypervisor images only)
- **hvgroupname** - Note: Not used. Name of xCAT group nodes will be added to when provisioned to this image
- **vmgroupname** - Note: Not used. Name of xCAT group VMs will be added to when hosted on a hypervisor of this image
- **comments** - User specified comments
- **disable** - Flag to temporarily disable use of this image

Ensure all xCAT group names in the `x_msm` table exist in the xCAT nodegroup table

```
> tabedit nodegroup
```

Edit as necessary to simulate the following example:

```
#groupname, grouptype, members, wherevals, comments, disable
"compute",,,,,,
"esxi4",,,,,,
"esxhv",,,,,,
"esxvmngt",,,,,,
```

After making any necessary edits, run the following command:

```
> nodels compute,esxi4,esxhv,esxvmngt
# should complete without error, ok if doesn't return anything
```

## MSM Configuration

Edit `$MSMHOMEDIR/msm.cfg` and configure the xCAT plug-in. Below is a generic example for use with TORQUE without virtualization. See the section on configuration parameters for a complete list of parameters and descriptions.

```
# MSM configuration options
RMCFG[msm]      PORT=24603
RMCFG[msm]      POLLINTERVAL=45
RMCFG[msm]      LOGFILE=/opt/moab/log/msm.log
RMCFG[msm]      LOGLEVEL=8
RMCFG[msm]      DEFAULTNODEAPP=xcat

# xCAT plugin specific options
APPCFG[xcat]    DESCRIPTION="xCAT plugin"
APPCFG[xcat]    MODULE=Moab::MSM::App::xCAT
APPCFG[xcat]    LOGLEVEL=3
APPCFG[xcat]    POLLINTERVAL=45
APPCFG[xcat]    TIMEOUT=3600
APPCFG[xcat]    _USEOPIDS=0
APPCFG[xcat]    _NODERANGE=moab,esxcompute
APPCFG[xcat]    _USESTATES=boot,netboot,install
APPCFG[xcat]    _LIMITCLUSTERQUERY=1
APPCFG[xcat]    _RPOWERTIMEOUT=120
APPCFG[xcat]    _DONODESTAT=1
APPCFG[xcat]    _REPORTNETADDR=1
APPCFG[xcat]    _CQXCATSESSIONS=4
```

## Configuration Validation

Set up environment to manually call MSM commands:

```
# substitute appropriate value(s) for path(s)
export MSMHOMEDIR=/opt/moab/tools/msm
export MSMLIBDIR=/opt/moab/tools/msm
export PATH=$PATH:/$MSMLIBDIR/contrib:$MSMLIBDIR/bin
```

Verify that MSM starts without errors:

```
> msmd
```

Verify that the expected nodes are listed, without errors, using the value of **\_NODERANGE** from `msm.cfg`.

```
> nodels <_NODERANGE>
```

Verify that the expected nodes, are listed in the cluster query output from MSM:

```
> cluster.query.pl
```

Provision all nodes through MSM for the first time (pick and image name from `x_msm`):

```
> for i in `nodels <_NODERANGE>`; do node.modify.pl $i --set os=<image_name>;done
```

Verify the nodes correctly provision and that the correct OS is reported (which may take some time after the provisioning requests are made):

```
> cluster.query.pl
```

## Troubleshooting

- **msmctl -a does not report the xCAT plugin** - Check the log file (path specified in `msm.cfg`) for error messages. A common cause is missing Perl modules (Storable, DBD::SQLite, xCAT::Client).
- **cluster.query.pl does not report any nodes** - Check that the xCAT command `nodels <noderange>`, where `<noderange>` is the value configured for `_NODERANGE` in `msm.cfg`, outputs the nodes expected.
- **cluster.query.pl does not report OS** - MSM must provision a node to recognize what the current operating system is. It is not sufficient to look up the values in the `nodetype` table because MSM has no way of recognizing whether `nodeset` and `rpower` were run with the current values in the `nodetype` table.
- **cluster.query.pl does not report OSLIST, or does not report the expected OSLIST for a node** - Check that the node belongs to the appropriate groups, particularly any listed in the `features` field of the `x_msm` table for the missing image name.

## Deploying Images with TORQUE

When using MSM + xCAT to deploy images with TORQUE, there are some special configuration considerations. Most of these also apply to other workload resource managers.

Note that while the MSM xCAT plugin contains support for manipulating TORQUE directly, this is not an ideal solution. If you are using a version of xCAT that supports prescripts, it is more appropriate to write prescripts that manipulate TORQUE based on the state of the xCAT tables. This approach is also applicable to other workload resource managers, while the xCAT plugin only deals with TORQUE.

Several use cases and configuration choices are discussed in what follows.

Each image should be configured to report its image name through TORQUE. In the TORQUE `pbs_mom_mom_config` file the `opsys` value should mirror the name of the image. See [Appendix C: Node manager \(MOM\) configuration on page 2783](#) in the TORQUE Administrator's Guide for more information.

## Installing Moab on the Management Node

Moab is the intelligence engine that coordinates the capabilities of xCAT and TORQUE to dynamically provision compute nodes to the requested operating system. Moab also schedules workload on the system and powers off idle nodes. [Download](#) and [install](#) Moab.

## Moab Configuration File Example

Moab stores its configuration in the `moab.cfg` file: `/opt/moab/etc/moab.cfg`. A sample configuration file, set up and optimized for adaptive computing follows:

```

SCHEDCFG[Moab]          SERVER=gpc-sched:42559
ADMINCFG[1]             USERS=root,egan
LOGLEVEL                7

# How often (in seconds) to refresh information from TORQUE and MSM
RMPOLLINTERVAL         60,60
RESERVATIONDEPTH       10
DEFERTIME               0
TOOLS DIR              /opt/moab/tools

#####
# TORQUE and MSM configuration                                     #
#####
RMCFG[torque]          TYPE=PBS
RMCFG[msm]             TYPE=NATIVE:msm FLAGS=autosync,NOCREATERESOURCE RESOURCETYPE=PROV
RMCFG[msm]             TIMEOUT=60
RMCFG[msm]             PROVDURATION=10:00
AGGREGATENODEACTIONS   TRUE

#####
# ON DEMAND PROVISIONING SETUP                                   #
#####
QOSCFG[od]             QFLAGS=PROVISION
USERCFG[DEFAULT]       QLIST=od
NODEALLOCATIONPOLICY    PRIORITY
NODECFG[DEFAULT]       PRIORITYF=1000*OS+1000*POWER
NODEAVAILABILITYPOLICY DEDICATED
CLASSCFG[DEFAULT]      DEFAULT.OS=scinetcompute

#####
# GREEN POLICIES   #
#####
NODECFG[DEFAULT]       POWERPOLICY=ONDEMAND
PARCFG[ALL]            NODEPOWEROFFDURATION=20:00
NODEIDLEPOWERTHRESHOLD 600
# END Example moab.cfg

```

## Verifying the Installation

When Moab starts it immediately communicates with its configured resource managers. In this case Moab communicates with TORQUE to get compute node and job queue information. It then communicates with MSM to determine the state of the nodes according to xCAT. It aggregates this information and processes the jobs discovered from TORQUE.

When a job is submitted, Moab determines whether nodes need to be provisioned to a particular operating system to satisfy the requirements of the job. If any nodes need to be provisioned Moab performs this action by creating a provisioning system job (a job that is internal to Moab). This system job communicates with xCAT to provision the nodes and remain active while the nodes are provisioning. Once the system job has provisioned the nodes it informs the user's job that the nodes are ready at which time the user's job starts running on the newly provisioned nodes.

When a node has been idle for a specified amount of time (see [NODEIDLEPOWERTHRESHOLD](#)), Moab creates a power-off system job. This job communicates with xCAT to power off the nodes and remains active in the job queue until the nodes have powered off. Then the system job informs Moab that the nodes are powered off but are still available to run jobs. The power off system job then exits.

To verify correct communication between Moab and MSM run the `mdiag -R -v msm` command.

```

$ mdiag -R -v msm
diagnosing resource managers
RM[msm]      State: Active  Type: NATIVE:MSM  ResourceType: PROV
