Total Time: 00:02:30  Up: 00:02:19 (92.67%)  Active: 00:00:11 (7.33%)

```

To verify nodes are configured for Green power management, run the `mdiag -G` command. Each node will show its power state.

```

$ mdiag -G
NOTE: power management enabled for all nodes
Partition ALL: power management enabled
Partition NodeList:
Partition local: power management enabled
Partition NodeList:
node n01 is in state Idle, power state On (green powerpolicy enabled)
node n02 is in state Idle, power state On (green powerpolicy enabled)
node n03 is in state Idle, power state On (green powerpolicy enabled)
node n04 is in state Idle, power state On (green powerpolicy enabled)
node n05 is in state Idle, power state On (green powerpolicy enabled)
node n06 is in state Idle, power state On (green powerpolicy enabled)
node n07 is in state Idle, power state On (green powerpolicy enabled)
node n08 is in state Idle, power state On (green powerpolicy enabled)
node n09 is in state Idle, power state On (green powerpolicy enabled)
node n10 is in state Idle, power state On (green powerpolicy enabled)
Partition SHARED: power management enabled

```

To submit a job that dynamically provisions compute nodes, run the `msub -l os=<image>` command.

```

$ msub -l os=computea job.sh
yuby.3
$ showq
active jobs-----
JOBID            USERNAME        STATE PROCS    REMAINING      STARTTIME
provision-4      root            Running      8      00:01:00  Fri Jun 19 09:12:56
1 active job
                  8 of 40 processors in use by local jobs (20.00%)
                  2 of 10 nodes active          (20.00%)

eligible jobs-----
JOBID            USERNAME        STATE PROCS    WCLIMIT        QUEUETIME
yuby.3           wightman        Idle         8      00:10:00  Fri Jun 19 09:12:55
1 eligible job

blocked jobs-----
JOBID            USERNAME        STATE PROCS    WCLIMIT        QUEUETIME

0 blocked jobs
Total jobs: 2

```

Notice that Moab created a provisioning system job named `provision-4` to provision the nodes. When `provision-4` detects that the nodes are correctly provisioned to the requested OS, the submitted job `yuby.3` runs:

```

$ showq
active jobs-----
JOBID            USERNAME        STATE PROCS    REMAINING      STARTTIME
yuby.3           wightman        Running      8      00:08:49  Fri Jun 19 09:13:29
1 active job
                  8 of 40 processors in use by local jobs (20.00%)
                  2 of 10 nodes active          (20.00%)

eligible jobs-----
JOBID            USERNAME        STATE PROCS    WCLIMIT        QUEUETIME

0 eligible jobs

blocked jobs-----
JOBID            USERNAME        STATE PROCS    WCLIMIT        QUEUETIME

0 blocked jobs
Total job: 1

```

The `checkjob` command shows information about the provisioning job as well as the submitted job. If any errors occur, run the `checkjob -v <jobid>` command to diagnose failures.

## xCAT Plug-in Configuration Parameters

Plugin parameters that begin with an underscore character are specific to the xCAT plug-in; others are common to all plug-ins and may either be set in the **RMCFG[msm]** for all plug-ins, or per plug-in in the **APPCFG[<plugin\_name>]**.

<u>Description</u>	<u>FeatureGroups</u>	<u>VerifyRPower</u>
<u>Module</u>	<u>DefaultVMCProc</u>	<u>RPowerTimeOut</u>
<u>LogLevel</u>	<u>DefaultVMDisk</u>	<u>QueueRPower</u>
<u>PollInterval</u>	<u>DefaultVMCMemory</u>	<u>RPowerQueueAge</u>
<u>TimeOut</u>	<u>KVMStoragePath</u>	<u>RPowerQueueSize</u>
<u>NodeRange</u>	<u>ESXStore</u>	<u>MaskOSWhenOff</u>
<u>CQxCATSessions</u>	<u>ESXCFGPath</u>	<u>ModifyTORQUE</u>
<u>DORVitals</u>	<u>VMInterfaces</u>	<u>ReportNETADDR</u>
<u>PowerString</u>	<u>XenHostInterfaces</u>	<u>UseOpIDs</u>
<u>DoNodeStat</u>	<u>KVMHostInterfaces</u>	<u>VMIPRange</u>
<u>DoxCATStats</u>	<u>VMSovereign</u>	<u>xCATHost</u>
<u>LockDir</u>	<u>UseStates</u>	<u>NoRollbackOnError</u>
<u>HVxCATPasswdKey</u>	<u>ImagesTabName</u>	

Description	
<b>Format</b>	Double quoted string containing brief description of plugin.
<b>Default</b>	---
<b>Description</b>	This information is not visible in Moab, but shows up in <code>msmctl -a</code> .

Module	
<b>Format</b>	Moab::MSM::App::xCAT
<b>Default</b>	---
<b>Description</b>	Name of the plugin module to load.

LogLevel	
<b>Format</b>	1-9
<b>Default</b>	5

LogLevel	
<b>Description</b>	Used to control the verbosity of logging, 1 being the lowest (least information logged) and 9 being the highest (most information logged). For initial setup and testing, 8 is recommended, then lowering to 3 (only errors logged) for normal operation. Use 9 for debugging, or when submitting a log file for support.

PollInterval	
<b>Format</b>	Integer > 0
<b>Default</b>	60
<b>Description</b>	MSM will query xCAT every <b>POLLINTERVAL</b> seconds to update general node status. This number will likely require tuning for each specific system. In general, to develop this number, you should pick a fraction of the total nodes MSM will be managing ( $1/_CQXCATSESSIONS$ ), and time how long it takes run nodestat, rpower stat, and optionally rvitals on these nodes, and add ~15%. Increasing the <b>POLLINTERVAL</b> will lower the overall load on the xCAT headnode, but decrease the responsiveness to provisioning and power operations.

TimeOut	
<b>Format</b>	Integer value > POLLINTERVAL
<b>Default</b>	300
<b>Description</b>	This parameter controls how long MSM will wait for child processed to complete (all xCAT commands are run in child processes). After <b>TIMEOUT</b> seconds, if a child has not returned it will be killed, and an error reported for the operation.

_NodeRange	
<b>Format</b>	Any valid noderange (see the xCAT noderange man page).
<b>Default</b>	All
<b>Description</b>	When MSM queries xCAT this is the noderange it will use. At sites where xCAT manages other hardware that Moab is not intended to control, it is important to change this.

<b>_CQxCATSessions</b>	
<b>Format</b>	Positive integer > 1
<b>Default</b>	<i>10</i>
<b>Description</b>	MSM will divide the node list generated by <code>nodels</code> into this many groups and simultaneously query xCAT for each group. The value may need tuning for large installations, higher values will cause the time to complete a single cluster query to go down, but cause a higher load on the xCAT headnode.

<b>_DORVitals</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>0</i>
<b>Description</b>	When set to <i>1</i> , MSM will poll rvitals power and led status (see the xCAT rvitals man page). This only works with IBM BMCs currently. In order to use this, xCAT should respond without error to the <code>rvitals &lt;noderange&gt; watts</code> and <code>rvitals &lt;noderange&gt; leds</code> commands. Status is reported as <b>GMETR TIC[watts]</b> and <b>GMETR IC[leds]</b> . See also the <a href="#">_PowerString on page 1090</a> configuration parameter.

<b>_PowerString</b>	
<b>Format</b>	single quote delimited string
<b>Default</b>	<i>'AC Avg Power'</i>
<b>Description</b>	Only meaningful when used with <a href="#">_DORVitals on page 1090</a> =1. Some BMCs return multiple responses to the rvitals command, or use slightly different text to describe the power metrics. Use this parameter to control what is reported to Moab. You can use <code>'\$MSMLIBDIR/contrib/xcat/dump.xcat.cmd.pl rvitals &lt;node_name&gt; power'</code> and examine the output to determine what the appropriate value of this string is.

<b>_DoNodeStat</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>1</i>

**\_DoNodeStat**

<b>Description</b>	If set to <i>0</i> , MSM will not call <code>nodestat</code> to generate a substate. This can be used to speed up the time it takes to query xCAT, and you do not need the substate visible to Moab.
--------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_DoxCATStats**

<b>Format</b>	<i>0</i> or <i>1</i>
---------------	----------------------

<b>Default</b>	<i>0</i>
----------------	----------

<b>Description</b>	If Set to <i>1</i> , MSM will track performance statistics about calls to xCAT, and the performance of higher level operations. The information is available via the script <code>\$MSMHOMEDIR/contrib/xcat/xcatstats.pl</code> . This parameter is useful for tuning the <b>POLLINTERVAL</b> and <b>CQxCATSessions</b> on page 1090 configuration parameters.
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_LockDir**

<b>Format</b>	Existing path on MSM host
---------------	---------------------------

<b>Default</b>	<i>\$MSMHOMEDIR/lck</i>
----------------	-------------------------

<b>Description</b>	This is a path to where MSM maintains lock files to control concurrency with some Xen and KVM operations.
--------------------	-----------------------------------------------------------------------------------------------------------

**\_HVxCATPasswdKey**

<b>Format</b>	key value in the xCAT passwd table
---------------	------------------------------------

<b>Default</b>	<i>vmware</i>
----------------	---------------

<b>Description</b>	This is where MSM gets the user/password to communicate with ESX hypervisors.
--------------------	-------------------------------------------------------------------------------

**\_FeatureGroups**

<b>Format</b>	Comma delimited string of xCAT group names.
---------------	---------------------------------------------

<b>Default</b>	<i>---</i>
----------------	------------

<b>_FeatureGroups</b>	
<b>Description</b>	MSM builds the OSLIST for a node as the intersection of <b>_FEATUREGROUPS</b> , features specified in <code>x_msm</code> for that image, and the nodes group membership. The value 'torque' is special, and indicates that the image uses TORQUE, and the node should be added/removed from TORQUE during provisioning when used in conjunction with the <a href="#">_ModifyTORQUE on page 1096</a> parameter.

<b>_DefaultVMCProc</b>	
<b>Format</b>	1-?
<b>Default</b>	1
<b>Description</b>	If not explicitly specified in the create request, MSM will create VMs with this many processors.

<b>_DefaultVMDisk</b>	
<b>Format</b>	Positive integer values, minimum is determined by your vm image needs
<b>Default</b>	4096
<b>Description</b>	If not explicitly specified in the create request, MSM will create VMs with this much disk allocated.

<b>_DefaultVMCMemory</b>	
<b>Format</b>	Positive integer values, minimum is determined by your vm image needs
<b>Default</b>	512
<b>Description</b>	If not specified, MSM will create VMs with this much memory allocated.

<b>_KVMStoragePath</b>	
<b>Format</b>	Existing path on MSM host
<b>Default</b>	<code>/vms</code>
<b>Description</b>	File backed disk location for stateful KVM VMS will be placed here.

<b>_ESXStore</b>	
<b>Format</b>	Mountable NFS Path
<b>Default</b>	---
<b>Description</b>	Location of ESX stores.

<b>_ESXCFGPath</b>	
<b>Format</b>	Mountable NFS Path
<b>Default</b>	<i>ESXStore</i>
<b>Description</b>	Location of ESX VM configuration files.

<b>_VMInterfaces</b>	
<b>Format</b>	Name of bridge device in your VM image
<b>Default</b>	<i>br0</i>
<b>Description</b>	Bridge device name passed to libvirt for network configuration of VMs (overrides _XENHOSTINTERFACES and _KVMHOSTINTERFACES if specified).

<b>_XenHostInterfaces</b>	
<b>Format</b>	Name of bridge device in your VM image
<b>Default</b>	<i>xenbr0</i>
<b>Description</b>	Bridge device name passed to libvirt for network configuration of Xen VMs.

<b>_KVMHostInterfaces</b>	
<b>Format</b>	Name of bridge device in your VM image
<b>Default</b>	<i>br0</i>

**\_KVMHostInterfaces**

<b>Description</b>	Bridge device name passed to libvirt for network configuration of KVM VMs.
--------------------	----------------------------------------------------------------------------

**\_VMsovereign**

<b>Format</b>	<i>0 or 1</i>
---------------	---------------

<b>Default</b>	<i>0</i>
----------------	----------

<b>Description</b>	Setting this attribute will cause Moab to reserve VMs' memory and procs on the hypervisor and treat the VM as the workload — additional workload cannot be scheduled on the VM.
--------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_UseStates**

<b>Format</b>	Valid xCAT chain.currstate values (see the xCAT chain man page)
---------------	-----------------------------------------------------------------

<b>Default</b>	<i>boot,netboot,install</i>
----------------	-----------------------------

<b>Description</b>	Nodes that do not have one of these values in the xCAT <code>chain.currstate</code> field will reported with <b>STATE=Updating</b> . Use this configuration parameter to prevent Moab from scheduling nodes that are updating firmware, etc.
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_ImagesTabName**

<b>Format</b>	Existing xCAT table that contains your image definitions.
---------------	-----------------------------------------------------------

<b>Default</b>	<i>x_msm</i>
----------------	--------------

<b>Description</b>	This table specifies the images that may be presented to Moab in a node's OSLIST. The xCAT schema for this table is defined in <code>\$MSMHOMEDIR/contrib/xcat/MSM.pm</code> , which needs to be copied to the <code>\$XCATROOT/lib/perl/xCAT_schema</code> directory.
--------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_VerifyRPower**

<b>Format</b>	<i>0 or 1</i>
---------------	---------------

<b>Default</b>	<i>0</i>
----------------	----------

**\_VerifyRPower**

<b>Description</b>	If set, MSM will attempt to confirm that rpower requests were successful by polling the power state with rpower stat until the node reports the expected state, or <a href="#">_RPowerTimeOut on page 1095</a> is reached. <b>NOTE:</b> This can create significant load on the xCAT headnode.
--------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**\_RPowerTimeOut**

<b>Format</b>	Positive integer values
<b>Default</b>	60
<b>Description</b>	Only meaningful when used with <a href="#">_VerifyRPower on page 1094</a> . If nodes do not report the expected power state in this amount of time, a GEVENT will be produced on the node (or system job).

**\_QueueRPower**

<b>Format</b>	0 or 1
<b>Default</b>	0
<b>Description</b>	When set, this parameter will cause MSM to aggregate rpower requests to xCAT into batches. The timing and size of these batches is controlled with the <a href="#">_RPowerQueueAge on page 1095</a> and <a href="#">_RPowerQueueSize on page 1096</a> parameters. <b>NOTE:</b> This can significantly reduce load on the xCAT headnode, but will cause the power commands to take longer, and MSM shutdown to take longer.

**\_RPowerQueueAge**

<b>Format</b>	Positive integer values
<b>Default</b>	30
<b>Description</b>	Only meaningful when used with <a href="#">_QueueRPower on page 1095</a> . MSM will send any pending rpower requests when the oldest request in the queue exceeds this value (seconds).

<b>_RPowerQueueSize</b>	
<b>Format</b>	Positive integer values
<b>Default</b>	<i>200</i>
<b>Description</b>	Only meaningful when used with <a href="#">_QueueRPower on page 1095</a> . MSM will send any pending rpower requests when the queue depth exceeds this value.

<b>_MaskOSWhenOff</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>0</i>
<b>Description</b>	When set, this parameter will cause MSM to report <i>OS=None</i> for nodes that are powered off. This may be useful when mixing stateless and stateful images, forcing Moab to request provisioning instead of just powering on a node.

<b>_ModifyTORQUE</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>0</i>
<b>Description</b>	When set, this parameter will cause MSM to add and removes nodes and VMs from TORQUE as required by provisioning. See the <a href="#">_FeatureGroups on page 1091</a> parameter as well.

<b>_ReportNETADDR</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>0</i>
<b>Description</b>	When set, this parameter will cause MSM to report NETADDR=<hosts.ip from xCAT>.

<b>_UseOpIDs</b>	
<b>Format</b>	<i>0 or 1</i>

<b>_UseOpIDs</b>	
<b>Default</b>	<i>0</i>
<b>Description</b>	When set, this parameter will cause errors to be reported as GEVENTs on the provided system job, instead of a node (Moab 5.4 only, with appropriate Moab CFG)

<b>_VMIPRange</b>	
<b>Format</b>	Comma separated list of dynamic ranges for VM (ex '10.10.23.100-200,10.10.24.1-255')
<b>Default</b>	---
<b>Description</b>	Use this parameter to specify a pool of IPs that MSM should assign to VMs at creation time. IPs are selected sequentially from this list as available. Omit this configuration parameter if an external service is managing IP assignment, or if they are all previously statically assigned.

<b>_xCATHost</b>	
<b>Format</b>	<code>&lt;xcat_headnode&gt;:&lt;xcatd_port&gt;</code>
<b>Default</b>	<i>localhost:3001</i>
<b>Description</b>	Use to configure MSM to communicate with xCAT on another host.

<b>_NoRollbackOnError</b>	
<b>Format</b>	<i>0 or 1</i>
<b>Default</b>	<i>0</i>
<b>Description</b>	When an error occurs and rollback is activated (as it is by default), rollback causes a reversion to the previous successful request. <b>_NoRollbackOnError</b> is useful for debugging to determine the xCAT state if no rollback occurred. If set to 1 and an error occurs between MSM and xCAT when creating a node, assigning a name (DNS) to a node, or assigning an IP address (DHCP) to a node, then no rollback occurs.

## Event Dictionary

See "[Logging Overview](#)" for more information about Moab logging.

### Moab Event Dictionary

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-0005</b>	USER	system.-moab	INFO	MWM_TESTING_INFO	Testing with argument1: %s. and argument2: %s and argument3: %s and argument4: %s	Internal error for testing diagnostics.
<b>0x100-0065</b>	USER	domain.lifecycle	INFO	MWM_JOB_CANCEL	Job %s was canceled. %s	The job was canceled.
<b>0x100-0066</b>	USER	domain.lifecycle	INFO	MWM_JOB_END_SUCCESSFUL	Job %s finished successfully. %s	The job finished successfully.
<b>0x100-0068</b>	USER	domain.lifecycle	INFO	MWM_JOB_USER_HOLD	Job %s had a user hold applied.	A user hold was applied to the job.
<b>0x100-0069</b>	USER	domain.lifecycle	INFO	MWM_JOB_SYSTEM_HOLD	Job %s had a system hold applied.	A system hold was applied to the job.
<b>0x100-006a</b>	USER	domain.lifecycle	INFO	MWM_JOB_BATCH_HOLD	Job %s had a batch hold applied.	A batch hold was applied to the job.
<b>0x100-006b</b>	USER	domain.lifecycle	INFO	MWM_JOB_DEFER_HOLD	Job %s had a defer hold applied.	A defer hold was applied to the job.
<b>0x100-006c</b>	USER	domain.lifecycle	INFO	MWM_JOB_MODIFY	Job %s was modified. %s	One of the attributes of the job was modified either via a user initiated action or an automated action.
<b>0x100-006d</b>	USER	domain.lifecycle	INFO	MWM_JOB_REJECT	Job %s was rejected. %s	The job was rejected for some reason.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-006e</b>	USER	domain.lifecycle	INFO	MWM_JOB_RELEASE	Job %s was released.	Any holds placed on the job have been released, and the job is not prevented from running due to any hold action. The job may still not be able to run due to other considerations.
<b>0x100-006f</b>	USER	domain.lifecycle	INFO	MWM_JOB_START	Job %s was started. %s	The job was started on its designated node[s].
<b>0x100-0070</b>	USER	domain.lifecycle	INFO	MWM_JOB_SUBMIT	Job %s was submitted. %s	The job has been submitted to Moab and is being evaluated and processed.
<b>0x100-0071</b>	USER	domain.lifecycle	INFO	MWM_JOB_CREATED	Job %s was created.	The job has been created and will be queued for execution.
<b>0x100-0072</b>	USER	domain.lifecycle	INFO	MWM_JOB_QUEUE	Job %s was requeued. %s	The job has been requeued so it can be executed again.
<b>0x100-0073</b>	USER	domain.lifecycle	INFO	MWM_JOB_CANCEL_CLEANUP_STARTED	Job %s is being cleaned up due to cancel request.	The job has been issued a cancel request and is being cleaned up.
<b>0x100-0074</b>	USER	domain.lifecycle	INFO	MWM_JOB_CLEANUP_STARTED	Job %s is being cleaned up.	The job has ended and is being cleaned up.
<b>0x100-0075</b>	USER	domain.lifecycle	INFO	MWM_JOB_DEFERRED	Job %s has been deferred.	The job has been deferred.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-00c9</b>	USER	domain.lifecycle	INFO	MWM_NODE_EVAC_VMS	Evacuating VMs off node %s.	Evacuating VMs off the node.
<b>0x100-012c</b>	USER	domain.lifecycle	INFO	MWM_RSV_CREATE	Reservation %s was created. %s	The reservation has been created and is stored in the system.
<b>0x100-012d</b>	USER	domain.lifecycle	INFO	MWM_RSV_START	Reservation %s has started.	The reservation has started.
<b>0x100-012e</b>	USER	domain.lifecycle	INFO	MWM_RSV_END	Reservation %s has ended.	The reservation has ended.
<b>0x100-0190</b>	USER	system-moab	INFO	MWM_SCHED_COMMAND	The following scheduler command was submitted: %s	External commands are submitted to Moab in a variety of ways. This event documents the command line and possibly other information associated with the command. These commands typically have the ability to change behavior/state within Moab. Commands that are typically queries are not included.
<b>0x100-0192</b>	USER	system-moab	INFO	MWM_SCHED_CYCLE_START	A scheduler iteration is beginning. %s	Moab periodically checks through submitted jobs and makes decisions regarding which jobs are scheduled. One of these iterations is beginning now.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-0193</b>	USER	system-moab	INFO	MWM_SCHED_CYCLE_END	A scheduler iteration is ending.	Moab periodically checks through submitted jobs and makes decisions regarding which jobs are scheduled. One of these iterations is ending now.
<b>0x100-0194</b>	USER	system-moab	INFO	MWM_SCHED_PAUSE	The scheduler has been paused. %s	The Moab scheduler has been administratively paused. New jobs may be submitted and existing jobs will continue to run, but no new jobs will be scheduled as long as Moab is paused.
<b>0x100-0195</b>	USER	system-moab	INFO	MWM_SCHED_RECYCLE	The scheduler has been recycled. %s	The Moab scheduler has been administratively recycled. The process will cleanly exit and save the state data. It will then restart, read in the data, and resume scheduling.
<b>0x100-0196</b>	USER	system-moab	INFO	MWM_SCHED_RESUME	The scheduler has been resumed.	The Moab scheduler has been administratively resumed. A new scheduling iteration will begin immediately and continue regularly.
<b>0x100-0197</b>	USER	system-moab	INFO	MWM_SCHED_START	The scheduler has started.	The Moab scheduler has started.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-0198</b>	USER	system-moab	INFO	MWM_SCHED_STOP	The scheduler has stopped. %s	The Moab scheduler has stopped.
<b>0x100-01f4</b>	USER	domain.lifecycle	INFO	MWM_TRIG_CREATE	Trigger %s has been created.	The named trigger has been created and is now recognized in the Moab system.
<b>0x100-01f5</b>	USER	domain.lifecycle	INFO	MWM_TRIG_START	Trigger %s has started.	The named trigger has started its action.
<b>0x100-01f6</b>	USER	domain.lifecycle	INFO	MWM_TRIG_END	Trigger %s has ended. %s	The named trigger has finished its action.
<b>0x100-01f8</b>	USER	domain.lifecycle	INFO	MWM_TRIG_THRESHOLD	Trigger %s threshold event: %s	A trigger threshold has been encountered. Additional details regarding the threshold may be included in the text.
<b>0x100-0258</b>	USER	domain.lifecycle	INFO	MWM_VM_SUBMIT	VM %s has been submitted.	The named VM has been submitted and is now recognized in the Moab system.
<b>0x100-0259</b>	USER	domain.lifecycle	INFO	MWM_VM_DESTROY	VM %s has been terminated.	The named VM has finished its lifecycle and is now removed and added to the completed table.
<b>0x100-025a</b>	USER	domain.lifecycle	INFO	MWM_VM_CANCEL	VM %s has been canceled.	The named VM has been canceled.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-025b</b>	USER	domain.lifecycle	INFO	MWM_VM_END	VM %s has been ended.	The named VM has been canceled because it has exceeded its allocated walltime.
<b>0x100-025c</b>	USER	domain.lifecycle	INFO	MWM_VM_MIGRATE_START	VM %s migration has started. (%s)	The named VM has started its migration. Additional information may be provided regarding source and destination nodes.
<b>0x100-025d</b>	USER	domain.lifecycle	INFO	MWM_VM_MIGRATE_END	VM %s migration has finished. (%s)	The named VM has finished its migration. Additional information may be provided regarding source and destination nodes.
<b>0x100-025f</b>	USER	domain.lifecycle	INFO	MWM_VM_MANUAL_MIGRATE_START	VM %s migration started manually. (%s)	The named VM migration has been started manually. Additional information may be provided regarding source and destination nodes.
<b>0x100-0260</b>	USER	domain.lifecycle	INFO	MWM_VM_READY	VM %s is ready.	The named VM is ready. It has been linked to an internal tracking job.
<b>0x100-2711</b>	USER	system-moab	INFO	MWM_PARAMETER_SET_TO_VALUE_INFO	Parameter '%s' is set to '%s'.	A parameter was set to a specified value. This is usually accomplished via a configuration file.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x100-2741</b>	USER	system.-moab	INFO	MWM_SOCKET_EXCEPTION	Exception detected in select for socket %s.	The select() system call indicated an exception for this socket.
<b>0x100-2742</b>	USER	system.-moab	INFO	MWM_SOCKET_EXCEPTION_REASON	Exception identified as '%s' in select for socket %s.	The select() system call indicated an exception for this socket. It has been identified with an error id by getsockopt().
<b>0x100-2748</b>	USER	system.-moab	INFO	MWM_MOAB_STARTED_ON_CORRECT_HOST	Server started on host '%s' %s.	Moab is started on either the primary or fallback server.
<b>0x100-2762</b>	USER	system.-moab	INFO	MWM_CONFIG_LINE_SUCCESSFUL	Configuration line '%s' successfully processed.	The line in the configuration file was processed without error.

## MWS Event Dictionary

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x02000100</b>	USER		INFO	Service Create	The service '{0}' was created	This marks when a service was created.
<b>0x02000101</b>	USER		INFO	Service Modify	The service '{0}' was modified	This marks when a service was modified.
<b>0x02000102</b>	USER		INFO	Service Transition	The service '{0}' took the '{1}' transition. It went from the '{2}' to the '{3}' phase.	This marks a service phase transition.
<b>0x02000103</b>	USER		INFO	Service Terminate	The service '{0}' was terminated	Service termination means that the resources are released and no more modifications may be made to the service or policies. However, it still resides in the database and shows as "Terminated".
<b>0x02000104</b>	USER		INFO	Service Delete	The service '{0}' was deleted and is no longer available	Service deletion occurs after termination and means that the service is fully removed from the database and will no longer be displayed in any queries to MWS.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x02000380</b>	USER		INFO	Notification Condition Create (User)	The notification condition '{0}' was created: {1}	This marks when a notification condition was created at the user escalation level.
<b>0x02000500</b>	USER		INFO	Service Template Create	The service template '{0}' was created	This marks when a service template was created.
<b>0x02000501</b>	USER		INFO	Service Template Modify	The service template '{0}' was modified	This marks when a service template was modified.
<b>0x02000502</b>	USER		INFO	Service Template Delete	The service template '{0}' was deleted and is no longer available	This marks when a service template was deleted.
<b>0x02000580</b>	USER		INFO	Service Hook Start	The service hook definition '{0}' on service '{1}' was executed with an ID of '{2}'	This marks the execution of a service hook definition for a given service.
<b>0x02000581</b>	USER		INFO	Service Hook End	The running service hook '{0}' on service '{1}' finished execution with status '{2}': {3}	This marks the end of execution for a running service hook.
<b>0x02000582</b>	USER		INFO	Service Hook Timeout	The running service hook '{0}' on service '{1}' timed out after {2} seconds.	This marks the execution of a service hook definition for a given service.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
0x02000583	USER		INFO	Service Hook Error	There was an error running service hook definition '{0}' on service '{1}' with an ID of '{2}'	This signifies that internal service hook processing has failed and the service hook could not be run successfully.
0x02004080	POWER_USER		INFO	Policy Modify	The policy '{0}' was modified	A policy modification occurs when a PUT client request is received by Moab Web Services for the policy resource.
0x02004381	POWER_USER		INFO	Notification Condition Create (Power User)	The notification condition '{0}' was created: {1}	This marks when a notification condition was created at the power user escalation level.
0x02008200	ADMIN		INFO	Permission Create	The permission '{0}' was created	This marks when a permission was created.
0x02008201	ADMIN		INFO	Permission Delete	The permission '{0}' was deleted	This marks when a permission was deleted.
0x02008280	ADMIN		INFO	Principal Create	The principal '{0}' was created	This marks when a principal was created.
0x02008281	ADMIN		INFO	Principal Modify	The principal '{0}' was modified	This marks when a principal was modified.
0x02008282	ADMIN		INFO	Principal Delete	The principal '{0}' was deleted	This marks when a principal was deleted.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
<b>0x02008300</b>	ADMIN		INFO	Role Create	The role '{0}' was created	This marks when a role was created.
<b>0x02008301</b>	ADMIN		INFO	Role Modify	The role '{0}' was modified	This marks when a role was modified.
<b>0x02008302</b>	ADMIN		INFO	Role Delete	The role '{0}' was deleted	This marks when a role was deleted.
<b>0x02008382</b>	ADMIN		INFO	Notification Condition Create (Admin)	The notification condition '{0}' was created: {1}	This marks when a notification condition was created at the administrator escalation level.
<b>0x02008400</b>	ADMIN		INFO	Tenant Create	The tenant '{0}' was created	This marks when a tenant was created.
<b>0x02008401</b>	ADMIN		INFO	Tenant Modify	The tenant '{0}' was modified	This marks when a tenant was modified.
<b>0x02008402</b>	ADMIN		INFO	Tenant Delete	The tenant '{0}' was deleted	This marks when a tenant was deleted.
<b>0x22004180</b>	POWER_USER		ERROR	LDAP Connect	Error communicating with the LDAP server: {0}	This occurs when communication could not be established with the configured LDAP server.

Code	Escalation level	Topic	Severity	Event name	Message template	Comment
0x22008105	ADMIN		ERROR	Service Transitions Missed	Service '{0}' ('{1}') is in phase '{2}' but should be in phase '{3}' according to the state reported by MWM. It is probable that one or more phase transitions were missed. Any hooks associated with those transitions were probably not executed.	This happens when the phase of a service as recorded by MWS differs from the phase expected according to the state of the service's jobs as reported by MWM. This means that one or more phase transitions were missed and thus any hooks on those transitions did not execute. This problem is most likely caused by either the message queue being misconfigured or MWS being down while MWM is running.
0x22008480	ADMIN		ERROR	Health Retrieval Failed	The health summary could not be retrieved successfully: {1}	This means a serious error occurred while attempting to retrieve the contents of the health summary REST resource from MWS.
0x22008481	ADMIN		ERROR	Health Create Failed	The notification condition for the failed health check could not be created: {1}	This marks when a notification condition failed to be created based on a health check.

## Appendix D: Adjusting Default Limits

Moab is distributed in a configuration capable of supporting multiple architectures and systems ranging from a few processors to several thousand processors. However, in spite of its flexibility, for performance reasons, it still contains a number of default object limits parameters and static structures defined in header files. These limits constrain such things as the maximum number of jobs, reservations, and nodes that Moab can handle and are set to values that provide a reasonable compromise between capability and memory consumption for most sites. However, many site administrators want to increase some of these settings to extend functionality, or decrease them to save consumed memory. The most common parameters are listed in what follows. Parameters listed in the Moab configuration file (`moab.cfg`) can be modified by restarting Moab. To change parameters listed in `moab.h`, please contact technical support.

### CLIENTMAXCONNECTIONS

<b>Location</b>	<code>moab.cfg</code> (dynamic parameter)
<b>Default</b>	128
<b>Max tested</b>	---
<b>Description</b>	Maximum number of connections that can simultaneously connect to Moab.

### JOBMAXNODECOUNT

<b>Location</b>	<code>moab.cfg</code> (dynamic parameter)
<b>Default</b>	1024
<b>Max tested</b>	8192
<b>Description</b>	Maximum number of compute nodes that can be allocated to a job. After changing this parameter, Moab must be restarted for changes to take effect. The value cannot exceed that of the <a href="#">MAXNODE on page 994</a> parameter (specified in <code>moab.cfg</code> ). If you specify a value higher than the limit set for the <code>MAXNODE</code> parameter, the value will match <code>MAXNODE</code> . <code>JOBMAXNODECOUNT</code> can also be specified within configure using <code>--with-maxjobsize=&lt;NODECOUNT&gt;</code> .

### MAXGRES

<b>Location</b>	<code>moab.cfg</code> (dynamic parameter)
<b>Default</b>	512

MAXGRES	
<b>Max tested</b>	---
<b>Description</b>	Total number of distinct generic resources that can be managed.

MAXJOB	
<b>Location</b>	moab.cfg (dynamic parameter)
<b>Default</b>	4096
<b>Max tested</b>	500,000
<b>Description</b>	Maximum number of jobs that can be evaluated simultaneously. (Can also be specified within <b>configure</b> using <b>--with-maxjobs=&lt;JOBCOUNT&gt;</b> .)

MAXRSVPERNODE	
<b>Location</b>	moab.cfg (dynamic parameter)
<b>Default</b>	48
<b>Max tested</b>	1024
<b>Description</b>	Maximum number of reservations a node can simultaneously support.

MMAX_ATTR	
<b>Location</b>	moab.h
<b>Default</b>	128
<b>Max tested</b>	512
<b>Description</b>	Total number of distinct node attributes (PBS node attributes/LL node features) that can be tracked.

MMAX_CLASS	
<b>Location</b>	moab.h
<b>Default</b>	24
<b>Max tested</b>	64
<b>Description</b>	Total number of distinct job classes/queues available.

MMAX_FSDEPTH	
<b>Location</b>	moab.h
<b>Default</b>	24
<b>Max tested</b>	32
<b>Description</b>	Number of active fairshare windows.

MAXNODE	
<b>Location</b>	moab.cfg (dynamic parameter)
<b>Default</b>	5120
<b>Max tested</b>	160000
<b>Description</b>	Maximum number of compute nodes supported.

MMAX_PAR	
<b>Location</b>	moab.h
<b>Default</b>	32
<b>Max tested</b>	32
<b>Description</b>	Maximum number of partitions supported.

MMAX_QOS	
<b>Location</b>	moab.h
<b>Default</b>	128
<b>Max tested</b>	128
<b>Description</b>	Total number of distinct QoS objects available to jobs.

MMAX_RACK	
<b>Location</b>	moab.h
<b>Default</b>	200
<b>Max tested</b>	200
<b>Description</b>	Total number of distinct rack objects available within cluster.

MMAX_RANGE	
<b>Location</b>	moab.h
<b>Default</b>	2048
<b>Max tested</b>	2048
<b>Description</b>	<p>Total number of distinct timeframes evaluated.</p> <p><b>Note:</b> This is proportional to the size of the cluster and the number of simultaneously active jobs in the cluster. (Can be specified within <code>./configure</code> using <code>--with-maxrange=&lt;RANGECOUNT&gt;</code>.) Increasing this value will not increase the size of total memory consumed by Moab but may result in minor slowdowns in the evaluation and optimization of reservations.</p>

MMAX_REQ_PER_JOB	
<b>Location</b>	moab.h
<b>Default</b>	5

MMAX_REQ_PER_JOB	
<b>Max tested</b>	64
<b>Description</b>	Total number of unique requirement structures a job can have. Limits the number of <code>-w</code> clauses in the <code>mshow -a</code> command. It also limits the number of <code>-l nodes=X+Y+Z</code> a normal HPC job can have.

JOBMAXTASKCOUNT	
<b>Location</b>	<code>moab.cfg</code> (dynamic parameter)
<b>Default</b>	4096
<b>Max tested</b>	250000
<b>Description</b>	Total number of tasks allowed per job.

Moab currently possesses hooks to allow sites to create local algorithms for handling site specific needs in several areas. The `contrib` directory contains a number of sample local algorithms for various purposes. The `MLocal.c` module incorporates the algorithm of interest into the main code. The following scheduling areas are currently handled via the `MLocal.c` hooks.

- Local Job Attributes
- Local Node Allocation Policies
- Local Job Priorities
- Local Fairness Policies

#### Related topics

- [Appendix I: Considerations for Large Clusters](#)

## Appendix E: Security

Moab provides role and host based authorization, encryption\*, and DES, HMAC, and MD5 based authentication. The following sections describe these features in more detail.

- [Authorization](#)
  - [Role Based Authorization Security Configuration](#)
- [Authentication](#)

- [Mauth Authentication](#)
- [Munge Authentication](#)

  - [Medium Host Security Enforcement](#)
  - [Strict Host Security Enforcement](#)
- [Access Portal Security](#)

## Authorization

### Role Based Authorization Security Configuration

Moab provides access control mechanisms to limit how the scheduling environment is managed. The primary means of accomplishing this is through limiting the users and hosts that are trusted and have access to privileged commands and data.

With regard to users, Moab breaks access into three distinct levels.

#### *Level 1 Moab Admin (Administrator Access)*

Level 1 Moab administrators have global access to information and unlimited control over scheduling operations. By default, they are allowed to control scheduler configuration, policies, jobs, reservations, and all scheduling functions. They are also granted access to all available statistics and state information. Level 1 administrators are specified using the [ADMINCFG\[1\]](#) parameter.

#### *Level 2 Moab Admin (Operator Access)*

Level 2 Moab administrators are specified using the [ADMINCFG\[2\]](#) parameter. By default, the users listed under this parameter are allowed to change all job attributes and are granted access to all informational Moab commands.

#### *Level 3 Moab Admin (Help Desk Access)*

Level 3 administrators are specified via the [ADMINCFG\[3\]](#) parameter. By default, they are allowed access to all informational Moab commands. They cannot change scheduler or job attributes.

#### *Configuring Role Based Access*

Moab allows site specific tuning of exactly which functions are available to each administrator level. Moab also provides two additional administrator levels ([ADMINCFG\[4\]](#) and [ADMINCFG\[5\]](#)) that may be used for site specific needs.

To configure Moab role based access, use the [ADMINCFG](#) parameter.

```

ADMINCFG [1]   USERS=root, john SERVICES=ALL NAME=admin
ADMINCFG [3]   USERS=joe, mary  SERVICES=mdiag, mrsvctl, mcredctl NAME=power
ADMINCFG [5]   USERS=joy, blake SERVICES=NONE NAME=users
...
    
```

**i** A *NONE* in services will still allow users to run [showq](#) and [checkjob](#) on their own jobs.

To determine the role of system users and what commands they can run, use the [mcredctl -q role user:<USERID>](#) command.

Using the **SERVICES** attribute of the **ADMINCFG** parameter, access to an arbitrary selection of services can be enabled on a per administrator-level basis. Possible services include the following:

Service	Description
<a href="#">changeparam</a>	Change any scheduling policy or parameter (This command is deprecated. Use <a href="#">mschedctl -m</a> instead).
<a href="#">checkjob</a>	View detailed information for any job.
<a href="#">checknode</a>	View detailed information for any node.
<b>mbal</b>	Perform real-time load-balancing of interactive commands.
<a href="#">mcredctl</a>	View and modify credential attributes.
<a href="#">mdiag</a>	Provide diagnostic reports for resources, workload, and scheduling.
<a href="#">mjobctl</a>	Modify, control, and view jobs.
<a href="#">mnodectl</a>	Modify, control, and view nodes.
<a href="#">mrmctl</a>	Modify, control, and view resource managers.
<a href="#">mrsvctl</a>	Modify, control, and view reservations.
<a href="#">mschedctl</a>	Modify, control, and view scheduler behavior.
<a href="#">mshow</a>	View existing configuration and predicted resource availability.
<a href="#">showstats</a>	View all scheduler and credential statistics.
<a href="#">releaseres</a>	Release all reservations (This command is deprecated. Use <a href="#">mrsvctl -r</a> instead).

Service	Description
<b>runjob</b>	Immediately execute any job (see <a href="#">mjobctl -x</a> ).
<a href="#">setqos</a>	Set QoS on any job (This command is deprecated. Use <a href="#">mjobctl -m</a> instead).
<a href="#">setres</a>	Create any reservation (This command is deprecated. Use <a href="#">mrsvctl -c</a> instead).
<a href="#">setspri</a>	Set system priority on any job (This command is deprecated. Use <a href="#">mjobctl -p</a> instead).
<a href="#">showconfig</a>	Show all scheduler configuration parameters (This command is deprecated. Use <a href="#">mschedctl -l</a> instead).
<a href="#">showres</a>	Show detailed information for any reservation.
<a href="#">showstate</a>	Show detailed information for all jobs, including their locations, and display job error messages, if any.

### Account and Class/Queue Admins

While the **ADMINCFG** parameter allows organizations to provide controlled access to scheduling objects, it does not allow for distribution along organizational boundaries. For example, a site may set up a level 3 administrator to be able to view statistics, diagnose jobs, and modify job priorities; it does not provide a way to differentiate one type of job from another. If a site administrator wanted to allow control based on the queue or account associated with a job, they would best accomplish this using the credential **MANAGERS** attribute.

A credential manager allows a user to be trusted to administer workload and policies for an associated subgroup of jobs. For example, in the configuration below, a number of queue and account managers are configured.

```
CLASSCFG[orion] MANAGERS=johns
CLASSCFG[xray]  MANAGERS=steve2
CLASSCFG[gamma] MANAGERS=steve2,jpw
ACCOUNTCFG[bio] MANAGERS=charles
```

By default, the specified managers can do anything to a job that the actual job owner could do. By default, this would include the ability to view cumulative and per job statistics, see job details, modify job priorities and holds, cancel and preempt jobs, and otherwise adjust policies and constraints within the associated credential.

## Authentication (Interface Security)

Moab supports password-challenge, DES, HMAC, and MD5 based authentication. Authentication protocols may be specified on a per interface basis allowing independent realms of trust with per realm secret keys and even per realm authentication protocols.

## Mauth Authentication

Mauth is a tool provided with Moab that provides client authentication services. With mauth enabled, each client request is packaged with the client ID, a timestamp, and an encrypted key of the entire request generated using the shared secret key.

This tool is enabled by providing a secret key. A random key is selected when the Moab `./configure` script is run and may be regenerated at any time by rerunning `./configure` and rebuilding Moab. If desired, this random key may be overridden by specifying a new key in the protected `.moab.key` file as in the example below:

Moab must be shut down before setting a new secret key. Use the `service moab stop` or `mschedctl -k` commands to shut down Moab.

```
> vi /opt/moab/etc/.moab.key
(insert key)
> cat /opt/moab/etc/.moab.key
XXXXXXXXX
# secure file by setting owner read-only permissions
> chmod 400 /opt/moab/etc/.moab.key
# verify file is owned by root and permissions allow only root to read file
> ls -l /opt/moab/etc/.moab.key
-r----- 1 root root 15 2007-04-05 03:47 /opt/moab/.moab.key
```

All directories in the path containing `.moab.key` must be owned by the root or primary Moab user. It must not be writable by "other" in its permissions.

If `.moab.key` is used, this protected file will need to be on each host that is authorized to run Moab client commands.

By default, this file will be owned by the user root and its contents will be read by the mauth tool which provides client authorization services. If desired, the ownership of this file can be changed so long as this file is readable by the Moab server and the mauth tool. This can be accomplished if the Moab [primary administrator](#), the owner of mauth, and the owner of `.moab.key` are the same.

By default, it is up to the individual cluster administrators to determine whether to use the `.moab.key` file. For sites with source code, the use of `.moab.key` can be mandated by using `./configure --with-keyfile`.

By default, mauth is located in the install `bin` directory. If an alternate name or alternate file location is desired, this can be specified by setting the **AUTHCMD** attribute of the [CLIENTCFG](#) parameter within the `moab.cfg` file as in the following example.

```
CLIENTCFG AUTHCMD=/opt/sbin/mauth
```

### Configuring Peer-Specific Secret Keys

Peer-specific secret keys can be specified using the `CLIENTCFG` parameter. This key information must be kept secret and consequently can only be specified in the `moab-private.cfg` file. With regard to security, there are two key attributes that can be set. (Other resource managers or clients such as Moab Accounting Manager or a SLURM/Wiki interface can also use the attributes to configure their authentication algorithms. The default, unless otherwise stated, is always *DES*. These attributes are listed in the table below:

AUTH	
<b>Format</b>	one of <i>ADMIN1</i> , <i>ADMIN2</i> , or <i>ADMIN3</i>
<b>Default</b>	---
<b>Description</b>	Specifies the level of control/information available to requests coming from this source/peer.
<b>Example</b>	<pre>CLIENTCFG[RM:clusterB] AUTH=admin1 KEY=14335443</pre>

AUTHTYPE	
<b>Format</b>	one of <i>DES</i> , <i>HMAC</i> , <i>HMAC64</i> , or <i>MD5</i> .
<b>Default</b>	<i>DES</i>
<b>Description</b>	Specifies the encryption algorithm to use when generating the message checksum.
<b>Example</b>	<pre>CLIENTCFG[AM:mam] AUTHTYPE=HMAC64</pre>

HOST	
<b>Format</b>	<STRING >
<b>Default</b>	---
<b>Description</b>	Specifies the hostname of the remote peer. Peer requests coming from this host will be authenticated using the specified mechanism. This parameter is optional.
<b>Example</b>	<pre>CLIENTCFG[RM:clusterA] HOST=orx.pb13.com KEY=banana6</pre>

KEY	
<b>Format</b>	<STRING >
<b>Default</b>	---
<b>Description</b>	Specifies the shared secret key to be used to generate the message checksum.
<b>Example</b>	<code>CLIENTCFG[RM:clusterA] KEY=banana6</code>

The **CLIENTCFG** parameter takes a string index indicating which peer service will use the specified attributes. In most cases, this string is simply the defined name of the peer service. However, for the special cases of resource and allocation managers, the peer name should be prepended with the prefix **RM:** or **AM:** respectively, as in `CLIENTCFG[AM:mam]` or `CLIENTCFG[RM:devcluster]`.

**i** The first character of any secret key can be viewed by trusted administrators using specific diagnostic commands to analyze Moab interfaces. If needed, increase the length of the secret keys to maintain the desired security level.

## Munge Authentication

Moab also integrates with MUNGE, an open source authentication service created by Lawrence Livermore National Laboratory (<http://home.gna.org/munge/>). MUNGE works with Moab to authenticate user credentials being passed between the Moab client and the Moab server or from Moab server to Moab server.

To set up MUNGE in a cluster or grid, download and install MUNGE on every node in the cluster or grid by following the installation steps found at <http://home.gna.org/munge/>. The MUNGE secret key must reside on each node in the cluster or grid. Before starting the Moab daemon, the MUNGE daemon must be running on all nodes.

To enable Moab to use MUNGE for authentication purposes, specify the MUNGE executable path in the `moab.cfg` file using **CLIENTCFG** and **AUTHCMD** as in the following example. The MUNGE executable path must reside in each client's `moab.cfg` file as well.

```
CLIENTCFG AUTHCMD=/usr/bin/munge
```

**i** Moab requires that the MUNGE and UNMUNGE executable names be "munge" and "unmunge" respectively. It also assumes that the UNMUNGE executable resides in the same directory as the MUNGE executable.

### Configuring Munge Command Options

Moab also integrates with MUNGE command line options. For example, to set up Moab to use a specific socket that was created when the MUNGE daemon was started, use **CLIENTCFG** and **AUTHCMDOPTIONS** to

specify the newly created socket. The **AUTHCMDOPTIONS** attribute, like **AUTHCMD**, must also reside in the client's `moab.cfg` file.

```
CLIENTCFG      AUTHCMD=/usr/bin/munge
CLIENTCFG      AUTHCMDOPTIONS="-S /var/run/munge/munge.socket.2"
```

## Server Response Control

If a request is received that is corrupt or cannot be authenticated, Moab will report some limited information to the client indicating the source of the failure, such as "bad key," "malformed header," and so forth. In the case of highly secure environments, or to minimize the impact of sniffing or denial of service attacks, Moab can be configured to simply drop invalid requests. This is accomplished by adding the **DROPBADREQUEST** attribute to the **CLIENTCFG** parameter in the `moab-private.cfg` file as in the following example:

```
CLIENTCFG[DEFAULT] DROPBADREQUEST=TRUE
```

## Interface Development Notes

Sample checksum generation algorithm code can be found in the [Socket Protocol Description](#) document.

## Host Security for Compute Resources

Host level security can vary widely from one site to another with everything from pure on-your-honor based clusters to complete encrypted VLAN based network security and government approved per job scrubbing procedures being used. The following documentation describes some best practices in use throughout the industry.

### Minimal Host Security Enforcement

For minimal host security, no additional configuration is required.

### Medium Host Security Enforcement

- Login Access
  - PAM — Enable/disable access by modifying `/etc/security/access.conf`.
- Processes
  - Kill all processes associated with job user (dedicated).
  - Kill all processes associated with job session (dedicated/shared). Use `ps -ju <USER>` or `ps -js <SESSID>`.
- IPC (Inter-Process Communication)
  - Remove shared memory, semaphores, and message queues (use `ipcs/ipcrm`).
  - Remove named pipes.

- Network/Global File System Access
  - Explicitly unmount user home and global file systems.
- Local Temporary File Systems
  - Where possible, mount local file systems read-only.
  - Clear `/tmp`, `/scratch` and other publicly available local file systems.
  - Remove user files with `shred`; `shred` is a Linux command that first overwrites files completely before removing them, preventing remnant data from surviving on the hard drive.

### Strict Host Security Enforcement

- VLAN creation
- Host rebuild
  - U.S Dept. of Energy Disk/File Sanitization ([SCRUB](#))
  - U.S Dept. of Defense Scrubbing [Software](#) (DOD-5520)

### Moab Access Portal Security Overview

The Moab Access Portal (MAP) security model is composed of several different components. First, users will use a Web browser to log in and interact with the Web server running MAP. This communication can be encrypted using industry standard SSL to protect usernames/passwords and other sensitive information that may be accessed by the user. (Instructions on how to set up SSL connections with popular Web servers and servlet engines are readily available on the Internet. A guide for setting up SSL with Apache is available in the [MAP documentation](#).)

When a user logs in via their Web browser, the JSP interface passes this request to a back-end Java infrastructure that then uses an encrypted SSH connection to authenticate the user's credentials at the cluster/grid head node. After the credentials are authenticated and the SSH connection established, further communication between MAP and the cluster/grid head node occurs over the encrypted SSH connection. These three components provide an end-to-end security solution for Web-based job submission and workload management.

## Appendix F: Initial Moab Testing

Moab has been designed with a number of key features that allow testing to occur in a *no risk* environment. These features allow you to safely run Moab in test mode even with another scheduler running whether it be an earlier version of Moab or another scheduler altogether. In test mode, Moab collects real-time job and node information from your resource managers and acts as if it were scheduling live. However, its ability to actually affect jobs (that is, start, modify, cancel, charge, and so forth) is disabled.

Moab offers the following test modes to provide a means for verifying such things as proper configuration and operation:

- [Minimal Configuration Required To Start](#)
  - [Normal Mode](#)
  - [Monitor Mode](#)
  - [Interactive Mode](#)
  - [Simulation Mode](#)

## Scheduler Modes

Central to Moab testing is the **MODE** attribute of the [SCHEDCFG](#) parameter. This parameter attribute allows administrators to determine how Moab will run. The possible values for **MODE** are *NORMAL*, *MONITOR*, *INTERACTIVE*, and *SIMULATION*. For example, to request monitor mode operation, include the following in the `moab.cfg` file:

```
SCHEDCFG MODE=MONITOR
```

### Normal Mode

If initial evaluation is complete or not required, you can place the scheduler directly into *production* by setting the **MODE** attribute of the **SCHEDCFG** parameter to *NORMAL* and (re)starting the scheduler.

### Monitor Mode (or Test Mode)

Monitor mode allows evaluation of new Moab releases, configurations, and policies in a risk-free manner. In monitor mode, the scheduler connects to the resource manager(s) and obtains live resource and workload information. Using the policies specified in the `moab.cfg` file, the monitor-mode Moab behaves identical to a live or normal-mode Moab except the ability to start, cancel, or modify jobs is disabled. In addition, allocation management does not occur in monitor mode. This allows safe diagnosis of the scheduling state and behavior using the various diagnostic client commands. Further, the log output can also be evaluated to see if any unexpected situations have arisen. At any point, the scheduler can be dynamically changed from monitor to normal mode to begin *live* scheduling.

To set up Moab in monitor mode, do the following:

```
> vi moab.cfg
  (change the MODE attribute of the SCHEDCFG parameter from NORMAL to MONITOR)
> moab
```

Remember that Moab running in monitor mode will not interfere with your production scheduler.

### Running Multiple Moab Instances Simultaneously

If running multiple instances of Moab, whether in simulation, normal, or monitor mode, make certain that each instance resides in a different home directory to prevent conflicts with configuration, log, and statistics files. Before starting each additional Moab, set the **MOABHOMEDIR** environment variable in the execution environment to point to the local home directory. Also, each instance of Moab should run using a different [port](#) to avoid conflicts.

**i** If running multiple versions of Moab, not just different Moab modes or configurations, set the `$PATH` variable to point to the appropriate Moab binaries.

To *point* Moab client commands (such as [showq](#)) to the proper Moab server, use the appropriate command line [arguments](#) or set the environment variable `MOABHOMEDIR` in the client execution environment as in the following example:

```
# point moab clients/server to new configuration
> export MOABHOMEDIR=/opt/moab-monitor
# set path to new binaries (optional)
> export PATH=/opt/moab-monitor/bin:/opt/moab-monitor/sbin:$PATH
# start Moab server
> moab
# query Moab server
> showq
```

**i** `moabd` is a safe and recommended method of starting Moab if things are not installed in their default locations.

## Interactive Mode

Interactive mode allows for evaluation of new versions and configurations in a manner different from monitor mode. Instead of disabling all resource and job control functions, Moab sends the desired change request to the screen and asks for permission to complete it. For example, before starting a job, Moab may post something like the following to the screen:

```
Command:  start job 1139.ncsa.edu on node list test013,test017,test018,test021
Accept:   (y/n) [default: n]?
```

The administrator must specifically accept each command request after verifying that it correctly meets desired site policies. Moab will then execute the specified command. This mode is useful in validating scheduler behavior and can be used until configuration is appropriately tuned and all parties are comfortable with the scheduler's performance. In most cases, sites will want to set the scheduling mode to normal after verifying correct behavior.

## Simulation Mode

Simulation mode is of value in performing a *test drive* of the scheduler or when a stable production system exists and an evaluation is desired of how various policies can improve the current performance. See the Simulations documentation for more information.

# Appendix G: Integrating Other Resources with Moab

Moab can interface with most popular resource managers, many cluster services, and numerous general protocols. The following links provide additional information.

### Moab-TORQUE Integration Guide

- [Overview](#)
- [Integration Steps](#)
  - [Install TORQUE](#)
  - [Install Moab](#)
  - [Configure TORQUE](#)
  - [TORQUE/Moab Considerations](#)
- [Current Limitations](#)
- [Troubleshooting](#)

## Install TORQUE

- Install [TORQUE](#)

Keep track of the PBS target directory, *\$PBSTARGDIR*

## Install Moab

- Untar the Moab distribution file.
- Change the directory to the `moab-<version>` directory.
- Run `./configure`.
- Specify the PBS target directory (**\$PBSTARGDIR** from step 2.1) when queried by `./configure`.

Moab interfaces to PBS by utilizing a few PBS libraries and include files. If you have a non-standard PBS installation, you may need to modify `Makefile` and change **PBSIP** and **PBSLP** values and references as necessary for your local site configuration.

The `./configure` script automatically sets up Moab so that the user running `configure` will become the default Primary Moab Administrator (**\$MOABADMIN**). This can be changed by modifying the **ADMINCFG** [1] **USERS**=<USERNAME> line in the Moab configuration file (`moab.cfg`). The primary administrator is the first user listed in the **USERS** attribute and is the ID under which the Moab daemon runs.

Some Tru64 and IRIX systems have a local `libnet` library that conflicts with PBS's `libnet` library. To resolve this, try setting **PBSLIB** to `'${PBSLIBDIR}/libnet.a -lpbs'` in the Moab `Makefile`.

Moab is 64-bit compatible. If PBS/TORQUE is running in 64-bit mode, Moab likewise needs to be built in this manner to use the PBS scheduling API (i.e., for IRIX compilers, add `-64` to **OSCCFLAGS** and **OSLDFLAGS** variables in the `Makefile`).

When starting both TORQUE and Moab it is best to have a small delay between starting the servers. In general (and especially for very fast or very large systems) this is recommended startup procedure:

- Start TORQUE.
- Start Moab with scheduling paused (`moab -P`) to give it a chance to load everything in the checkpoint file and to sync with TORQUE.
- Unpause Moab with `mschedctl -r`.

## General Configuration for All Versions of TORQUE

- Make `$MOABADMIN` a PBS admin.
  - By default, Moab only communicates with the `pbs_server` daemons and the `$MOABADMIN` should be authorized to talk to this daemon (See [suggestions](#) for more information).
- (OPTIONAL) Set default PBS queue, nodecount, and walltime attributes. ( See [suggestions](#) for more information.)
- (OPTIONAL - TORQUE Only) Configure TORQUE to report completed job information by setting the `qmgrkeep_completed` parameter:>

```
> qmgr -c 'set server keep_completed = 300'
```

PBS nodes can be configured as *time shared* or *space shared* according to local needs. In almost all cases, space shared nodes provide the desired behavior.

**i** PBS/TORQUE supports the concept of virtual nodes. Using this feature, Moab can individually schedule processors on SMP nodes. The online [TORQUE](#) documentation describes how to set up the `$PBS_HOME/server_priv/nodes` file to enable this capability. (For example, `<NODENAME> np=<VIRTUAL NODE COUNT>`)

## Version-Specific Configuration for [TORQUE](#)

Do not start the `pbs_sched` daemon. This is the default scheduler for TORQUE; Moab provides this service.

**i** Moab uses PBS's scheduling port to obtain real-time event information from PBS regarding job and node transitions. Leaving the default `qmgr` setting of `set server scheduling=True` allows Moab to receive and process this real-time information.

## Configure Moab

By default, Moab automatically interfaces with TORQUE/PBS when it is installed. Consequently, in most cases, the following steps are not required:

- Specify PBS as the primary resource manager by setting `RMCFG[base] TYPE=PBS` in the Moab configuration file (`moab.cfg`).

If a non-standard PBS installation/configuration is being used, additional Moab parameters may be required to enable the Moab/PBS interface as in the line `RMCFG[base] HOST=$PBSSERVERHOST PORT=$PBSSERVERPORT`. See the [Resource Manager Overview](#) for more information.

**i** Moab's user interface port is set using the `SCHEDCFG` parameter and is used for user-scheduler communication. This port must be different from the PBS scheduler port used for resource manager-scheduler communication.

## TORQUE/Moab Considerations

The default meaning of a node for TORQUE and Moab are not the same. By default, a node is a host in TORQUE. The node may have one or more execution slots (procs) allocated to it in the [\\$TORQUE\\_HOME/server\\_priv/nodes](#) file. However, the number of nodes recognized by TORQUE is equivalent to the number of node entries in the `$TORQUE_HOME/server_priv/nodes` file. A node specification from `qsub` such as `-1 nodes=2:ppn=2` will direct TORQUE to allocate to execution slots on two separate nodes.

Moab is more liberal in its interpretations of a node. To Moab, the `qsub` request above would be interpreted to mean allocate four tasks with at least two tasks on a node. Where TORQUE would require two nodes for the request, Moab will place all four tasks on the name node (host) if four execution slots are available.

If a cluster has four nodes with eight processors each, TORQUE still sees only four nodes. Moab sees 32 nodes. However, if a user made a `qsub` request with `-1 nodes=10`, TORQUE would reject the request because there are only four nodes available. To enable TORQUE to accommodate Moab's more liberal

node interpretation, the server parameter [available\\_resources.nodect](#) can be set as a server parameter in TORQUE. The value of [available\\_resources.nodect](#) should equal at least the number of execution slots in the cluster.

For our example, cluster [available\\_resources.nodect](#) should be `32`. With this parameter set, the user can now make a request such as `-1 nodes=8:ppn=2`. In this example, the user is still limited to a maximum node request of 32.

With [available\\_resources.nodect](#) set in TORQUE, Moab can be directed to honor the default TORQUE behavior by setting [JOBNODEMATCHPOLICY](#) to `EXACTNODE`.

## PBS Features Not Supported by Moab

Moab supports basic scheduling of all PBS node specifications.

## Moab Features Not Supported by PBS

PBS does not support the concept of a job QoS or other extended scheduling features by default. This can be handled using the techniques described in the [PBS Resource Manager Extensions](#) section. See the [Resource Manager Extensions Overview](#) for more information.

## Troubleshooting

On TRU64 systems, the PBS `libpbs` library does not properly export a number of symbols required by Moab. This can be worked around by modifying the Moab `Makefile` to link the PBS `rm.o` object file directly into Moab.

### TORQUE/PBS Integration Guide - RM Access Control

## Server Configuration

Using the PBS [qmgr](#) command, add the Moab administrator as both a *manager* and *operator*.

```
> qmgr
Qmgr: set server managers += <MOABADMIN>@*.<YOURDOMAIN>
Qmgr: set server operators += <MOABADMIN>@*.<YOURDOMAIN>
Qmgr: quit
```

For example:

```
> qmgr
Qmgr: set server managers += staff@*.ucsd.edu
Qmgr: set operators += staff@*.ucsd.edu
Qmgr: quit
```

**i** If desired, the Moab administrator can be enabled as a manager and operator only on the host on which Moab is running by replacing `"*.<YOURDOMAIN>"` with `"<MOABSERVERHOSTNAME>"`.

## Mom Configuration (optional)

If direct Moab to pbs\_mom communication is required, the mom\_priv/config file on each compute node where pbs\_mom runs should be set as in the following example:

```
$restricted *.<YOURDOMAIN>
$clienthost <MOABSERVERHOSTNAME>
```

**i** For security purposes, sites may want to run Moab under a non-root user id. If so, and Moab-pbs\_mom communication is required, the mom\_priv/config files must be world-readable and contain the line '\$restricted \*.<YOURDOMAIN>'. (i.e., '\$restricted \*.uconn.edu')

### TORQUE/PBS Config - Default Queue Settings

## Default Queue

To set the default queue (the queue used by jobs if a queue is not explicitly specified by the user), issue the following:

```
>> qmgr
Qmgr: set system default_queue = <QUEUENAME>
Qmgr: quit
```

## Queue Default Node and Walltime Attributes

To set a default of one node and 15 minutes of walltime for a particular queue, issue the following:

```
> qmgr
Qmgr: set queue <QUEUENAME> resources_default.nodect = 1
Qmgr: set queue <QUEUENAME> resources_default.walltime = 00:15:00
Qmgr: quit
```

## Default System Wide Node and Walltime Attributes

To set system wide defaults, set the following:

```
> qmgr
Qmgr: set server resources_default.nodect = 1
Qmgr: set server resources_default.walltime = 00:15:00
Qmgr: quit
```

### Moab-SLURM Integration Guide

- [Overview](#)
- [SLURM Configuration Steps](#)
- [Moab Configuration Steps](#)
  - [Configuration for Standby and Expedite](#)
  - [Configuration for the Quadrics Switch](#)

- [Authentication](#)
- [Queue/Class Support](#)
- [Policies](#)
- [Moab Queue and RM Emulation](#)
- [SLURM High Availability](#)

## Overview

Moab can be used as the scheduler for the [SLURM](#) resource manager. In this configuration, the SLURM handles the job queue and the compute resources while Moab determines when, where and how jobs should be executed according to current cluster state and site mission objectives.

The documentation below describes how to configure Moab to interface with SLURM.

**i** For Moab-SLURM integration, Moab 6.0 or higher and SLURM 2.2 or higher are recommended. From the [downloads](#) page, the generic version is needed to install SLURM.

## SLURM Configuration Steps

To configure SLURM to utilize Moab as the scheduler, the **SchedulerType** parameters must be set in the `slurm.conf` config file located in the SLURM `etc` directory (`/usr/local/etc` by default)

```
# slurm.conf
SchedulerType=sched/wiki2
```

The **SchedulerType** parameter controls the communication protocol used between Moab and SLURM. This interface can be customized using the [wiki.conf](#) configuration file located in the same directory and further documented in the SLURM [Admin Manual](#).

**Note:** To allow sharing of nodes, the SLURM partition should be configured with 'Shared=yes' attribute.

## Moab Configuration Steps

By default, Moab is built with WIKI interface support (which is used to interface with SLURM) when running the standard `configure` and `make` process.

To configure Moab to use SLURM, the parameter '[RMCFG](#)' should be set to use the **WIKI:SLURM** protocol as in the example below.

```
# moab.cfg
SCHEDCFG[base] MODE=NORMAL
RMCFG[base] TYPE=WIKI:SLURM
...
```

**Note:** The **RMCFG** index (set to *base* in the example above) can be any value chosen by the site. Also, if SLURM is running on a node other than the one on which Moab is running, then the **SERVER** attribute of the [RMCFG](#) parameter should be set.

**Note:** SLURM possesses a [SchedulerPort](#) parameter which is used to communicate with the scheduler. Moab will auto-detect this port and communicate with SLURM automatically with no explicit configuration required. Do NOT set Moab's [SCHEDCFG\[ \] PORT](#) attribute to this value, this port controls Moab client communication and setting it to match the [SchedulerPort](#) value will cause conflicts. With no changes, the default configuration will work fine.

**Note:** If the SLURM client commands/executables are not available on the machine running Moab, SLURM partition and other certain configuration information will not be automatically imported from SLURM, thereby requiring a manual setup of this information in Moab. In addition, the SLURM [VERSION](#) should be set as an attribute on the [RMCFG](#) parameter. If it is not set, the default is version 1.2.0. The following example shows how to set this line if SLURM v1.1.24 is running on a host named Node01 (set using the [SERVER](#) attribute).

```
# moab.cfg with SLURM on Host Node01
RMCFG[base] TYPE=WIKI:SLURM SERVER=Node01 VERSION=10124
...
```

## Configuration for Standby and Expedite Support

SLURM's 'Standby' and 'Expedite' options are mapped to the Moab [QoS](#) feature. By default, when a SLURM interface is detected, Moab will automatically create a 'standby' and an 'expedite' QoS. By default, the 'standby' QoS will be globally accessible to all users and on all nodes and will have a lower than normal priority. Also by default, the 'expedite' QoS will not be accessible by any user, will have no node constraints, and will have a higher than normal priority.

### Authorizing Users to Use 'Expedite'

To allow users to request 'expedite' jobs, the user will need to be added to the 'expedite' QoS. This can be accomplished using the [MEMBERULIST](#) attribute as in the following example:

```
MEMBERULIST
# allow josh, steve, and user c1443 to submit 'expedite' jobs
QOSCFG[expedite] MEMBERULIST=josh,steve,c1443
...
```

### Excluding Nodes for 'Expedite' and 'Standby' Usage

Both 'expedite' and 'standby' jobs can be independently excluded from certain nodes by creating a QoS-based [standing reservation](#).

Specifically, this is accomplished by creating a reservation with a logical-*not* QoS ACL and a hostlist indicating which nodes are to be exempted as in the following example:

```
MEMBERULIST

# block expedite jobs from reserved nodes
SRCFG[expedite-blocker] QOSLIST=!expedite
SRCFG[expedite-blocker] HOSTLIST=c001[3-7],c200
SRCFG[expedite-blocker] PERIOD=INFINITY

# block standby jobs from rack 13
SRCFG[standby-blocker] QOSLIST=!standby
SRCFG[standby-blocker] HOSTLIST=R:r13-[0-13]
SRCFG[standby-blocker] PERIOD=INFINITY
...
```

## Quadrics Integration

If managing a cluster with a Quadrics high speed network, significant performance improvement can be obtained by instructing Moab to allocate contiguous collections of nodes. This can be accomplished by setting the `NODEALLOCATIONPOLICY` parameter to `CONTIGUOUS` as in the example below:

```
# moab.cfg

SCHEDCFG[cluster1]  MODE=NORMAL SERVER=head.cluster1.org
RMCFG[slurm]        TYPE=wiki:slurm
NODEALLOCATIONPOLICY CONTIGUOUS
...
```

## Setting Up Authentication

By default, Moab will not require server authentication. However, if SLURM's `wiki.conf` file (default location is `/usr/local/etc`) contains the `AuthKey` parameter or a secret key is specified via SLURM's `configure` using the `--with-key` option, Moab must be configured to honor this setting. Moab configuration is specified by setting the resource manager `AUTHTYPE` attribute to `CHECKSUM` and the `KEY` value in the `moab-private.cfg` file to the secret key as in the example below.

```
# /usr/local/etc/wiki.conf

AuthKey=4322953
...
```

```
# moab.cfg

RMCFG[slurm]        TYPE=wiki:slurm AUTHTYPE=CHECKSUM
...
```

```
# moab-private.cfg

CLIENTCFG[RM:slurm] KEY=4322953
...
```

**Note:** For the `CHECKSUM` authorization method, the key value specified in the `moab-private.cfg` file must be a decimal, octal, or hexadecimal value, it cannot be an arbitrary non-numeric string.

## Queue/Class Support

While SLURM supports the concept of classes and queues, Moab provides a flexible alternative queue interface system. In most cases, sites can create and manage queues by defining partitions within SLURM. Internally, these SLURM partitions are mapped to Moab [classes](#) which can then be managed and configured using Moab's [CLASSCFG](#) parameter and [mdiag -c](#) command.

## Policies

By default, SLURM systems only allow tasks from a single job to utilize the resources of a compute node. Consequently, when a SLURM interface is detected, Moab will automatically set the [NODEACCESSPOLICY](#) parameter to *SINGLEJOB*. To allow node sharing, the SLURM partition attribute '**Shared**' should be set to *FORCE* in the `slurm.conf` as in the example below:

```
# slurm.conf
PartitionName=batch Nodes=node[1-64] Default=YES MaxTime=INFINITE State=UP
Shared=FORCE
```

## Moab Queue and RM Emulation

With a SLURM system, jobs can be submitted either to SLURM or to Moab. If submitted to SLURM, the standard SLURM job submission language must be used. If jobs are submitted to Moab using the [msub](#) command, then either LSF\*, PBS, or Loadleveler\* job submission syntax can be used. These jobs will be translated by Moab and migrated to SLURM using its native job language.

## SLURM High Availability

If SLURM high availability mode is enabled, Moab will automatically detect the presence of the SLURM BackupController and utilize it if the primary fails. To verify SLURM is properly configured, issue the SLURM command '`scontrol show config | grep Backup`'. To verify Moab properly detects this information, run '`mdiag -R -v | grep FallBack`'.

**Note:** To use SLURM high availability, the SLURM parameter **StateSaveLocation** must point to a shared directory which is readable and writable by both the primary and backup hosts. See the `slurm.conf` man page for additional information.

### Installation Notes for Moab and TORQUE for Cray

## Overview

Moab and TORQUE can be used to manage the batch system for Cray. This document describes how to configure Moab and TORQUE to bring Moab's unmatched scheduling capabilities to the Cray.

New to TORQUE 4.1, TORQUE now handles all communication with ALPS, specifically the pbs\_mom. Previously, communication with ALPS was handled by a combination of Moab, scripts and TORQUE. In the new model, Moab treats TORQUE as a regular TORQUE cluster without any special configuration. TORQUE now uses an extra MOM called the alps\_reporter MOM to communicate with ALPS regarding configured and available resources. From the information reported by the alps\_reporter mom, TORQUE creates a virtual node for each Cray compute node. Previously, TORQUE only reported the login nodes.

**Note:** For clarity this document assumes that your SDB node is mounting a persistent `/var` filesystem from the bootnode. If you have chosen not to use persistent `/var` filesystems please be aware that the instructions below would have to be modified for your situation.

## Upgrade Notes

When upgrading to TORQUE 4.1.0 and using the new Cray model as described in this document, there should be no running jobs. Jobs may be queued but not running.

## Installing TORQUE on a Cray

**i** These instructions are written for a partitioned system, with separate SDB and boot nodes. A combined SDB/boot node configuration is not supported.

For non-partitioned systems, change `sdb-p1` to `sdb` in these instructions.

Before beginning, note the SDB and login nodes' IDs as you will need them throughout the install process.

```
crayadm@smw> ssh root@boot-p1
boot# grep sdb /etc/hosts
10.128.0.32      nid00031      c0-0c0s0n3      sdb001  sdb002
10.131.255.253 sdb sdb-p1 syslog syslog-p1 ufs ufs-p1

boot# grep login /etc/hosts
10.128.0.3      nid00002      c0-0c0s1n0      login  login-p1      login1  castor-p1
```

*In this example, and throughout this page, the login node has NID 2 and the SDB has NID 31.*

### 1. Copy Moab/TORQUE software to SMW and boot node

```
workstation> scp -p /cray/css/release/cray/build/batch/moab-
torque/torque.5.0.0.tar.gz crayadm@smw:/home/crayadm/<yourusername>
workstation> scp -p /cray/css/release/cray/build/batch/moab-torque/moab-8.0.0-
SUSE11-linux-x86_64-torque.tar.gz crayadm@smw:/home/crayadm/<yourusername>

crayadm@smw> cd /home/crayadm/<yourusername>
crayadm@smw> scp -p torque-5.0.0.tar.gz root@boot-p1:/rr/current/software
crayadm@smw> scp -p moab-8.0.0-SUSE11-linux-x86_64-torque.tar.gz root@boot-
p1:/rr/current/software
```

### 2. Install TORQUE. SSH to the boot node and unpack the TORQUE tarball within `xtopview`.

```

crayadm@smw> ssh root@boot-pl
boot# xtopview -m "Installing TORQUE"
default:/# cd /software/
default:/# tar -zxvf torque-5.0.0.tar.gz

(or, if installing on an esMS)
esms# cd /path/to/software/
esms# tar -zxvf torque-5.0.0.tar.gz

```

### 3. Configure, build, and install TORQUE within xtopview.

```

default:/# cd torque-5.0.0
default:/# ./configure --prefix=/opt/torque/5.0.0 --with-server-
home=/var/spool/torque --with-default-server=sdb-p1 --enable-syslog --disable-gcc-
warnings --with-debug --with-modulefiles=/opt/modulefiles --with-job-create
CFLAGS="-DCRAY_MOAB_PASSTHRU"

(or, if installing on an esMS)
esms# cd /path/to/software/torque-5.0.0
esms# ./configure --prefix=/opt/torque/5.0.0 --with-server-home=/var/spool/torque -
-with-default-server=this-esms --enable-syslog --disable-gcc-warnings --with-debug
--with-modulefiles=/cm/local/modulefiles CFLAGS="-DCRAY_MOAB_PASSTHRU"

```

*The server name in the example is **sdb-p1**. Change this to **sdb** on a non-partitioned system.*

### 4. Make and install TORQUE.

```

default:/# make
default:/# make packages
default:/# make install
default:/# ln -sf /opt/torque/5.0.0 /opt/torque/default # The previous default
symlink might need to be deleted first if it exists
default:/# exit

```

### 5. Copy the TORQUE server directory to the Moab server host.

```

boot# cd /rr/current/var/spool
boot# cp -pr torque /snv/31/var/spool
boot# cp -pr torque /snv/2/var/spool

```

*In this example, the SDB node has NID 31, and the login node NID 2.*

### 6. Set up TORQUE on the SDB node.

```

boot# ssh sdb-p1
sdb# export PATH=/opt/torque/default/sbin:/opt/torque/default/bin:$PATH
sdb# cd /software/torque-5.0.0
sdb# ./torque.setup root
root
pbs_server port is: 15001
trqauthd daemonized - port 15005
trqauthd successfully started
initializing TORQUE (admin: root@boot)

You have selected to start pbs_server in create mode.
If the server database exists it will be overwritten.
do you wish to continue y/(n)?

# Type y

sdb# qmgr
Qmgr: set server keep_completed = 60 # Number of seconds to keep completed jobs in
qstat
unset queue batch resources_default.nodes
set server acl_host_enable = true
set server acl_hosts += nid00002
set server acl_hosts += castor-p1 # Where castor-p1 is the hostname of the login
node
set server acl_hosts += sdb-p1
set server submit_hosts += login
set server submit_hosts += login-p1 # Only needed on partitioned systems
set server submit_hosts += castor-p1 # Where castor-p1 is the hostname of the login
node
set server submit_hosts += nid00002 # Where nid00002 is the NID of the login node
set server tcp_timeout = 30
set server query_other_jobs = True
set server disable_server_id_check = True
set queue batch resources_default.mppnppn=16 # On Cascade systems with aprun -j1
set as default
set server cray_enabled = True
set server resources_default.partition = castor # Where "castor" is the same as the
RMCFG[clustername] in moab.cfg
exit

```

#### 7. Get the number of nodes available on the system.

```
sdb# echo Node count is $(( $(apstat -v | grep XT | awk '{print \$3}') ))
```

In the *nodes* / *nodect* commands, put in your system's number of nodes.

```

sdb# qmgr
set server resources_available.nodes = 20
set server resources_available.nodect = 20
set queue batch resources_available.nodes = 20
set queue batch resources_available.nodect = 20
exit

```

#### 8. Create TORQUE nodes file.

```
sdb# vi /var/spool/torque/server_priv/nodes  
  
    castor-p1 alps_login np=1000 # Where "castor-p1" is the hostname of your login  
node  
    sdb-p1 alps_reporter  
  
sdb# exit
```

*The np attribute is the number of processes that can be running at once. This number should be set appropriately high, depending on the number of nodes on the system.*

9. Install the `torque_server` `init.d` script on the SDB node.

**i** There is a known issue with some of the `init` scripts included with TORQUE. If the included `init` script doesn't work for you, use the process below to create a workaround `torque_server` `init.d` script for your system.

```

boot# xtopview -n 31 -m "torque_server init.d"
node/31:/ # touch /etc/init.d/torque_server
node/31:/ # xtspec -n 31 /etc/init.d/torque_server
node/31:/ # chmod a+x /etc/init.d/torque_server
node/31:/ # vi /etc/init.d/torque_server

#!/bin/sh
#
# pbs_server This script will start and stop the PBS Server
#
### BEGIN INIT INFO
# Provides:          pbs_server
# Required-Start:    $local_fs network
# Should-Start:
# Required-Stop:
# Should-Stop:
# Default-Start:    2 3 5
# Default-Stop:
# Description:       Torque is a versatile batch system for SMPs and clusters
### END INIT INFO

PBS_DAEMON=/opt/torque/default/sbin/pbs_server
PBS_HOME=/var/spool/torque
PIDFILE=$PBS_HOME/server_priv/server.lock
export PBS_DAEMON PBS_HOME PIDFILE

# Source the library functions
. /etc/rc.status
rc_reset

[ -f /etc/sysconfig/pbs_server ] && . /etc/sysconfig/pbs_server
[ -x $PBS_DAEMON ] || exit

# How were we called
case "$1" in
  start)
    echo -n "Starting TORQUE Server: "
    ulimit -c unlimited
    if [ -r $PBS_HOME/server_priv/serverdb ]
    then
      startproc $PBS_DAEMON $SERVER_ARGS
    else
      startproc $PBS_DAEMON -t create $DAEMON_ARGS
    fi
    rc_status -v
    ;;
  stop)
    echo -n "Shutting down TORQUE Server: "
    killproc -p $PIDFILE $PBS_DAEMON
    rc_status -v
    ;;
  status)
    echo -n "Checking TORQUE Server: "
    checkproc -p $PIDFILE pbs_server
    rc_status -v
    ;;
  restart)
    $0 stop

```

```

        $0 start
        rc_status
        ;;
    try-restart)
        $0 status >/dev/null && $0 restart
        rc_status
        ;;
    reload|force-reload)
        echo -n "Reloading TORQUE Server: "
        killproc -p $PIDFILE pbs_server -HUP
        rc_status -v
        ;;
    *)
        echo "Usage: torque_server {start|stop|status|try-
restart|restart|force-reload|reload}"
        exit 1
esac
rc_exit

```

10. Install the `torque_mom` `init.d` script on the SDB (or other node that runs the `alps_reporter` service for TORQUE) and login nodes.

**i** There is a known issue with some of the init scripts included with TORQUE. If the included init script doesn't work for you, use the process below to create a workaround `torque_mom` `init.d` script for your system.

*Example 3-177: SDB node*

```

boot# xtopview -n 31 -m "torque_mom init.d"
node/31:/ # touch /etc/init.d/torque_mom
node/31:/ # xtspec -n 31 /etc/init.d/torque_mom
node/31:/ # chmod +x /etc/init.d/torque_mom
node/31:/ # vi /etc/init.d/torque_mom

#!/bin/sh
#
# pbs_mom          This script will start and stop the PBS Mom
#
### BEGIN INIT INFO
# Provides:        pbs_mom
# Required-Start:  $local_fs
# Should-Start:    pbs_server pbs_sched
# Required-Stop:
# Should-Stop:
# Default-Start:   2 3 5
# Default-Stop:
# Description:     Torque is a versatile batch system for SMPs and clusters
### END INIT INFO

PBS_DAEMON=/opt/torque/default/sbin/pbs_mom
PBS_HOME=/var/spool/torque
PIDFILE=$PBS_HOME/mom_priv/mom.lock
export PBS_DAEMON PBS_HOME PIDFILE

ulimit -n 32768
# Source the library functions
. /etc/rc.status
rc_reset

[ -f /etc/sysconfig/pbs_mom ] && . /etc/sysconfig/pbs_mom
[ -x $PBS_DAEMON ] || exit

args=""
if [ -z "$PREVLEVEL" ];then
# being run manually, don't disturb jobs
args="-p"
fi

# How were we called
case "$1" in
  start)
    echo -n "Starting TORQUE Mom: "
    #ulimit -c unlimited
    /sbin/startproc $PBS_DAEMON $args $DAEMON_ARGS
    rc_status -v
    ;;
  purge)
    [ -f /var/lock/subsys/pbs_mom ] && $0 stop
    echo -n "Starting TORQUE Mom with purge: "
    startproc $PBS_DAEMON -r $DAEMON_ARGS
    rc_status -v
    ;;
  stop)
    echo -n "Shutting down TORQUE Mom: "
    /sbin/killproc -p $PIDFILE $PBS_DAEMON
    rc_status -v
    ;;
)

```

```

status)
    echo -n "Checking TORQUE Mom: "
    checkproc -p $PIDFILE $PBS_DAEMON
    rc_status -v
    ;;
restart)
    $0 stop
    sleep 1
    $0 start -p
    rc_status
    ;;
try-restart)
    $0 status >/dev/null && $0 restart
    rc_status
    ;;
reload|force-reload)
    echo -n "Re-reading TORQUE Mom config file: "
    killproc -p $PIDFILE -HUP pbs_mom
    rc_status -v
    ;;
*)
    echo "Usage: torque_mom {start|stop|status|try-restart|restart|force-
reload|reload|purge}"
    exit 1
esac

```

#### Example 3-178: Login nodes

```

boot# xtopview -c login -m "torque_mom init.d"
class/login:/ # touch /etc/init.d/torque_mom
class/login:/ # xtspec -c login /etc/init.d/torque_mom
class/login:/ # chmod +x /etc/init.d/torque_mom
class/login:/ # vi /etc/init.d/torque_mom

# Use the same script as the SDB node above

```

11. Create the MOM configuration file. This must be done on every login node and also the alps\_reporter node (typically the SDB) specified in the TORQUE `server_priv/nodes` file.
  - a. First, determine if the ALPS path needs to be configured in the MOM configuration file.

```

login# which apbasil
/usr/bin/apbasil
# No configuration change needed

login# which apbasil
/opt/cray/alps/5.0.2-2.0500.7827.1.1.ari/bin/apbasil
# MOM configuration change is needed. This path needs to be declared in the mom_
priv/config file.

```

- b. Create and populate the MOM configuration file on the nodes.

```
login and sdb# vi /var/spool/torque/mom_priv/config

$usecp */:/ufs /ufs
$usecp */:/home /home
$usecp */:/home/users /home/users
$usecp */:/scratch /scratch
$usecp */:/lus /lus
$usecp */:/extlus /extlus
$login_node true # For login node
$reporter_mom true # For SDB node
$apbasil_protocol 1.2
$prologalarm 120
$apbasil_path /opt/cray/alps/default/bin/apbasil # Only if needed. Use the path
discovered above.
```

- c. If needed, you can add CPR information to the MOM configuration on the login nodes .

```
$checkpoint_run_exe /opt/cray/blcr/default/bin/cr_run
$checkpoint_script /opt/cray/cprbatchutils/default/libexec/checkpoint.torque
$restart_script /opt/cray/cprbatchutils/default/libexec/restart.torque
$remote_checkpoint_dirs /lus/scratch/BLCR_checkpoint_dir
```

12. Create the `torque.cfg` file (useful if having issues with LDAP users submitting jobs) on the SDB node.

```
sdb# vi /var/spool/torque/torque.cfg

QSUBSENDUID true
VALIDATEPATH FALSE
```

13. Install the `trqauthd` init.d script on the SDB and login nodes.

```
boot# xtopview -n <SDB or login> -m "trqauthd"
node/<SDB or login>:/ # cp /software/torque-5.0.0/contrib/init.d/suse.trqauthd
/etc/init.d/trqauthd
node/<SDB or login>:/ # chmod +x /etc/init.d/trqauthd
node/<SDB or login>:/ # vi /etc/init.d/trqauthd

PBS_DAEMON=/opt/torque/default/sbin/trqauthd
```

14. Start the `trqauthd` daemon on the SDB and login nodes.

```
<SDB or login># /etc/init.d/trqauthd start
```

## Enabling node features for Cray compute nodes

Node features can be set for Cray compute nodes. To add node features to a Cray compute node, use the `cray_compute` keyword on designated nodes in the `nodes` file.:

```
# node_id cray_compute feature_name
2 cray_compute bigmem
```

## Configuring TORQUE for ALPS 1.3

To configure TORQUE for ALPS 1.3, configure the `apbasil_protocol` parameter in `mom_priv/config` and set the `nppcu` server parameter. The `nppcu` parameter has three options that

determine whether to use Hyper-Threading:

Table 3-6: nppcu values

Value	Description
0	Allow ALPS to choose
1	Hyper-Threading disabled (default)
2	Hyper-Threading enabled

When nppcu is set to 0 or 2, pbs\_nodes reports twice as many cores.

### apbasil\_protocol:

```
$apbasil_protocol 1.3
$loglevel 3
```

### nppcu:

```
qmgr -c 'set server nppcu=1'
```

## Installing Moab Workload Manager

1. Unpack the Moab tarball within xtopview.

```
boot# xtopview -m "Installing Moab"
default:/# cd /software/
default:/# tar -zxvf moab-8.0.0-linux-x86_64-torque-xt4.tar.gz
default:/# cd moab-8.0.0
```

2. Configure, build, and install Moab within xtopview.

```
default:/# ./configure --prefix=/opt/moab/8.0.0 --with-homedir=/var/spool/moab --
with-torque=/opt/torque/default --with-modulefiles=/opt/modulefiles --with-xt4

(or, if installing on an esMS)
default:/# ./configure --prefix=/opt/moab/8.0.0 --with-homedir=/var/spool/moab --
with-torque=/opt/torque/default --with-modulefiles=/cm/local/modulefiles --with-xt4

default:/# make install
default:/# ln -sf /opt/moab/8.0.0 /opt/moab/default # The previous default symlink
may need to be deleted first if it exists
default:/# exit
```

3. Configure the moab.cfg file.

```

boot# cd /rr/current/var/spool/moab/etc
boot# vi moab.cfg

    Change the value of SCHEDCFG[Moab] to SERVER=sdb-pl:42559 # Leave the port
    number as whatever default is present
    Change ADMINCFG[1] USERS=root to USERS=root,crayadm # Where "crayadm" is the
    administrative user
    If applicable, change TOOLSDIR from /opt/moab/8.0.0/tools to
    /opt/moab/default/tools

    Change RMCFG[boot]      TYPE=PBS to
    RMCFG[castor]          TYPE=TORQUE # "castor" can be any logical name for the
    partition

    For Moab version 6.x, use TYPE=NATIVE:XT4

    Example:
    RMCFG[tuna]  TYPE=TORQUE SUBMITCMD=/opt/torque/default/bin/qsub
    FLAGS=asyncstart

    Add:
    RMPOLLINTERVAL      00:00:10
    DEFERTIME           00:05:00
    JOBNODEMATCHPOLICY EXACTNODE
    NODECFG[DEFAULT]   OS=linux ARCH=XT
    NODEACCESSPOLICY   SINGLEJOB
    JOBMIGRATEPOLICY   IMMEDIATE
    NODEALLOCATIONPOLICY PRIORITY
    NODECFG[DEFAULT]   PRIORITYF='PRIORITY'
    NODECFG[castor-pl] Partition=login # Use a logical name such as "login" to
    keep the MOM nodes in a separate
    # partition from the compute nodes
    # "castor-pl" in this case is the hostname
    of the login node
    CLIENTCFG[DEFAULT] DEFAULTSUBMITPARTITION=castor # Where "castor" is the name
    of the partition (see RMCFG[castor] above)
    JOBMAXTASKCOUNT   <total number of processors>

    # Comment out USEDATABASE INTERNAL

    # If using a re-purposed compute node as the alps_reporter MOM, add:
    NODECFG[nid00060]  Partition=login # Where nid00060 is the nid of the RCN

    # If necessary to ignore nodes (such as 24 core nodes on a primarily 32 core
    system), add:
    IGNORENODES       57,58 # Where "57" and "58" are node hostnames

```

#### 4. Configure the config.xt4.pl file.

```

boot# vi config.xt4.pl

$basilProtocol = "1.2";

# Uncomment the %loginReplaceTable line, and update the hostnames:
%loginReplaceTable = (nid00002 => "login-p1"); # Where "login-p1" is the exact
hostname of the login node, for example, "castor-p3"

# Uncomment:
$topologyOrdering = 1;

# If on a system that has undergone ALPS standardization (See the apbasil notes
above), replace the $torquePath line with:
my $torquePath = "/opt/torque/default/bin:/usr/bin:/opt/cray/alps/default/bin";

```

#### 5. Copy Moab to the SDB node.

```

boot# cd /rr/current/var/spool/
boot# cp -pr moab /snv/31/var/spool/

For Moab version 6.x only:
boot# mv /snv/31/var/spool/moab/etc/moab.cfg /snv/31/var/spool/moab/

For all versions:
boot# mkdir -p /snv/2/var/spool/moab/etc /snv/2/var/spool/moab/log
boot# cp moab/etc/moab.cfg /snv/2/var/spool/moab/etc/
boot# cp moab/etc/config.xt4.pl /snv/2/var/spool/moab/etc/

```

#### 6. Install the moab init.d script

**i** There is a known issue with some of the init scripts included with Moab. If the included init script doesn't work for you, use the process below to create a workaround moab init.d script for your system.

```

boot# xtopview -n 31 -m "Moab init.d"
node/31:/ # touch /etc/init.d/moab
node/31:/ # xtspec -n 31 /etc/init.d/moab
node/31:/ # chmod a+x /etc/init.d/moab
node/31:/ # vi /etc/init.d/moab
#!/bin/bash
#
# Starts the Moab daemon
#
# chkconfig: 345 96 6
# description: Moab Workload Manager
# processname: moab
#
### BEGIN INIT INFO
# Provides: Moab
# Required-Start: $local_fs $syslog $network $named
# Required-Stop: $local_fs $syslog $network $named
# Default-Start: 3 5
# Default-Stop: 0 1 2 6
# Short-Description: Moab daemon management
# Description: Start Moab Workload Manager
### END INIT INFO
#
# 1. This file should be installed as /etc/init.d/moab
#
# 2. Start Moab with:
#
#     /etc/init.d/moab start
#
# Source function library.
[ -f /etc/rc.status ] || exit 0
. /etc/rc.status

export MOABHOMEDIR=/var/spool/moab
export MOABPARCLEANUP=Full
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/opt/torque/default/lib

prog=moab
path=/opt/moab/default/sbin
RETVAL=0

function start()
{
    echo -n "Starting $prog: "
    ulimit -s unlimited      # Increase stack size to unlimited
    ulimit -c unlimited     # Uncomment to preserve core files

    export MOABNOALLOCMASTER=1
    sleep 2
    startproc $path/moab

    RETVAL=$?
    echo
    [ $RETVAL -eq 0 ] && touch /var/lock/subsys/moab
    return $RETVAL
}

```

```

function stop()
{
    echo -n "Shutting down $prog: "
    killproc moab
    RETVAL=$?
    echo
    [ $RETVAL -eq 0 ] && rm -f /var/lock/subsys/moab
    return $RETVAL
}

function restart()
{
    stop
    sleep 2
    start
}

function condrestart()
{
    if [ -f /var/lock/subsys/capi ] ; then
        restart
    fi
}

function reload()
{
    echo -n $"Reloading $prog: "
    schedctl -R
    RETVAL=$?
    echo
    return $RETVAL
}

case "$1" in
    start)
        start
        rc_status -v
        ;;
    status)
        status moab
        RETVAL=$?
        rc_status -v
        ;;
    stop)
        stop
        rc_status -v
        ;;
    restart)
        restart
        rc_status -v
        ;;
    condrestart)
        condrestart
        ;;
    reload)
        reload
        rc_status -v
        ;;
    *)

```

```

    echo "Usage: $prog {start|stop|restart|reload|status|condrestart}"
    exit 1
esac

exit $RETVAL

```

7. For versions of Moab earlier than 7.1.3 and TORQUE 4.1.4, root must be allowed to submit jobs.

```

boot# ssh sdb
sdb# module load moab torque
sdb# qmgr
qmgr> set server acl_roots = root
qmgr> exit
sdb# /etc/init.d/torque_server restart

sdb# vi /var/spool/moab/etc/moab.cfg # or /var/spool/moab/moab.cfg for Moab version
6

Add
ALLOWROOTJOBS TRUE

sdb# /etc/init.d/moab restart
or
sdb# mschedctl -R

```

8. For versions of Moab newer than 7.1.3, the root user can submit jobs as another user.

```

sdb# qmgr
qmgr> set server managers += root@*
qmgr> exit

sdb# ssh login

login# qsub -I -l mppwidth=1 -P <otherusername>

```

9. Copy your Moab license file to the SDB node in the `/var/spool/moab/` directory.

## Provisioning Resource Managers

- [Validating an xCAT Installation for Use with Moab on page 1252](#)

### Validating an xCAT Installation for Use with Moab

- [Introduction to Validating xCAT Configuration](#)
- [Verifying Node List](#)
- [Reporting Node Status](#)
- [Verifying Hardware Management Configuration](#)
- [Verifying Provisioning Images](#)
- [Verifying VM Migration](#)

## Introduction to Validating xCAT Configuration

This document describes a series of steps to validate xCAT configuration prior to configuring Moab to manage hardware via xCAT. It is assumed the reader is familiar with xCAT and the xCAT configuration on

the target site. This document does not provide xCAT configuration documentation or troubleshooting information; please refer to the [xCAT documentation](#) for such information.

## Verifying Node List

Verify that all nodes that Moab will manage are known to xCAT with the xCAT `nodels` command. Ensure that all expected (and no unexpected) nodes are listed. You may find it useful to create new group names to identify Moab-managed nodes.

```
[root@h0 moab]# nodels hyper,compute
h1
h2
h3
h4
h5
h7
kvmm1
kvmm10
kvmm2
kvmm3
kvmm4
kvmm5
kvmm6
kvmm7
kvmm8
[root@h0 moab]#
```

## Reporting Node Status

Verify that all nodes report their status correctly using the xCAT `nodestat` command. Ensure that all nodes show the correct status (`sshd`, `installing`, `noping`, and so forth); there should not be any timeouts or error messages.

```
[root@h0 moab]# nodestat hyper,compute |sort
h1: pbs,sshd
h2: pbs,sshd
h3: pbs,sshd
h4: pbs,sshd
h5: pbs,sshd
h7: noping
kvmm10: noping
kvmm1: pbs,sshd
kvmm2: pbs,sshd
kvmm3: pbs,sshd
kvmm4: pbs,sshd
kvmm5: pbs,sshd
kvmm6: pbs,sshd
kvmm7: pbs,sshd
kvmm8: noping
kvmm9: noping
[root@h0 moab]#
```

## Verifying Hardware Management Configuration

Verify that all nodes that Moab will manage have hardware management interfaces correctly configured using the xCAT `nodels` and `rpower` commands. After each of the `rpower` commands, verify the requested state was achieved with `rpower stat`.

```
[root@h0 moab]# nodels h1,kvmm1 nodehm.mgt nodehm.power
h1: nodehm.power: ilo
h1: nodehm.mgt: ilo
kvmm1: nodehm.power: kvm
kvmm1: nodehm.mgt: kvm
[root@h0 moab]# rpower h1,kvmm1 off
h1: off
kvmm1: off
[root@h0 moab]# rpower h1,kvmm1 stat
h1: off
kvmm1: off
[root@h0 moab]# rpower h1,kvmm1 boot
h1: on reset
kvmm1: on reset
[root@h0 moab]# rpower h1,kvmm1 stat
h1: on
kvmm1: on
[root@h0 moab]#
```

## Verifying Provisioning Images

Verify that all operating system images that Moab uses are configured correctly in xCAT. For stateful images, test that all combinations of operating system, architecture, and profile install correctly.

```
[root@h0 moab]# rinstall -o centos5.3 -a x86_64 -p hyper h1
h1: install centos3.2-x86_64-hyper
h1: on reset
[root@n100 ~]# sleep 15 && nodestat n05
n05: ping install centos5.3-x86_64-hyper
[root@h0 moab]#
```

For stateless images, test that nodes are able to network boot the images.

```
[root@h0 moab]# nodech h5 nodetype.os=centos5.3 nodetype.arch=x86_64
nodetype.profile=hyper
[root@h0 moab]# nodeset h5 netboot
h5: netboot centos5.3-x86_64-hyper
[root@h0 moab]# rpower h5 boot
h5: on reset
[root@h0 moab]# sleep 60 && nodestat h5
h5: pbs, sshd
[root@h0 moab]#
```

## Verifying VM Migration

If you use VM migration, verify that xCAT can successfully perform migrations using the `rmigrate` command.

```
[root@h0 moab]# rmigrate kvmm7 h1
kvmm7: migrated to h1
[root@h0 moab]# ssh h1 virsh list
Id Name State
-----
33 kvmm1 running
34 kvmm2 running
35 kvmm7 running
```

### Moab-NUMA Integration Guide

Scheduling a shared-memory NUMA type system (not the same as a modern SMP-based individual compute node, which cannot share memory between compute nodes) requires some special configuration. Additionally, Moab can use [NODESETs](#) to guarantee feasibility of large memory jobs and to enforce node allocation based on the system's interconnect network topology.

## Configuration

### To integrate Moab and NUMA

1. Configure Moab to schedule large memory jobs. Because Moab creates a partition for each resource manager by default, you must configure the cluster controlled by the resource manager to be a shared-memory system to support jobs spanning multiple nodes/blades. To do so, use the [PARCFG](#) parameter.

```
RMCFG[sys-uv] TYPE=TORQUE
PARCFG[sys-uv] FLAGS=SharedMem
```

*Cluster `sys-uv` is now configured as a shared-memory system to Moab.*

2. Configure **NODESETs** as shown below.

```
NODESETISOPTIONAL FALSE
NODESETATTRIBUTE FEATURE
NODESETPOLICY ONEOF
NODESETPRIORITYTYPE FIRSTFIT
```

*The **NODESET** parameters tell Moab that performing node allocation using node sets is required, that the node set name is a feature name assigned to compute nodes, that a job must fit within the available nodes of one node set, and that Moab should use the first node set that contains sufficient available nodes to satisfy the job's request.*

3. To configure Moab to perform topology-aware node allocation using node sets, you must create a node set definition for each set of nodes that has the same number of maximum network "hops" from any node to every other node within the node set. For an example, see the following sample scenario:

### Use case

The SGI UV 1000 has a two-socket blade with a physical organization of 16 blades within a blade chassis (SGI term is Intra-Rack Unit or IRU), two blade chassis (IRUs) within a rack, and up to four racks within a single UV system. The UV 1000 interconnect network has a topology that requires zero hops between the two sockets on the same physical blade, one hop between an even-odd blade pair (e.g. blades 0 and 1, 2 and 3, etc.), two hops between all even-numbered or all odd-numbered blades within an IRU, three hops maximum between all blades within an IRU, four hops maximum between all even-numbered blades or all odd-numbered blades within a UV system, and five hops maximum between all blades within a UV system.

- a. Define topology-aware node definitions to parallel the compute nodes reachable within a specific hop count. For the UV 1000, this means the sockets of each blade will belong to six separate node set definitions; i.e., one each for 0, 1, 2, 3, 4, and 5 hops).
- b. Define multiple node sets for different nodes reachable in a specific hop count based on the context of where they are in the network topology; that is, you must create a separate and distinct node set definition for each pair of blades reachable with one hop, for each IRU for its nodes reachable in three hops, etc.
- c. Moab node sets are usually defined as compute node features; that is, each node set defined to Moab should appear as a "feature" name on one or more compute nodes. Which node set/feature names appear on each compute node depends on where the compute node is in the interconnect network topology.

Since the SGI UV operating system identifies each blade socket as a separate NUMA node, each NUMA node within a UV system is traditionally an individual compute node to Moab (although TORQUE has the ability to redefine a compute node definition by grouping OS NUMA nodes, which some UV installations do to define a blade as a compute node).

For the sake of illustration, this example assumes each OS NUMA node, which is a UV blade socket, is also a compute node in Moab. This means each compute node (blade socket) will have six feature names assigned, where each feature name must reflect both the compute node's location in the network topology and the hop count the name represents. A feature name is constructed by using the same root name for a hop count and a number for the topology location at the hop-count level.

For example, the root feature name "blade" represents the zero-hop count and the numbers "0", "1", etc, represent the consecutively numbered blades throughout the entire UV system, which yields feature names of "blade0" for the first blade in the system, "blade1" for the second blade, etc, to "blade127" for the last blade in a fully populated 4-rack UV system. To illustrate further, the root feature name "iru" represents the 3-hops count and the numbers "0" through "7" represent the eight IRUs within a full 4-rack UV system.

- d. For each compute node, configure the correct feature name for each of the hop counts possible and its location within the topology at the hop-count level (e.g., blade (0 hops), blade pair (1 hop), odd- or even-numbered nodes within an IRU (2 hops), IRU (3 hops), odd- or even-numbered nodes within the UV (4 hops), and UV system (5 hops)). The following example illustrates the feature names assigned to the compute nodes for an SGI UV 1000 system using the following root feature

names.

- blade (0 hops)
- pair (1 hop)
- eiru (2 hops for even-numbered blades within an IRU)
- oiru (2 hops for odd-numbered blades within an IRU)
- iru (3 hops)
- esys (4 hops for even-numbered blades within a UV system)
- osys (4 hops for odd-numbered blades within a UV system)
- sys (5 hops)

Note that nodes 0 and 1 are not given any feature names. This is because the operating system instance for the UV system runs on the first blade and in order to not adversely affect OS performance, no jobs should run on the same compute resources as the operating system; hence, these nodes have no node set feature names and therefore will never be chosen to run jobs. In addition, some of the first feature names at a specific hop count-level are omitted (such as pair0) since it makes no sense to define them when the first blade is a substantial part of the nodes making up a node set.

The node name of a UV system has the same name as the UV system's host name plus the NUMA node's relative socket number.

```

```

- Define the order in which Moab should check node sets for available nodes. Since the `NODESETPRIORITYTYPE` has a value of `FIRSTFIT`, the node sets must be ordered from smallest to largest so Moab will always choose the node set with the fewest nodes required to satisfy the job's request. This means listing all blades, blade pairs, even and odd IRUs, IRUs, even and odd system, and system, respectively.

```

moab.cfg:
NODESETLIST
blade1,blade2,blade3,...,blade127,pair1,pair2,pair3,...,pair63,eiru0,oiru0,eiru1,oiru1,
...,eiru7,oiru7,iru0,iru1,...,iru7,esys,osys,sys

```

- Configure Moab to use the `PRIORITY NODEALLOCATIONPOLICY`. This allocation policy causes Moab to allocate enough nodes to fulfill a job's processor and memory requirement.

```

NODEALLOCATIONPOLICY PRIORITY

```

- Set `NODEACCESSPOLICY` to `SINGLEJOB` to ensure that Moab will schedule large memory requests correctly and efficiently. This is necessary even when a job uses only the memory of a NUMA node.

```

NODEACCESSPOLICY SINGLEJOB

```

The policy `SINGLEJOB` tells Moab not to allow jobs to share NUMA resources (cores and memory), which for a shared-memory system is very important for fast job execution. For example, if Moab scheduled a job to use the cores of a NUMA node where memory is used by another job, both jobs would execute slowly (up to 10 times more slowly).

## Job Submission

Jobs can request processors and memory using the `-l nodes=<number of cpus>` and `-l mem=<amount of memory>` syntaxes. You should not have `JOBNODEMATCHPOLICY EXACTNODE` configured on a NUMA system. You must use the `sharedmem` job flag on submission to force the job to

run only on a sharedmem partition or cluster and to indicate that the job can span multiple nodes. For example:

```
qsub -l nodes=3,mem=640sgb,flags=sharedmem
```

## Appendix H: Interfacing with Moab (APIs)

Moab provides numerous interfaces allowing it to monitor and manage most services and resources. It also possesses flexible interfaces to allow it to interact with peer services and applications as both a broker and an information service. This appendix is designed to provide a general overview and links to more detailed interface documentation.

- [H.1 Moab Query and Control APIs](#)
  - Allow external portals and services to obtain information about compute resources, workload, and usage statistics.
- [H.2 Resource Management Interfaces](#)
  - Allow Moab to monitor, schedule, and control services and resources.
- [H.3 Identity and Credential Management Interfaces](#)
  - Allow monitoring and active management of user configuration, credentials, policies, and usage information.
- [H.4 Accounting and Event Interfaces](#)
  - Allow import/export of accounting and event information to external entities.
- [H.5 Job Submission and Management Interface](#)
  - Query resource availability, submit, modify, and manage jobs, and query the status of active and completed jobs.
- [H.6 Grid Services API](#)
  - Provide and use information, data, job, and resource management services in a distributed environment.

Moab interfaces to systems providing various services and using various protocols. This appendix is designed to assist users who want to enable Moab in new environments using one of the existing interfaces. It does not cover the steps required to create a new interface.

### H.1 Query and Control APIs

The Moab Cluster and Grid Suites provides a (Moab) workload manager server that supports a broad array of client services. These services can be directly accessed via Moab client commands.

## H.1.1 CLI (Command Line Interface) XML API

All Moab client commands can report results in XML format to allow the information to be easily integrated into peer services, portals, databases, and other applications. To request that a client command report its output in XML, specify the `--format=xml` flag as in the following example:

```
> showq --format=xml
<Data>
<Object>queue</Object>
<cluster LocalActiveNodes="1" LocalAllocProcs="1" LocalIdleNodes="0"
LocalIdleProcs="3" LocalUpNodes="1"
LocalUpProcs="4" RemoteActiveNodes="0" RemoteAllocProcs="0" RemoteIdleNodes="0"

### Common Query/Control Services

- jobs
  - query status - [mdiag -j](#) ([XML details](#))
  - submit - [msub](#) ([XML format](#))
  - cancel - [mjobctl -c](#)
- nodes
  - query status - [mdiag -n](#) ([XML details](#))
  - create resource reservation - [mrsvctl -c](#)
  - destroy resource reservation - [mrsvctl -r](#)

## H.2 Resource Management Interfaces

Moab can monitor, schedule, and control services and resources using multiple protocols. These protocols include the following:

- [LDAP](#)
- [script/flat file](#)
- [Resource Manager Specific Interfaces](#) - LSF, SGE, TORQUE, PBSPro, Loadleveler, and so forth

Using the resource manager interfaces, Moab can do the following:

- monitor resources (compute host, network, storage, and software license based resources)
  - load configuration, architecture, and feature information
  - load state, utilization, and workload information
  - load policy and ownership information
- manage resources
  - dynamically reconfigure and reprovision resource hardware (processors, memory, etc.)
  - dynamically reconfigure and reprovision resource software (operating system, application software, filesystem mounts, etc.)
  - dynamically reconfigure and reprovision resource security (VPN's, VLAN's, host security, etc.)
- monitor workload (batch jobs, interactive jobs, persistent services, dynamic services, distributed services)
  - load state, resource requirement, and required environment information
  - load user, group, and credential information
  - load utilization, resource allocation, and policy information
- manage workload
  - migrate jobs from one resource to another (intra-cluster and inter-cluster)
  - modify jobs for translation and optimization purposes
  - suspend, resume, checkpoint, restart, and cancel jobs
- query cluster policies and configuration

### H.3 Identity and Credential Management Interfaces

Moab's identity and credential management interfaces allow Moab to exchange credential and user configuration, access, policy, and usage information.

- [Identity Manager](#)
- Allocation Manager
- [Moab Workload Manager for Grids](#)

### H.4 Accounting Interfaces

Moab accounting interfaces allow Moab to export local utilization statistics, events, and accounting information to site specific scripts.

- [Accounting Interface](#)

## H.6 Job Submission and Management Interface

Moab provides interfaces to enable the following services:

- Resource Availability Query
  - Determine quantity, state, and configuration of configured resources (idle, busy, and down nodes)
  - Determine quantity and configuration of all available resources (idle nodes)
  - Determine resources available subject now and in the future for potential job
  - Determine best target cluster destination for potential job
  - Determine largest/longest job which could start immediately
  - Determine estimated start time for potential job
  - Determine earliest guaranteed start time for potential job
- Reserve Resources
  - Reserve specific resources for desired time frame
- Submit Job ([XML format](#))
  - Submit job to specific cluster
  - Submit job to global job queue
- Manage Job
  - Hold job
  - Adjust job priority
  - Modify job executable, args, data requirements, job dependencies, duration, hostcount, or other attributes
  - Suspend/resume job
  - Checkpoint/requeue job
  - Cancel job
  - Migrate job
  - Adjust job quality of service (QoS)
- Query Job
  - Determine job state, utilization, or output results for idle, active, or completed job
  - Determine estimated start time
  - Determine guaranteed start time

## H.7 Grid Interfaces

Moab provides interfaces to allow interaction with various grid brokers and services. These interfaces allow Moab to provide services as well as utilize services.

### Services Utilized

- Information Services (import and utilize information service data in making scheduling decisions)
- Job Migration
- Data Migration
- Credential Mapping
- Security and Delegation

See [Moab Workload Manager for Grids](#) for more information on utilized services.

### Services Provided

- Information Services (provide resource, workload, and credential information)
- Job Migration
- Data Migration
- Credential Mapping

See [Moab Workload Manager Grid Basics](#) for more information on provided services.

## Appendix I: Considerations for Large Clusters

- [I.1 Resource Manager Scaling](#)
- [I.2 Handling Large Numbers of Jobs](#)
- [I.3 Handling Large Numbers of Nodes](#)
- [I.4 Handling Large Jobs](#)
- [I.5 Handling Large SMP Systems](#)
- [I.6 Server Sizing](#)

There are several key considerations in getting a batch system to scale.

### I.1 Resource Manager Scaling

#### Proper Resource Manager Configuration

- [TORQUE](#)
  - [General Scaling Overview](#)

- OpenPBS/PBSPro
  - Manage Direct Node Communication with [NODEPOLLFREQUENCY](#)

## I.2 Handling Large Numbers of Jobs

### Set a minimum RMPOLLINTERVAL

With event driven resource managers like TORQUE, each time a job is submitted the resource manager notifies the scheduler. In an attempt to minimize response time, the scheduler starts a new scheduling cycle to determine if the newly submitted job can run. In systems with large numbers of jobs submitted at once, this might not result in the desired behavior for two reasons. First, by scheduling at every job submission Moab schedules newly submitted jobs onto available resources in a first come, first served basis rather than evaluating the entire group of new jobs at once and optimizing the placement accordingly. Second, by launching a scheduling iteration for every job submitted, Moab places a heavy load on the resource manager. For example, if a user were to submit 1000 new jobs simultaneously, for each job submitted, the resource manager contacts the scheduler, the scheduler starts a new iteration, and in this iteration, the scheduler contacts the resource manager requesting updated information on all jobs and resources available.

Setting a minimum **RMPOLLINTERVAL** causes the scheduler to not process jobs as quickly as they are submitted, but rather to wait a minimum amount of time to allow more jobs be submitted and to process these new jobs in groups.

```
RMPOLLINTERVAL 30,60
```

*If the system is busy, schedule every 30 seconds. If it is not busy, schedule every 60 seconds.*

### Reduce command processing time

If your system's scheduling cycle regularly takes longer than the [CLIENTTIMEOUT](#) value, you can configure Moab to fork a copy of itself that will respond to certain information-only client commands ([checkjob](#), [showbf](#), [showres](#), and [showstart](#)). This enables you to run intense diagnostic commands while Moab is in the middle of its scheduling process.

When you set **UIMANAGEMENTPOLICY FORK**, Moab forks a copy of itself that will listen for client commands on a separate port, which you must configure with **CLIENTUIPORT**. This forked process responds to `checkjob`, `showbf`, `showres`, and `showstart` until the main scheduling cycle has finished. After that, it is killed and the normal process resumes responding to client commands. Moab prints a disclaimer at the top of each command that was populated by the forked process stating that the information may be a few seconds stale.

*Example 3-179: Sample configuration*

```
UIMANAGEMENTPOLICY    FORK
CLIENTUIPORT          41560
```

*Moab forks a copy of itself on port 41560, where it will watch for checkjob, showbf, showres, and showstart commands until the main scheduling process completes.*

**Example 3-180: Sample command output**

```

$ checkjob 34
-----
NOTE: The following information has been cached by the remote server
and may be slightly out of date.
-----

job 34

State: Idle
Creds: user:wightman group:company class:batch
WallTime: 00:00:00 of 00:01:00
SubmitTime: Thu May 22 14:17:06
(Time Queued Total: 00:00:18 Eligible: 00:00:18)

TemplateSets: DEFAULT
Total Requested Tasks: 1

Req[0] TaskCount: 1 Partition: ALL

SystemID: scale
SystemJID: 34

IWD: $HOME/test/scale
SubmitDir: $HOME/test/scale
Executable: sleep 60

```

**Limited Job Checkpointing**

Use the [LIMITEDJOBBCP on page 987](#) parameter. By default, Moab will checkpoint information about every job it reads from its resource managers. When a cluster routinely runs more than 15000 jobs, they may see some speed-ups by limiting which jobs are checkpointed. When **LIMITEDJOBBCP** is set to **TRUE**, Moab will only checkpoint jobs that have a hold, a system priority, jobs that have had their QoS modified, and a few other limited attributes. Some minimal statistical information is lost for jobs that are not checkpointed.

**Minimize Job Processing Time**

Use the [ENABLEHIGHTHROUGHPUT on page 950](#) parameter. By default, Moab processes all job attributes, filters, remap classes, job arrays, and other information when a job is submitted. This requires full access to the Moab configuration and significantly increases the processing time Moab needs when jobs are submitted. By setting **ENABLEHIGHTHROUGHPUT** to **TRUE**, Moab stores the job information in an internal queue and returns the job ID immediately. The internal queue is processed when Moab begins its next scheduling iteration. This enables Moab to process hundreds of jobs per second rather than 20-30 per second. Because the jobs are processed in a separate queue after the job has been returned, it is recommended that [MAILPROGRAM](#) be configured. Moab will send an email to the user if a job is rejected.

Because the job is not fully processed, some attributes may change after the job has been submitted. For example, when a job class is remapped, the new class is not reflected until Moab begins its next scheduling iteration. Additionally, job arrays are not instantiated until Moab begins its next scheduling cycle.

**i** If **ENABLEHIGHTHROUGHPUT** on page 950 is **TRUE**, you must set **NODEALLOCATIONPOLICY** on page 999 to **FIRSTAVAILABLE**.

## Load all Non-Completed Jobs at Startup

Use the **LOADALLJOB** on page 988 parameter. By default, Moab loads non-complete jobs for active resource managers only. By setting **LOADALLJOB** to **TRUE**, Moab will load all non-complete jobs from all checkpoint files at startup, regardless of whether their corresponding resource manager is active.

## Reducing Job Start Time

Use the **ASYNCSTART** parameter. By default, Moab will launch one job at a time and verify that each job successfully started before launching a subsequent job. For organizations with large numbers of very short jobs (less than 2 minutes in duration), the delay associated with confirming successful job start can lead to productivity losses. If tens or hundreds of jobs must be started per minute, and especially if the workload is composed primarily of serial jobs, then the resource manager **ASYNCSTART** flag may be set. When set, Moab will launch jobs optimistically and confirm success or failure of the job start on the subsequent scheduling iteration. Also consider adding the **ASYNCDELETE** flag if users frequently cancel jobs.

## Reducing Job Reservation Creation Time

Use the **RMCFG** on page 1035 **JOBRSVRECREATE** on page 598 attribute. By default, Moab destroys and re-creates job reservations each time a resource manager updates any aspect of a job. Historically, this stems from the fact that certain resource managers would inadvertently or intentionally migrate job tasks from originally requested nodes to other nodes. To maintain synchronization, Moab would re-create reservations each iteration thus incorporating these changes. On most modern resource managers, these changes never occur, but the effort required to handle this case grows with the size of the cluster and the size of the queue. Consequently, on very large systems with thousands of nodes and thousands of jobs, a noticeable delay is present. By setting **JOBRSVRECREATE** to **FALSE** on resource managers that do not exhibit this behavior, significant time savings per iteration can be obtained.

## Optimizing Backfill Time

Use the **OPTIMIZEDBACKFILL** flag. Speeds up backfill when a system reservation is in use.

## Constraining Moab Logging - LOGLEVEL

Use the **LOGLEVEL** on page 990 parameter. When running on large systems, setting **LOGLEVEL** to 0 or 1 is normal and recommended. Only increase **LOGLEVEL** above 0 or 1 if you have been instructed to do so by Moab support.

## Preemption

When preemption is enabled Moab can take considerably more time scheduling jobs for every scheduling iteration. Preemption increases the number of options available to Moab and therefore takes more time for Moab to optimally place jobs. If you are running a large cluster or have more than the usual amount

of jobs (>10000), consider disabling preemption. If disabling preemption is not possible, consider limiting its scope to only a small subset of jobs (as both preemptors and preemptees).

### Handling Transient Resource Manager Failures

Use the **RMCFG** [MAXITERATIONFAILURECOUNT](#) on page 600 attribute.

### Constrain the number of jobs preempted per iteration

Use the [JOBMAXPREEMPTPERITERATION](#) parameter.

**i** For very large job count systems, configuration options controlling the maximum supported limits may need to be adjusted including the maximum number of [reservations](#) and the maximum number of supported evaluation [ranges](#).

### Scheduler settings

If using Moab, there are a number of parameters which can be set on the scheduler which may improve TORQUE performance. In an environment containing a large number of short-running jobs, the **JOBAGGREGATIONTIME** parameter can be set to reduce the number of workload and resource queries performed by the scheduler when an event based interface is enabled. Setting **JOBAGGREGATIONTIME** instructs the scheduler to ignore events coming from the resource manager and to scheduling at regular intervals, rather than around resource manager events. If the `pbs_server` daemon is heavily loaded and PBS API timeout errors (i.e. "Premature end of message") are reported within the scheduler, the **TIMEOUT** attribute of the **RMCFG** parameter may be set with a value of between 30 and 90 seconds.

## 1.3 Handling Large Numbers of Nodes

For very large clusters (>= 10,000 processors) default scheduling behavior may not scale as desired. To address this, the following parameters should be considered:

Parameter	Recommended Settings
<a href="#">RMPOLLINTERVAL</a>	In large node environments with large and long jobs, scheduling overhead can be minimized by increasing <b>RMPOLLINTERVAL</b> above its default setting. If an event-driven resource management interface is available, values of two minutes or higher may be used. Scheduling overhead can be determined by looking at the scheduling load reported by <a href="#">mdiag -S</a> .
<a href="#">LIMITEDNODECP</a>	Startup/shutdown time can be minimized by disabling full node state checkpointing that includes some statistics covering node availability.
<b>SCHEDCFG</b> <b>FLAGS="</b> <a href="#">FASTRSVSTARTUP</a> <b>on page 1391</b>	When you have reservations on a large number of nodes, it can take Moab a long time to recreate them on startup. Setting the <b>FASTRSVSTARTUP</b> scheduler flag greatly reduces startup time.

\* For clusters where the number of nodes or processors exceeds 50,000, the maximum stack size for the shell in which Moab is started may need to be increased (as Moab may crash if the stack size is too small). On most Unix/Linux based systems, the command `ulimit -s unlimited` may be used to increase the stack size limit before starting Moab. This may be placed in your Moab startup script.

 See [Appendix D](#) for further information on default and supported object limits.

Avoid adding large numbers of [NODECFG](#) lines in the `moab.cfg` or `moab.d/*.cfg` files to keep the Moab boot time low.

For example, adding a configuration line to define features for each node in a large cluster (such as `NODECFG[x] Features+=green,purple`) can greatly increase the Moab boot time. If Moab processes 15 node configuration lines per second for a 50,000-node system, it could add approximately 55 minutes of node configuration processing to the Moab boot time.

In this case, it is better to define the node features in the resource manager configuration.

## 1.4 Handling Large Jobs

For large jobs, additional parameters beyond those specified for [large node](#) systems may be required. These include settings for the maximum number of [tasks per job](#), and the maximum number of [nodes per job](#).

## 1.5 Handling Large SMP Systems

For large-way SMP systems (> 512 processors/node) Moab defaults may need adjustment.

Parameter	Recommended Settings
<a href="#">MAXRSVPERNODE</a>	By default, Moab does not expect more than 48 jobs per node to be running or have future reservations. Increasing this parameter to a value larger than the expected maximum number of jobs per node is advised.

## 1.6 Server Sizing

See Hardware and Software Requirements for recommendations.

## Appendix J: Configuring Moab as a Service

Scripts that follow can be used to start up Moab services automatically upon a reboot. To enable a service script, copy the script to `/etc/rc.d/init.d/S97moab`, edit the file to make needed localization changes (adjust binary paths, execution user, etc), and add links to the `rc3.d` and `rc5.d` directories as in the example that follows:

```

> cp mwm.service /etc/rc.d/init.d/S97moab
> vi /etc/rc.d/init.d/S97moab
   (make needed localizations)
> ln -s /etc/rc.d/init.d/S97moab /etc/rc.d/rc3.d
> ln -s /etc/rc.d/init.d/S97moab /etc/rc.d/rc5.d

```

# Appendix K: Migrating from 3.2

## Overview

This guide is intended to help facilitate migrating from Maui to Moab. If you do not have Moab yet, you can download a [free evaluation version](#). At a high level, migrating from Maui 3.2 to Moab involves minimal effort. In fact, Moab fully supports all Maui parameters and commands. Migration can consist of nothing more than renaming `maui.cfg` to `moab.cfg` and launching Moab using the `moab` command. With this migration, the biggest single issue is becoming aware of all the new facilities and capabilities available within Moab. Beyond this, migration consists of a few minor issues that may require attention such as some [statistics and priorities](#).

Another approach of migrating from Maui to Moab is to configure Moab in Monitor mode and run it beside Maui. Maui will continue to perform the scheduling and control workload. Moab will simply monitor the cluster environment using the policies configured in `moab.cfg`. Moab will not have the ability to affect workload, providing a safe and risk-free environment to evaluate Moab without affecting your production environment. You can also have Moab capture resource and workload trace files and allow Moab to simulate what it would have done if it controlled workload. When you feel comfortable with and want to run Moab live on your cluster, all you need to do is change the mode to NORMAL, stop Maui, and restart Moab. Current jobs will remain running and Moab will take over control of scheduling.

As with any migration, we suggest that you back up important files such as the following: `maui.cfg`, `maui.log` and `maui.ck`.

[View the Flash demo of migrating from Maui to Moab.](#)

## Migrating from Maui to Moab

1. Install Moab Workload Manager. (Installation Instructions)
2. Copy your `maui.cfg` file to the `MOABHOMEDIR/etc (/opt/moab/etc)` and rename it `moab.cfg`.
3. Stop Maui.
4. Start Moab.

5. If Applicable: Re-apply those configurations found in the [Statistics and Checkpointing](#) section that need adjustment after migration as well as any parameters in `moab.cfg` that point to a Maui file like `maui.log`.

## Running Maui and Moab Side-By-Side

1. Install Moab Workload Manager on your cluster. (Installation steps will differ slightly from a typical installation.)
  - a. Run `./configure`.
  - b. Run `make`.
  - c. You will need to set your `MOABHOMEDIR` environment variable to the location where you built Moab by typing `export MOABHOMEDIR=[make directory]`.
2. To have Moab use all the same policies as Maui, copy `maui.cfg` to the `MOABHOMEDIR/etc` and rename it `moab.cfg`.
  - You can also start your `moab.cfg` file from scratch. Just use the `moab.cfg` already in the `MOABHOMEDIR/etc`.
3. Make sure that the port in `moab.cfg` is different than the port used in `maui.cfg`.
4. In the `moab.cfg` file, add the parameter, `SERVERMODE=MONITOR`.
  - If you used the `moab.cfg` from scratch, on the **SCHEDCFG** line add `MODE=MONITOR`.
5. You will need to either put the Moab commands in your environment path (located in `MOABHOMEDIR/bin`) or run the commands from their location if you still want to use the Maui commands in your environment path.
6. Run Moab Workload Manager using the `moab` command located in `MOABHOMEDIR/bin`.

## Other Notes

The following are minor differences between Maui and Moab and changes you may need to make:

## File Naming

Moab uses slightly different naming than Maui. The following table displays these changes:

File	Maui	Moab
<b>executable</b>	<code>maui</code>	<code>moab</code>
<b>logs</b>	<code>maui.log</code>	<code>moab.log</code>
<b>configuration file</b>	<code>maui.cfg</code>	<code>moab.cfg</code>

## Statistics and Checkpointing

Moab supports Maui version 3.2 or higher workload traces (statistics) allowing it to process historical statistics based on these traces as well as generate simulations based on them. No changes are required to use these statistics. See the Simulation Configuration documentation for more information on trace files. You can also view a [flash demonstration](#) of the simulation mode.

Moab does not support the Maui 3.2 checkpointing format. Because of this, state information checkpointed under Maui will not be available at the time of the migration. The loss of this information will have the following impact:

- Admin reservations, if any, will need to be re-created.
- Processed credential and scheduler statistics (displayed by `showstats`) will be lost.
- Admin job system priority configured by the `setspri` command and QoS assignments configured by the `setqos` command, if any, will be lost.

## Verify Configuration File Compatibility

The command `mdiag -C` will perform diagnostics on your new configuration file and may prove helpful in identifying any issues.

## Environment Variables

Scheduler environment variables are supported under Moab with obvious naming changes. Sample environment variables follow:

Maui	Moab
<code>MAUIHOMEDIR</code>	<code>MOABHOMEDIR</code>
<code>MAUIDEBUG</code>	<code>MOABDEBUG</code>
<code>MAUICRASHVARIBALE</code>	<code>MOABCRASHVARIABLE</code>
<code>MAUIENABLELOGBUFFERING</code>	<code>MOABENABLELOGBUFFERING</code>
<code>MAUIRECOVERYACTION</code>	<code>MOABRECOVERYACTION</code>
<code>MAUI-COMMANDS-PATH</code>	<code>MOAB-COMMANDS-PATH</code>
<code>MAUIENABLELOGBUFFERING</code>	<code>MOABENABLELOGBUFFERING</code>

## Appendix R: Node Allocation Plug-in Developer Kit

- [R.1 Overview](#)
  - [R.1.1 Writing the plugin](#)
    - [R.1.1.1 API & Data Structures](#)
  - [R.1.2 Moab configuration](#)
    - [R.1.2.1 Moab.cfg](#)
    - [R.1.2.2 Syntax rules](#)
    - [R.1.2.3 Troubleshooting](#)

### R.1 Overview

Each time Moab schedules a job, it must choose the nodes on which the job will run. Moab uses the Node Allocation policy to select the available nodes to be used. Because there are so many different systems and cluster topologies, you now have the ability to create and use a node allocation plugin for allocating nodes based on your cluster's interconnect topology.

The plugin policy allows you to write your own algorithm to choose which nodes will be used. This algorithm is contained in a shared library that Moab loads at run time.

To obtain the Plug-in Developer Kit (PDK) with the header file and example code, contact your sales representative.

#### R.1.1 Writing the plugin

A plugin is a shared library that has specific functions and variables that will be called directly from Moab. The plugin conforms to a C language API. The API is specified through an include file: `moab-plugin.h`. This file must be included in the plugin code. The include file provides function definitions, structures and variables that will be used when communicating with Moab.

When you write the plugin, you need to ensure that the plugin code is robust. If the plugin crashes, Moab will crash. You will need to handle your own memory appropriately. If the plugin has memory leaks, Moab will have similar issues. If you want to maintain logs, the plugin will need to be responsible for its own logging.

##### *R.1.1.1 API and Data Structures*

The Application Programmer Interface (API) for the Moab Node Allocation Plugin consists of three data items and three entry points that must be supplied to Moab by the plugin.

Plugin Supplied Data	Description
<b>const char *PLUGIN_NAME = "Node Allocation plugin 1.1";</b>	This character pointer is used by Moab when logging information regarding the operation of the plugin.
<b>const char *PLUGIN_TYPE = PLUGIN_TYPE_NAME_NODEALLOCATION;</b>	This character pointer is used by Moab to verify the type of plugin. The value of this data is supplied by the <code>moab-plugin.h</code> source file. The plugin must set this as shown so that Moab does not attempt to use a plugin incorrectly. Moab uses this to determine whether the plugin API type is correct and to allow Moab to correctly communicate with the plugin.
<b>const char *PLUGIN_VERSION = PLUGIN_API_VERSION;</b>	This character pointer is used by Moab to verify the API version number. The value of this data is supplied by the <code>moab-plugin.h</code> source file. The plugin must set this as shown so that the correct version of the <code>moab-plugin.h</code> is supplied to Moab. Moab uses this to determine whether the API version is correct and to allow Moab to correctly communicate with the plugin.

Load Time API	Description
<b>initialize()</b>	<pre>int initialize(const char *name, void **data_handle)</pre> <p>The plugin must supply an <code>initialize()</code> entry point. This entry point is called for each use instance of the plugin. For example, if the plugin is used on two different partitions, the <code>initialize()</code> entry point will be called once for each partition.</p> <ul style="list-style-type: none"> <li>• Name — The name is the unique identifier which is used to distinguish multiple instances of the plugin and for logging. When configured globally, the name "ALL" will be given.</li> <li>• Data handle — The <code>data_handle</code> points to a location where the plugin should store a pointer to any internal data needed by the plugin between calls to the API. The actual format and structure of the data is up to the plugin. Moab will supply this pointer back to the plugin each time a plugin entry point is called. This data can provide context for the plugin usage instance.</li> </ul>
<b>Return codes</b>	<p>The <code>initialize()</code> entry point should return one of two return statuses as defined in <code>moab-plugin.h</code>:</p> <pre>#define PLUGIN_RC_SUCCESS 0 #define PLUGIN_RC_FAILURE 1</pre>

Load Time API	Description
<b>Gathering node info</b>	The initialize() entry point must gather any information about system nodes, their topology, interconnection, and configuration that it needs to make correct node allocations. Since Moab does not know what information the plugin may need, the plugin must gather this information itself.
<b>Memory considerations</b>	The plugin may allocate memory for temporary or persistent data as needed, but <i>must</i> de-allocate or return the memory when finished. Not returning memory can result in memory leaks and unstable operation on the part of Moab.
<b>Multiple access</b>	A given loaded plugin can be used by more than one partition. This means that the plugin must maintain its internal data in such a way that calls to the plugin for the separate partitions do not conflict. It is recommended that internal data be allocated and a pointer to the data be kept in the data_handle described above as opposed to using global or static variables. Any global or static data will be shared between possible multiple instances of the plugin.

Runtime API	Description
<b>node_allocate</b>	<pre>int node_allocate (     void          *data_handle,     const char    *job_name,     int           container_count,     nalloc_container_t container[])</pre> <p>The plugin must provide a node_allocate() entry point. This entry point is called each time Moab needs to determine where (on what nodes) a job will eventually run. Note that this entry point can be called many times before the job is actually scheduled to run.</p> <ul style="list-style-type: none"> <li>• Data structures — Moab uses C data structures to pass information and lists of nodes to the plugin and receive them back from the plugin. See moab-plugin.h for the definitions of these structures and for information on how they relate to one another.</li> </ul>

Runtime API	Description																	
<b>Operations</b>	A node allocation request consists of one or more requirements. Each of these requirements is provided within a “container” structure. The container has information regarding the requirement to be met, the count and list of all nodes that are available to meet the requirement and a place to return the list of nodes that the plugin has chosen to use for the job.																	
	<table border="1"> <thead> <tr> <th data-bbox="380 531 558 793">Command</th> <th data-bbox="558 531 656 793">Moab Job Task Count</th> <th data-bbox="656 531 753 793">Job Node Count</th> <th data-bbox="753 531 850 793">Job Tasks Per Node</th> <th data-bbox="850 531 948 793">Node CFG Procs</th> <th data-bbox="948 531 1045 793">Node AV-L Procs</th> <th data-bbox="1045 531 1143 793">Plugin Node Mapped TC</th> <th data-bbox="1143 531 1321 793">requirement -&gt;taskcount</th> <th data-bbox="1321 531 1430 793">return_node_count</th> </tr> </thead> </table>									Command	Moab Job Task Count	Job Node Count	Job Tasks Per Node	Node CFG Procs	Node AV-L Procs	Plugin Node Mapped TC	requirement ->taskcount	return_node_count
	Command	Moab Job Task Count	Job Node Count	Job Tasks Per Node	Node CFG Procs	Node AV-L Procs	Plugin Node Mapped TC	requirement ->taskcount	return_node_count									
	<b>Non-ExactNode</b>																	
	-l nodes=12	12	0	0	8	8	8	12	2									
	-l nodes=12:ppn=2	24	0	2	8	8	8	24	3									
	<b>ExactNode</b>																	
	-l nodes=4	4	4	0	8	8	1	4	4									
	-l nodes=4:ppn=2	8	4	2	8	8	2	8	4									
	-l nodes=12	12	0	0	8	6	6	12	2									
The duty of the plugin is to use the information that it has previously gathered (during the initialization) to select from the available nodes those that will best fulfill the requirements.																		
The basic algorithm is to consume all the taskcount and memory on each node until the consumed task count is greater than or equal to the container's task_count and memory requirements.																		
A job's taskcount is calculated differently based on the JOBNODEMATCHPOLICY parameter. By default, it isn't defined and <code>-l nodes=#</code> actually requests the number of tasks without respect to the number of nodes. In this case, the plugin should consume all the tasks of each chosen node until the taskcount is greater and/or equal to the container's taskcount requirement. The plugin is for node allocation and not task placement.																		

Runtime API	Description
	<p>When the JOBNODEMATCHPOLICY EXACTNODE is configured, then <code>-l nodes=#</code> means the job wants # of nodes with 1 task per node. In this case, the nodes passed to the plugin will have a taskcount that is mapped down to what the job can only use on that node. Each node's taskcount should be consumed on each node until the summed amount is equal to the container's requirement taskcount requirement.</p> <p>The following table shows how commands are interpreted by Moab and translated to the plugin and what is expected of the plugin.</p>
<b>Errors and return codes</b>	<p>The plugin may internally log any errors encountered and must return a success or error status as defined in <code>moab-plugin.h</code>:</p> <pre>#define PLUGIN_RC_SUCCESS 0 #define PLUGIN_RC_FAILURE 1</pre>
<b>Multiple access safe</b>	<p>The <code>node_allocate()</code> entry point must support multiple access as described above.</p>

Unload Time API	Description
<b>finish()</b>	<p><code>void finish(void *data_handle)</code>                      The plugin must supply a <code>finish()</code> entry point. This entry point is called when Moab is preparing to disable and/or unload an instance of the plugin.</p>
<b>Memory/resource cleanup</b>	<p>The plugin must de-allocate and free up any resources acquired either during the <code>initialize()</code> entry point or during any calls to the <code>node_allocate()</code> entry point. When the last entry point returns, there should be no allocated memory or other resources still in use by the plugin instance.</p>
<b>Multiple access safe</b>	<p>The <code>finish()</code> entry point must support multiple access as described above.</p>

### R.1.2 Moab configuration

The actual loading of a plugin is accomplished by specifying the plugin in the Moab configuration file, `moab.cfg`.

### R.1.2.1 Moab.cfg

We recommend that you store all Moab plugins in the `$MOABHOMEDIR/lib` directory (e.g., `/opt/moab/lib`) as shared libraries (`*.so`). The name of the actual plugin shared library file is up to the plugin developer, which means you must give the correct name in the `moab.cfg` file to form the absolute plugin filename.

If a plug-in's specified shared library filename starts with a forward slash (`/`), it is an absolute file path name and Moab simply uses it without alteration. For example, if a plugin's specified shared library filename is `/opt/moab/plugins/plugin.so`, Moab will use it as the absolute plugin file path name.

If a plugin's specified shared library filename does not start with a forward slash (`/`), it is a plugin name and Moab forms the plugin's absolute path name by concatenating the Moab home directory, `"/lib/lib"`, the specified plugin name, and `".so"` to obtain the absolute path name. For example, if the `$MOABHOMEDIR` environment variable contains `/opt/moab` and the plugin name is `plugin`, Moab will create `/opt/moab/lib/libplugin.so` and use it as the absolute plugin file path name.

### R.1.2.2 Syntax rules

In order for Moab to use a plugin for the Node Allocation policy, instead of a built-in Moab policy, you must configure the policy in the `moab.cfg` file with the value "PLUGIN:" followed by the plugin's shared library file name. The examples below assume the environment variable `$MOABHOMEDIR` has a value of `/opt/moab`. Note the use of relative and absolute plugin shared library file path names in the parameter value and how they affect Moab's construction of the full path name.

Partition	Plug-in Name	moab.cfg Parameter	Moab-derived Full Path Name
global	plugin.so	<b>NODEALLOCATIONPOLICY</b> <i>PLUGIN:plugin.so</i>	/opt/moab/lib/libplugin.so
global	/usr/local/plugins/plugin.so	<b>NODEALLOCATIONPOLICY</b> <i>PLUGIN:/usr/local/plugins/plugin.so</i>	/usr/local/plugins/plugin.so
abc	plugin.so	<b>PARCFG[abc]</b> <b>NODEALLOCATIONPOLICY</b> <i>=PLUGIN:plugin.so</i>	/opt/moab/lib/libplugin.so
xyz	/usr/local/plugins/plugin.so	<b>PARCFG[xyz]</b> <b>NODEALLOCATIONPOLICY=</b> <i>PLUGIN:/usr/local/plugins/plugin.so</i>	/usr/local/plugins/plugin.so

### R.1.2.3 Troubleshooting

There are several commands that can be used to confirm that the Plugin Node Allocation Policy was loaded properly.

**mschedctl -l**

`mschedctl -l` is used to print out Moab's in memory configurations. If the plugin policy, with its full path, doesn't show for the configured partition then Moab failed to load the partition. Note that when the **NODEALLOCATIONPOLICY** is configured globally, it is configured on the "ALL" partition.

```
$ mschedctl -l -v|grep ^NODEALLOCATIONPOLICY
NODEALLOCATIONPOLICY[ALL] PLUGIN:/opt/moab/lib/libfirstavailable.so
NODEALLOCATIONPOLICY[a]  PLUGIN:/opt/moab/lib/liblastavailable.so
NODEALLOCATIONPOLICY[b]  CONTIGUOUS
NODEALLOCATIONPOLICY[c]  PLUGIN:/opt/moab/lib/libfirstavailable.so
NODEALLOCATIONPOLICY[d]  [NONE]
```

### mdiag -C

`mdiag -C` is used to validate the `moab.cfg` configuration. With a plugin node allocation policy, Moab will validate that it can successfully load the plugin and that all of the required symbols are present.

```
$ mdiag -C
...
INFO: line #35 is valid: 'NODEALLOCATIONPOLICY PLUGIN:firstavailable'
INFO: line #36 is valid: 'PARCFG[a]NODEALLOCATIONPOLICY=PLUGIN:lastavailable'
INFO: line #37 is valid: 'PARCFG[b]NODEALLOCATIONPOLICY=CONTIGUOUS'
INFO: line #38 is valid: 'PARCFG[d]NODEALLOCATIONPOLICY=PLUGIN:firstavailable'
```

### Scalable Systems Software Job Object Specification

SSS Job Object Specification  
Draft Release Version 3.1.0  
26 April 2011

Scott Jackson, PNNLStringDavid Jackson, Ames Lab  
Brett Bode, Ames Lab

### Status of This Memo

This document describes the job object to be used by Scalable Systems Software compliant components. It is envisioned for this specification to be used in conjunction with the SSSRMAP protocol with the job object passed in the Data field of Requests and Responses. Queries can be issued to a job-cognizant component in the form of modified XPATH expressions to the Get field to extract specific information from the job object as described in the SSSRMAP protocol.

## Abstract

This document describes the syntax and structure of the SSS job object. A job model is described that is flexible enough to support the specification of very simple jobs as well as jobs with elaborate and complex specification requirements in a way that avoids complex structures and syntax when it is not needed. The basic assumption is that a solitary job specification should be usable for all phases of the job lifecycle and can be used at submission, queuing, staging, reservations, quotations, execution, charging, accounting, etc. This job specification provides support for multi-step jobs, as well as jobs with disparate task descriptions. It accounts for operational requirements in a grid or meta-scheduled environment where the job is executed by multiple hosts in different administrative domains that support different resource management systems.

## 1.0 Introduction

This specification proposes a standard XML representation for a job object for use by the various components in the SSS Resource Management System. This object will be used in multiple contexts and by multiple components. It is anticipated that this object will be passed via the Data Element of SSSRMAP Requests and Responses.

### 1.1 Goals

There are several goals motivating the design of this representation.

The representation needs to be inherently flexible. We recognize we will not be able to exhaustively include the ever-changing job properties and capabilities that constantly arise.

The representation should use the same job object at all stages of that job's lifecycle. This object will be used at job submission, queuing, scheduling, charging and accounting, hence it may need to distinguish between requested and delivered properties.

The design must account for the properties and structure required to function in a meta or grid environment. It needs to include the capability to support local mapping of properties, global namespaces, etc.

The equivalent of multi-step jobs must be supported. Each step (job) can have multiple logical task descriptions.

Many potential users of the specification will not be prepared to implement the complex portions or fine-granularity that others need. There needs to be a way to allow the more complicated structure to be added as needed while leaving more straightforward cases simple.

There needs to be guidance for how to understand a given job object when higher order features are not supported by an implementation, and which parts are required, recommended and optional for implementers to implement.

It needs to support composite resources.

It should include the ability to specify preferences or fuzzy requirements.

### 1.2 Non-Goals

Namespace considerations and naming conventions for most property values are outside of the scope of this document.

### 1.3 Examples

#### *Example 3-181: Very Simple Example*

This example shows a simple job object that captures the requirements of a simple job.

```

<Job>
  <Id>PBS.1234.0</Id>
  <State>Idle</State>
  <User>scottmo</User>
  <Executable>/bin/hostname</Executable>
  <Processors>16</Processors>
  <Duration>3600</Duration>
</Job>

```

### Example 3-182: Moderate Example

This example shows a moderately complex job object that uses features such as required versus delivered properties.

```

<Job>
  <Id>PBS.1234.0</Id>
  <Name>Heavy Water</Name>
  <Project>nwchemdev</Project>
  <User>peterk</User>
  <Application>NWChem</Application>
  <Executable>/usr/local/nwchem/bin/nwchem</Executable>
  <Arguments>-input basis.in</Arguments>
  <InitialWorkingDirectory>/home/peterk</InitialWorkingDirectory>
  <Machine>Colony</Machine>
  <QualityOfService>BottomFeeder</QualityOfService>
  <Queue>batch_normal</Queue>
  <State>Completed</State>
  <StartTime>1051557713</StartTime>
  <EndTime>1051558868</EndTime>
  <Charge>25410</Charge>
  <Requested>
    <Processors op="GE">12</Processors>
    <Memory op="GE" units="GB">2</Memory>
    <Duration>3600</Duration>
  </Requested>
  <Delivered>
    <Processors>16</Processors>
    <Memory metric="Average" units="GB">1.89</Memory>
    <Duration>1155</Duration>
  </Delivered>
  <Environment>
    <Variable name="PATH">/usr/bin:/home/peterk</Variable>
  </Environment>
</Job>

```

### Example 3-183: Elaborate Example

This example uses a job group to encapsulate a multi-step job. It shows this protocol's ability to characterize complex job processing capabilities. A component that processes this message is free to retain only that part of the information that it requires. Superfluous information can be ignored by the component or filtered out (by XSLT for example).

```

<JobGroup>
  <Id>workflow1</Id>
  <State>Active</State>
  <Name>ShuttleTakeoff</Name>
  <JobDefaults>
    <StagedTime>1051557859</StagedTime>
    <SubmitHost>asteroid.lbl.gov</SubmitHost>
    <SubmitTime>1051556734</SubmitTime>
    <Project>GrandChallenge18</Project>
    <GlobalUser>C=US,O=LBNL,CN=Keith Jackson</GlobalUser>
    <User>keith</User>
    <Environment>
      <Variable name="LD_LIBRARY_PATH"/>usr/lib</Variable>
      <Variable name="PATH"/>usr/bin:~/bin:</Variable>
    </Environment>
  </JobDefaults>
  <Job>
    <Id>fr15n05.1234.0</Id>
    <Name>Launch Vector Initialization</Name>
    <Executable>usr/local/gridphys/bin/lvcalc</Executable>
    <Queue>batch</Queue>
    <State>Completed</State>
    <Machine>SMP2.emsl.pnl.gov</Machine>
    <StartTime>1051557713</StartTime>
    <EndTime>1051558868</EndTime>
    <Quote>http://www.pnl.gov/SMP2#654321</Quote>
    <Charge units="USD">12.75</Charge>
    <Requested>
      <Duration>3600</Duration>
      <Processors>2</Processors>
      <Memory>1024</Memory>
    </Requested>
    <Delivered>
      <Duration>1155</Duration>
      <Processors consumptionRate="0.78">2</Processors>
      <Memory metric="Max">975</Memory>
    </Delivered>
    <TaskGroup>
      <TaskCount>2</TaskCount>
      <TaskDistribution type="TasksPerNode">1</TaskDistribution>
      <Task>
        <Node>node1</Node>
        <Process>99353</Process>
      </Task>
      <Task>
        <Node>node12</Node>
        <Process>80209</Process>
      </Task>
    </TaskGroup>
  </Job>
  <Job>
    <Id>fr15n05.1234.1</Id>
    <Name>3-Phase Ascension</Name>
    <Queue>batch_normal</Queue>
    <State>Idle</State>
    <Machine>Colony.emsl.pnl.gov</Machine>
    <Priority>1032847</Priority>
    <Hold>System</Hold>
    <StatusMessage>Insufficient funds to start job</StatusMessage>
    <Requested>

```

```

    <Duration>43200</Duration>
  </Requested>
</TaskGroup>
<TaskGroup>
  <TaskCount>1</TaskCount>
  <Name>Master</Name>
  <Executable>/usr/local/bin/stage-coordinator</Executable>
  <Memory>2048<Memory>
  <Resource name="License" type="ESSL2">1</Resource>
  <Feature>Jumbo-Frame</Feature>
</TaskGroup>
<TaskGroup>
  <Name>Slave</Name>
  <TaskDistribution type="Rule">RoundRobin</TaskDistribution>
  <Executable>/usr/local/bin/stage-slave</Executable>
  <NodeCount>4</NodeCount>
  <Requested>
    <Processors group="-1">12</Processors>
    <Processors conj="Or" group="1">16</Processors>
    <Memory>512</Memory>
    <Node aggregation="Pattern">fr15n.*</Node>
  </Requested>
</TaskGroup>
</Job>
</JobGroup>

```

## 2.0 Conventions Used in This Document

### 2.1 Keywords

The keywords MUST, MUST NOT, REQUIRED, SHALL, SHALL NOT, SHOULD, RECOMMENDED, MAY, and OPTIONAL in this document are to be interpreted as described in [RFC2119](#).

### 2.2 Table Column Interpretations

The columns of the property tables in this document have the following meanings:

Element Name	Name of the XML element (xsd;element) see [DATATYPES]
<b>Type</b>	Data type defined by xsd (XML Schema Definition) as: <ul style="list-style-type: none"> <li>• String — xsd:string (a finite length sequence of printable characters)</li> <li>• Integer — xsd:integer (a signed finite length sequence of decimal digits)</li> <li>• Float — xsd:float (single-precision 32-bit floating point)</li> <li>• Boolean — xsd:boolean (consists of the literals “true” or “false”)</li> <li>• DateTime — xsd:int (a 32-bit unsigned long in GMT seconds since the EPOCH)</li> <li>• Duration — xsd:int (a 32-bit unsigned long measured in seconds)</li> </ul>
<b>Description</b>	Brief description of the meaning of the property

Element Name	Name of the XML element (xsd:element) see [DATATYPES]
<b>Appearance</b>	<p>An indication of whether the given property must appear in the parent element. It assumes the following meanings:</p> <ul style="list-style-type: none"> <li>• <b>MUST</b> — This property is <b>REQUIRED</b> when the parent is specified</li> <li>• <b>SHOULD</b> — This property is <b>RECOMMENDED</b> when the parent is specified.</li> <li>• <b>MAY</b> — This property is <b>OPTIONAL</b> when the parent is specified.</li> </ul>
<b>Compliance</b>	<p>An indication of the relative importance of supporting the given property.</p> <ul style="list-style-type: none"> <li>• <b>MUST</b> — A compliant implementation <b>MUST</b> support this property.</li> <li>• <b>SHOULD</b> — A compliant implementation <b>SHOULD</b> support this property.</li> <li>• <b>MAY</b> — A compliant implementation <b>MAY</b> support this property.</li> </ul>
<b>Categories</b>	<p>Some properties may be categorized into one of several categories. Letters in this column indicate that the given property can be classified in the following property categories.</p> <ul style="list-style-type: none"> <li>• <b>R</b> — This property can be encompassed in a Requested element.</li> <li>• <b>D</b> — This property can be encompassed in a Delivered element.</li> </ul>

### 2.3 Element Syntax Cardinality

Selected elements in the element syntax sections use regular expression wildcards with the following meanings:

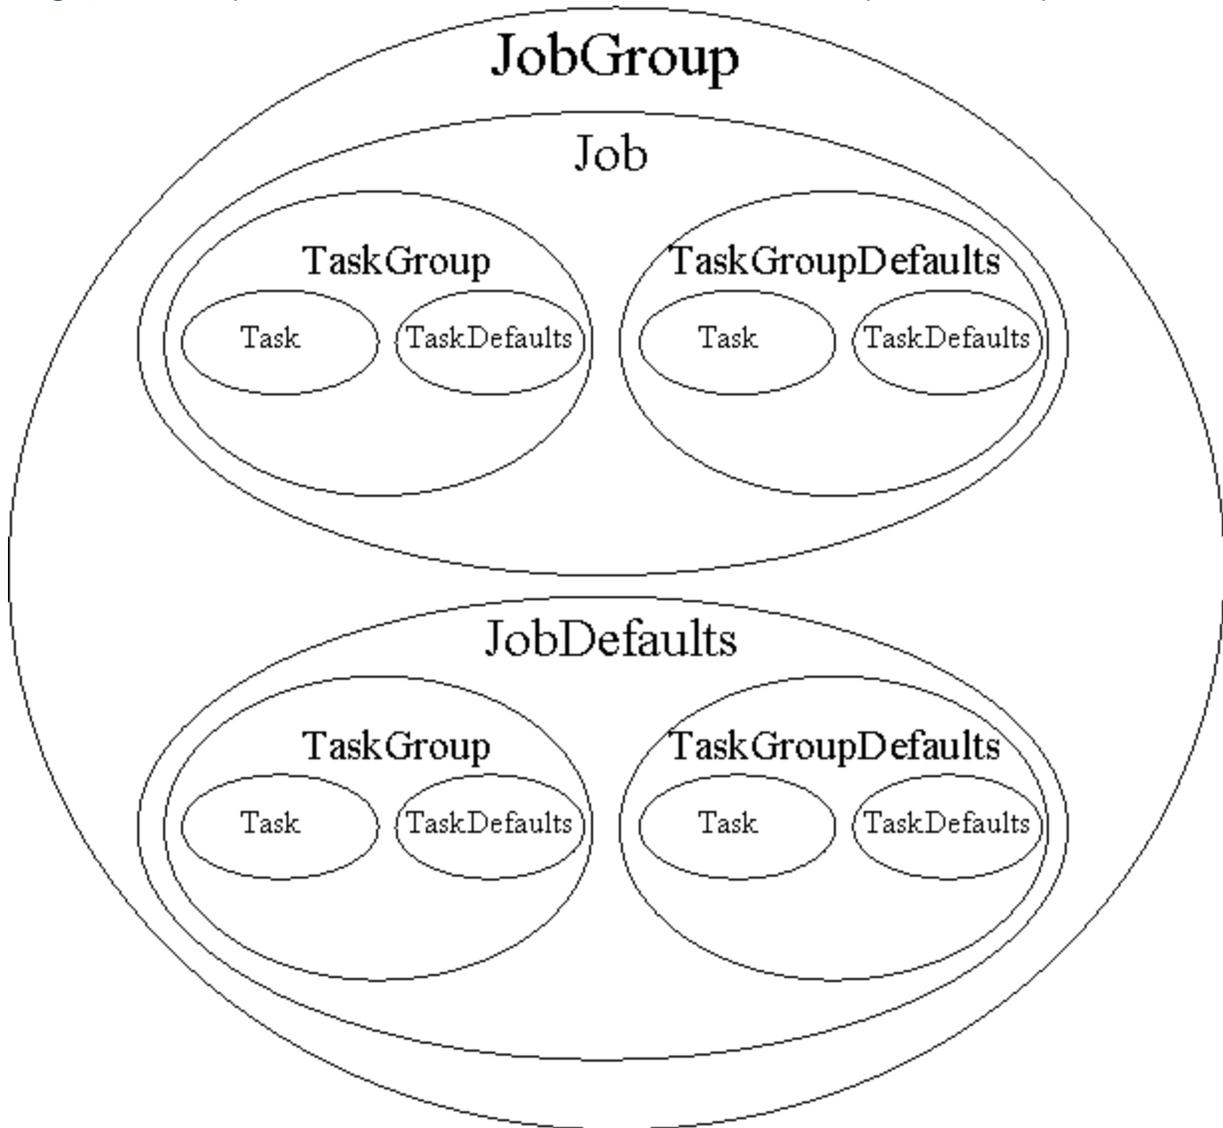

Wildcard	Description
*	Zero or more occurrences
+	One or more occurrences
?	Zero or one occurrences

The absence of one of these symbols implies exactly one occurrence.

## 3.0 The Job Model

The primary object within the job model is a job. A job can be thought of as a single schedulable entity and will be the object normally seen in job queues.

Image 3-16: JobGroup contains Job and JobDefaults, which contain TaskGroup and TaskGroupDefaults

Jobs with dependencies on other jobs may be submitted in a job group. Jobs within a job group form a DAG (directed acyclic graph) where the nodes are jobs and the edges represent dependencies on the status of previous jobs. A job group will consist of at least one job. A job group can optionally specify job defaults which are a set of job properties to be assumed by all jobs within the job group unless overridden within the job.

A job may consist of multiple tasks, which are the finest grained work unit and represent an endpoint for executing a given process instance. For example, a job that requests 3 nodes and 4 processors will have 4 tasks, two on one node and one on each of two nodes. Tasks may be grouped into task groups, which are logical aggregations of tasks and their common properties. Submit filters, prologs, epilogs, notification scripts, etc. run once only for each job. Whereas task groups function as logical descriptions of tasks and their properties, they also describe the number of such tasks and the nodes that they run on. As an example, a master task group (consisting of a single task) might ask for a node with a MATLAB license,

2GB of memory and an Internet connected network adapter while a slave task group (consisting of 12 tasks) could be targeted for nodes with more CPU bandwidth -- all within the same job and utilizing a common MPI ring. Tasks (and hence taskgroups) can have different executables or environments, specify different consumable resources or node properties. A job, therefore, may specify one or more task group. A job that does not specify an explicit task group is considered as having a single implicit task group. A job can optionally specify task group defaults which are a set of task group properties to be assumed by all task groups within the job unless overridden within a task group.

A task group may specify one or more tasks. A task group that does not specify an explicit task is considered as having a single implicit task. A task group can optionally specify task defaults which are a set of task properties to be assumed by all tasks within the task group unless overridden within a task.

## 4.0 JobGroup Element

A JobGroup is an optional element that aggregates one or more interdependent jobs. Some resource managers support the submission of job groups (multi-step jobs) and queries on the status of an entire job group.

- A compliant implementation MAY support this element.
- A JobGroup MUST specify one or more JobGroup Properties.
- A JobGroup MUST contain one or more Jobs.
- A JobGroup MAY contain zero or more JobsDefaults.

The following illustrates this element’s syntax:

```
C<JobGroup>
  <!-- JobGroup Properties -->+
  <Job/>+
  <JobDefaults/>?
</JobGroup>
```

### 4.1 JobGroup Properties

JobGroup Properties are properties that apply to the job group as a whole. These include the job group id, jobs and job defaults, and other simple optional job properties.

#### Simple JobGroup Properties

Simple (unstructured) job group properties are enumerated in the table below.

Table 3-7: Simple JobGroup Properties

Element Name	Type	Description	Appearance	Compliance
<b>CreationTime</b>	DateTime	Date and time that the job group was instantiated	MAY	MAY

Element Name	Type	Description	Appearance	Compliance
<b>Description</b>	String	Description of the job group	MAY	MAY
<b>Id</b>	String	Job group identifier	MUST	MUST
<b>Name</b>	String	Name of the job group	MAY	SHOULD
<b>State</b>	String	State of the job group as a whole. Valid states may include NotQueued, Unstarted, Active, and Completed.	MAY	SHOULD

*Job*

A job group **MUST** contain one or more jobs.

See the next section for element details.

*JobDefaults*

A job group **MAY** contain zero or one job defaults.

See the next section for element details.

**4.2 JobGroup Reference**

When a simple reference to a predefined job group is needed in an encapsulating element, a JobGroup element is used with the text content being the job group id:

```
<JobGroup> workflow1</JobGroup>
```

## 5.0 Job and JobDefaults Element

The Job and JobDefaults elements are of the same structure. A Job element encapsulates a job and may be expressed as a standalone object. A JobDefaults element may only appear within a JobGroup and represents the defaults to be taken by all jobs within the job group. Job properties in Job elements override any properties found in a sibling JobDefaults element.

- A compliant implementation **MUST** support the Job element.
- A compliant implementation **MAY** support the JobDefaults element only if it supports the JobGroup element.
- A job **MUST** specify one or more Job Properties.
- One or more TaskGroup elements **MAY** appear at this level.
- Zero or one TaskGroupDefaults elements **MAY** appear at this level.

The following illustrates this element’s syntax:

```
<Job>
  <!-- Job Properties -->+
  <TaskGroup/>*
  <TaskGroupDefaults/>?
</Job>
```

### 5.1 Job Properties

Job Properties apply to a particular job or as default properties to all jobs. They include the job id, job credentials, task groups, task group defaults, and other simple optional properties.

#### Simple Job Properties

Simple (unstructured) job properties are enumerated in the table below.

Table 3-8: Simple Job Properties

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Application</b>	String	Type of application such as Gaussian or Nwchem	MAY	MAY	

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Architecture</b>	String	Type architecture for the nodes on which this job must run	MAY	MAY	RD
<b>Arguments</b>	String	The arguments for the executable	MAY	SHOULD	
<b>Charge</b>	Float	The amount charged for the job	MAY	SHOULD	
<b>Checkpointable</b>	Boolean	Can this job be checkpointed?	MAY	MAY	
<b>CpuDuration</b>	Duration	Number of cpu seconds used by the job	MAY	SHOULD	
<b>DeadlineTime</b>	DateTime	Date and time that a job must end by	MAY	MAY	
<b>EligibleTime</b>	DateTime	Date and time that a job must start after	MAY	MAY	
<b>EndTime</b>	DateTime	Date and time that a job ended (independent of success or failure)	MAY	MUST	
<b>Executable</b>	String	Executable. This may be an absolute or relative path or a URI.*	MAY	MUST	

Element Name	Type	Description	Appearance	Compliance	Categories
<b>ExitCode</b>	Integer	Exit code for the job	MAY	SHOULD	
<b>GlobalJob</b>	String	Globally unique job identifier (possibly in the form of a URI)	MAY	SHOULD	
<b>Hold</b>	String	Hold(s) on the job. There may be multiple instances of this element if there is more than one ld on the job	MAY	SHOULD	
<b>InitialWorking-Directory</b>	String	Initial working directory	MAY	SHOULD	
<b>Interactive</b>	Boolean	Is this an interactive job?	MAY	SHOULD	
<b>Id</b>	String	A local job identifier assigned to the job by the local resource manager	MUST	MUST	
<b>Name</b>	String	Name of the job	MAY	SHOULD	
<b>State</b>	String	State of the job. Valid states may include Idle, Hold, Running, Suspended, or Completed	MAY	MUST	

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Type</b>	String	Type of job. Meaning of this extension property is context specific.	MAY	MAY	
<b>Machine</b>	String	Name of the system or cluster that runs the job	MAY	MUST	RD
<b>Network</b>	String	Type of network adapter required by the job	MAY	MAY	RD
<b>NodeCount</b>	Integer	Number of nodes used by the job	MAY	MUST	RD
<b>OperatingSystem</b>	String	Operating System required by the job	MAY	MAY	RD
<b>Partition</b>	String	Name of the partition in which the job should run	MAY	MAY	RD
<b>Priority</b>	Integer	Current queue priority (or rank)for the job	MAY	SHOULD	
<b>QualityOfService</b>	String	Name of the Quality of Service (QoS)	MAY	SHOULD	RD
<b>Queue</b>	String	Name of the Queue (or class) that the job runs in	MAY	SHOULD	RD

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Quote</b>	String	Identifier for a guaranteed charge rate quote obtained by the job	MAY	MAY	
<b>Reservation</b>	String	Identifier for a reservation used by the job	MAY	MAY	RD
<b>ReservationTime</b>	DateTime	Date and time that a reservation was placed for the job	MAY	MAY	
<b>ResourceManagerType</b>	String	Type of resource manager required to run this job	MAY	MAY	RD
<b>Restartable</b>	Boolean	Can this job be restarted?	MAY	MAY	
<b>Shell</b>	String	Specified the shell necessary to interpret the job script	MAY	MAY	
<b>StagedTime</b>	DateTime	Date and time that a job was staged to the local resource management system	MAY	MAY	
<b>StartCount</b>	Integer	Number of times the scheduler tried to start the job	MAY	MAY	

Element Name	Type	Description	Appearance	Compliance	Categories
<b>StartTime</b>	DateTime	Date and time that the job started	MAY	MUST	
<b>StatusMessage</b>	String	Natural language message that can be used to provide detail on why a job failed, isn't running, etc.	MAY	SHOULD	
<b>SubmitTime</b>	DateTime	Date and time that a job was submitted	MAY	SHOULD	
<b>SubmitHost</b>	String	FQDN of host where the job was submitted from	MAY	SHOULD	
<b>Suspendable</b>	Boolean	Can this job be suspended?	MAY	MAY	
<b>SuspendDuration</b>	Integer	Number of seconds the job was in the Suspended state	MAY	MAY	
<b>TimeCategory</b>	String	This allows the specification of shifts like PrimeTime for charging purposes	MAY	MAY	
<b>Duration</b>	Duration	Number of seconds in the Running state	SHOULD	MUST	RD

\* The Executable may be a script or a binary executable. If it is already on the target system it may be referenced by an absolute or relative pathname (relative to InitialWorkingDirectory). If it is passed with the job in a File object (see SSSRMAP), it can be referenced by an absolute or relative URI. An absolute

URI would specify a URL where the file can be downloaded (like with `wget`). A relative URI is specified by preceding an identifier by a pound sign, as in

```
<Executable>#Script</Executable>
```

It will be found in a `File` object included along with the `Job` object with the `Script` as an identifier, as in

```
<File id="Script">echo hello world</File>
```

### Feature Element

The `Feature` element connotes an arbitrary named feature of a node.

- A compliant implementation **SHOULD** support this element.
- This element **MAY** appear zero or one times within a given set of `Job Properties`.
- This element is of type `String`.
- This element **MAY** have an `aggregation` attribute of type `String` that provides a way to indicate multiple values with a single expression. A compliant implementation **MAY** support the `aggregation` attribute if the `Feature` element is supported. Possible values for this attribute include:
  - `List` — a comma-separated list of features
  - `Pattern` — a regular expression (perl5) matching desired features
- If an `aggregation` attribute is specified with the value of `List`, this element **MAY** also have a `delimiter` attribute of type `String` that indicates what delimiter is used to separate list elements. The default list delimiter is a comma.
- This element **MAY** be categorized as a requested or delivered property by being encompassed by the appropriate element.

The following is an example of a feature element:

```
<Feature aggregation="List">feature1,feature2</Feature>
```

### OutputFile Element

The `OutputFile` element specifies the name of the file to which the output stream (`stdout`) from the job will be written.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate output file is auto-determined by the queuing system.
- This element **MAY** have a `redirectList` attribute which is a comma-separated list of output redirection attributes of type `String`. A compliant implementation **SHOULD** support this attribute if `OutputFile` is supported. Possible values for this attribute include:
  - `Append` — opens the output file for append
  - `Close` — closes and discards the output stream
  - `Flush` — output is written to output file as it is generated

- Keep — leave the output file on the execution host
- Merge — merges the output stream into the error stream

Note that when using the `redirectList` attributes, the cumulative effect of the `ErrorFile` and `OutputFile` directives may be order dependent.

The following is an example of an `OutputFile` element:

```
<OutputFile redirectList="Append">~/myjob.out</OutputFile>
```

### *ErrorFile Element*

The `ErrorFile` element specifies the name of the file to which the error stream (`stderr`) from the job will be written.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate error file is auto-determined by the queuing system.
- This element MAY have a `redirectList` attribute which is a comma-separated list of error redirection attributes of type `String`. A compliant implementation SHOULD support this attribute if `ErrorFile` is supported. Possible values for this attribute include:
  - Close — closes and discards the error stream
  - Append — opens the error file for append
  - Flush — output is written to output file as it is generated
  - Keep — leave the output file on the execution host
  - Merge — merges the error stream into the output stream

Note that when using the `redirectList` attributes, the cumulative effect of the `ErrorFile` and `OutputFile` directives may be order dependent.

The following is an example of an `ErrorFile` element:

```
<ErrorFile redirectList="Merge"></ErrorFile>
```

### *InputFile Element*

The `InputFile` element specifies the name of the file from which the input stream (stdin) for the job will be read.

- This element's character content is the name of the file. If this element is omitted or it is empty, then an appropriate input file is auto-determined by the queuing system.
- This element MAY have a `redirectList` attribute which is a comma-separated list of input attributes of type String. A compliant implementation SHOULD support this attribute if `InputFile` is supported. Possible values for this attribute include:
  - `Close` — closes and discards the input stream

The following is an example of an `InputFile` element:

```
<InputFile redirectList="Close"></InputFile>
```

### *NotificationList Element*

The `NotificationList` element specifies the job-related events or conditions for which a notification will be sent.

- This element's character content is a comma-separated list of events or conditions for which a notification should be sent. Possible values for the elements of this list include:
  - `JobStart` — send a notification when the job starts
  - `JobEnd` — send a notification when the job ends
  - `All` — send notifications for all notifiable events
  - `None` — do not send notifications for any events
- This element MAY have a `uri` attribute of type String which indicates where the notification is to be sent. A compliant implementation MAY support this attribute if `NotificationList` is supported. The `uri` is in the format: `[scheme://]authority` with the scheme being `smtp` and the authority being an email address by default.

The following is an example of a `NotificationList` element:

```
<NotificationList uri="smith@business.com">JobStart,JobEnd</NotificationList>
```

### *ResourceLimitElement*

The `ResourceLimit` element represents a resource limit with its name and value.

- This element MUST have a `name` attribute of type String. A compliant implementation MUST support the `name` attribute if `ResourceLimit` is supported.
- This element MAY have a `type` attribute of type String that may have the values `Hard` or `Soft`. If the limit is enforced by the operating system, a hard limit is one that cannot be increased once

it is set while a soft limit may be increased up to the value of the hard limit. If the type attribute is omitted, both the soft and hard limits are set.

- This element's character content is the resource limit's value.

Some typical names include:

Name	Description
<b>CoreFileSize</b>	Maximum core file size
<b>CpuTime</b>	CPU time in seconds
<b>DataSegSize</b>	Maximum data size
<b>FileSize</b>	Maximum file size
<b>MaxMemorySize</b>	Maximum resident set size
<b>MaxProcesses</b>	Maximum number of processes
<b>MaxSwap</b>	Virtual memory limit
<b>MaxMemLock</b>	Maximum locked-in-memory address space
<b>MaxProcessors</b>	Maximum processors
<b>MaxMemory</b>	Maximum memory
<b>MaxDisk</b>	Maximum disk space
<b>MaxNetwork</b>	Maximum network bandwidth
<b>MaxFileIO</b>	Maximum file i/o
<b>OpenFiles</b>	Maximum number of open files
<b>Stacksize</b>	Maximum stack size

The following is an example of a ResourceLimit element:

```
<ResourceLimit name="CpuTime">1000000</ResourceLimit>
```

### Credentials

Credentials are a special group of job properties that characterize an authenticated token or id. They can be categorized in both requested and delivered forms.

Credential job properties are enumerated in the table below.

Table 3-9: Credential Job Properties

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Project</b>	String	Name of the Project or Charge Account	MAY	SHOULD	RD
<b>GlobalUser</b>	String	Globally unique user identifier. This may be an X.509 DN for example	MAY	SHOULD	RD
<b>Group</b>	String	Name of the local group id	MAY	MAY	RD
<b>User</b>	String	Name of the local user id for the job	MAY	MUST	RD

### Environment Element

The Environment element encapsulates environment variables.

- This element MAY have an export attribute of type Boolean that which if set to `True` indicates that all environment variables in the context of the job submission process should be exported in the job’s execution environment.
- A compliant implementation SHOULD support this element.
- An Environment element MAY appear zero or one times within a given set of Job (or TaskGroup) Properties.
- An Environment element MAY contain one or more Variable elements.

The following illustrates this element’s syntax:

```
<Environment>
  <Variable/>+
</Environment>
```

### Variable Element

The Variable element represents an environment variable with its name and value.

This element **MUST** have a `name` attribute of type `String`. A compliant implementation **MUST** support the `name` attribute if `Variable` is supported. This element's character content is the environment variable's value.

The following is an example of a `Variable` element:

```
<Variable name="PATH"/usr/bin:/home/sssdemo</Variable>
```

### Node Element

The `Node` element represents a node.

- A compliant implementation **SHOULD** support this element.
- This element **MAY** appear zero or one times within a given set of Job Properties.
- This element is of type `String`.
- This element **MAY** have an `aggregation` attribute of type `String` that provides a way to indicate multiple values with a single expression. A compliant implementation **MAY** support the `aggregation` attribute if the `Feature` element is supported. Possible values for this attribute include:
  - `List` - a comma-separated list of features
  - `Pattern` - a regular expression (perl5) matching desired features
  - `Range` - a range of nodes of the form: `<prefix>[5-23,77]`
- If an `aggregation` attribute is specified with the value of `List`, this element **MAY** also have a `delimiter` attribute of type `String` that indicates what delimiter is used to separate list elements. The default list delimiter is a comma.
- This element **MAY** have a `count` attribute of type `Integer` that indicates the instance count of the specified node(s).
- This element **MAY** be categorized as a requested or delivered property by being encompassed by the appropriate element.

The following is an example of a `Node` element:

```
<Node aggregation="Pattern">node[1-5]</Node>
```

### TaskDistribution Element

The `TaskDistribution` element describes how tasks are to be mapped to nodes. This mapping may be expressed as a rule name, a task per node ratio or an arbitrary geometry.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or one times in a given set of Job (or TaskGroup) Properties.
- This element is of type String.
- This element MAY have a `type` attribute of type String that provides a hint as to the type of mapping guidance provided. It may have values including `Rule`, `TasksPerNode`, `ProcessorsPerTask` or `Geometry`. A compliant implementation MAY support the `type` attribute if the `TaskDistribution` element is supported.
- It is possible to use `Processors`, `NodeCount` and `TaskCount` elements to specify a set of mutually contradictory task parameters. When this occurs, components are responsible for resolving conflicting requirements.

The following are three examples of a `TaskDistribution` element:

```
<TaskDistribution type="TasksPerNode">2</TaskDistribution>
<TaskDistribution type="Rule">RoundRobin</TaskDistribution>
<TaskDistribution type="Geometry">{1,4}{2}{3,5}</TaskDistribution>
```

### Dependency Element

The `Dependency` element allows a job's execution to depend on the status of other jobs. In a job group (multi-step job), some jobs may delay execution until the failure or success of other jobs creating in general a Directed Acyclic Graph relationship between the jobs. This element's content is of type String and represents the job that the current job is dependent upon. Since a job may have two or more dependencies, this element may appear more than once in a given job scope. A compliant implementation SHOULD support this element if job groups are supported.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times in a given set of Job (or TaskGroup) Properties.
- This element is of type String and contains the JobId that the current job is dependent upon.
- This element MAY have a `condition` attribute of type String that indicates the basis for determining when the current job executes in relation to the specified job. A compliant implementation MUST support this attribute if this element is supported. Possible values for this attribute include:
  - `OnSuccess` this job should run after the referenced job only if it completes successfully (this is the default if the `type` attribute is omitted)

- OnFailure this job should run after the referenced job only if it fails
- OnExit this job should run after the referenced job exits
- If the `condition` attribute is equal to OnExit, this element MAY have a `code` attribute of type Integer that indicates the exit code that will trigger this job to run. If the `code` attribute is omitted, then the current job should run after the referenced job for any exit status.
- This element MAY have a `designator` attribute of type String that indicates that indicates the property of the job that identifies it as the dependent job. A compliant implementation MAY support this attribute if this element is supported. Possible values for this attribute include:
  - JobId the job this job is dependent upon is specified by JobId (this is the default if the `designator` attribute is omitted)
  - JobName the job(s) this job is dependent upon are specified by JobName

The following is an example of a Dependency element:

```
<Dependency condition="OnSuccess" designator="JobId">PBS.1234.0</Dependency>
```

### Consumable Resources

Consumable Resources are a special group of properties that can have additional attributes and can be used in multiple contexts. In general a consumable resource is a resource that can be consumed in a measurable quantity.

- A consumable resource MAY have a `context` attribute of type String that indicates the sense in which the resource is used. A compliant implementation MAY support this attribute. Possible values for this attribute include:
  - Configured — run this task only on nodes having the specified configured resources
  - Available — run this task only on nodes having the specified available resources. (this is the default if the `context` attribute is omitted)
  - Used — the task used the indicated resources (this is analogous to being including in a Delivered block)
  - Dedicated — the indicated amount of the resource should be dedicated to the task
- A consumable resource MAY have a `units` attribute that is of type String that specifies the units by which it is being measured. If this attribute is omitted, a default unit is implied. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `metric` attribute that is of type String that specifies the type of measurement being described. For example, the measurement may be a Total, an Average, a Min or a Max. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `duration` attribute of type Duration that indicates the amount of time for which that resource was used. This need only be specified if the resource was

used for a different amount of time than the duration for the job. A compliant implementation MAY support this attribute if the element is supported.

- A consumable resource MAY have a `consumptionRate` attribute of type Float that indicates the average percentage that a resource was used over its duration. For example, an overbooked SMP running 100 jobs across 32 processors may wish to scale the usage and charge by the average fraction of processor usage actually delivered. A compliant implementation MAY support this attribute if the element is supported.
- A consumable resource MAY have a `dynamic` attribute of type Boolean that indicates whether the resource allocated for this job should be allowed to grow or shrink dynamically. For example, if processors is specified with `dynamic` equal to True, the job may be dynamically allocated more processors as they become available. The growth bounds can be indicated via the `op` attribute which is inherited when a consumable resource element is encapsulated within a *Requested* element. A compliant implementation MAY support this attribute if the element is supported.

A list of simple consumable resources is listed in the table below.

Table 3-10: Simple Consumable Resources

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Disk</b>	Float	Amount of disk	MAY	SHOULD	RD
<b>Memory</b>	Float	Amount of memory	MAY	SHOULD	RD
<b>Network</b>	Float	Amount of network	MAY	MAY	RD
<b>Processors</b>	Integer	Number of processors	MAY	MUST	RD
<b>Swap</b>	Float	Amount of virtual memory	MAY	MAY	RD

The following are two examples for specifying a consumable resource:

```
<Memory metric="Max" units="GB">483</Memory>
<Processors duration="1234" consumptionRate="0.63">4</Processors>
```

### Resource Element

In addition to the consumable resources enumerated in the above table, an extensible consumable resource is defined by the Resource element.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times within a given set of job (or task group) properties.
- Like the other consumable resources, this property MAY be categorized as a requested or delivered property by being encompassed in the appropriate element.
- This element is of type Float.
- This element shares the *same properties and attributes as the other consumable resources* but it requires an additional name (and optional type) attribute to describe it.
- It MUST have a name attribute of type String that indicates the type of consumable resource being measured. A compliant implementation MUST support this attribute if the element is supported.
- It MAY have a type attribute of type String that distinguishes it within a general resource class. A compliant implementation SHOULD support this attribute if the element is supported.

The following are two examples for specifying a Resource element:

```
<Resource name="License" type="MATLAB">1</Resource>
<Resource name="Telescope" type="Zoom2000" duration="750" metric="KX">10</Resource>
```

### Extension Element

The Extension element provides a means to pass extensible properties with the job object.

Some applications may find it easier to use a named extension property than discover and handle elements they do not understand or anticipate by name.

- A compliant implementation MAY support this element.
- This element MUST have a name attribute of type String that gives the extension property's name. A compliant implementation MUST support this attribute if this element is supported.
- This element MAY have a type attribute of type String that characterizes the context within which the property should be understood. A compliant implementation SHOULD support this attribute if this element is supported.
- This element's character content, which is of type String, is the extension property's value.

The following is an example of an Extension element:

```
<Extension type="Scheduler" name="Restartable">true</Extension>
```

### *TaskGroup*

A job MAY specify one or more task groups.

See the next section for element details.

### *TaskGroupDefaults*

A job MAY specify zero or more task group defaults.

See the next section for element details.

## 5.2 Job Reference

When a simple reference to a predefined job is needed in an encapsulating element, a Job element is used with the text content being the job id:

```
<Job> job123</Job>
```

## 6.0 TaskGroup and TaskGroupDefaults Element

The `TaskGroup` and `TaskGroupDefaults` elements have the same structure. A `TaskGroup` element aggregates tasks. A `TaskGroupDefaults` element may only appear within a Job (or JobDefaults) and represents the defaults to be taken by all task groups within the job. Task group properties in `TaskGroup` elements override any properties found in a sibling `TaskGroupDefaults` element.

- A compliant implementation MAY support the `TaskGroup` element.
- A compliant implementation MAY support the `TaskGroupDefaults` element.
- A task group MUST specify one or more `TaskGroup` Properties.
- One or more `Task` elements MAY appear at this level.
- Zero or one `TaskDefaults` elements MAY appear at this level.

The following illustrates this element's syntax:

```
<TaskGroup>
  <!-- TaskGroup Properties -->+
  <!-- Job Properties -->*
  <Task>+
  <TaskDefaults>?
</TaskGroup>
```

### 6.1 TaskGroup Properties

`TaskGroup` Properties apply to a particular task group or as default properties to encompassed task groups. These properties include the task group id, its tasks, task defaults, and other simple task group properties.

### Simple TaskGroup Properties

Simple (unstructured) task group properties are enumerated in Table 6.

Table 3-11: Simple TaskGroup Properties

Element Name	Type	Description	Appearance	Compliance	Categories
<b>TaskCount</b>	Integer	Number of tasks in this taskgroup	MAY	MUST	
<b>Id</b>	String	A task group identifier unique within the job	MAY	MAY	
<b>Name</b>	String	A task group name (such as Master)	MAY	SHOULD	

#### Task

A task group MAY specify zero or more tasks.

See the next section for element details.

#### TaskDefaults

A task group MAY specify zero or more task defaults.

See the next section for element details.

## 6.2 TaskGroup Reference

When a simple reference to a predefined task group is needed in an encapsulating element, a TaskGroup element is used with the text content being the task group id:

```
<TaskGroup> tgl</TaskGroup>
```

## 7.0 Task and TaskDefaults Element

The `Task` and `TaskDefaults` elements have the same structure. A `Task` element contains information specific to a task (like the process id or the host it ran on). A `TaskDefaults` element may only appear within a `TaskGroup` (or `TaskGroupDefaults`) element and represents the defaults for all tasks within the task group. Task properties in `Task` elements override any properties found in a sibling `TaskDefaults` element.

- A compliant implementation MAY support the `TaskGroup` element.
- A compliant implementation MAY support the `TaskGroupDefaults` element.
- A task group MUST specify one or more `TaskGroup` Properties.
- One or more `Task` elements MAY appear at this level.
- Zero or one `TaskDefaults` elements MAY appear at this level.

The following illustrates this element’s syntax:

```
<Task>
  <!-- Task Properties -->+
  <!-- Job Properties -->*
</Task>
```

### 7.1 Task Properties

Task Properties are properties that apply to a particular task or as default properties to encompassed tasks. These properties include the task id and other task properties.

#### Simple Task Properties

Simple (unstructured) task properties are enumerated in the table below.

Table 3-12: Simple Task Properties

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Node</b>	String	Name of the node this task ran on	MAY	MUST	
<b>Session</b>	Integer	Session id for the task group or job	MAY	MAY	

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Id</b>	String	A task identifier unique within the taskgroup	MAY	MAY	

## 7.2 Task Reference

When a simple reference to a predefined task is needed in an encapsulating element, a `Task` element is used with the text content being the task id:

```
<Task>1</Task>
```

## 8.0 Property Categories

Certain properties need to be classified as being in a particular category. This is done when it is necessary to distinguish between a property that is requested and a property that was delivered. When no such distinction is necessary, it is recommended that the property not be enveloped in one of these elements. In general, a property should be enveloped in a category element only if it is expected that the property will need to be attributed to more than one property category, or if it needs to make use of some of the special attributes inherited from the category.

### 8.1 Requested Element

A requested property reflects properties as they were requested. A disparity might occur between the requested value and the value delivered if a preference was expressed, if multiple options were specified, or if ranges or pattern matching was specified.

- A compliant implementation SHOULD support this element.

The following illustrates the syntax of this element:

```
<Requested>
  <!-- Requested Properties -->+
</Requested>
```

The following describes the attributes and elements for the example above:

```
/Requested
```

This element is used to encapsulate requested properties.

```
/Requested/<Requested Property>
```

Requested properties appear at this level.

Requested Properties inherit some additional attributes.

- A requested property MAY have an `op` attribute of type String that indicates a conditional operation on the value. A compliant implementation SHOULD support this attribute. Valid values for the `op` attribute include EQ meaning equals (which is the default), NE meaning not equal, LT meaning less than, GT meaning greater than, LE meaning less than or equal to, GE meaning greater than or equal to, Match which implies the value is a pattern to be matched.
- A requested property MAY have a `conj` attribute of type String that indicates a conjunctive relationship with the previous element. A compliant implementation MAY support this attribute. Valid values for the `conj` attribute include And (which is the default), Or, Nand meaning and not, and Nor meaning or not.
- A requested property MAY have a `group` attribute of type Integer that indicates expression grouping and operator precedence much like parenthetical groupings. A compliant implementation MAY support this attribute. A positive grouping indicates the number of nested expressions being opened with the property while a negative grouping indicates the number of nested expressions being closed with the property.
- A requested property MAY have a `preference` attribute of type Integer that indicates a preference for the property along with a weight (the weights are taken as a ratio to the sum of all weights in the same group). A compliant implementation MAY support this attribute. If a group of positive valued preference alternatives are specified, at least one of the preferences must be satisfied for the job to run. If a group of negative valued preferences are specified, the preferences will try to be met according to their weights but the job will still run even if it can't satisfy any of the preferred properties. (Weight ranking can be removed by making all weights the same value (1 or -1 for example).
- A requested property MAY have a `performanceFactor` attribute of type Float that provides a hint to the scheduler of what performance tradeoffs to make in terms of resources and start time. A compliant implementation MAY support this attribute.

The following are four examples of using Requested Properties:

```

<Requested>
  <Processors op="GE">8</Processors>
  <Processors op="LE">16</Processors>
  <Duration>3600</Duration>
</Requested>
<Requested>
  <NodeCount>1</NodeCount>
  <Node aggregation="Pattern">fr15.*</Node>
</Requested>
<Requested>
  <User group="1">scottmo</User>
  <Account group="-1">mscfops</Account>
  <User conj="Or" group="1">amy</User>
  <Account group="-1">chemistry</Account>
</Requested>
<Requested>
  <Memory preference="2">1024</Memory>
  <Memory preference="1">512</Memory>
</Requested>

```

## 8.2 Delivered Element

A delivered property reflects properties as they were actually utilized, realized or consumed. It reflects the actual amounts or values that are used, as opposed to a limit, choice or pattern as may be the case with a requested property.

- A compliant implementation SHOULD support this element.

The following illustrates the syntax of this element:

```
<Delivered>
  <!-- Delivered Properties -->+
</Delivered>
```

The following describes the attributes and elements for the example above:

```
/Delivered
```

This element is used to encapsulate delivered properties.

```
/Delivered/<Delivered Property>
```

Delivered properties appear at this level.

Delivered Properties inherit some additional attributes.

- A delivered property MAY have a `group` attribute of type Integer that indicates expression grouping and operator precedence much like parenthetical groupings. A compliant implementation MAY support this attribute. A positive grouping indicates the number of nested expressions being opened with the property while a negative grouping indicates the number of nested expressions being closed with the property. The purpose of this attribute would be to logically group delivered properties if they were used in certain aggregations (like a job that spanned machines).

The following are the same four examples distinguishing the delivered amounts and values:

```

<Delivered>
  <Processors>12</Processors>
  <Duration>1234</Duration>
</Delivered>
<Delivered>
  <Node>fr15n03</Node>
</Delivered>
<Delivered>
  <User>scottmo</User>
  <Account>mscfops</Account>
</Delivered>
<Delivered>
  <Memory>1024</Memory>
</Delivered>

```

## 9.0 AwarenessPolicy Attribute

A word or two should be said about compatibility mechanisms. With all the leeway in the specification with regard to implementing various portions of the specification, problems might arise if an implementation simply ignores a portion of a job specification that is critical to the job function in certain contexts. Given this situation, it might be desirable in some circumstances for jobs to be rejected by sites that fail to fully support that job's element or attributes. At other times, it might be desirable for a job to run, using a best-effort approach to supporting unimplemented features. Consequently, we define an `awarenessPolicy` attribute which can be added as an optional attribute to the Job element or any other containment or property element to indicate how the property (or the default action for the elements that the containment element encloses) must react when the implementation does not understand an element or attribute.

An awareness policy of `Reject` will cause the server to return a failure if it receives a client request in which it does not support an associated element name or attribute name or value. It is reasonable for an implementation to ignore (not even look for) an element or attribute that would not be critical to its function as long as ignoring this attribute or element would not cause an incorrect result. However, any element or attribute that was present that would be expected to be handled in a manner that the implementation does not support must result in a failure.

An awareness policy of `Warn` will accept the misunderstood element or attribute and continue to process the job object on a best effort basis. However a warning **MUST** be sent (if possible) to the requestor enumerating the elements and attributes that are not understood.

An awareness policy of `Ignore` will accept the unsupported element or attribute and continue to process the job object on a best effort basis. The action could be to simply ignore the attribute.

- This name of this attribute is `awarenessPolicy`.
- This attribute is of type `String`.
- This attribute can have values of `Reject`, `Warn` or `Ignore`.
- A compliant implementation **MAY** support this attribute.

- An implementation that does not support an attribute **MUST** reject any job object which contains elements or attributes that it does not support. Furthermore, it **SHOULD** return a message to the requestor with an indication of the element or attribute name it did not understand.
- This attribute **MAY** be present in a property or containment element.
- If an implementation does support the attribute, but it is absent, the default value of `Reject` is implied.
- Individual elements in the job object may override the containing object's awareness policy default by including this attribute. For example, a job might specify an `awarenessPolicy` of `Reject` at its root (the `Job` element) but may want to allow a particular subset of elements or attributes to be ignored if not understood. Conversely, a job with a default `awarenessPolicy` of `Ignore` might want to classify a subset of its optional elements as `Reject` if they are indispensable to its correct interpretation. An implementation can opt to check or not check for this attribute at any level it wants but must assume a `Reject` policy for any elements it does not check.

## Scalable Systems Software Resource Management and Accounting Protocol (SSSRMAP) Message Format

Resource Management Interface Specs

Release v. 3.0.4

18 JUL 2005

Scott Jackson  
Brett Bode  
David Jackson  
Kevin Walker

### Status of This Memo

This is a specification defining an XML message format used between Scalable Systems Software components. It is intended that this specification will continue to evolve as these interfaces are implemented and thoroughly tested by time and experience.

### Abstract

This document is a specification describing a message format for the interaction of resource management and accounting software components developed as part of the Scalable Systems Software Center. The SSSRMAP Message Format defines a request-response syntax supporting both functional and object-oriented messages. The protocol is specified in XML Schema Definition. The message elements defined in this specification are intended to be framed within the Envelope and Body elements defined in the SSSRMAP Wire Protocol specification document.

## 1.0 Introduction

A major objective of the Scalable Systems Software [SSS] Center is to create a scalable and modular infrastructure for resource management and accounting on terascale clusters including resource scheduling, grid-scheduling, node daemon support, comprehensive usage accounting and user interfaces emphasizing portability to terascale vendor operating systems. Existing resource management and accounting components feature disparate APIs (Application Programming Interfaces) requiring various forms of application coding to interact with other components.

This document proposes a common message format expressed in an XML request-response syntax to be considered as the foundation of a standard for communications between and among resource management and accounting software components. In this document this standard is expressed in two levels of generality. The features of the core SSSRMAP protocol common to all resource management and accounting components in general are described in the main body of this document. The aspects of the syntax specific to individual components are described in component-specific binding documents.

## 2.0 Conventions Used in This Document

### 2.1 Keywords

The keywords “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “RECOMMENDED”, “MAY”, and “OPTIONAL” in this document are to be interpreted as described in RFC2119 [RFC2119].

### 2.2 XML Case Conventions

In order to enforce a consistent capitalization and naming convention across all SSSRMAP specifications “Upper Camel Case” (UCC) and “Lower Camel Case” (LCC) Capitalization styles shall be used. UCC style capitalizes the first character of each word and compounds the name. LCC style capitalizes the first character of each word except the first word. [XML\_CONV][FED\_XML]

1. SSSRMAP XML Schema and XML instance documents SHALL use the following conventions:
  - Element names SHALL be in UCC convention (example: <UpperCamelCaseElement/>).
  - Attribute names SHALL be in LCC convention (example: <UpperCamelCaseElement lowerCamelCaseAttribute="Whatever"/>).
2. General rules for all names are:
  - Acronyms SHOULD be avoided, but in cases where they are used, the capitalization SHALL remain (example: XMLSignature).
  - Underscores (`_`), periods (`.`) and dashes (`-`) MUST NOT be used (example: use JobId instead of JOB.ID, Job\_ID or job-id).

### 2.3 Schema Definitions

SSSRMAP Schema Definitions appear like this

In case of disagreement between the schema file and this specification, the schema file takes precedence.

## 3.0 Encoding

Encoding tells how a message is represented when exchanged. SSSRMAP data exchange messages SHALL be defined in terms of XML schema [XML\_SCHEMA].

### 3.1 Schema Header and Namespaces

The header of the schema definition is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema
  xmlns="http://www.w3.org/2001/XMLSchema"
  xmlns:sssrmmap="http://scidac.org/ScalableSystems/SSSRMAP"
  targetNamespace="http://www.scidac.org/ScalableSystems/SSSRMAP"
  elementFormDefault="qualified">
```

### 3.2 Element Descriptions

The following subsections describe the elements that make up SSSRMAP messages. SSSRMAP messages are transmitted in the Body and Envelope elements as described in the SSSRMAP Wire Protocol specification [WIRE\_PROTOCOL].

#### *The Request Element*

The `Request` element specifies an individual request. An object-oriented request will have at least one `Object` element while a functional request will not have one. Depending on context, the `Request` element MAY contain one or more `Get` elements or one or more `Set` elements and any number of `Where` elements. `Option`, `Data`, `File` or `Count` elements may also be included. If a component supports it, chunking may be requested where large response data is possible. Setting the chunking attribute to “True” requests that the server break a large response into multiple chunks (each with their own envelope) so they can be processed in separate pieces.

Only an `action` attribute is required. All other attributes are optional.

Attribute	Description
<b>action</b>	Specifies the action or function to be performed
<b>actor</b>	The authenticated user sending the request
<b>id</b>	Uniquely maps the request to the appropriate response
<b>chunking</b>	Requests that segmentation be used for large response data if set to “True”
<b>chunkSize</b>	Requests that the segmentation size be no larger than the specified amount

```

<complexType name="RequestType">
  <choice minOccurs="0" maxOccurs="unbounded">
    <element ref="sssrmmap:Object" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmmap:Option" minOccurs="0" maxOccurs="unbounded"/>
    <choice minOccurs="0" maxOccurs="1">
      <element ref="sssrmmap:Get" minOccurs="1" maxOccurs="unbounded"/>
      <element ref="sssrmmap:Set" minOccurs="1" maxOccurs="unbounded"/>
    </choice>
    <element ref="sssrmmap:Where" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmmap:Data" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmmap:Count" minOccurs="0" maxOccurs="1"/>
    <any namespace="##other" minOccurs="0" maxOccurs="unbounded"/>
  </choice>
  <attribute name="action" type="string" use="required"/>
  <attribute name="actor" type="string" use="required"/>
  <attribute name="id" type="string" use="optional"/>
  <attribute name="chunking" type="sssrmmap:BoolType" use="optional"/>
  <attribute name="chunkSize" type="positiveInteger" use="optional"/>
</complexType>

<element name="Request" type="sssrmmap:RequestType"/>

```

### The Object Element

The `Object` element is used in an object-oriented request to specify the object receiving the action. It is possible to have multiple `Object` elements in a request if an implementation supports multi-object queries.

The object class name is specified as text content. All attributes are optional.

- `join` – the type of join to be performed with the preceding object
  - A `join` attribute of “Inner” specifies an inner join. This is the default.
  - A `join` attribute of “FullOuter” specifies a full outer join.
  - A `join` attribute of “LeftOuter” specifies a left outer join.
  - A `join` attribute of “RightOuter” specifies a right outer join.
  - A `join` attribute of “Cross” specifies a cross join.
  - A `join` attribute of “Union” specifies a union join.

```

<complexType name="ObjectType">
  <simpleContent>
    <extension base="string">
      <attribute name="join" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Object" type="sssrmmap:ObjectType"/>

```

### The Get Element

The `Get` element is used to indicate the data fields to be returned in a query. `Get` is typically used within requests with `action="query"`. Multiple `Get` elements cause the fields to be returned in the order specified. If no `Get` elements are specified, the query will return a default set of fields.

Only a name attribute is required. All other attributes are optional.

Attribute	Description
<b>name</b>	The name of the data field to be returned. This MUST be of the form of a “Modified XPATH expression” as described in a later section.
<b>op</b>	The operator to be used to aggregate or perform an operation on the returned values. <ul style="list-style-type: none"> <li>• An <i>op</i> attribute of “Sort” specifies an ascending sort operation</li> <li>• An <i>op</i> attribute of “Tros” specifies a descending sort operation</li> <li>• An <i>op</i> attribute of “Sum” returns the sum (only valid for numeric values)</li> <li>• An <i>op</i> attribute of “Max” returns the maximum value</li> <li>• An <i>op</i> attribute of “Min” returns the minimum value</li> <li>• An <i>op</i> attribute of “Count” returns the number of values</li> <li>• An <i>op</i> attribute of “Average” returns the average of the values</li> <li>• An <i>op</i> attribute of “GroupBy” signifies that aggregates are grouped by this field</li> </ul>
<b>object</b>	Specifies the object for which you want the named attribute in a multi-object query.
<b>units</b>	The units in which to return the value (if applicable)

```

<complexType name="GetType">
  <attribute name="name" type="string" use="required"/>
  <attribute name="object" type="string" use="optional"/>
  <attribute name="op" type="sssrmapi:GetOperatorType" use="optional"/>
  <attribute name="units" type="string" use="optional"/>
</complexType>

<element name="Get" type="sssrmapi:GetType"/>

<simpleType name="GetOperatorType">
  <restriction base="string">
    <enumeration value="Sort"/>
    <enumeration value="Tros"/>
    <enumeration value="Count"/>
    <enumeration value="Sum"/>
    <enumeration value="Max"/>
    <enumeration value="Min"/>
    <enumeration value="Average"/>
    <enumeration value="GroupBy"/>
  </restriction>
</simpleType>

```

### The Set Element

The Set element is used to specify the object data fields to be assigned values. Set is typically used within requests with `action="Create"` or `action="Modify"`. The use of Get or Set elements within a request is mutually exclusive.

The assignment value (to which the field is being changed) is specified as the text content. A Set element without a value may be used as an assertion flag. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
<b>name</b>	The name of the field being assigned a value. This MUST be of the form of a “Modified XPATH expression” as described in a later section.
<b>op</b>	The operator to be used in assigning a new value to the name. If an <code>op</code> attribute is not specified and a value is specified, the specified value will be assigned to the named field (“assign”). <ul style="list-style-type: none"> <li>• An <code>op</code> attribute of “Assign” assigns value to the named field</li> <li>• An <code>op</code> attribute of “Inc” increments the named field by the value</li> <li>• An <code>op</code> attribute of “Dec” decrements the named field by the value</li> </ul>
<b>units</b>	The units corresponding to the value being set

```

<complexType name="SetType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmap:SetOperatorType" use="optional"/>
      <attribute name="units" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Set" type="sssrmap:SetType"/>

<simpleType name="SetOperatorType">
  <restriction base="string">
    <enumeration value="Assign"/>
    <enumeration value="Inc"/>
    <enumeration value="Dec"/>
  </restriction>
</simpleType>

```

### The Where Element

A `Request` element may contain one or more `Where` elements that specify the search conditions for which objects the action is to be performed on.

The condition value (against which the field is tested) is specified as the text content. A `Where` element without a value may be used as a truth test. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
<b>name</b>	The name of the data field to be tested. This MUST be of the form of a “Modified XPATH expression” as described in a later section.

Attribute	Description
<b>op</b>	<p>The operator to be used to test the name against the value. If an <code>op</code> attribute is not specified and a value is specified, the field will be tested whether it is equal to the value ("EQ").</p> <ul style="list-style-type: none"> <li>• An <code>op</code> attribute of "EQ" specifies an equality comparison</li> <li>• An <code>op</code> attribute of "LT" specifies a "less than" comparison</li> <li>• An <code>op</code> attribute of "GT" specifies a "greater than" comparison</li> <li>• An <code>op</code> attribute of "LE" specifies a "less than or equal to" test</li> <li>• An <code>op</code> attribute of "GE" specifies a "greater than or equal to" test</li> <li>• An <code>op</code> attribute of "NE" specifies a "not equal to" test</li> <li>• An <code>op</code> attribute of "Match" specifies a regular expression matching comparison</li> </ul>
<b>conj</b>	<p>Indicates whether this test is to be anded or ored with the immediately preceding where condition</p> <ul style="list-style-type: none"> <li>• A <code>conj</code> attribute of "And" specifies an "and" conjunction</li> <li>• A <code>conj</code> attribute of "Or" specifies an "or" condition</li> <li>• A <code>conj</code> attribute of "AndNot" specifies an "and not" conjunction</li> <li>• A <code>conj</code> attribute of "OrNot" specifies an "or not" condition</li> </ul>
<b>group</b>	<p>Indicates an increase or decrease of parentheses grouping depth</p> <ul style="list-style-type: none"> <li>• A positive number indicates the number of left parentheses to precede the condition, i.e. <code>group="2"</code> represents "((condition)".</li> <li>• A negative number indicates the number of right parentheses to follow the condition, i.e. <code>group="-2"</code> represents "condition))".</li> </ul>
<b>object</b>	Specifies the object for the first operand in a multi-object query.
<b>subject</b>	Specifies the object for the second operand in a multi-object query.
<b>units</b>	Indicates the units to be used in the value comparison

```

<complexType name="WhereType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmop:OperatorType" use="optional"/>
      <attribute name="conj" type="sssrmop:ConjunctionType" use="optional"/>
      <attribute name="group" type="integer" use="optional"/>
      <attribute name="units" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Where" type="sssrmop:WhereType"/>

<simpleType name="WhereOperatorType">
  <restriction base="string">
    <enumeration value="EQ"/>
    <enumeration value="GT"/>
    <enumeration value="LT"/>
    <enumeration value="GE"/>
    <enumeration value="LE"/>
    <enumeration value="NE"/>
    <enumeration value="Match"/>
  </restriction>
</simpleType>

```

### The Option Element

The `Option` element is used to indicate processing options for the command. An option might be used to indicate that command usage or special formatting is desired, or that the command is to be invoked with particular options.

The option value is specified as the text content. An `Option` element without a value may be used as an assertion flag. Only the `name` attribute is required. All other attributes are optional.

Attribute	Description
<b>name</b>	The name of the field being assigned a value
<b>op</b>	The operator to be used to disassert the option <ul style="list-style-type: none"> <li>An <code>op</code> attribute of "Not" specifies that the option is not asserted</li> </ul>
<b>conj</b>	Indicates whether this test is to be anded or ored with the immediately preceding where condition <ul style="list-style-type: none"> <li>A <code>conj</code> attribute of "And" specifies an "and" conjunction</li> <li>A <code>conj</code> attribute of "Or" specifies an "or" condition</li> <li>A <code>conj</code> attribute of "AndNot" specifies an "and not" conjunction</li> <li>A <code>conj</code> attribute of "OrNot" specifies an "or not" condition</li> </ul>

```

<complexType name="OptionType">
  <simpleContent>
    <extension base="string">
      <attribute name="name" type="string" use="required"/>
      <attribute name="op" type="sssrmap:OptionOperatorType" use="optional"/>
      <attribute name="conj" type="sssrmap:ConjunctionType" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="Option" type="sssrmap:OptionType"/>

<simpleType name="OptionOperatorType">
  <restriction base="string">
    <enumeration value="Not"/>
  </restriction>
</simpleType>

```

### The Data Element

A Request or Response element may have one or more Data elements that allow the supplying of context-specific data. A request might pass in a structured object via a Data element to be acted upon. Typically a query will result in a response with the data encapsulated within a Data element.

The following attributes are optional:

Attribute	Description
<b>name</b>	Object name describing the contents of the data
<b>type</b>	Describing the form in which the data is represented <ul style="list-style-type: none"> <li>• A <code>type</code> attribute of "XML" indicates the data has internal xml structure and can be recursively parsed by an XML parser</li> <li>• A <code>type</code> attribute of "Binary" indicates the data is an opaque dataset consisting of binary data</li> <li>• A <code>type</code> attribute of "String" indicates the data is an ASCII string</li> <li>• A <code>type</code> attribute of "Int" indicates the data is an integer</li> <li>• A <code>type</code> attribute of "Text" indicates the data is in formatted human-readable text</li> <li>• A <code>type</code> attribute of "HTML" indicates the data is represented in HTML</li> </ul>

```

<complexType name="DataType">
  <sequence>
    <any namespace="##any" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute name="name" type="string" use="optional"/>
  <attribute ref="sssrmap:Type" use="optional"/>
</complexType>

<element name="data" type="sssrmap:DataType"/>

```

### The File Element

A Request or Response element may have one or more File elements of type String that allow the inclusion of files. The files may be either text or binary and may be referenced by objects inside the Data element. A file may be compressed using the gzip algorithm [ZIP]. A binary file or a compressed file must

be base64 encoded as defined in XML Digital Signatures (“<http://www.w3.org/2000/09/xmlldsig#base64>”). Metadata describing the modes and properties of the resulting file are passed as parameters. The text or base64 encoded file data forms the string content of the `File` element.

The following attributes are optional:

Attribute	Description
<b>id</b>	Specifies an identifier that allows the file to be referenced from within another object. If more than one <code>File</code> elements are specified, this attribute is REQUIRED in each of them.
<b>name</b>	Specifies the name to give the file upon creation on the target system. This can be an absolute or relative pathname (relative to the <code>InitialWorkingDirectory</code> ).
<b>owner</b>	Indicates what owner the file should be changed to. By default it will be changed to the <code>UserId</code> that the authenticated actor maps to on the target system. Note that this function should succeed only if the requestor has the privileges to do so (i.e. authenticated as root).
<b>group</b>	Indicates what group the file should be changed to. By default it will be set to the primary groupid of the <code>UserId</code> that the authenticated actor maps to on the target system. Note that this function should succeed only if the requestor has the proper privileges.
<b>mode</b>	Indicates the permissions the file should possess. By default it will be set according to the default <code>umask</code> for the <code>UserId</code> that the authenticated actor maps to on the target system. Note that this function should not set permissions for the file that exceed the privileges for the actor. These permissions can be specified using either an octal number or symbolic operations (as accepted by the GNU <code>chmod(1)</code> command).
<b>compressed</b>	Indicates whether the file has been compressed <ul style="list-style-type: none"> <li>• A <code>compressed</code> attribute of “True” indicates the file has been compressed.</li> <li>• A <code>compressed</code> attribute of “False” indicates the file has not been compressed. This is the default.</li> </ul>
<b>encoded</b>	Indicates whether the file has been base64 encoded <ul style="list-style-type: none"> <li>• An <code>encoded</code> attribute of “True” indicates the file has been encoded.</li> <li>• An <code>encoded</code> attribute of “False” indicates the file has not been encoded. This is the default.</li> </ul>

```

<complexType name="FileType">
  <sequence>
    <any namespace="##any" processContents="lax" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <attribute name="name" type="string" use="optional"/>
  <attribute name="owner" type="string" use="optional"/>
  <attribute name="group" type="string" use="optional"/>
  <attribute name="mode" type="string" use="optional"/>
  <attribute name="compressed" type="boolean" use="optional"/>
  <attribute name="encoded" type="boolean" use="optional"/>
</complexType>

<element name="file" type="sssrmap:FileType"/>

```

### The Count Element

A single `Count` element may be included within a `Request` or `Response` and is context-specific. This can be used to represent the number of objects acted upon or returned.

```
<element name="Count" type="positiveInteger"/>
```

### The Response Element

The `Response` element specifies an individual response. It **MUST** contain a `Status` element. It **MAY** also contain `Count` and any number of `Data` or `File` elements. If chunking has been requested and is supported by the server, a large response may be broken up into multiple chunks (each with their own envelope). The `chunkNum` attribute can be used to indicate which chunk the current one is. The `chunkMax` attribute can be used to determine when all the chunks have been received (all chunks have been received if `chunkNum=chunkMax` or `chunkMax=0`).

It **MAY** have any of the following attributes:

Attribute	Description
<b>id</b>	Uniquely maps the response to the corresponding request
<b>chunkNum</b>	Integer indicating the current chunk number [1 is implied when this attribute is missing or blank]
<b>chunkMax</b>	Integer indicating the number of chunks expected [-1 means unknown but more chunks to follow; 0 means unknown but this is the last chunk; 0 is implied if this attribute is missing or blank]

```

<complexType name="ResponseType">
  <choice minOccurs="0" maxOccurs="unbounded">
    <element ref="sssrmap:Status" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmap:Count" minOccurs="0" maxOccurs="1"/>
    <element ref="sssrmap:Data" minOccurs="0" maxOccurs="unbounded"/>
    <element ref="sssrmap:File" minOccurs="0" maxOccurs="unbounded"/>
    <any minOccurs="0" maxOccurs="unbounded" namespace="##other"/>
  </choice>
  <attribute name="object" type="string" use="optional"/>
  <attribute name="action" type="string" use="optional"/>
  <attribute name="id" type="string" use="optional"/>
  <attribute name="chunkNum" type="integer" use="optional"/>
  <attribute name="chunkMax" type="integer" use="optional"/>
</complexType>

<element name="Response" type="sssrmap:ResponseType"/>

```

### The Status Element

A Response element **MUST** contain a single Status element that indicates whether the reply represents a success, warning or failure. This element is composed of the child elements Value, Code and Message. Of these, Value and Code are required, and Message is optional.

```
<complexType name="StatusType">
  <choice minOccurs="1" maxOccurs="unbounded">
    <element ref="sssrmmap:Value" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmmap:Code" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmmap:Message" minOccurs="0" maxOccurs="1"/>
    <any minOccurs="0" maxOccurs="unbounded" namespace="##other"/>
  </choice>
</complexType>

<element name="Status" type="sssrmmap:StatusType"/>
```

### The Value Element

The Value element is of type String and **MUST** have a value of "Success", "Warning" or "Failure".

```
<simpleType name="StatusValueType">
  <restriction base="string">
    <enumeration value="Success"/>
    <enumeration value="Warning"/>
    <enumeration value="Failure"/>
  </restriction>
</simpleType>

<element name="Value" type="sssrmmap:StatusValueType"/>
```

### The Code Element

A Response element must contain a single Code element that specifies the 3-digit status code for the response. Refer to the next section on Error Reporting for a description and listing of supported status codes.

```
<simpleType name="CodeType">
  <restriction base="string">
    <pattern value="[0-9]{3}"/>
  </restriction>
</simpleType>

<element name="Code" type="sssrmmap:CodeType"/>
```

### The Message Element

A Response element may contain a single Message element that is context specific to the success or failure response. The message should be an error message if status is false. If present for a successful response, it may be used as a human readable message for a user interface.

```
<element name="Message" type="string"/>
```

## 3.3 Modified XPATH Expressions

The name attribute used within the Get, Set and Where Elements **MUST** have the form of a modified XPATH expression as defined in this section. Usually this will just be the simple name of the object property. Some complex objects, such as the SSS Job Object and the SSS Node Object, however, are

represented in a structured way with nested elements. In order to define a consistent and flexible way to access and manipulate these objects as well as keeping the flat XML objects simple and straightforward, SSSRMAP specifies that a “Modified XPATH” syntax be used.

In essence, “Modified XPATH” is defined to be an XPATH [XPATH] expression with the exception that the “//” may be omitted from the beginning of the expression when a document search is desired. Thus, on the server side, a standard XPATH routine can be used by prepending “//” to any expression that does not begin with a “/”.

The response data should always include all of the structure of the queried object necessary to place the requested data in its proper context.

See the XPATH specification for a full description of XPATH. The XPath 1.0 Recommendation is <http://www.w3.org/TR/1999/REC-xpath-19991116>. The [latest version of XPath 1.0](#) is available at <http://www.w3.org/TR/xpath>.

### Sample Modified XPATH Expressions

Consider the following hypothetical object(s) (which might be returned within a Data element).

```
<Job>
  <JobId>PBS.1234.0</JobId>
  <Requested>
    <Memory op="GE">512</Memory>
    <Processors>2</Processors>
    <WallDuration>P3600S</WallDuration>
  </Requested>
  <Utilized>
    <Memory metric="Average">488</Memory>
    <WallDuration>P1441S</WallDuration>
  </Utilized>
</Job>
```

To get everything above for this job you would not need a Get element:

```
<Request action="Query">
  <Object>Job</Object>
  <Where name="JobId">PBS.1234.0</Where>
</Request>
```

If you used `<Get name="JobId"/>` you would get back:

```
<Job>
  <JobId>PBS.1234.0</JobId>
</Job>
```

If you used `<Get name="Memory"/>` (or `name="/Job/*/Memory"`) you would get:

```
<Job>
  <Requested>
    <Memory op="GE">512</Memory>
  </Requested>
  <Utilized>
    <Memory metric="Average">488</Memory>
  </Utilized>
</Job>
```

If you used `<Get name="Requested/Memory"/>` (or `name="/Job/Requested/Memory"`) you would get:

```
<Job>
  <Requested>
    <Memory op="GE">512</Memory>
  </Requested>
</Job>
```

If you used `<Get name="Memory[@metric='Average']"/>` (or `name="Memory[@metric]"`) you would get:

```
<Job>
  <Utilized>
    <Memory metric="Average">488</Memory>
  </Utilized>
</Job>
```

### 3.4 Examples

#### Sample Requests

Requesting a list of nodes with a certain configured memory threshold (batch format):

```
<Request action="Query" id="1">
  <Object>Node</Object>
  <Get name="Name" />
  <Get name="Configured/Memory" />
  <Where name="Configured/Memory" op="GE" units="MB">512</Where>
</Request>
```

Activating a couple of users:

```
<Request action="Modify">
  <Object>User</Object>
  <Set name="Active">True</Set>
  <Where name="Name">scott</Where>
  <Where name="Name" conj="Or"/>brett</Where>
</Request>
```

Submitting a simple job:

```
<Request action="Submit">
  <Object>Job</Object>
  <Data>
    <Job>
      <User>xdp</User>
      <Account>youraccount</Account>
      <Command>myprogram</Command>
      <InitialWorkingDirectory>/usr/home/scl/xdp</InitialWorkingDirectory>
      <RequestedNodes>4</RequestedNodes>
      <RequestedWCTime>100</RequestedWCTime>
    </Job>
  </Data>
</Request>
```

## Sample Responses

A response to the available memory nodes query (batch format)

```
<Response id="1">
  <Status>
    <Value>Success</Value>
    <Code>000</Code>
  </Status>
  <Count>2</Count>
  <Data>
    <Node>
      <Name>fr01n01</Name>
      <Configured>
        <Memory>512</Memory>
      </Configured>
    </Node>
    <Node>
      <Name>fr12n04</Name>
      <Configured>
        <Memory>1024</Memory>
      </Configured>
    </Node>
  </Data>
</Response>
```

Two users successfully activated

```
<Response>
  <Status>
    <Code>000</Code>
    <Message>Two users were successfully modified</Message>
  </Status>
  <Count>2</Count>
</Response>
```

A failed job submission:

```
<Response>
  <Status>
    <Value>Failure</Value>
    <Code>711</Code>
    <Message>Invalid account specified. The job was not submitted.</Message>
  </Status>
</Response>
```

## 4.0 Error Reporting

SSSRMAP requests will return a status and a 3-digit response code to signify success or failure conditions. When a request is successful, a corresponding response is returned with the `status` element set to `Success` and the `code` element set to "000". When a request results in an error detected by the server, a response is returned with the `status` element set to `Failure` and a 3-digit error code in the `code` element. An optional human-readable message may also be included in a failure response providing context-specific detail about the failure. The default message language is US English. (The status flag makes it easy to signal success or failure and allows the receiving peer some freedom in the amount of parsing it wants to do on failure [BXXP]).

**Success codes:**

Code	Response Text in US English
<b>0xx</b>	Request was successful
<b>000</b>	General Success
<b>010</b>	Help/usage reply
<b>020</b>	Status reply
<b>030</b>	Subscription successful
<b>035</b>	Notification successful (Ack)
<b>040</b>	Registration successful
<b>050-079</b>	Component-defined
<b>080-099</b>	Application-defined

**Warning codes:**

Code	Response Text in US English
<b>1xx</b>	Request was successful but includes a warning
<b>100</b>	General warning (examine message for details)
<b>102</b>	Check result (Did what you asked but may not have been what you intended -- or information is suspect)
<b>110</b>	Wire Protocol or Network warning
<b>112</b>	Redirect
<b>114</b>	Protocol warning (something was wrong with the protocol, but best effort guesses were applied to fulfill the request)
<b>120</b>	Message Format warning

Code	Response Text in US English
122	Incomplete specification (request missing some essential information -- best effort guess applied)
124	Format warning (something was wrong with the format but best effort guesses were applied to fulfill the request)
130	Security warning
132	Insecure request
134	Insufficient privileges (Response was sanitized or reduced in scope due to lack of privileges)
140	Content or action warning
142	No content (The server has processed the request but there is no data to be returned)
144	No action taken (nothing acted upon -- i.e. deletion request did not match any objects)
146	Partial content
148	Partial action taken
150-179	Component-defined
180-199	Application-defined

### Wire protocol codes:

Code	Response Text in US English
2xx	A problem occurred in the wire protocol or network
200	General wire protocol or network error
210	Network failure
212	Cannot resolve host name

Code	Response Text in US English
214	Cannot resolve service port
216	Cannot create socket
218	Cannot bind socket
220	Connection failure
222	Cannot connect
224	Cannot send data
226	Cannot receive data
230	Connection rejected
232	Timed out
234	Too busy
236	Message too large
240	Framing failure
242	Malformed framing protocol
244	Invalid payload size
246	Unexpected end of file
250-279	Component-defined
280-299	Application-defined

**Message format codes:**

Code	Response Text in US English
<b>3xx</b>	A problem occurred in the message format
<b>300</b>	General message format error
<b>302</b>	Malformed XML document
<b>304</b>	Validation error(XML Schema)
<b>306</b>	Namespace error
<b>308</b>	Invalid message type (Something other than Request or Response in Body
<b>310</b>	General syntax error in request
<b>311</b>	Object incorrectly (or not) specified
<b>312</b>	Action incorrectly (or not) specified
<b>313</b>	Invalid Action
<b>314</b>	Missing required element or attribute
<b>315</b>	Invalid Object (or Object-Action combination
<b>316</b>	Invalid element or attribute name
<b>317</b>	Illegal value for element or attribute
<b>318</b>	Illegal combination
<b>319</b>	Malformed Data
<b>320</b>	General syntax error in response
<b>321</b>	Status incorrectly (or not)specified
<b>322</b>	Code incorrectly (or not)specified

Code	Response Text in US English
324	Missing required element or attribute
326	Invalid element or attribute name
327	Illegal value for element or attribute
328	Illegal combination
329	Malformed Data
340	Pipelining failure
342	Request identifier is not unique
344	Multiple messages not supported
346	Mixed messages not supported (Both requests and responses in same batch)
348	Request/response count mismatch
350-379	Component-defined
380-399	Application-defined

**Security codes:**

Code	Response Text in US English
4xx	A security requirement was not fulfilled
400	General security error
410	Negotiation failure
412	Not understood
414	Not supported

Code	Response Text in US English
416	Not accepted
420	Authentication failure
422	Signature failed at client
424	Authentication failed at server
426	Signature failed at server
428	Authentication failed at client
430	Encryption failure
432	Encryption failed at client
434	Decryption failed at server
436	Encryption failed at server
438	Decryption failed at client
440	Authorization failure
442	Authorization failed at client
444	Authorization failed at server
450-479	Component-defined
480-499	Application-defined

**Event management codes:**

Code	Response Text in US English
5xx	Failure conditions in event messaging

Code	Response Text in US English
500	General Event Management failure
510	Subscription failed
520	Notification failed
550-579	Component-defined
580-599	Application-defined

**Reserved codes:**

Code	Response Text in US English
6xx	Reserved for future use

**Server application codes:**

Code	Response Text in US English
7xx	A server-side application-specific error occurred
700	General failure
710	Not supported
712	Not understood
720	Internal error
730	Resource unavailable (insufficient resources -- software, hardware or a service I rely upon is down)
740	Business logic
750-779	Component-defined
780-799	Application-defined

**Client application codes:**

Code	Response Text in US English
<b>8xx</b>	A client-side application-specific error occurred
<b>800</b>	General failure
<b>810</b>	Not supported
<b>812</b>	Not understood
<b>820</b>	Internal error
<b>830</b>	Resource unavailable
<b>840</b>	Business logic
<b>850-879</b>	Component-defined
<b>880-899</b>	Application-defined

**Miscellaneous codes:**

Code	Response Text in US English
<b>9xx</b>	Miscellaneous failures
<b>999</b>	Unknown failure

## Scalable Systems Software Node Object Specification

SSS Node Object Specification  
Release Version 3.1.0  
26 April 2011

Scott Jackson, PNNL  
David Jackson, Ames Lab  
Brett Bode, Ames Lab

### Status of This Memo

This is a specification of the node object to be used by Scalable Systems Software compliant components. It is envisioned for this specification to be used in conjunction with the SSSRMAP protocol with the node object passed in the Data field of Requests and Responses. Queries can be issued to a node-cognizant component in the form of modified XPATH expressions to the Get field to extract specific information from the node object as described in the SSSRMAP protocol.

### Abstract

This document describes the syntax and structure of the SSS node object. This node model takes into account various node property categories such as whether it represents a configured, available or utilized property.

    - [4.3.1 Consumable Resources](#)
    - [4.3.2 Resource Element](#)
- [Appendix A](#)
- [Units of Measure Abbreviations](#)

## 1.0 Introduction

This specification proposes a standard XML representation for a node object for use by the various components in the SSS Resource Management System. This object will be used in multiple contexts and by multiple components. It is anticipated that this object will be passed via the Data Element of SSSRMAP Requests and Responses.

## 1.1 Goals

There are several goals motivating the design of this representation.

It needs to be inherently flexible. We recognize we will not be able to exhaustively include the ever-changing node properties and capabilities that constantly arise.

The same node object should be used at all stages of its lifecycle. This object needs to distinguish between configured, available and utilized properties of a node.

Its design takes into account the properties and structure required to function in a meta or grid environment. It should eventually include the capability of resolving namespace and locality issues, though the earliest versions will ignore this requirement.

One should not have to make multiple queries to obtain a single piece of information — i.e. there should not be two mutually exclusive ways to represent a node resource.

It needs to support resource metric as well as unit specifications.

## 1.2 Examples

### Simple Example

This example shows a simple expression of the Node object.

```
<Node>
  <Id>Node64</Id>
  <Configured>
    <Processors>2</Processors>
    <Memory>512</Memory>
  </Configured>
</Node>
```

### Elaborate Example

This example shows a more elaborate Node object.

```
<Node>
  <Id>64</Id>
  <Name>Netpipe2</Name>
  <Feature>BigMem</Feature>
  <Feature>NetOC12</Feature>
  <Opsys>AIX</Opsys>
  <Arch>Power4</Arch>
  <Configured>
    <Processors>16</Processors>
    <Memory units="MB">512</Memory>
    <Swap>512</Swap>
  </Configured>
  <Available>
    <Processors>7</Processors>
    <Memory metric="Instantaneous">143</Memory>
  </Available>
  <Utilized>
    <Processors wallDuration="3576">8</Processors>
    <Memory metric="Average" wallDuration="3576">400</Memory>
  </Utilized>
</Node>
```

## 2.0 Conventions Used in This Document

### 2.1 Keywords

The keywords **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **RECOMMENDED**, **MAY**, and **OPTIONAL** in this document are to be interpreted as described in [RFC2119](#).

### 2.2 Table Column Interpretations

In the property tables, the columns are interpreted to have the following meanings:

Property	Description
<b>Element Name</b>	Name of the XML element (xsd:element)
<b>Type</b>	Data type defined by xsd (XML Schema Definition) as: <ul style="list-style-type: none"> <li>• String — xsd:string(a finite length sequence of printable characters)</li> <li>• Integer — xsd:integer(a signed finite length sequence of decimal digits)</li> <li>• Float — xsd:float (single-precision 32-bit floating point)</li> <li>• Boolean — xsd:boolean (consists of the literals “true” or “false”)</li> <li>• DateTime — xsd:dateTime (discreet time values are represented in ISO 8601 extended format CCYY-MM-DDThh:mm:ss where CC represents the century, YY the year, MM the month and DD the day. The letter T is the date/time separator and hh, mm, ss represent hour, minute and second respectively. This representation may be immediately followed by a Z to indicate Coordinated Universal Time (UTC) or, to indicate the time zone, i.e. the difference between the local time and Coordinated Universal Time, immediately followed by a sign, + or -, followed by the difference from UTC.)</li> <li>• Duration — xsd:duration (a duration of time is represented in ISO 8601 extended format PnYnMnDtnHnMnS, where nY represents the number of years, nM the number of months, nD the number of days, T is the date/time separator, nH the number of hours, nM the number of minutes and nS the number of seconds. The number of seconds can include decimal digits to arbitrary precision.)</li> </ul>
<b>Description</b>	Brief description of the meaning of the property
<b>Appearance</b>	This column indicates whether the given property has to appear within the parent element. It assumes the following meanings: <ul style="list-style-type: none"> <li>• <b>MUST</b> — This property is <b>REQUIRED</b> when the parent is specified.</li> <li>• <b>SHOULD</b> — A compliant implementation <b>SHOULD</b> support this property.</li> <li>• <b>MAY</b> — A compliant implementation <b>MAY</b> support this property.</li> </ul>

Property	Description
<b>Compliance</b>	<p>The column indicates whether a compliant implementation has to support the given property.</p> <ul style="list-style-type: none"> <li>• <b>MUST</b> — A compliant implementation <b>MUST</b> support this property.</li> <li>• <b>SHOULD</b> — A compliant implementation <b>SHOULD</b> support this property.</li> <li>• <b>MAY</b> — A compliant implementation <b>MAY</b> support this property.</li> </ul>
<b>Categories</b>	<p>Some properties may be categorized into one of several categories. Letters in this column indicate that the given property can be classified in the following property categories.</p> <ul style="list-style-type: none"> <li>• <b>C</b> — This property can be encompassed in a Configured element.</li> <li>• <b>A</b> — This property can be encompassed in an Available element.</li> <li>• <b>U</b> — This property can be encompassed in a Utilized element.</li> </ul>

### 2.3 Element Syntax Cardinality

The cardinality of elements in the element syntax sections may make use of regular expression wildcards with the following meanings:

Wildcard	Description
*	Zero or more occurrences
+	One or more occurrences
?	Zero or one occurrences

The absence of one of these symbols implies one and only one occurrence.

### 3.0 The Node Model

The primary element within the node model is a node. One can speak of some node properties as being a configured, available or utilized property of the node.

### 4.0 Node Element

The Node element is the root element of a node object and is used to encapsulate a node.

- A node object **MUST** have exactly one Node element.
- A compliant implementation **MUST** support this element.
- A node **MUST** specify one or more Node Properties.

## 4.1 Uncategorized Node Properties

Uncategorized Node Properties are properties that apply to the node as a whole and do not need to be distinguished between being configured, available or utilized. These include the node id and other optional node properties.

### Simple Node Properties

Simple (unstructured) node properties are enumerated in the table below.

Table 3-13: Simple Node Properties

Element Name	Type	Description	Appearance	Compliance
<b>Id</b>	String	Node identifier	MUST	MUST
<b>Name</b>	String	Node name or pattern	MAY	MAY
<b>OpSys</b>	String	Operating System	MAY	SHOULD
<b>Arch</b>	String	Architecture	MAY	SHOULD
<b>Description</b>	String	Description of the node	MAY	MAY
<b>State</b>	String	State of the node. Valid states may include Offline, Configured, Unknown, Idle, and Busy.	SHOULD	MUST
<b>Features</b>	String	Arbitrary named features of the node (comma-delimited string)	MAY	SHOULD

### Extension Element

The `Extension` element provides a means to pass extensible properties with the node object. Some applications may find it easier to deal with a named extension property than discover and handle elements for which they do not understand or anticipate by name.

- A compliant implementation **MAY** support this element.
- This element **MUST** have a name attribute that is of type `String` and represents the name of the extension property. A compliant implementation **MUST** support this attribute if this element is supported.
- This element **MAY** have a type attribute that is of type `String` and provides a hint about the context within which the property should be understood. A compliant implementation **SHOULD** support this attribute if this element is supported.
- The character content of this element is of type `String` and is the value of the extension property.

The following is an example of an `Extension` element:

```
<Extension type="Chemistry" name="Software">NWChem</Extension>
```

## 4.2 Property Categories

Certain node properties (particularly consumable resources) need to be classified as being in a particular category. This is done when it is necessary to distinguish between a property that is configured versus a property that is available or utilized. For example, a node might be configured with 16 processors. At a particular time, 8 might be utilized, 7 might be available and 1 disabled. When a node property must be categorized to be understood properly, the property **MUST** be enveloped within the appropriate Property Category Element.

### *Configured Element*

A configured node property reflects resources pertaining to the node that could in principle be used though they may not be available at this time. This information could be used to determine if a job could ever conceivably run on a given node.

- A compliant implementation **MUST** support this element.

The following is an example of using Configured Properties:

```
<Configured>
  <Processors>16</Processors>
  <Memory units="MB">512</Memory>
</Configured>
```

### *Available Element*

An available node property refers to a resource that is currently available for use.

- A compliant implementation **SHOULD** support this element.

The following is an example of specifying available properties:

```
<Available>
  <Processors>7</Processors>
  <Memory units="MB">256</Memory>
</Available>
```

### *Utilized Element*

A utilized node property reflects resources that are currently utilized.

- A compliant implementation **SHOULD** support this element.

The following is an example of specifying utilized properties:

```
<Utilized>
  <Processors>8</Processors>
  <Memory metric="Average">207</Memory>
</Utilized>
```

### 4.3 Categorized Node Properties

#### Consumable Resources

Consumable Resources are a special group of node properties that can have additional attributes and can be used in multiple categories. In general a consumable resource is a resource that can be consumed in a measurable quantity.

- A consumable resource **MUST** be categorized as being a configured, available or utilized node property by being a child element of a Configured, Available or Utilized element respectively.
- A consumable resource **MAY** have a units attribute that is of type String that specifies the units by which it is being measured. If this attribute is omitted, a default unit is implied. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a metric attribute that is of type String that specifies the type of measurement being described. For example, the measurement may be a Total, an Average, a Min or a Max. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a wallDuration attribute of type Duration that indicates the amount of time for which that resource was used. This need only be specified if the resource was used for a different amount of time than the wallDuration for the step. A compliant implementation **MAY** support this attribute if the element is supported.
- A consumable resource **MAY** have a consumptionRate attribute of type Float that indicates the average percentage that a resource was used over its wallDuration. For example, an overbooked SMP running 100 jobs across 32 processors may wish to scale the usage and charge by the average fraction of processor usage actually delivered. A compliant implementation **MAY** support this attribute if the element is supported.

A list of simple consumable resources is listed in the table below.

Table 3-14: Consumable Resource Node Properties

Element Name	Type	Description	Appearance	Compliance	Categories
<b>Processors</b>	Integer	Number of processors	MAY	MUST	CAU
<b>Memory</b>	Float	Amount of memory	MAY	SHOULD	CAU
<b>Disk</b>	Float	Amount of disk	MAY	SHOULD	CAU
<b>Swap</b>	Float	Amount of virtual memory	MAY	MAY	CAU
<b>Network</b>	Float	Amount of network	MAY	MAY	CAU

The following are two examples for specifying a consumable resource:

```
<Memory metric="Max" units="GB">483</Memory>
<Processors wallDuration="1234" consumptionRate="0.63">4</Processors>
```

### Resource Element

In addition to the consumable resources enumerated in the above table, an extensible consumable resource is defined by the Resource element.

- A compliant implementation SHOULD support this element.
- This element MAY appear zero or more times within a given set of node properties.
- Like the other consumable resources, this property MUST be categorized as a configured, available or utilized property by being encompassed in the appropriate elements.
- This element is of type Float.
- It shares the other same properties and attributes as the other consumable resources but it requires an additional name (and optional type) attribute to describe it.
- This element MUST have a name attribute of type String that indicates the type of consumable resource being measured. A compliant implementation MUST support this attribute if the element is supported.
- This element MAY have a type attribute of type String that distinguishes it within a general resource class. A compliant implementation SHOULD support this attribute if the element is supported.

The following are two examples for specifying a Resource element:

```
<Resource name="License" type="MATLAB">1</Resource>
<Resource name="Telescope" type="Zoom2000" wallDuration="750"
metric="KX">10</Resource>
```

## 4.4 Node Reference

When a simple reference to a predefined node is needed in an encapsulating element, a Node element is used with the text content being the node id:

```
<Node>node1</Node>
```

- This element MAY have an aggregation attribute of type String that provides a way to indicate multiple values with a single expression. A compliant implementation MAY support the aggregation attribute if the Feature element is supported. Possible values for this attribute include:
  - List a comma-separated list of features
  - Pattern a regular expression (perl5) matching desired features
  - Range a range of nodes of the form: `<prefix>[5-23,77]`
- If an aggregation attribute is specified with the value of List, this element MAY also have a delimiter attribute of type String that indicates what delimiter is used to separate list elements. The default list delimiter is a comma.

- This element MAY have a count attribute of type Integer that indicates the instance count of the specified node(s).

The following is another example of a Node element:

```
<Node aggregation="Pattern">node[1-5]</Node>
```

## Appendix A

### Units of Measure Abbreviations

Abbreviation	Definition	Quantity
<b>B</b>	byte	1 byte
<b>KB</b>	Kilobyte	2 <sup>10</sup> bytes
<b>MB</b>	Megabyte	2 <sup>20</sup> bytes
<b>GB</b>	Gigabyte	2 <sup>30</sup> bytes
<b>TB</b>	Terabyte	2 <sup>40</sup> bytes
<b>PB</b>	Petabyte	2 <sup>50</sup> bytes
<b>EB</b>	Exabyte	2 <sup>60</sup> bytes
<b>ZB</b>	Aettabyte	2 <sup>70</sup> bytes
<b>YB</b>	Yottabyte	2 <sup>80</sup> bytes
<b>NB</b>	Nonabyte	2 <sup>90</sup> bytes
<b>DB</b>	Doggabyte	2 <sup>100</sup> bytes

## Scalable Systems Software Resource Management and Accounting Protocol (SSSRMAP) Wire Protocol

Resource Management Interface Specs  
 Release v. 3.0.3  
 13 May 2004

Scott Jackson  
 Brett Bode

## Status of This Memo

This is a specification defining a wire level protocol used between Scalable Systems Software components. It is intended that this specification will continue to evolve as these interfaces are implemented and thoroughly tested by time and experience.

## Abstract

This document is a specification describing a connection-oriented XML-based application layer client-server protocol for the interaction of resource management and accounting software components developed as part of the Scalable Systems Software Center. The SSSRMAP Wire Protocol defines a framing protocol that includes provisions for security. The protocol is specified in XML Schema Definition and rides on the HTTP protocol.

## 1.0 Introduction

A major objective of the Scalable Systems Software [SSS] Center is to create a scalable and modular infrastructure for resource management and accounting on terascale clusters including resource

scheduling, grid-scheduling, node daemon support, comprehensive usage accounting and user interfaces emphasizing portability to terascale vendor operating systems. Existing resource management and accounting components feature disparate APIs (Application Programming Interfaces) requiring various forms of application coding to interact with other components.

This document proposes a wire level protocol expressed in an XML envelope to be considered as the foundation of a standard for communications between and among resource management and accounting software components. Individual components additionally need to define the particular XML binding necessary to represent the message format for communicating with the component.

## 2.0 Conventions Used in this Document

### 2.1 Keywords

The keywords **MUST**, **MUST NOT**, **REQUIRED**, **SHALL**, **SHALL NOT**, **SHOULD**, **RECOMMENDED**, **MAY**, and **OPTIONAL** in this document are to be interpreted as described in [RFC2119](#).

### 2.2 XML Case Conventions

In order to enforce a consistent capitalization and naming convention across all SSSRMAP specifications “Upper Camel Case” (UCC) and “Lower Camel Case” (LCC) Capitalization styles shall be used. UCC style capitalizes the first character of each word and compounds the name. LCC style capitalizes the first character of each word except the first word. [XML\_CONV][FED\_XML]

1. SSSRMAP XML Schema and XML instance documents **SHALL** use the following conventions:

- Element names **SHALL** be in UCC convention (example: <UpperCamelCaseElement/>).
- Attribute names **SHALL** be in LCC convention (example: <UpperCamelCaseElement lowerCamelCaseAttribute="Whatever"/>).

2. General rules for all names are:

- Acronyms **SHOULD** be avoided, but in cases where they are used, the capitalization **SHALL** remain (example: XMLSignature).
- Underscores (`_`), periods (`.`) and dashes (`-`) **MUST NOT** be used (example: use JobId instead of JOB.ID, Job\_ID or job-id).

### 2.3 Schema Definitions

SSSRMAP Schema Definitions appear like this

In case of disagreement between the schema file and this specification, the schema file takes precedence.

## 3.0 Encoding

Encoding tells how a message is represented when exchanged. SSSRMAP data exchange messages **SHALL** be defined in terms of XML schema [XML\_SCHEMA].

### 3.1 Schema Header and Namespaces

The header of the schema definition is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<schema
  xmlns="http://www.w3.org/2001/XMLSchema"
  xmlns:sssrmmap="http://www.scidac.org/ScalableSystems/SSSRMAP"
  targetNamespace="http://www.scidac.org/ScalableSystems/SSSRMAP"
  elementFormDefault="qualified">
```

### 3.2 The Envelope Element

SSSRMAP messages and replies are encapsulated in the `Envelope` element. There are two possibilities for the contents of this element. If the contents are unencrypted, this element **MUST** contain a `Body` element and **MAY** contain a `Signature` element (refer to the section on [Security](#)). If the contents are encrypted, this element **MUST** contain exactly one `EncryptedData` element (refer to the section on [Security](#)). The `Envelope` element **MAY** contain namespace and other xsd-specific information necessary to validate the document against the schema. In addition, it **MAY** have any of the following attributes which may serve as processing clues to the parser:

Attribute	Description
<b>type</b>	A message type providing a hint as to the body contents such as “Request” or “Notification”
<b>component</b>	A component type such as “QueueManager” or “LocalScheduler”
<b>name</b>	A component name such as “OpenPBS” or “Maui”
<b>version</b>	A component version such as “2.2p12” or “3.2.2”

```
<complexType name=EnvelopeType">
  <choice minOccurs="1" maxOccurs="1">
    <choice minOccurs="1" maxOccurs="2">
      <element ref="sssrmmap:Signature" minOccurs="0" maxOccurs="1"/>
      <element ref="sssrmmap:Body" minOccurs="1" maxOccurs="1"/>
    </choice>
    <element ref="sssrmmap:EncryptedData" minOccurs="1" maxOccurs="1"/>
  </choice>
  <attribute name="type" type="string" use="optional"/>
  <attribute name="component" type="string" use="optional"/>
  <attribute name="name" type="string" use="optional"/>
  <attribute name="version" type="string" use="optional"/>
</complexType>

<element name="Envelope" type="sssrmmap:EnvelopeType"/>
```

### 3.3 The Body Element

- SSSRMAP messages and replies are encapsulated in the `Body` element. This element **MUST** contain exactly one `Request` or `Response` element.

```
<complexType name="BodyType">
  <choice minOccurs="1" maxOccurs="1">
    <element ref="sssrmap:Request" minOccurs="0" maxOccurs="1"/>
    <element ref="sssrmap:Response" minOccurs="0" maxOccurs="1"/>
    <any minOccurs="0" maxOccurs="1" namespace="##other"/>
  </choice>
</complexType>

<element name="Body" type="sssrmap:BodyType"/>
```

### 4.0 Transport Layer

This protocol will be built over the connection-oriented reliable transport layer TCP/IP. Support for other transport layers could also be considered, but native support for TCP/IP can be found on most terascale clusters and automatically handles issues such as reliability and connection fullness for the application developer implementing the SSSRMAP protocol.

### 5.0 Framing

Framing specifies how the beginning and ending of each message is delimited. Given that the encoding will be expressed as one or more XML documents, clients and servers need to know when an XML document has been fully read in order to be parsed and acted upon.

SSSRMAP uses the HTTP 1.1 [HTTP] protocol for framing. HTTP uses a byte-counting mechanism to delimit the message segments. HTTP chunked encoding is used. This allows for optional support for batched messages, large message segmentation and persistent connections.

#### 5.1 Message Header Requirements

The HTTP request line (first line of the HTTP request header) begins with POST and is followed by a URI and the version of the HTTP protocol that the client understands. It is suggested for this protocol that the URI consist of a single slash, followed by the protocol name in uppercase (i.e. /SSSRMAP), though this field is not checked and could be empty, a single slash or any URI.

The Content-Type must be specified as test/xml. Charset may be optionally specified and defaults to US-ASCII. It is recommended that charset be specified as "utf-8" for maximum interoperability.

The Transfer-Encoding must be specified as chunked. The Content-Length must NOT be specified as the chunk size is specified in the message chunk.

Other properties such as User-Agent, Host and Date are strictly optional.

#### 5.2 Message Chunk Format

A message chunk consists of a chunk size in hexadecimal format (whose value is the number of bytes in the XML message not including the chunk size and delimiter) delimited by a CR/LF "\r\n" and followed

by the message payload in XML that consists of a single XML document having a root element of `Envelope`.

### 5.3 Reply Header Requirements

The HTTP response line (first line of the HTTP response header) begins with HTTP and a version number, followed by a numeric code and a message indicating what sort of response is made. These response codes and messages indicate the status of the entire response and are as defined by the HTTP standard. The most common response is 200 OK, indicating that the message was received and an appropriate response is being returned.

The Content-Type must be specified as `text/xml`. Charset may be optionally specified and defaults to US-ASCII. It is recommended that charset be specified as “utf-8” for maximum interoperability.

The Transfer-Encoding MUST be specified as `chunked`. The Content-Length must NOT be specified.

Other properties such as Server, Host and Date are strictly optional.

### 5.4 Reply Chunk Format

A reply chunk consists of a chunk size in hexadecimal format (whose value is the number of bytes in the XML reply not including the chunk size and delimiter) delimited by a CR/LF “\r\n” and followed by the reply payload in XML that consists of a single XML document having a root element of `Envelope`.

### 5.5 Message and Reply Tail Requirements and Multiple Chunks

This specification only requires that single chunks be supported. A server may optionally be configured to handle requests with persistent connections (multiple chunks). It will be the responsibility of clients to know whether a particular server supports this additional functionality. After all chunks have been sent, a connection is terminated by sending a zero followed by a carriage return-linefeed combination (0\r\n) and closing the connection.

### 5.6 Examples

#### *Sample SSSRMAP Message Embedded in HTTP Request*

```
POST /SSSRMAP HTTP/1.1\r\n
Content-Type: text/xml; charset="utf-8"\r\n
Transfer-Encoding: chunked\r\n
\r\n
9A\r\n
<Envelope .../>
0\r\n
```

#### *Sample SSSRMAP Reply Embedded in HTTP Response*

```
HTTP/1.1 200 OK\r\n
Content-Type: text/xml; charset="utf-8"\r\n
Transfer-Encoding: chunked\r\n
\r\n
2B4\r\n
<Envelope .../>
0\r\n
```

## 6.0 Asynchrony

Asynchrony (or multiplexing) allows for the handling of independent exchanges over the same connection. A widely-implemented approach is to allow pipelining (or boxcarring) by aggregating requests or responses within the body of the message or via persistent connections and chunking in HTTP 1.1. Pipelining helps reduce network latency by allowing a client to make multiple requests of a server, but requires the requests to be processed serially [RFC3117]. Parallelism could be employed to further reduce server latency by allowing multiple requests to be processed in parallel by multi-threaded applications.

Segmentation may become necessary if the messages are larger than the available window. With support for segmentation, the octet-counting requirement that you need to know the length of the whole message before sending it can be relegated to the segment level – and you can start sending segments before the whole message is available. Segmentation is facilitated via “chunking” in HTTP 1.1.

The current SSSRMAP strategy supports only a single request or response within the Body element. A server may optionally support persistent connections from a client via HTTP chunking. Segmentation of large responses is also optionally supported via HTTP chunking. Later versions of the protocol could allow pipelined requests and responses in a single Body element.

## 7.0 Security

SSSRMAP security features include capabilities for integrity, authentication, confidentiality, and non-repudiation. The absence or presence of the various security features depend upon the type of security token used and the protection methods you choose to specify in the request.

For compatibility reasons, SSSRMAP specifies six supported security token types. Extensibility features are included allowing an implementation to use alternate security algorithms and security tokens. It is also possible for an implementation to ignore security features if it is deemed nonessential for the component. However, it is highly RECOMMENDED that an implementation support at least the default security token type in both authentication and encryption.

### 7.1 Security Token

A security token may be included in either the Signature block, and/or in the EncryptedData block (both described later) as an implicit or explicit cryptographic key. If this element is omitted, the security token is assumed to be a secret key shared between the client and the server.

#### *The SecurityToken Element*

This element is of type String. If the security token conveys an explicit key, this element’s content is the value of the key. If the key is natively expressed in a binary form, it must be converted to base64 encoding as defined in XML Digital Signatures (“<http://www.w3.org/2000/09/xmldsig#base64>”). If the type is not specified, it is assumed to be of type “Symmetric”.

It may have any of the following optional attributes:

Attribute	Description
<b>type</b>	<p>The type of security token (described subsequently)</p> <ul style="list-style-type: none"> <li>• A <code>type</code> attribute of “Symmetric” specifies a shared secret key between the client and server. This is the default.</li> <li>• A <code>type</code> attribute of “Asymmetric” specifies the use of public private key pairs between the client and server.</li> <li>• A <code>type</code> attribute of “Password” encrypts and authenticates with a user password known to both the client and server.</li> <li>• A <code>type</code> attribute of “Cleartext” allows the passing of a cleartext username and password and depends on the use of a secure transport (such as SSL or IPsec).</li> <li>• A <code>type</code> attribute of “Kerberos5” specifies a kerberos token.</li> <li>• A <code>type</code> attribute of “X509v3” specifies an X.509 certificate.</li> </ul>
<b>name</b>	<p>The name of the security token which serves as an identifier for the actor making the request (useful when the key is a password, or when the key value is implicit as when a public key is named but not included)</p>

```

<complexType name="SecurityTokenType" mixed="true">
  <simpleContent>
    <extension base="string">
      <attribute name="type" type="string" use="optional">
        <attribute name="name" type="string" use="optional">
        </extension>
      </simpleContent>
    </complexType>
  </complexType>

<element name="SecurityToken" type="sssrmap:SecurityTokenType"/>

```

## Security Token Types

SSSRMAP defines six standard security token types:

### Symmetric Key

The default security token specifies the use of a shared secret key. The secret key is up to 128-bits long and known by both client and server. When using a symmetric key as a security token, it is not necessary to specify the `type` attribute with value “Symmetric” because this is assumed when the attribute is absent. The `name` attribute should be specified indicating the actor issuing the request. If the user provides a password to be sent to the server for authentication, then the password is encrypted with the secret key using a default `method="kw-tripledes"` (XML ENCRYPTION <http://www.w3.org/2001/04/xmlenc#kw-tripledes>), base64 encoded and included as the string content of the `SecurityToken` element. If the client authenticated the user, then the `SecurityToken` element is empty. The same symmetric key is used in both authentication and encryption.

### Asymmetric Key

Public and private key pairs can be used to provide non-repudiation of the client (or server). The client and the server must each have their own asymmetric key pairs. This mode is indicated by specifying the `type` attribute as “Asymmetric”. The `name` attribute should be specified indicating the actor issuing the request. If the user provides a password to be sent to the server for authentication, then the password is

encrypted with the server's public key using a default `method="rsa-1_5"` (XML ENCRYPTION [http://www.w3.org/2001/04/xmlenc#rsa-1\\_5](http://www.w3.org/2001/04/xmlenc#rsa-1_5)), base64 encoded and included as the string content of the `SecurityToken` element. If the client authenticated the user, then the `SecurityToken` element is empty. The sender's private key is used in authentication (signing) while the recipient's public key is used for encryption.

### Password

This mode allows for a username password combination to be used under the assumption that the server also knows the password for the user. This security token type is indicated by specifying a value of "Password" for the `type` attribute. The password itself is used as the cryptographic key for authentication and encryption. The `name` attribute contains the user name of the actor making the request. The `SecurityToken` element itself is empty.

### Cleartext

This security mode is equivalent to passing the username and password in the clear and depends upon the use of a secure transport (such as SSL or IPsec). The purpose of including this security token type is to enable authentication to occur from web browsers over SSL or over internal LANs who use IPsec to encrypt all traffic. The password (or a hash of the password like in `/etc/passwd`) would have to be known by the server for authentication to occur. In this mode, neither encryption nor signing of the hash is performed at the application layer. This mode is indicated by specifying a value of "Cleartext" for the `type` attribute. The `name` attribute contains the user name of the actor making the request and the string content of the `SecurityToken` element is the unencrypted plaintext password.

### Kerberos

The use of a Kerberos version 5 token is indicated by specifying "Kerberos5" in the `type` attribute. The `name` attribute is used to contain the kerberos user id of the actor making the request. The `SecurityToken` element contains two sub elements. The `Authenticator` element contains the authenticator encoded in base64. A `Ticket` element contains the service-granting ticket, also base64 encoded.

### GSI (X.509)

The Grid Security Infrastructure (GSI) which is based on public key encryption, X.509 certificates, and the Secure Sockets Layer (SSL) communication protocol can be indicated by specifying a `type` attribute of "X509v3". The `name` attribute contains the userid used that the actor was mapped to in the local system. The string content of the `SecurityToken` element is the GSI authentication message including the X.509 identity of the sender encoded in base64.

### Example

```
<SecurityToken type="Asymmetric" name="scottmo">
MIIEZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
</SecurityToken>
```

## 7.2 Authentication

Authentication entails how the peers at each end of the connection are identified and verified. Authentication is optional in an SSSRMAP message or reply. SSSRMAP uses a digital signature scheme for authentication that borrows from concepts in XML Digital Signatures [XML\_DSIG]. In addition to

authentication, the use of digital signatures also ensures integrity of the message, protecting exchanges from third-party modification.

When authentication is used, a `Signature` element is prepended as the first element within the `Envelope` element. All of the security modes will create a digest of the data for integrity checking and store this in base64 encoding in a `DigestValue` element as a child of the `Signature` element. The digital signature is created by encrypting the hash with the appropriate security token and storing this value in a `SignatureValue` element as a child of the `Signature` element. The security token itself is included as a child of the `Security` element within a `SecurityToken` element.

There are a number of procedural practices that must be followed in order to standardize this approach. The digest (or hash) is created over the contents of the `Envelope` element (not including the `Element` tag or its attributes). This might be over one or more `Request` or `Notify` elements (or `Response` or `Ack` elements) and necessarily excludes the `Signature` Element itself. (Note that any data encryption is performed after the creation of the digital signature and any decryption is performed before authenticating so the `EncryptedData` element will not interfere with this process. Hence, the signature is always based on the (hashed but) unencrypted data). For the purposes of generating the digest over the same value, it is assumed that the data is first canonicalized to remove extraneous whitespace, comments, etc according to the XML Digital Signature algorithm ("<http://www.w3.org/TR/2001/REC-xml-c14n-20010315>") and a transform is applied to remove namespace information. As a rule, any binary values are always transformed into their base64 encoded values when represented in XML.

### The Signature Element

The `Signature` element **MUST** contain a `DigestValue` element that is used for integrity checking. It **MUST** also contain a `SecurityToken` element that is used to indicate the security mode and token type, and to verify the signature. It **MUST** contain a `SignatureValue` element that contains the base64 encrypted value of the signature wrought on the hash **UNLESS** the security token type indicates `Cleartext` mode where a signature would be of no value with the encryption key being sent in the clear -- in this case we use the password itself for authentication).

```
<complexType name="SignatureType">
  <choice minOccurs="2" maxOccurs="3">
    <element ref="sssrmmap:DigestValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmmap:SignatureValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssrmmap:SecurityToken" minOccurs="0" maxOccurs="1"/>
  </choice>
</complexType>

<element name="Signature" type="sssrmmap:SignatureType"/>
```

### The DigestValue Element

The `DigestValue` element contains the cryptographic digest of the message data. As described above, the hash is generated over the `Body` element. The data to be hashed must first be canonicalized and appropriately transformed before generating the digest since typically an application will read in the XML document into an internal binary form, then marshal (or serialize) the data into a string which is passed as input to the hash algorithm. Different implementations marshal the data differently so it is necessary to convert this to a well-defined format before generating the digest or the clients will generate different digest values for the same XML. The SHA-1 [SHA-1] message digest algorithm (<http://www.w3.org/2000/09/xmldsig#sha1>) SHALL be used as the default method for generating the

digest. A *method* attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate message digest algorithms.

It MAY have a method attribute:

Attribute	Description
<b>method</b>	The message digest algorithm. <ul style="list-style-type: none"> <li>A <i>method</i> attribute of “sha1” specifies the SHA-1 message digest algorithm. This is the default and is implied if this attribute is omitted.</li> </ul>

```
<complexType name="DigestValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="DigestValue" type="sssrmap:DigestValueType"/>
```

### The SignatureValue Element

The SignatureValue element contains the digital signature that serves the authentication (and potentially non-repudiation) function. The string content of the SignatureValue element is a base64 encoding of the encrypted digest value. The HMAC algorithm [HMAC] based on the SHA1 message digest (<http://www.w3.org/2000/09/xmldsig#hmac-sha1>) SHALL be used as the default message authentication code algorithm for user identification and message integrity. A *method* attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate digital signature algorithms.

It MAY have a method attribute:

Attribute	Description
<b>method</b>	The digest signature algorithm. <ul style="list-style-type: none"> <li>A <i>method</i> attribute of “hmac-sha1” specifies the HMAC SHA-1 digital signature algorithm. This is the default and is implied if this attribute is omitted.</li> </ul>

```
<complexType name="SignatureValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="SignatureValue" type="sssrmap:SignatureValueType"/>
```

### Signature Example

Pre-authentication:

```

<Envelope>
  <Body>
    <Request action="Query" actor="kenneth">
      <Object>User</Object>
      <Get name="EmailAddress"></Get>
      <Where name="Name">scott</Where>
    </Request>
  </Body>
</Envelope>

```

#### Post-authentication:

```

<Envelope>
  <Signature>
    <DigestValue>
      LyLsF0Pi4wPU...
    </DigestValue>
    <SignatureValue>
      DJbchm5gK...
    </SignatureValue>
    <SecurityToken type="Asymmetric" name="kenneth">
      MIIEZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
    </SecurityToken>
  </Signature>
  <Body>
    <Request action="Query" actor="kenneth">
      <Object>User</Object>
      <Get name="EmailAddress"></Get>
      <Where name="Name">scottmo</Where>
    </Request>
  </Body>
</Envelope>

```

## 7.3 Confidentiality

Confidentiality involves encrypting the sensitive data in the message, protecting exchanges against third-party interception and modification. Confidentiality is optional in an SSSRMAP message or reply. When confidentiality is required, SSSRMAP sessions use block cipher encryption with concepts borrowed from the emerging XML Encryption [XML\_ENC] standard.

When confidentiality is used, encryption is performed over all child elements of the `Envelope` element, i.e. on the message data as well as any signature (The encrypted data is not signed -- rather the signature is encrypted). This data is replaced in-place within the envelope with an `EncryptedData` element. The data is first compressed using the gzip algorithm [ZIP]. Instead of encrypting this compressed data with the security token directly, a 192-bit random session key is generated by the sender and used to perform symmetric encryption on the compressed data. This key is itself encrypted with the security token and included with the encrypted data as the value of the `EncryptedKey` element as a child of the `EncryptedData` element. The ciphertext resulting from the data being encrypted with the session key is passed as the value of a `CipherValue` element (also a child of the `EncryptedData` element). As in the case with authentication, the security token itself is included as a child of the `Security` element within a `SecurityToken` element.

### The EncryptedData Element

When SSSRMAP confidentiality is required, the EncryptedData element MUST appear as the only child element in the Envelope element. It directly replaces the contents of these elements including the data and any digital signature. It MUST contain an EncryptedKey element that is used to encrypt the data. It MUST contain a CipherValue element that holds the base64 encoded ciphertext. It MAY also contain a SecurityToken element that is used to indicate the security mode and token type. If the SecurityToken element is omitted, a Symmetric key token type is assumed. Confidentiality is not used when a security token type of "Cleartext" is specified since it would be pointless to encrypt the data with the encryption key in the clear.

```
<complexType name="EncryptionDataType">
  <choice minOccurs="0" maxOccurs="1">
    <element ref="sssmap:EncryptedKey" minOccurs="1" maxOccurs="1"/>
    <element ref="sssmap:CipherValue" minOccurs="1" maxOccurs="1"/>
    <element ref="sssmap:SecurityToken" minOccurs="1" maxOccurs="1"/>
  </choice>
</complexType>

<element name="EncryptedData" type="sssmap:EncryptionDataType"/>
```

### The EncryptedKey Element

The EncryptedKey element is a random session key encrypted with the security token. This approach is used for a couple of reasons. In the case where public key encryption is used, asymmetric encryption is much slower than symmetric encryption and it makes sense to use a symmetric key for encryption and pass along it along by encrypting it with the recipient’s public key. It is also useful in that the security token which does not change very often (compared to the session key which changes for every connection) is used on a very small sampling of data (the session key), whereas if it was used to encrypt the whole message an attacker could more effectively exploit an attack against the ciphertext. The CMS Triple DES Key Wrap algorithm “kw-tripledes” SHALL be used as the default method for key encryption. The session key is encrypted using the security token, base64 encoded and specified as the string content of the EncryptedKey element. A method attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate key encryption algorithms.

It is REQUIRED that an implementation use a cryptographically secure Pseudo-Random number generator. It is RECOMMENDED that the session key be cryptographically generated (such as cyclic encryption, DES OFB, ANSI X9.17 PRNG, SHA1PRNG, or ANSI X12.17 (used by PGP)).

It MAY have a method attribute:

Attribute	Description
<b>method</b>	<p>The key encryption algorithm.</p> <ul style="list-style-type: none"> <li>A method attribute of “kw-tripledes” specifies the CMS Triple DES Key Wrap algorithm. This algorithm is specified by the XML Encryption [XML_ENC] URI “http://www.w3.org/2001/04/xmlenc#kw-tripledes”. It involves two Triple DES encryptions, a random and known Initialization Vector (IV) and a CMS key checksum. A 192-bit key encryption key is generated from the security token, lengthened as necessary by zero-padding. No additional padding is performed in the encryptions. This is the default and is implied if this attribute is omitted.</li> </ul>

```

<complexType name="EncryptedKeyType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="EncryptedKey" type="sssrmmap:EncryptedKeyType"/>

```

### The CipherValue Element

The CipherValue element contains the message (and possibly signature) data encrypted with the random session key. The ciphertext is compressed using the gzip algorithm [ZIP], encrypted by the designated method, base64 encoded and included as the string content of the CipherValue element. The Triple DES algorithm with Cipher Block Chaining (CBC) feedback mode SHALL be used as the default method for encryption. A *method* attribute is defined as an extensibility option in case an implementation wants to be able to specify alternate data encryption algorithms.

It MAY have a method attribute:

Attribute	Description
<b>method</b>	<p>The data encryption algorithm.</p> <ul style="list-style-type: none"> <li>A <i>method</i> attribute of "tripleDES-cbc" specifies the Triple DES algorithm with Cipher Block Chaining (CBC) feedback mode. This algorithm is specified by the XML Encryption [XML_ENC] URI identifier "<a href="http://www.w3.org/2001/04/xmlenc#tripleDES-cbc">http://www.w3.org/2001/04/xmlenc#tripleDES-cbc</a>". It specifies the use of a 192-bit encryption key and a 64-bit Initialization Vector (IV). Of the key bits, the first 64 are used in the first DES operation, the second 64 bits in the middle DES operation, and the third 64 bits in the last DES operation. The plaintext is first padded to a multiple of the block size (8 octets) using the padding scheme described in [XML_ENC] for Block Encryption Algorithms (Padding per PKCS #5 will suffice for this). The resulting cipher text is prefixed by the IV. This is the default and is implied if this attribute is omitted.</li> </ul>

```

<complexType name="CipherValueType">
  <simpleContent>
    <extension base="string">
      <attribute name="method" type="string" use="optional"/>
    </extension>
  </simpleContent>
</complexType>

<element name="CipherValue" type="sssrmmap:CipherValueType"/>

```

### Encryption Example

In this example, a simple request is demonstrated without a digital signature for the sake of emphasizing the encryption plaintext replacement.

Pre-encryption:

```

<Envelope>
  <Body>
    <Response>
      <Status>true</Status>
      <Code>000</Code>
      <Count>1</Count>
      <Data>
        <User>
          <EmailAddress>Scott.Jackson@pnl.gov</EmailAddress>
        </User>
      </Data>
    </Response>
  </Body>
</Envelope>

```

#### Post-encryption:

```

<Envelope>
  <EncryptedData>
    <EncryptedKey>
      NAKe9iQofYhyOfiHZ29kkEFVJ30CAwEAAaMSM...
    </EncryptedKey>
    <CipherValue>
      mPCadVfOMx1NzDaKMHNgFkR9upTW4kgBxyPW...
    </CipherValue>
    <SecurityToken type="Asymmetric" name="kenneth">
      MIIEZzCCA9CggAwIBAgIQEmtJZc0rqrKh5i...
    </SecurityToken>
  </EncryptedData>
</Envelope>

```

## Appendix W: Moab Resource Manager Language Interface Overview

The Moab RM Language (formerly called WIKI) is the language that some resource managers use to communicate with Moab, specifically a native RM. Generally each line represents a single resource or workload in Moab. The line contains the name of the resource or workload followed by a set of `<attr>=<val>` pairs. Although the Moab RM language follows the same data format for all RMs, each RM type receives and returns it differently. For instructions and examples on using Moab RM language with SLURM or a native RM, see [W.2 Managing Resources with SLURM on page 1372](#) and [Managing Resources Directly with the Native Interface on page 650](#) respectively.

### W.1 Moab Resource Manager Language Data Format

- [W.1.1 Query Resources Data Format](#)
- [W.1.2 Query Workload Data Format](#)

#### W.1.1 Query Resources Data Format

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>ADISK</b>	<code>&lt;INTEGER&gt;</code>	0	Available local disk on node (in MB)
<b>AFS</b>	<code>&lt;fs id="X" size="X" io="Y" rcount="X" wcount="X" ocoun- t="X"&gt;&lt;/fs&gt; [...]</code>	0	Available filesystem state

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>AMEMORY</b>	<INTEGER>	0	Available/free RAM on node (in MB)
<b>APROC</b>	<INTEGER>	1	Available processors on node
<b>ARCH</b>	<STRING>	---	Compute architecture of node
<b>ARES</b>	one or more comma delimited <NAME>: <VALUE> pairs (ie, MATLAB: 6, COMPILER: 100)	---	Arbitrary consumable resources currently available on the node
<b>ASWAP</b>	<INTEGER>	0	Available swap on node (in MB)
<b>CCLASS</b>	one or more bracket enclosed <NAME>: <COUNT> pairs (ie, [batch:5] [sge:3])	---	Run classes supported by node. Typically, one class is 'consumed' per task. Thus, an 8 processor node may have 8 instances of each class it supports present, ie [batch:8] [interactive:8]
<b>CDISK</b>	<INTEGER>	0	Configured local disk on node (in MB)
<b>CFS</b>	<STRING>	0	Configured filesystem state
<b>CMEMORY</b>	<INTEGER>	0	Configured RAM on node (in MB)
<b>CONTAINERNODE</b>	<STRING>	---	The physical machine that is host- ing the virtual machine. Only valid on VMs.
<b>CPROC</b>	<INTEGER>	1	Configured processors on node
<b>CPULOAD</b>	<DOUBLE>	0.0	One minute BSD load average
<b>CPUSPEED</b>	<INTEGER>	---	The node's processor speed in MHz

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>CRES</b>	one or more comma delimited <NAME>: <VALUE> pairs (ie, MATLAB:6, COMPILER:100)	---	Arbitrary consumable resources supported and tracked on the node, ie software licenses or tape drives
<b>CSWAP</b>	<INTEGER>	0	Configured swap on node (in MB)
<b>FEATURE</b>	one or more colon delimited <STRING>'s (ie, WIDE:HSM)	---	Generic attributes, often describing hardware or software features, associated with the node
<b>GEVENT</b>	GEVENT [ <EVENTNAME> ] = <STRING>	---	<a href="#">Generic event</a> occurrence and context data
<b>GMETRIC</b>	GMETRIC [ <METRICNAME> ] = <DOUBLE>	---	Current value of <a href="#">generic metric</a> , i.e., 'GMETRIC [temp]=103.5'.
<b>IDLETIME</b>	<INTEGER>	---	Number of seconds since last detected keyboard or mouse activity (often used with <a href="#">desktop harvesting</a> )
<b>MAXTASK</b>	<INTEGER>	<CPROC>	Maximum number of tasks allowed on the node at any given time
<b>NETADDR</b>	<STRING>	---	The IP address of the machine
<b>NODEINDEX</b>	<INTEGER>	---	The <a href="#">node's index</a>
<b>OS</b>	<STRING>	---	Operating system running on node
<b>OSLIST</b>	One or more comma delimited <STRING>'s with quotes if the string has spaces (ie. "SAS7 AS3 Core Baseline Build v0.1.0", "RedHat AS3-U5Development Build v0.2").	---	Operating systems accepted by node

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>OTHER</b>	<ATTR>=<VALUE> [, <ATTR>=<VALUE>] . . .	---	Opaque node attributes assigned to node
<b>PARTITION</b>	<STRING>	DEFAULT	Partition to which node belongs
<b>POWER</b>	<BOOLEAN>		Whether the machine is on or off
<b>PRIORITY</b>	<INTEGER>	---	<a href="#">Node allocation priority</a>
<b>RACK</b>	<INTEGER>	0	Rack location of the node
<b>SLOT</b>	<INTEGER>	0	Slot location of the node
<b>STATE*</b>	one of the following: Idle, Running, Busy, Unknown, Drained, Draining, or Down	Down	State of the node
<b>UPDATETIME*</b>	<EPOCHTIME>	0	Time node information was last updated
<b>VARATTR</b>	<ATTR1>=<VAL1>[=<display- name1>] [+<ATTR2>=<VAL2> [=<display- name2>]] . . .	---	<p>Plus-delimited (+) list of &lt;ATTR&gt;=&lt;VAL&gt; [=&lt;displayName&gt;] pairs that jobs can request. You can replace any of the equals signs with colons if desired.</p> <p>Specifying a display name allows you to choose a name that will be displayed in the Mongo database instead of the unique ID (the &lt;VALUE&gt;).</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> If you give two different attributes the same value and one of them also has a display name specified, both attributes will appear with the same display name.</p> </div>
<b>VARIABLE</b>	<ATTR>=<VAL>	---	Generic variables to be associated with node

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>VMOSLIST</b>	<STRING>	---	Comma-delimited list (,) of supported virtual machine operating systems for this node
<b>XRES</b>	one or more comma delimited <NAME>: <VALUE> pairs (ie, MATLAB:6, COMPILER:100)	---	Amount of external usage of a particular generic resource

\* indicates required field

Node states have the following definitions:

State	Description
<b>Busy</b>	Node is running some jobs and will not accept additional jobs
<b>Down</b>	Resource Manager problems have been detected. Node is incapable of running jobs.
<b>Draining</b>	Node is responding but will not accept new jobs
<b>Idle</b>	Node is ready to run jobs but currently is not running any.
<b>Running</b>	Node is running some jobs and will accept additional jobs
<b>Unknown</b>	Node is capable of running jobs but the scheduler will need to determine if the node state is actually Idle, Running, or Busy.

## W.1.2 Query Workload Data Format

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>ACCOUNT</b>	<STRING>	---	AccountID associated with job
<b>ARGS</b>	<STRING>	---	job command-line arguments
<b>COMMENT</b>	<STRING>	0	job <a href="#">resource manager extension</a> arguments including qos, dependencies, reservation constraints, etc
<b>COMPLETETIME*</b>	<EPOCHTIME>	0	time job completed execution

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>DDISK</b>	<INTEGER>	0	quantity of local disk space (in MB) which must be dedicated to each task of the job
<b>DGRES</b>	name:value [,name:value]	---	Dedicated generic resources per task.
<b>DPROCS</b>	<INTEGER>	1	number of processors dedicated per task
<b>DSWAP</b>	<INTEGER>	0	quantity of virtual memory (swap, in MB) which must be dedicated to each task of the job
<b>ENDDATE</b>	<EPOCHTIME>	[ANY]	time by which job must complete
<b>ENV</b>	<STRING>	---	job environment variables
<b>ERROR</b>	<STRING>	---	file to contain STDERR
<b>EVENT</b>	<EVENT>	---	event or exception experienced by job
<b>EXEC</b>	<STRING>	---	job executable command
<b>EXITCODE</b>	<INTEGER>	---	job exit code
<b>FLAGS</b>	<STRING>	---	job flags
<b>GEOMETRY</b>	<STRING>	---	String describing task geometry required by job
<b>GNAME*</b>	<STRING>	---	GroupID under which job will run

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>HOSTLIST</b>	comma or colon delimited list of hostnames - suffix the hostlist with a caret (^) to mean superset; suffix with an asterisk (*) to mean subset; otherwise, the hostlist is interpreted as an exact set	[ANY]	list of required hosts on which job must run. (see <a href="#">TASKLIST</a> ) A subset means the specified hostlist is used first to select hosts for the job. If the job requires more hosts than are in the hostlist, they will be obtained from elsewhere if possible. If the job does not require all of the jobs in the hostlist, it will use only the ones it needs. A superset means the hostlist is the <i>only</i> source of hosts that should be considered for running the job. If the job can't find the necessary resources in the hosts in this list it should <i>not</i> run. No other hosts should be considered in allocating the job.
<b>INPUT</b>	<STRING>	---	file containing STDIN
<b>IWD</b>	<STRING>	---	job's initial working directory
<b>NAME</b>	<STRING>	---	User specified name of job
<b>NODES</b>	<INTEGER>	1	Number of nodes required by job (See <a href="#">Node Definition</a> for more info)
<b>OUTPUT</b>	<STRING>	---	file to contain STDOUT
<b>PARTITIONMASK</b>	one or more colon delimited <STRING>s	[ANY]	list of partitions in which job can run
<b>PREF</b>	colon delimited list of <STRING>s	---	List of preferred node features or variables. (See <a href="#">PREF</a> for more information.)
<b>PRIORITY</b>	<INTEGER>	---	system priority (absolute or relative - use '+' and '-' to specify relative)
<b>QOS</b>	<INTEGER>	0	quality of service requested
<b>QUEUETIME*</b>	<EPOCHTIME>	0	time job was submitted to resource manager
<b>RARCH</b>	<STRING>	---	architecture required by job

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>RCLASS</b>	list of bracket enclosed <STRING> :<INTEGER> pairs	---	list of <CLASSNAME>:<COUNT> pairs indicating type and number of class instances required per task. (ie, [batch:1] or [batch:2] [tape:1])
<b>RDISK</b>	<INTEGER>	0	local disk space (in MB) required to be configured on nodes allocated to the job
<b>RDISKCMP</b>	one of >=, >, ==, <, or <=	>=	local disk comparison (ie, node must have > 2048 MB local disk)
<b>REJCODE</b>	<INTEGER>	0	reason job was rejected
<b>REJCOUNT</b>	<INTEGER>	0	number of times job was rejected
<b>REJMESSAGE</b>	<STRING>	---	text description of reason job was rejected
<b>REQRSV</b>	<STRING>	---	Name of reservation in which job must run
<b>RESACCESS</b>	<STRING>	---	List of reservations in which job can run
<b>RFEATURES</b>	colon delimited list <STRING>'s	---	List of features required on nodes
<b>RMEM</b>	<INTEGER>	0	real memory (RAM, in MB) required to be configured on nodes allocated to the job
<b>RMEMCMP</b>	one of '>=', '>', '==', '<', or '<='	>=	real memory comparison (ie, node must have >= 512MB RAM)
<b>ROPSYS</b>	<STRING>	---	operating system required by job
<b>RSOFTWARE</b>	<RESTYPE>[{:+}] <COUNT>] [@<TIMEFRAME>]	---	software required by job
<b>RSWAP</b>	<INTEGER>	0	virtual memory (swap, in MB) required to be configured on nodes allocated to the job

NAME	FORMAT	DEFAULT	DESCRIPTION
<b>RSWAPCMP</b>	one of '>=', '>', '==', '<', or '<='	>=	virtual memory comparison (ie, node must have ==4096 MB virtual memory)
<b>SID</b>	<STRING>	---	system id (global job system owner)
<b>STARTDATE</b>	<EPOCHTIME>	0	earliest time job should be allowed to start
<b>STARTTIME*</b>	<EPOCHTIME>	0	time job was started by the resource manager
<b>STATE*</b>	one of <a href="#">Idle</a> , Running, Hold, Suspended, Completed, or Removed	Idle	State of job
<b>SUSPENDTIME</b>	<INTEGER>	0	Number of seconds job has been suspended
<b>TASKLIST</b>	one or more comma-delimited <STRING>'s	---	list of <b>allocated</b> tasks, or in other words, comma-delimited list of node ID's associated with each active task of job (i.e., cl01, cl02, cl01, cl02, cl03) The tasklist is initially selected by the scheduler at the time the StartJob command is issued. The resource manager is then responsible for starting the job on these nodes and maintaining this task distribution information throughout the life of the job. (see <a href="#">HOSTLIST</a> )
<b>TASKS*</b>	<INTEGER>	1	Number of tasks required by job (See <a href="#">Task Definition</a> for more info)
<b>TASKPERNODE</b>	<INTEGER>	0	exact number of tasks required per node
<b>UNAME*</b>	<STRING>	---	UserID under which job will run
<b>UPDATETIME*</b>	<EPOCHTIME>	0	Time job was last updated
<b>WCLIMIT*</b>	[[HH:]MM:]SS	864000	walltime required by job

\* indicates required field

Job states have the following definitions:

State	Definition
<b>Completed</b>	Job has completed
<b>Hold</b>	Job is in the queue but is not allowed to run
<b>Idle</b>	Job is ready to run
<b>Removed</b>	Job has been canceled or otherwise terminated externally
<b>Running</b>	Job is currently executing
<b>Suspended</b>	job has started but execution has temporarily been suspended

**i** Completed and canceled jobs should be maintained by the resource manager for a brief time, perhaps 1 to 5 minutes, before being purged. This provides the scheduler time to obtain all final job state information for scheduler statistics.

## W.2.1 Commands

All commands are requested via a socket interface, one command per socket connection. All fields and values are specified in ASCII text.

Supported Commands are:

- [Query Resources](#)
- [Query Workload](#)
- [Start Job](#)
- [Cancel Job](#)
- [Suspend Job](#)
- [Resume Job](#)
- [Requeue Job](#)
- JOBADDTASK
- JOBRELEASETASK

### W.2.1.1 Moab RM Language Query Resources

#### W.2.1.1.1 Moab RM Language Query Resources Request Format

```
CMD=GETNODES ARG={ <UPDATETIME>:<NODEID>[:<NODEID>] . . . | <UPDATETIME>:ALL }
```

Only nodes updated more recently than *<UPDATETIME>* will be returned where *<UPDATETIME>* is specified as the epoch time of interest. Setting *<UPDATETIME>* to 0 will return information for all nodes. Specify a colon delimited list of *NODEIDs* if specific nodes are desired or use the keyword *ALL* to receive information for all nodes.

#### W.2.1.1.2 Moab RM Language Resources Response Format

The query resources response format is one or more line of the following format (separated with a new line):

```
<NODEID><ATTR>=<VALUE>[ ; <ATTR>=<VALUE>] . . .
```

*<ATTR>* is one of the names in the [table below](#) and the format of *<VALUE>* is dependent on *<ATTR>*.

**Example 3-184: Moab RM language resource query and response****Request:**

```
CMD=GETNODES ARG=0:node001:node002:node003
```

**Response:**

```
node001 UPDATETIME=963004212;STATE=Busy;OS=AIX43;ARCH=RS6000...
node002 UPDATETIME=963004213;STATE=Busy;OS=AIX43;ARCH=RS6000...
...
```

**W.2.1.2 Moab RM Language Query Workload****W.2.1.2.1 Moab RM Language Query Workload Request Format**

```
CMD=GETJOBS ARG={<UPDATETIME>:<JOBID>[:<JOBID>]... | <UPDATETIME>:ALL }
```

Only jobs updated more recently than *<UPDATETIME>* will be returned where *<UPDATETIME>* is specified as the epoch time of interest. Setting *<UPDATETIME>* to 0 will return information for all jobs. Specify a colon delimited list of *JOBID*'s if information for specific jobs is desired or use the keyword *ALL* to receive information about all jobs.

**W.2.1.2.2 Moab RM Language Query Workload Response Format**

```
SC=<STATUSCODE> ARG=<JOBCOUNT>#<JOBID>:<FIELD>=<VALUE>; [ <FIELD>=<VALUE>; ] ...
[ #<JOBID>:<FIELD>=<VALUE>; [ <FIELD>=<VALUE>; ] ... ] ...
```

or

```
SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*FIELD* is either the text name listed below or A<*FIELDNUM*>  
(ie, UPDATETIME or A2)

*STATUSCODE* values:

- 0 SUCCESS
- -1 INTERNAL ERROR

*RESPONSE* is a statuscode sensitive message describing error or state details.

**W.2.1.2.3 Moab RM Language Query Workload Example****Request:**

```
CMD=GETJOBS ARG=0:ALL
```

**Response:**

```
ARG=2#nebo3001.0:UPDATETIME=9780000320;STATE=Idle;WCLIMIT=3600;...
```

### W.2.1.3 StartJob

The `StartJob` command may only be applied to jobs in the `Idle` state. It causes the job to begin running using the resources listed in the `NodeID` list.

```
send CMD=STARTJOB ARG=<JOBID> TASKLIST=<NODEID>[:<NODEID>]...
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

`STATUSCODE`  $\geq 0$  indicates SUCCESS

`STATUSCODE`  $< 0$  indicates FAILURE

`RESPONSE` is a text message possibly further describing an error or state

*Example 3-185: Job start*

```
# Start job nebo.1 on nodes cluster001 and cluster002
# send
CMD=STARTJOB ARG=nebo.1 TASKLIST=cluster001:cluster002
# receive
SC=0;RESPONSE=job nebo.1 started with 2 tasks
```

### W.2.1.4 CancelJob

The `CancelJob` command, if applied to an active job, will terminate its execution. If applied to an idle or active job, the `CancelJob` command will change the job's state to `Canceled`.

```
send CMD=CANCELJOB ARG=<JOBID> TYPE=<CANCELTYPE>
```

`<CANCELTYPE>` is one of the following:

ADMIN (command initiated by scheduler administrator)

WALLCLOCK (command initiated by scheduler because job exceeded its specified wallclock limit)

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

`STATUSCODE`  $\geq 0$  indicates SUCCESS

`STATUSCODE`  $< 0$  indicates FAILURE

`RESPONSE` is a text message further describing an error or state

*Example 3-186: Job cancel*

```
# Cancel job nebo.2
# send
CMD=CANCELJOB ARG=nebo.2 TYPE=ADMIN'
# receive
SC=0 RESPONSE=job nebo.2 canceled
```

### W.2.1.5 SuspendJob

The `SuspendJob` command can only be issued against a job in the state `Running`. This command [suspends](#) job execution and results in the job changing to the `Suspended` [state](#).

```
send CMD=SUSPENDJOB ARG=<JOBID>
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE* >= 0 indicates SUCCESS

*STATUSCODE* < 0 indicates FAILURE

*RESPONSE* is a text message possibly further describing an error or state

*Example 3-187: Job suspend*

```
# Suspend job nebo.3
# send
CMD=SUSPENDJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 suspended
```

### W.2.1.6 ResumeJob

The `ResumeJob` command can only be issued against a job in the state `Suspended`. This command resumes a suspended job returning it to the `Running` state.

```
send CMD=RESUMEJOB ARG=<JOBID>
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE* >= 0 indicates SUCCESS

*STATUSCODE* < 0 indicates FAILURE

*RESPONSE* is a text message further describing an error or state

*Example 3-188: Job resume*

```
# Resume job nebo.3
# send
CMD=RESUMEJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 resumed
```

### W.2.1.7 RequeueJob

The `RequeueJob` command can only be issued against an active job in the state `Starting` or `Running`. This command [requeues](#) the job, stopping execution and returning the job to an idle [state](#) in the queue. The queued job will be eligible for execution the next time resources are available.

```
send CMD=REQUEUEJOB ARG=<JOBID>
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE* >= 0 indicates SUCCESS

*STATUSCODE* < 0 indicates FAILURE

*RESPONSE* is a text message further describing an error or state

**Example 3-189: job requeue**

```
# Requeue job nebo.3
# send
CMD=REQUEUEJOB ARG=nebo.3
# receive
SC=0 RESPONSE=job nebo.3 requeued
```

**W.2.1.8 SignalJob**

The `SignalJob` command can only be issued against an active job in the state `Starting` or `Running`. This command signals the job, sending the specified signal to the master process. The signaled job will remain in the same state it was before the signal was issued.

```
send CMD=SIGNALJOB ARG=<JOBID> ACTION=signal VALUE=<SIGNAL>
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE*  $\geq 0$  indicates SUCCESS

*STATUSCODE*  $< 0$  indicates FAILURE

*RESPONSE* is a text message further describing an error or state

**Example 3-190: Job signal**

```
# Signal job nebo.3
# send
CMD=SIGNALJOB ARG=nebo.3 ACTION=signal VALUE=13
# receive
SC=0 RESPONSE=job nebo.3 signaled
```

**W.2.1.9 ModifyJob**

The `ModifyJob` command can be issued against any active or queued job. This command modifies specified attributes of the job.

```
send CMD=MODIFYJOB ARG=<JOBID> [BANK=name] [NODES=num] [PARTITION=name]
[TIMELIMIT=minutes]
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE*  $\geq 0$  indicates SUCCESS

*STATUSCODE*  $< 0$  indicates FAILURE

*RESPONSE* is a text message further describing an error or state

**Example 3-191: Job modify**

```
# Signal job nebo.3
# send
CMD=MODIFYJOB ARG=nebo.3 TIMELIMIT=9600
# receive
SC=0 RESPONSE=job nebo.3 modified
```

### W.2.1.10 JobAddTask

The `JobAddTask` command allocates additional tasks to an active job.

```
send CMD=JOBADDTASK ARG=<JOBID> <NODEID> [<NODEID>] ...
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE*  $\geq 0$  indicates SUCCESS

*STATUSCODE*  $< 0$  indicates FAILURE

*RESPONSE* is a text message possibly further describing an error or state

*Example 3-192: Job addtask*

```
# Add 3 default tasks to job nebo30023.0 using resources located on nodes cluster002,
cluster016, and cluster112.

# send
CMD=JOBADDTASK ARG=nebo30023.0 DEFAULT cluster002 cluster016 cluster112
# receive
SC=0 RESPONSE=3 tasks added
```

### W.2.1.11 JobRemoveTask

The `JobRemoveTask` command removes tasks from an active job.

```
send CMD=JOBREMOVETASK ARG=<JOBID> <TASKID> [<TASKID>] ...
```

```
receive SC=<STATUSCODE> RESPONSE=<RESPONSE>
```

*STATUSCODE*  $\geq 0$  indicates SUCCESS

*STATUSCODE*  $< 0$  indicates FAILURE

*RESPONSE* is a text message further describing an error or state

*Example 3-193: Job removetask*

```
# Free resources allocated to tasks 14, 15, and 16 of job nebo30023.0

# send
CMD=JOBREMOVETASK ARG=nebo30023.0 14 15 16
# receive
SC=0 RESPONSE=3 tasks removed
```

## W.2.2 Rejection Codes

- 0xx - success - no error
  - 00x - success
    - 000 - success
  - 01x - usage/help reply
    - 010 - usage/help reply
  - 02x - status reply
    - 020 - general status reply

- 1xx - warning
  - 10x - general warning
    - 100 - general warning
  - 11x - no content
    - 110 - general wire protocol or network warning
    - 112 - redirect
    - 114 - protocol warning
  - 12x - no matching results
    - 120 - general message format warning
    - 122 - incomplete specification (best guess action/response applied)
  - 13x - security warning
    - 130 - general security warning
    - 132 - insecure request
    - 134 - insufficient privileges (response was censored/action reduced in scope)
  - 14x - content or action warning
    - 140 - general content/action warning
    - 142 - no content (server has processed the request but there is no data to be returned)
    - 144 - no action (no object to act upon)
    - 146 - partial content
    - 148 - partial action
  - 15x - component defined
  - 18x - application defined
- 2xx - wire protocol/network failure
  - 20x - protocol failure
    - 200 - general protocol/network failure
  - 21x - network failure
    - 210 - general network failure
    - 212 - cannot resolve host
    - 214 - cannot resolve port

- 216 - cannot create socket
- 218 - cannot bind socket
- 22x - connection failure
  - 220 - general connection failure
  - 222 - cannot connect to service
  - 224 - cannot send data
  - 226 - cannot receive data
- 23x - connection rejected
  - 230 - general connection failure
  - 232 - connection timed-out
  - 234 - connection rejected - too busy
  - 236 - connection rejected - message too big
- 24x - malformed framing
  - 240 - general framing failure
  - 242 - malformed framing protocol
  - 244 - invalid message size
  - 246 - unexpected end of file
- 25x - component defined
- 28x - application defined
- 3xx - messaging format error
  - 30x - general messaging format error
    - 300 - general messaging format error
  - 31x - malformed XML document
    - 310 - general malformed XML error
  - 32x - XML schema validation error
    - 320 - general XML schema validation
  - 33x - general syntax error in request
    - 330 - general syntax error in response
    - 332 - object incorrectly specified
    - 334 - action incorrectly specified
    - 336 - option/parameter incorrectly specified

- 34x - general syntax error in response
  - 340 - general response syntax error
  - 342 - object incorrectly specified
  - 344 - action incorrectly specified
  - 346 - option/parameter incorrectly specified
- 35x - synchronization failure
  - 350 - general synchronization failure
  - 352 - request identifier is not unique
  - 354 - request id values do not match
  - 356 - request id count does not match
- 4xx - security error occurred
  - 40x - authentication failure - client signature
    - 400 - general client signature failure
    - 402 - invalid authentication type
    - 404 - cannot generate security token key - inadequate information
    - 406 - cannot canonicalize request
    - 408 - cannot sign request
  - 41x - negotiation failure
    - 410 - general negotiation failure
    - 412 - negotiation request malformed
    - 414 - negotiation request not understood
    - 416 - negotiation request not supported
  - 42x - authentication failure
    - 420 - general authentication failure
    - 422 - client signature failure
    - 424 - server authentication failure
    - 426 - server signature failure
    - 428 - client authentication failure
  - 43x - encryption failure
    - 430 - general encryption failure
    - 432 - client encryption failure

- 434 - server decryption failure
  - 436 - server encryption failure
  - 438 - client decryption failure
- 44x - authorization failure
  - 440 - general authorization failure
  - 442 - client authorization failure
  - 444 - server authorization failure
- 45x - component defined failure
- 48x - application defined failure
- 5xx - event management request failure
  - 50x - reserved
    - 500 - reserved
- 6xx - reserved for future use
  - 60x - reserved
    - 600 - reserved
- 7xx - server side error occurred
  - 70x - server side error
    - 700 - general server side error
  - 71x - server does not support requested function
    - 710 - server does not support requested function
  - 72x - internal server error
    - 720 - general internal server error
  - 73x - resource unavailable
    - 730 - general resource unavailable error
    - 732 - software resource unavailable error
    - 734 - hardware resource unavailable error
  - 74x - request violates policy
    - 740 - general policy violation
  - 75x - component-defined failure
  - 78x - application-defined failure

- 8xx - client side error occurred
  - 80x - general client side error
    - 800 - general client side error
  - 81x - request not supported
    - 810 - request not supported
  - 82x - application specific failure
    - 820 - general application specific failure
- 9xx - miscellaneous
  - 90x - general miscellaneous error
    - 900 - general miscellaneous error
  - 91x - general insufficient resources error
    - 910 - general insufficient resources error
  - 99x - general unknown error
    - 999 - unknown error

### W.3 Moab RM Language Socket Protocol Description

Moab RM language is formerly known as WIKI. The Moab scheduler uses a simple protocol for socket connections to the user client and the resource manager as described below:

`<SIZE><CHAR>CK=<CKSUM><WS>TS=<TIMESTAMP><WS>AUTH=<AUTH><WS>DT=<DATA>`

Attribute	Description
<b>&lt;SIZE&gt;</b>	8 character decimal ASCII representation of the size of the packet following ' <code>&lt;SIZE&gt;&lt;CHAR&gt;</code> ' Leading zeroes must be used to pad this value to 8 characters if necessary.
<b>&lt;CHAR&gt;</b>	A single ASCII character
<b>&lt;CKSUM&gt;</b>	A 16 character hexadecimal ASCII DES-based checksum calculated using the algorithm below* and <code>&lt;SEED&gt;</code> selected and kept secret by the site admins. The checksum is performed on the line from <code>TS=</code> to the end of the message including <code>&lt;DATA&gt;</code> .
<b>&lt;WS&gt;</b>	a series of white space characters consisting of either tabs and/or space characters.

Attribute	Description
<TIMESTAMP>	ASCII representation of epoch time
<AUTH>	Identifier of user requesting service (i.e., USERNAME)
<DT>	Data to be sent

An example header follows:

```
00001057 CK=cdf6d7a7ad45026f TS=922401962 AUTH=sched DT=<DATA>
```

where <DATA> is replaced by actual message data.

### W.3.1 Checksum Algorithm ('C' version)

```

#define MAX_CKSUM_ITERATION 4

int GetChecksum(
    char *Buf,
    int BufSize,
    char *Checksum,
    char *CSKey) /* Note: pass in secret key */
{
    unsigned int crc;
    unsigned int lword;
    unsigned int irword;
    int index;
    unsigned int Seed;
    Seed = (unsigned int) strtoul(CSKey, NULL, 0);
    crc = 0;
    for (index = 0; index < BufSize; index++)
    {
        crc = (unsigned int) DoCRC((unsigned short) crc, Buf[index]);
    }
    lword = crc;
    irword = Seed;
    PSDES(&lword, &irword);
    sprintf(Checksum, "%08x%08x",
        lword,
        irword);
    return(SUCCESS);
}

unsigned short DoCRC(
    unsigned short crc,
    unsigned char onech)
{
    int index;
    unsigned int ans;
    ans = (crc ^ onech << 8);
    for (index = 0; index < 8; index++)
    {
        if (ans & 0x8000)
            ans = (ans <<= 1) ^ 4129;
        else
            ans <<= 1;
    }
    return((unsigned short) ans);
}

int PSDES(
    unsigned int *lword,
    unsigned int *irword)
{
    int index;
    unsigned int ia;
    unsigned int ib;
    unsigned int iswap;
    unsigned int itmph;
    unsigned int itmpl;
    static unsigned int c1[MAX_CKSUM_ITERATION] = {
        0xcba4e531, 0x537158eb, 0x145cdc3c, 0x0d3fdeb2 };
    static unsigned int c2[MAX_CKSUM_ITERATION] = {
        0x12be4590, 0xab54ce58, 0x6954c7a6, 0x15a2ca46 };
    itmph = 0;

```

```
itmpl = 0;
for (index = 0; index < MAX_CKSUM_ITERATION; index++)
{
    iswap = *irword;
    ia = iswap ^ c1[index];
    itmpl = ia & 0xffff;
    itmph = ia >> 16;
    ib = (itmpl * itmpl) + ~(itmph*itmph);
    ia = (ib >> 16) | ((ib & 0xffff) << 16);
    *irword = (*lword) ^ ((ia ^ c2[index]) + (itmpl * itmph));
    *lword = iswap;
}
return(SUCCESS);
}
```

### W.3.2 Header Creation (PERL code)

(taken from PNNL's QBank client code)

```
#####
#
# subroutine wiki($COMMAND)
#
# Sends command to Moab server and returns the parsed result and status
#
#####
sub wiki
{
  my($COMMAND,$REQUEST,$result);
  my($sockaddr,$hostname);
  my($name,$aliases,$proto,$port,$type,$len,$thisaddr);
  my($thisport,$thatport,$response,$result);
  $COMMAND = shift;
  #
  # Establish socket connection
  #
  $sockaddr = 'S n a4 x8';
  chop ($hostname = `hostname`);
  ($name,$aliases,$proto)=getprotobyname('tcp');
  ($name,$aliases,$type,$len,$thisaddr)=gethostbyname($hostname);
  ($name,$aliases,$type,$len,$thataddr)=gethostbyname($BANKHOST);
  $thisport=pack($sockaddr, &AF_INET,0,$thisaddr);
  $thatport=pack($sockaddr, &AF_INET,$BANKPORT,$thataddr);
  socket(S, &PF_INET,&SOCK_STREAM,$proto) || die "cannot create socket\n";
  bind(S,$thisport) || die "cannot bind socket\n";
  connect(S,$thatport) || die "cannot connect socket\n";
  select(S); $| = 1; # Turn on autoflushing
  select(stdout); $| = 1; # Select STDOUT as default output
  #
  # Build and send command
  #
  $REQUEST="COMMAND=$COMMAND AUTH=$AUTH";
  chomp($CHECKSUM = `QSUM "$REQUEST"`);
  $REQUEST .= " CHECKSUM=$CHECKSUM";
  my $command=pack "a8 a1 A*",sprintf("%08d",length($REQUEST))," ",$REQUEST;
  print S "$command"; # Send Command to server
  @REPLY=();
  while () { push(@REPLY,$_); } # Listen for Reply

  $STATUS=grep(/STATUSCODE=(\d*)/,&&$1,@REPLY); # STATUSCODE stored in $STATUS
  grep(s/.*RESULT=//,@REPLY); # Parse out the RESULT
  return @REPLY;

}

```

### W.3.3 Header Processing (PERL code)

```

sysread(NS,$length,8); # Read length string
sysread(NS,$delimiter,1); # Read delimiter byte
$DEBUG && print STDERR "length=[$length]\tdelimiter=[$delimiter]\n";
while($length) {
  $DEBUG && print STDERR "Awaiting $length bytes -- ".`date`;
  $length-=sysread(NS,$request,$length); # Read request
  sleep 1;
}
%REQUEST=();
chomp($request);
foreach (@REQUEST=&shellwords($request)) # Parse arguments into array
{
  ($key,$value)=split(/=/,$_);
  $REQUEST{$key}=$value unless defined $REQUEST{$key};
}
$request =~ s/\s+CHECKSUM=.*//; # Strip off the checksum
print STDERR "REQUEST=$request\n";
chomp($checksum=`$QSUM "$request"`);
$me=$REQUEST{AUTH};
$command=$REQUEST{COMMAND};
if (!grep($command eq $_,@VALIDCMDS))
{ $REPLY = "STATUSCODE=0 RESULT=$command is not a valid command\n";}
elsif ($checksum ne $REQUEST{CHECKSUM})
{ $REPLY = "STATUSCODE=0 RESULT=Invalid Checksum\n";}
else
{ $REPLY = do $command(@REQUEST); }
$len=sprintf("%08d",length($REPLY)-1);
$delim=' ';
$DEBUG && print STDERR "REPLY=${len}${delim}$REPLY\n";
$buf="$len"."$delim"."$REPLY";
syswrite(NS,$buf,length($buf));
close NS;

```

## SCHEDCFG flags

Flag	Description
<b>AGGREGATENODEFEATURES</b>	<i>AGGREGATENODEFEATURES</i> causes Moab to aggregate features reported by the different RMs. For example, if you have two RMs reporting different features for the same node, Moab will add both features together (instead of one being overwritten by the other). In order to set features manually, you can use <code>mnodectl -m features</code> (for details, see <a href="#">mnodectl on page 229</a> ).
<b>ALLOWINFINITEJOBS</b>	<i>ALLOWINFINITEJOBS</i> allows infinite wallclock times to be accepted. Previously, jobs with infinite job times were allowed by default.

Flag	Description
<b>ALLOWMULTICOMPUTE</b>	<i>ALLOWMULTICOMPUTE</i> tells Moab how to resolve conflicting information from different resource managers. If <i>ALLOWMULTICOMPUTE</i> is specified, Moab will use the STATE and OS information from the resource manager that reports the node as online.
<b>CANCELFAILEDDEPENDENCYJOBS</b>	Automatically cancels dependency jobs that will never run because of an unmet requirement. For example, if you ran a job with both an afterok and afternotok job attached to it and that job was successful, the afterok job would run, leaving the afternotok job idle in the queue. If you set <i>CANCELFAILEDDEPENDENCYJOBS</i> , Moab will cancel the job with the failed dependency and remove it from the queue. For more information about job dependencies, see <a href="#">Job Dependencies on page 528</a> .
<b>DISABLEPERJOBNODESETS</b>	Disables a job's ability to override the system specified node set. See <a href="#">13.3 Resource Manager Extensions</a> for more information.
<b>DISABLEPARTIALNODERESERVATIONS</b>	Blocks partial node reservations.
<b>ENABLESLURMMEMPERCPU</b>	By default Moab calls sbatch or srun with a --mem= request in a SLURM environment. When you set <i>ENABLESLURMMEMPERCPU</i> , Moab instead calls --mem-per-cpu=. This is to allow sites with policies that require the other parameter to use --mem-per-cpu.
<b>ENFORCERESERVEDNODES</b>	Without this flag Moab tries to optimize the reservation for a job before it starts, meaning a job may start on nodes that weren't part of its reservation. With this flag Moab tries to start jobs only on the nodes that were reserved.
<b>ENFORCESAMENODESET</b>	The same nodeset is not enforced across job requirements by default, rather each requirement is scheduled separately and the nodesets are determined on a per-req basis. To have Moab enforce the same nodeset across all job requirements set this flag.
<b>EXTENDEDGROUPSUPPORT</b>	Allows Moab to consider a user's secondary Linux groups when dealing with reservation <a href="#">ACLs</a> .
<b>FASTGROUPLOOKUP</b>	Moab will use the system call <code>getgrouplist</code> to gather group information. This can significantly improve performance on some LDAP systems.

Flag	Description
<b>FASTRSVSTARTUP</b>	<p>Speeds up start time if there are existing reservations.</p> <div data-bbox="716 359 1432 447" style="border: 1px solid #ccc; padding: 5px; margin-bottom: 10px;">  <b>FASTRSVSTARTUP</b> is incompatible with partial node reservations. </div> <p>On very large systems, if there is a reservation in the checkpoint file on all the nodes, it would take a really long time for Moab to start up. For every node in the reservation, Moab checks every other node. With this flag, Moab just uses the nodelist that was checkpointed to create the reservation. It speeds up the startup process because it doesn't have to check every node. Where Moab would take 8 - 10 minutes to start up with an 18,000 node reservation without the flag, Moab can start up in 2-3 minutes with the flag.</p> <p>With the flag you will see one difference in <a href="#">checknode</a>. A reservation that uses all the procs on a node initially shows that all the procs are blocked. Without the flag, and as jobs fill on the node, the blocked resources will be configured - dedicated (ex. 5/6). With the flag, the blocked resources will always be what the reservation is blocking and won't change when jobs fill on the node.</p> <p>Without flag:  Reservations:  brian.1x1 User -00:12:52 -&gt; INFINITY ( INFINITY)  Blocked Resources@-00:00:02 Procs: 5/6 (83.33%) Mem: 0/5000 (0.00%)  Blocked Resources@00:04:58 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%)  m.2x1 Job:Running -00:00:02 -&gt; 00:04:58 (00:05:00)  Jobs: m.2</p> <p>With flag:  Reservations:  brian.1x1 User -00:00:15 -&gt; INFINITY ( INFINITY)  Blocked Resources@-00:00:02 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%)  Blocked Resources@00:04:58 Procs: 6/6 (100.00%) Mem: 0/5000 (0.00%)  m.1x1 Job:Running -00:00:02 -&gt; 00:04:58 (00:05:00)  Jobs: m.1</p> <div data-bbox="716 1539 1432 1627" style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;">  When you set the FASTRVSTARTUP flag, Moab will also set the <a href="#">DISABLEPARTIALNODERESERVATIONS</a> flag. </div>
<u><a href="#">FILELOCKHA</a></u>	<p>This is a <a href="#">High Availability</a> feature. <b>FILELOCKHA</b> prevents scheduling conflicts between multiple Moab servers.</p>

Flag	Description
<b>FREECOMPLETEDJOBSSUBMITSTRING</b>	Moab frees the job submit string for completed jobs, decreasing the amount of memory needed during operation. This is useful in environments with large job scripts that can create a large memory footprint.
<b>IGNOREPIDFILELOCK</b>	Moab will not fail if it cannot get a lock on the <code>.moab.pid</code> file. This is useful when Moab is running on a shared filesystem where file locking can be unpredictable.
<b>JOBSUSERSVWALLTIME</b>	Allows jobs submitted without a walltime request or default walltime received from a class or queue but with an <code>ADVRES:reservation</code> to inherit their walltime limit from the reservation instead of the Moab default. The job walltime limit is then the remaining time of the reservation to which the job was submitted.
<b>NOCLASSUPDATE</b>	While running against TORQUE, Moab will not update classes when it refreshes each iteration. Moab loads the classes at startup, but does not refresh them until the next time it is restarted.
<b>NORMALIZETASKDEFINITIONS</b>	<p>Instructs Moab to normalize all tasks that it receives via an <a href="#">mshow -a</a> command. Moab normalizes the task definition to one processor and then changes the tasks requested to the number of processors requested. For example, when the following is received by Moab:</p> <pre>mshow -a -w mintasks=1@procs:4+mem:4096</pre> <p>It is changed to this:</p> <pre>mshow -a -w mintasks=4@procs:1+,mem:1024,tpn=4</pre>
<b>OPTIMIZEDBACKFILL</b>	On large systems that utilize system-wide reservations, backfill can take a considerable amount of time. This flag speeds up backfill scheduling by using an alternative BETA backfill algorithm. This flag will be the default in future versions of Moab.

Flag	Description
<b>PRIORITYPOLICYBLOCKING</b>	<p>By default, a job that violates a policy is placed into the blocked queue. Jobs with a lower priority, but that do not violate the policy, will run. This can lead to situations in which small jobs starve out larger, higher priority jobs.</p> <p>When you set the <i>PRIORITYPOLICYBLOCKING</i> flag, Moab allows the job that violates the policy to continue consuming the policy slots while it remains blocked. With the policy slots consumed, the smaller, lower priority jobs will not run. The higher priority job will continue to consume the policy slots until it has consumed enough to actually run.</p> <p>Note that because the blocked job consumes policy slots, this will inevitably lead to lower system utilization.</p>
<b>SHOWREQUESTEDPROCS</b>	<p>Shows requested processors regardless of NodeAccessPolicy in <a href="#">showq</a>. When <i>SINGLEJOB NODEACCESSPOLICY</i> is used and the job requests one processor, <a href="#">showq</a> displays the job with one processor.</p>
<b>SHOWUSERJOBONLY</b>	<p>Causes Moab, when a non-admin user runs <a href="#">showq</a>, to return only that user's jobs. If an administrator runs <a href="#">showq</a> when this flag is set, Moab returns the jobs of all users; no restrictions are placed on administrators.</p>
<b>STRICTSPOOLDIRPERMISSIONS</b>	<p>Enforces at least a 511 permission on the Moab spool directory.</p>
<b>UNMIGRATEONDEFER</b>	<p>Forces Moab to unmigrate a job in a grid if it enters a deferred state.</p>

# Moab Web Services

## Moab Web Services overview

Moab Web Services (MWS) is a component of Adaptive Computing Suites that enables programmatic interaction with Moab Workload Manager via a RESTful interface. MWS lets you create and interact with Moab objects and properties such as jobs, nodes, virtual machines, and reservations. MWS is the preferred method for those wishing to create custom user interfaces for Moab and is the primary method by which Moab Viewpoint communicates with Moab.

MWS communicates with the Moab Workload Manager (Moab) server using the same wire protocol as the Moab command-line interface. By publishing a standard interface into Moab's intelligence, MWS significantly reduces the amount of work required to integrate Moab into your solution.

This documentation is intended for developers performing such integrations. If you are a Moab administrator, and for conceptual information about Moab, see [Moab Workload Manager overview on page 89](#).

## Setup

### Moab Web Services setup

This section explains what you need to know in order to get MWS configured, and secured correctly. It contains the following topics:

- [Configuring Moab Web Services on page 1395](#)
- [Setting up MWS security on page 1410](#)
- [Version and build information on page 1418](#)

Related topics

- [Moab Web Services overview on page 1395](#)
- [Access control on page 1420](#)

### Configuring Moab Web Services

This section describes the location of the MWS configuration files. It also shows some examples of how to configure logging.

**i** To see a full reference to all configuration and logging parameters available in MWS, see [Configuration on page 1772](#).

This topic contains these sections:

- [Home directory on page 1396](#)
- [Configuration files on page 1396](#)
- [Logging configuration using mws-config.groovy on page 1396](#)
- [LDAP Configuration using mws-config.groovy on page 1402](#)
- [PAM \(pluggable authentication module\) configuration using mws-config.groovy on page 1405](#)
- [OAuth configuration using mws-config.groovy on page 1407](#)

## Home directory

The MWS home directory contains configuration files, log files, and files that serve features of MWS such as hooks and plugins. You should set the location of the MWS home directory using the **MWS\_HOME** property. If you do not set **MWS\_HOME** as a Java property or as an environment variable, then MWS will use `/opt/mws` as the default **MWS\_HOME**.

## Configuration files

The primary configuration file is `MWS_HOME/etc/mws-config.groovy`. If this file is missing or contains errors, MWS will not start.

Configuration files can also be placed in the `MWS_HOME/etc/mws.d` directory. Any configuration files here get merged with `MWS_HOME/etc/mws-config.groovy`. In case of conflict, the configuration in `MWS_HOME/etc/mws.d` takes precedence.

If `MWS_HOME/etc/log4j.properties` exists, MWS will load it as well.

## Logging configuration using mws-config.groovy

Shown below is an example that logs all error messages and fatal messages to `/opt/mws/log/mws.log` (For information about the format of the MWS logs, see "[Standard Log Format](#)" in the *Moab Workload Manager Administrator Guide*). It also logs all stack traces to `/opt/mws/log/stacktrace.log`. Note that this example is not configured to log events; for details on logging events, see [Configuring an event log on page 1397](#).

## Minimal logging configuration

```

log4j = {
  appenders {
    rollingFile name: 'stacktrace',
      file: '/opt/mws/log/stacktrace.log',
      maxFileSize: '1GB'
    rollingFile name: 'rootLog',
      file: '/opt/mws/log/mws.log',
      threshold: org.apache.log4j.Level.ERROR,
      maxFileSize: '1GB'
  }
  root {
    debug 'rootLog'
  }
}

```

Alternatively, you may configure a console appender instead of a rolling file, as shown below.

## Console logging configuration

```

log4j = {
  appenders {
    rollingFile name: 'stacktrace',
      file: '/opt/mws/log/stacktrace.log',
      maxFileSize: '1GB'
    console name: 'consoleLog',
      threshold: org.apache.log4j.Level.ERROR
  }
  root {
    debug 'consoleLog'
  }
}

```

You may configure logging by using either `MWS_HOME/etc/mws-config.groovy` or `MWS_HOME/etc/log4j.properties`.

If you do not define any `log4j` configuration, MWS will write its log files to `java.io.tmpdir`. For Tomcat, `java.io.tmpdir` is generally set to `$CATALINA_BASE/temp` or `CATALINA_TMPDIR`.

## Configuring an event log

Logging events to a flat file requires that you make a few changes to the configuration in the **log4j** section of the `mws-config.groovy` file so that events will be logged to the `events.log` file, and all other MWS logging information will be sent to the `mws.log` file.

### Causing events.log to roll based on a time window

You can specify how often the `events.log` file rolls. The following example illustrates the configuration changes you will need make to `mws-config.groovy` to cause the `events.log` file to roll based on a time window. Note the following three examples:

- In this example, `mws-config.groovy` is configured so that `events.log` rolls daily at midnight.

```

Daily rolling events.log configuration in mws-config.groovy
-----

log4j = {
  def eventAppender = new org.apache.log4j.rolling.RollingFileAppender(name:
'events', layout: pattern(conversionPattern: "%m%n"))
  def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM-dd}', activeFileName:
'/tmp/events.log')
  rollingPolicy.activateOptions()
  eventAppender.setRollingPolicy(rollingPolicy)

  appenders {
    appender eventAppender

    rollingFile name: 'rootLog',
      file: '/tmp/mws.log',
      maxFileSize: '1GB'
  }

  root {
    warn 'rootLog'
  }

  trace additivity:false, events:'com.ace.mws.events.EventFlatFileWriter'
}

```

Note the **RollingFileAppender** and the **TimeBasedRollingPolicy** lines. These lines configure MWS to write the event log to the `events.log` file. Rolled log files will have a date appended to their name in this format: "yyyy-MM-dd" (for example, `events.log.2012-02-28`).

- If you want the event log file to roll at the beginning of each month, change the **fileNamePattern** `TimeBasedRollingPolicy` date format to `yyyy-MM`. For example:

```

Monthly event logs
-----

def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM}', activeFileName: '/tmp/events.log')

```

- If you want the event log file to roll at the beginning of each hour, change the date format to `yyyy-MM-dd_HH:00`. For example:

```

Hourly event logs
-----

def rollingPolicy = new org.apache.log4j.rolling.TimeBasedRollingPolicy
(fileNamePattern: '/tmp/events.%d{yyyy-MM-dd_HH:00}', activeFileName:
'/tmp/events.log')

```

### Configuring events.log to roll based on a file size threshold

You can also configure the `events.log` file to roll when the log size exceeds a specified threshold. The following example illustrates the configuration changes you will need to make to `mws-config.groovy` to cause the `events.log` file to roll on a size threshold. (In this example, `mws-config.groovy` is configured so that `events.log` rolls when its size exceeds 50 MB.)

```
mws-config.groovy configuration that rolls events.log based on file size
```

```
-----
log4j = {
  appenders {
    rollingFile name: 'events',
      file: '/tmp/events.log',
      maxFileSize: '50MB',
      maxBackupIndex:10

    rollingFile name: 'rootLog',
      file: '/tmp/mws.log',
      maxFileSize: '1GB'
  }

  root {
    warn 'rootLog'
  }

  trace additivity:false, events:'com.ace.mws.events.EventFlatFileWriter'
}

```

Note that **maxFileSize** is set to "50MB." This means that when the `events.log` file exceeds 50 MB, it will roll.

The name for the rolled log will be "events.log.1". When the *new* `events.log` file exceeds 50 MB, *it* will roll and be named "events.log.1", while the old "events.log.1" file will be renamed "events.log.2". This process will continue until the optional **maxBackupIndex** value is met. In the example above, **maxBackIndex** is set to 10. This means that MWS will delete all but the ten most recent `events.log` files. Using this feature helps prevent hard drives from filling up.

### Additivity

The **additivity** attribute of the `EventFlatFileWriter` logger can be either `true` or `false`. If you specify `true`, events will be logged to the `events.log` file *and* the `mws.log` file. If you specify `false`, events will be logged to the `events.log` file only. (All other MWS logging information will be logged to the `mws.log` file, as configured by the `rootLog` appender.)

To log events to the `mws.log` file in addition to the `events.log` file, make the `additivity:true` configuration. For example:

```
-----
Logging events to both events.log and mws.log

trace additivity:true, events:'com.ace.mws.events.EventFlatFileWriter'
```

For more configuration options, see [Apache Extras Companion for log4j](#).

### Deleting old events

If your MongoDB server is version 2.2 or later, MongoDB will automatically delete events older than 30 days (by default). For more information, including how to change this default, see `mws.events.expireAfterSeconds` in [Configuration on page 1772](#).

If your MongoDB server is older than version 2.2, MongoDB will store event data indefinitely. However, if disk space is limited, you may want to regularly delete old, unneeded events from MongoDB. This section contains some examples of how you can do this.

Let's say that you want to delete events that are older than 90 days. (There are 86,400,000 milliseconds in a day, so in this example,  $90 \times 86400000$  corresponds to 90 days in milliseconds.):

- You could run this script:

```

Delete events older than 90 days
-----
$ mongo
MongoDB shell version: 2.4.8
connecting to: test
> use mws
> db.event.remove({eventTime:{$lt:new Date(new Date()).getTime()-90*86400000}})
> exit

```

- To create a script to perform this task:

```

deleteOldEvents.sh
-----
#!/bin/bash
printf 'use mws_dev\ndb.event.remove({eventTime:{$lt:new Date(new Date()).getTime()-90*86400000}})\nexit' | mongo

```

- Now say that you want to set up a [cron job](#) (`crontab -e`) so that old events are automatically deleted on a certain day of the week (for example, every Sunday at 2:00 a.m.), you would add an entry like this:

```

cron table entry to delete old events
-----
00 02 * * 0 /root/deleteOldEvents.sh

```

## Configuring an audit trail log

Audit logging enables you to track changes to [Permissions on page 1593](#), [Roles on page 1655](#), and [Principals on page 1627](#).

Sample audit.log format:

```
Audit trail log format
-----
2013-10-30 14:39:32,120 TENANT 'admin' updated resource named 'Engineering2' with
values:
  "name": "Engineering3",
  "attachedPrincipals": [{"name": "Engineering"}]
```

## LDAP Configuration using `mws-config.groovy`

### Using a supported LDAP directory type

To configure an MWS connection to an LDAP server, add the following parameters to `mws-config.groovy`:

**i** Throughout the following examples in this topic, you will see **dc=acme,dc=com**. "acme" is only used as an example to illustrate what you would use as your own domain controller if your domain name was "acme.com." You should replace any references to "acme" with your own organization's domain name.

Parameter	Description
<b>ldap.server</b>	The hostname or IP address of the LDAP server.
<b>ldap.port</b>	The port the LDAP server is listening on.
<b>ldap.baseDNs</b>	A list of distinguished names that are the root entries for LDAP searches.
<b>ldap.bindUser</b>	The distinguished name of the bind user.
<b>ldap.password</b>	The password of the ldap.bindUser.
<b>ldap.directory.type</b>	The type of LDAP directory (e.g. "Microsoft Active Directory"). This parameter can have the following values: <ul style="list-style-type: none"> <li>• Microsoft Active Directory</li> <li>• OpenLDAP Using InetOrgPerson Schema</li> <li>• OpenLDAP Using NIS Schema</li> <li>• OpenLDAP Using Samba Schema</li> </ul>

Here is a sample configuration for OpenLDAP.

**i** If you followed the Adaptive Computing tutorial [\[link\]"Setting up OpenLDAP on CentOS 6"](#) your **ldap.directory.type** should be set to "OpenLDAP Using InetOrgPerson Schema".

## Sample OpenLDAP configuration

```

ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.directory.type = "OpenLDAP Using InetOrgPerson Schema"

```

Here is a sample configuration for Microsoft Active Directory.

## Sample Active Directory configuration

```

ldap.server = "192.168.0.5"
ldap.port = 389
ldap.baseDNs = ["CN=Users,DC=acme,DC=com", "OU=Europe,DC=acme,DC=com"]
ldap.bindUser = "cn=Administrator,cn=Users,DC=acme,DC=com"
ldap.password = "*****"
ldap.directory.type = "Microsoft Active Directory"

```

To see how to configure a secure connection to the LDAP server, see [Securing the LDAP connection on page 1416](#).

## Using an unsupported LDAP directory type

If you are not using one of the supported directory types, you can explicitly configure MWS to work with your LDAP schema by using the following parameters:

Parameter	Description
<b>ldap.user.objectClass</b>	The name of the class used for the LDAP user object. For example: <ul style="list-style-type: none"> <li>• user</li> <li>• person</li> <li>• inetOrgPerson</li> <li>• posixAccount</li> </ul>
<b>ldap.group.objectClass</b>	The name of the class used for the LDAP group object. For example: <ul style="list-style-type: none"> <li>• group</li> <li>• groupOfNames</li> <li>• posixGroup</li> </ul>
<b>ldap.ou.objectClass</b>	The name of the class used for the LDAP organizational unit object. for example: <ul style="list-style-type: none"> <li>• organizationalUnit</li> </ul>

Parameter	Description
<b>ldap.user.membership.attribute</b>	The attribute field in a user entry to use when loading the user's groups (optional if <b>ldap.group.membership.attribute</b> is defined). For example: <ul style="list-style-type: none"> <li>• memberOf</li> </ul>
<b>ldap.group.membership.attribute</b>	The attribute field in a group entry to use when loading the group's members (optional if <b>ldap.user.membership.attribute</b> is defined). For example: <ul style="list-style-type: none"> <li>• member</li> <li>• memberUid</li> </ul>
<b>ldap.user.name.attribute</b>	The attribute field to use when loading the username. This field must uniquely identify a user. For example: <ul style="list-style-type: none"> <li>• sAMAccountName</li> <li>• uid</li> </ul>

For example:

```
Advanced Active Directory configuration
-----
ldap.server = "myldaphostname"
ldap.port = 389
ldap.baseDNs = ["CN=Users,DC=acme,DC=com", "OU=Europe,DC=acme,DC=com"]
ldap.bindUser = "cn=Administrator,cn=Users,DC=acme,DC=com"
ldap.password = "*****"
ldap.user.objectClass = "person"
ldap.group.objectClass = "group"
ldap.ou.objectClass = "organizationalUnit"
ldap.user.membership.attribute = "memberof"
ldap.group.membership.attribute = "member"
ldap.user.name.attribute = "sAMAccountName"
```

Here is a similar example for OpenLDAP. Note there is no user membership attribute in the OpenLDAP InetOrgPerson schema and thus **ldap.user.membership.attribute** is set to null. This is allowable because the **ldap.group.membership.attribute** is set.

```
Advanced OpenLDAP configuration
-----
ldap.server = "myldaphostname"
ldap.port = 389
ldap.baseDNs = ["dc=acme,dc=com"]
ldap.bindUser = "cn=Manager,dc=acme,dc=com"
ldap.password = "*****"
ldap.user.objectClass = "inetOrgPerson"
ldap.group.objectClass = "groupOfNames"
ldap.ou.objectClass = "organizationalUnit"
ldap.user.membership.attribute = null
ldap.group.membership.attribute = "memberUid"
ldap.user.name.attribute = "uid"
```

## Overriding attributes in a supported LDAP directory type

You can also override attributes in supported directory types. For example, say you are using OpenLDAP with an NIS Schema. The group objectClass for NIS defaults to "groupOfNames," but you want to use "groupOfUniqueNames" instead while retaining all other defaults for NIS. You can do this by setting **ldap.directory.type** to "OpenLDAP Using NIS Schema" and overriding the **ldap.group.objectClass** attribute as follows:

```
Advanced OpenLDAP configuration
-----
ldap.directory.type = "OpenLDAP Using NIS Schema"
ldap.group.objectClass = "groupOfUniqueNames"
```

**i** LDAP is *not* currently used to authenticate users to MWS. LDAP is only used to map principals to roles, as explained in [Principals on page 1627](#).

The user class in your LDAP schema must have an attribute that uniquely identifies a user (for example: "uid" or "sAMAccountName").

## PAM (pluggable authentication module) configuration using `mws-config.groovy`

PAM functions as bridge to the underlying Unix authentication system. PAM treats the user as if it is local to the Unix machine doing the authenticating and uses whatever the Unix user is authenticating with, whether it be LDAP or NIS. PAM uses configuration files that specify the how, when, or what for authentication, session management, and account management. Each configuration file can be different. For example, `sudo` configuration file for the "sudo" command will handle authentication differently than the `login` configuration file. These configuration files are dynamically read for `/etc/pam.d`.

### Requirements for PAM

In order to use PAM with MWS, the following is required:

- The PAM application package must be installed. For example:

```
yum install pam
```

- You must have a PAM configuration file in the `/etc/pam.d` directory. The following is an example of what a PAM configuration file might look like:

```

#%PAM-1.0
auth        required      pam_env.so
auth        sufficient    pam_unix.so nullok try_first_pass
auth        requisite     pam_succeed_if.so uid >= 1000 quiet_success
auth        required      pam_deny.so

account     required      pam_unix.so
account     sufficient    pam_localuser.so
account     sufficient    pam_succeed_if.so uid < 1000 quiet
account     required      pam_permit.so

password    requisite     pam_pwquality.so try_first_pass retry=3 authtok_type=
password    sufficient    pam_unix.so sha512 shadow nullok try_first_pass use_
authtok
password    required      pam_deny.so

session     optional      pam_keyinit.so revoke
session     required     pam_limits.so
-session    optional     pam_systemd.so
session     [success=1 default=ignore] pam_succeed_if.so service in crond quiet
use_uid
session     required     pam_unix.so
    
```

- (Optional) You must have PAM modules installed for your specific needs.

The PAM application comes with default modules—for example, **pam\_unix.xo**—that will check username and password credentials with Unix. You may have to install others for your distribution.

### Configuring MWS to use PAM

To configure an MWS connection to PAM, add the following parameter to `mws-config.groovy`:

Parameter	Description
<b>pam.configuration.service</b>	The name of the PAM configuration file located in <code>/etc/pam.d</code> . This parameter and specification tells MWS which PAM configuration file you want to use.

For example:

```
pam.configuration.service = "system-auth"
```

**i** You can configure only one authentication method in `mws-config.groovy`—LDAP or PAM, but not both. If you have configured both LDAP and PAM, MWS defaults to using LDAP.

If you need multiple authentication methods, you must add them to your local PAM configuration. See your distribution documentation for details.

There is a security risk when authenticating local users through your PAM configuration. This behavior is highly discouraged and not supported by Adaptive Computing.

For more information about PAM, please see the following [SLES](#) and [RedHat](#) documentation.

## OAuth configuration using `mws-config.groovy`

OAuth is a security framework designed to simplify authentication in web technologies. In the case of MWS, OAuth allows trusted client applications to securely delegate authentication to MWS. Once MWS has authenticated a user by verifying the username and password in LDAP, PAM, or NIS, MWS returns an access token to the client. The client then presents this access token to MWS to access resources. OAuth is very flexible and allows MWS to work in many different scenarios by use of grant types. For more information on OAuth and grant types, please see the following [OAuth](#) documentation.

### Example using 'password' grant type

#### [Terminology](#)

**Resource Owner:** The person accessing and manipulating data. For MWS, this would be the person who logs into the client (the user).

**Service Provider:** The site or service where protected resources live. This can be (but is not necessarily) also the identify provider, where usernames and passwords are stored. This is the MWS service itself.

**Client:** The application that wants to access a resource. For MWS this is the user interface, potentially including APIs and command-line tools.

**Protected Resource:** The data for which protection is desired. For MWS this would be Moab itself, and interaction with Moab.

**Access Token:** Instead of user credentials, OAuth uses tokens to issue requests, and the tokens get signed to indicate authorization.

### Register a client in MWS

OAuth requires client registration. Its client credentials are used to validate that the client is allowed to authenticate on behalf of a resource owner. It involves giving the client its own credentials (username and password). MWS will first authenticate the client using a client id (username) and client secret (password), then will authenticate the resource owner.

Add the following line to `/opt/mws/etc/mws-config.groovy`:

```
grails.plugin.springsecurity.oauthProvider.clients = [
  [
    clientId:"THE_CLIENT_ID",
    clientSecret:"THE_CLIENT_SECRET",
    authorizedGrantTypes:["password"]
  ]
]
```

Replace `THE_CLIENT_ID` with client id (username). For example: `clientId:"iris"`. Also, replace `THE_CLIENT_SECRET` with client secret (password). For example: `clientSecret:"irisclientpassword"`,. Note that the values for `clientId` and `clientSecret` are case sensitive.

You can register more than one client. For example:

```
grails.plugin.springsecurity.oauthProvider.clients = [
  [
    clientId:"client_id_1",
    clientSecret:"client_secret_1",
    authorizedGrantTypes:["password"]
  ],
  [
    clientId:"client_id_2",
    clientSecret:"client_secret_1",
    authorizedGrantTypes:["password"]
  ]
]
```

### Obtain an access token from MWS for a resource owner (logging in)

Before the client can access private data in MWS, the client must obtain an access token that grants access to the API. The token endpoint url is only used to gain an access token and log in a user.

Getting an access token:

```
POST http://localhost:8080/mws/rest/oauth/token?api-version=3
Adding header:
  "Content-Type: application/x-www-form-urlencoded"
Request body (String):
grant_type=password&client_id=THE_CLIENT_ID&client_secret=THE_CLIENT_SECRET&username=RESOURCE_OWNER_USERNAME&password=RESOURCE_OWNER_PASSWORD
```

Example using curl:

```
curl -X POST -H "Content-Type: application/x-www-form-urlencoded" -v -d 'grant_type=password&client_id=iris&client_secret=irisclientpassword&username=moab-admin&password=secret' 'http://localhost:8080/mws/oauth/token'
```

Produces the following response:

```

* About to connect() to localhost port 8080 (#0)
*   Trying 127.0.0.1... connected
* Connected to localhost (127.0.0.1) port 8080 (#0)
> POST /mws/oauth/token HTTP/1.1
> User-Agent: curl/7.19.7 (x86_64-redhat-linux-gnu) libcurl/7.19.7 NSS/3.14.0.0
zlib/1.2.3 libidn/1.18 libssh2/1.4.2
> Host: localhost:8080
> Accept: */*
> Content-Type: application/x-www-form-urlencoded
> Content-Length: 126
>
< HTTP/1.1 200 OK
< Server: Apache-Coyote/1.1
< Cache-Control: no-store
< Pragma: no-cache
< Set-Cookie: JSESSIONID=6CE8F9E7C454575FABCF3D156B153CFD; Path=/mws
< Content-Type: application/json;charset=UTF-8
< Transfer-Encoding: chunked
< Date: Fri, 18 May 2014 18:16:42 GMT
<
* Connection #0 to host localhost left intact
* Closing connection #0
{"access_token":"b693eec0-6c93-4540-8b2f-1e170be08046","token_type":"bearer","expires_in":43096}

```

### Send the access token to MWS when requesting protected resource

After the client obtains an access token, it will send the access token to MWS in an HTTP authorization header for each rest call.

 The client is responsible for handling user sessions with each access token, meaning the client has to request a new access token when a new user logs in.

Requesting an MWS resource (getting list of all nodes for example):

```

GET http://localhost:8080/mws/rest/nodes?api-version=3&fields=name
Adding authorization header:
    "Authorization: Bearer ACCESS_TOKEN"

```

Example using curl:

```

curl -X GET -H "Authorization: Bearer b693eec0-6c93-4540-8b2f-1e170be08046" -v
'http://localhost:8080/mws/rest/nodes?api-version=3&fields=name'

```

Produces the following response:

```

* About to connect() to localhost port 8080 (#0)
* Trying 127.0.0.1... connected
* Connected to localhost (127.0.0.1) port 8080 (#0)
> GET /mws/rest/nodes?api-version=3&fields=name HTTP/1.1
> User-Agent: curl/7.19.7 (x86_64-redhat-linux-gnu) libcurl/7.19.7 NSS/3.14.0.0
zlib/1.2.3 libidn/1.18 libssh2/1.4.2
> Host: localhost:8080
> Accept: */*
> Authorization: Bearer b693eec0-6c93-4540-8b2f-1e170be08046
>
< HTTP/1.1 200 OK
< Server: Apache-Coyote/1.1
< Content-Type: application/json;charset=UTF-8

## Setting up MWS security

When running MWS in production environments, security is a major concern. This section focuses on securing the connections with MWS:

- The connection between MWS and Moab Workload Manager (see [Securing the connection with Moab on page 1411](#)).
- The connection between MWS and MongoDB (see [Securing the connection with MongoDB on page 1411](#)).
- The connections between clients and MWS (see [Securing client connections to MWS on page 1412](#)).
- The connection between MWS and LDAP (see [Securing the LDAP connection on page 1416](#)).
- The connection with the message queue (see [Securing the connection with the message queue on page 1417](#)).

### Related topics

- [Configuring Moab Web Services on page 1395](#)
- [Version and build information on page 1418](#)

## Securing the connection with Moab

MWS communicates with Moab via the Moab Wire Protocol, which uses a direct connection between the two applications. The communication over this connection uses a shared secret key, which is discussed in the installation instructions (see "[Installing Moab Web Services on page 31](#)" in the installation documentation). However, the communication is not encrypted and is therefore susceptible to eavesdropping and replay attacks. For this reason, MWS is supported only when running on the same machine as Moab. This assures that any connections between the two applications occur internally on the server and are not exposed to external users.

### Related topics

- [Setting up MWS security on page 1410](#)

## Securing the connection with MongoDB

By default, the connection between MWS and MongoDB is not authenticated. To enable authentication, follow the instructions below. For further reading, see the MongoDB tutorial "[Control Access to MongoDB Instances with Authentication](#)."

### To enable an authenticated connection between MWS and MongoDB

1. Add an administrative user to the `admin` database.
2. Add an MWS user to the `mws` database.
3. To support MWS API version 2, add an MWS user with "read-only" rights to the `moab` database.

Here is an example of how to create all the required users. The users in the `moab` database are required only for MWS API version 2.

```
[root]# service mongod start
[root]# mongo
> use admin;
> db.addUser("admin_user", "secret1");
> use moab;
> db.addUser("moab_user", "secret2");
> db.addUser("mws_user", "secret3", true);
> use mws;
> db.addUser("mws_user", "secret3");
> exit;
```

**i** The passwords used here ("secret1," "secret2," and "secret3") are examples. Choose your own passwords for these users.

4. Add the MWS user credentials (the ones you just created) to the `mws-config.groovy` file. For example:

```
grails.mongo.username = "mws_user"
grails.mongo.password = "secret3"
```

5. Enable authentication in the MongoDB configuration file (called `/etc/mongodb.conf` on many Linux distributions). In that file, look for `#auth = true` and uncomment it.
6. Restart MongoDB.
7. Restart Tomcat.

If authentication is enabled in MongoDB, but the MWS user was not properly created or configured, MWS will not start. In this case, see the log file(s) for additional information.

#### Related topics

- [Setting up MWS security on page 1410](#)

## Securing client connections to MWS

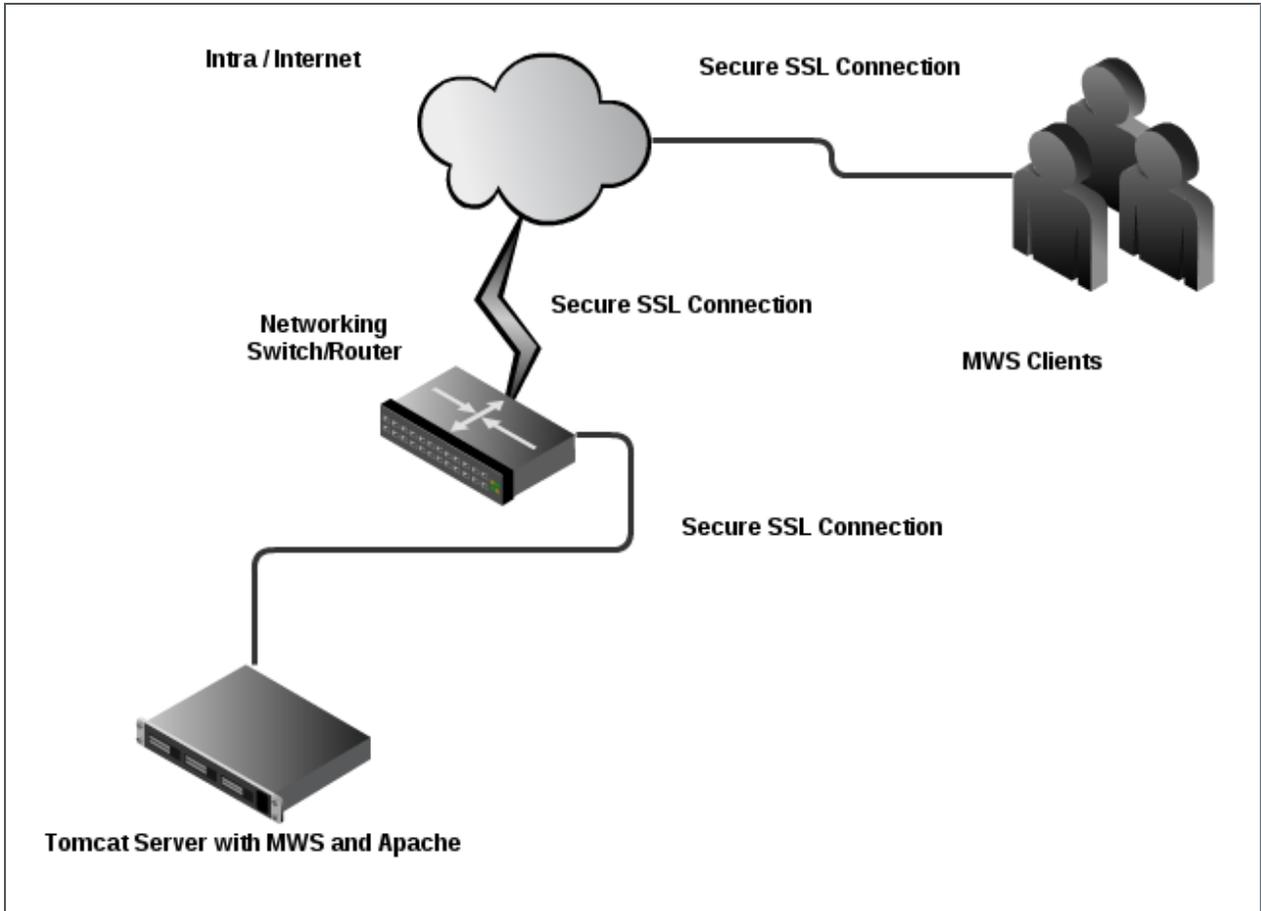

All connections to MWS, except those requesting the documentation or the main page, must be authenticated properly. MWS uses a single-trusted-user authentication model, meaning a single user exists that has access to all aspects of MWS. The username and password for this user are configured with the `auth.defaultUser` properties in the configuration file. For more information, see [Configuration on page 1772](#).

When using the MWS user interface in a browser, the user will be prompted for username and password. For information on how to authenticate requests when not using a browser, see [Authentication on page 1443](#).

 The username and password in the Basic Authentication header are encoded but not encrypted. Therefore, it is *strongly* recommended that MWS be run behind a proxy (like Apache) with SSL enabled. The instructions below provide an example of how to do this.

## Encrypting client connections using Apache and SSL

This section shows how to encrypt client connections to MWS using Apache and SSL. These instructions have been tested on CentOS™ 6.2 with the "Web Server" software set installed. The same ideas are applicable to other operating systems, but the details might be different. As shown in the diagram below, these instructions assume that Tomcat and Apache are running on the same server.

### To encrypt client connections using Apache and SSL

1. Create a self-signed certificate. (If desired, see <http://www.openssl.org/docs/HOWTO/certificates.txt> for more information.)

**i** Instead of creating a self-signed certificate, you can buy a certificate from a certificate vendor. If you do, then the vendor will provide instructions on how to configure Apache with your certificate.

2. Do the following:
  - a. Run these commands:

```
cd /etc/pki/tls/certs
cp -p make-dummy-cert make-dummy-cert.bak
cp -p localhost.crt localhost.crt.bak
```

- b. Edit `make-dummy-cert` and replace the `answers()` function with code similar to this:

```

answers() {
  echo US
  echo Utah
  echo Provo
  echo Adaptive Computing Enterprises, Inc.
  echo Engineering
  echo test1.adaptivecomputing.com
  echo
}

```

- c. Run this command:

```
./make-dummy-cert localhost.crt
```

3. Configure Apache to use the new certificate and to redirect MWS requests to Tomcat. To do so, edit `/etc/httpd/conf.d/ssl.conf`. Do the following"

- a. Comment out this line:

```
SSLCertificateKeyFile /etc/pki/tls/private/localhost.key
```

- b. Add these lines near the end, just above `</VirtualHost>`:

```
ProxyPass /mws http://127.0.0.1:8080/mws retry=5
ProxyPassReverse /mws http://127.0.0.1:8080/mws
```

4. Configure Apache to use SSL for all MWS requests. Add these lines to the end of `/etc/httpd/conf/httpd.conf`:

```
RewriteEngine On
RewriteCond %{HTTPS} off
RewriteRule (/mws.*) https://%{HTTP_HOST}%{REQUEST_URI}
```

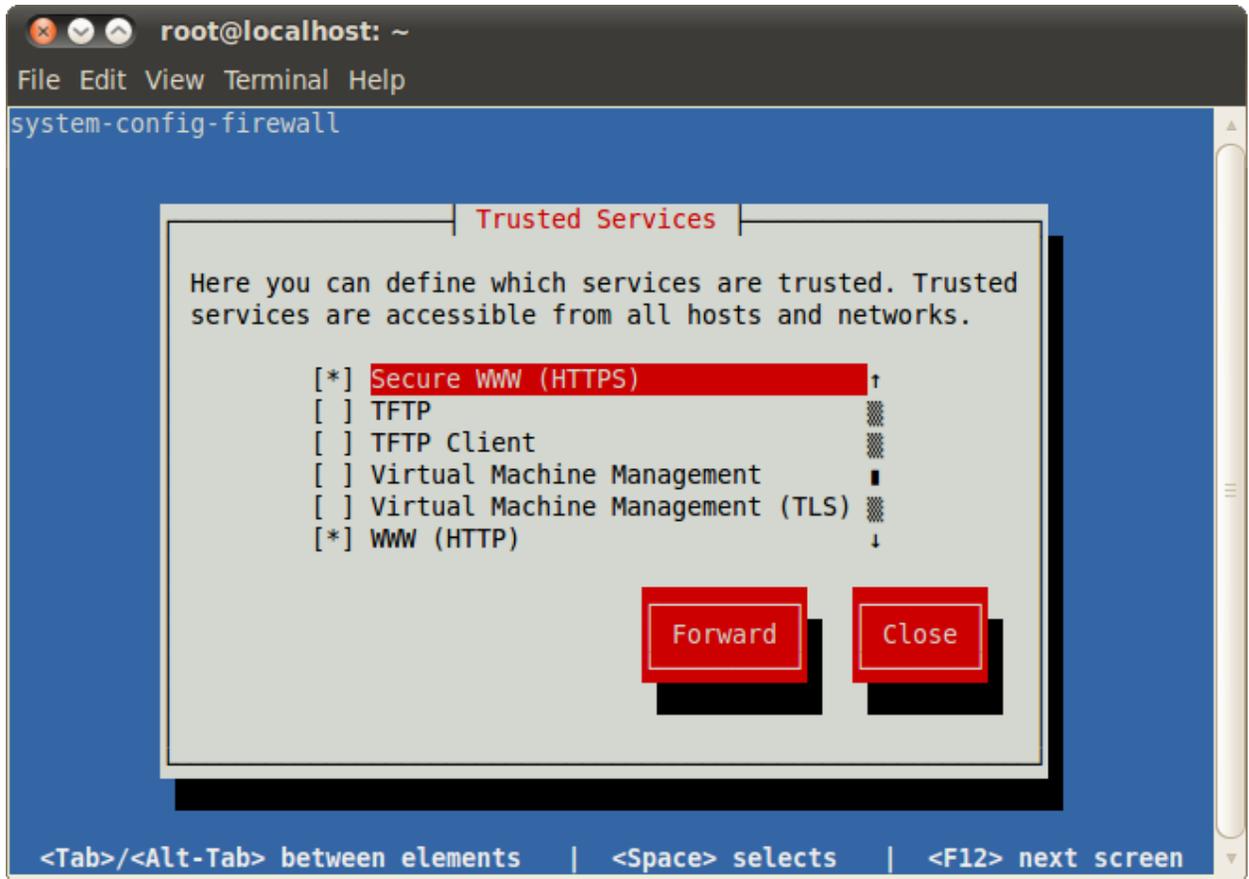

5. Give Apache permission to connect to Tomcat.

```
setsebool -P httpd_can_network_connect 1
```

6. Turn on Apache.

```
chkconfig httpd on
service httpd start
```

7. Using `system-config-firewall-tui`, enable "Secure WWW (HTTPS)" and "WWW (HTTP)" as trusted services.

## Encrypting client connections using Tomcat and SSL

This section shows how to encrypt client connections to MWS using Tomcat and SSL but without requiring the use of Apache. These instructions have been tested on CentOS™ 6.2 with Tomcat 6.0.

### To encrypt client connections using Tomcat and SSL

1. First, you must generate a certificate. Do the following:
  - a. Use the keytool utility that is shipped with the Oracle Java Runtime Environment. As the Tomcat user, run the following:
 

```
keytool -genkey -alias tomcat -keyalg RSA
```
  - b. Specify a password value of "changeit". This will create a .keystore file that contains the new certificate in the user's home directory.
2. Enable the Tomcat SSL connector. Do the following:
  - a. Open the `server.xml` file, usually located in `$CATALINA_HOME/conf/` (`$CATALINA_HOME` represents the directory where Tomcat is installed).

- b. Verify the SSL HTTP/1.1 Connector entry is enabled. To do so locate the SSL HTTP/1.1 Connector entry and uncomment it.

```
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true" maxThreads="150"
scheme="https" secure="true" clientAuth="false" sslProtocol="TLS" />
```

**i** The code above enables SSL access on port 8443. The default for HTTPS is 443, but just as Tomcat uses 8080 instead of 80 to avoid conflicts, 8443 is used instead of 443.

- c. Save the `server.xml` file.
- d. Verify that `server.xml` is owned by the Tomcat user.

```
chown -R tomcat:tomcat server.xml
```

- e. Next modify the `MWSweb.xml` file. Add a security-constraint section to the `$_CATALINA_HOME/webapps/mws/WEB-INF/web.xml` file found in your Tomcat directory.

```
<web-app>
...
  <security-constraint>
    <web-resource-collection>
      <web-resource-name>MWS Secure URLs</web-resource-name>
      <url-pattern>/*</url-pattern>
    </web-resource-collection>
    <user-data-constraint>
      <transport-guarantee>CONFIDENTIAL</transport-guarantee>
    </user-data-constraint>
  </security-constraint>
</web-app>
```

- f. Now restart tomcat.

## Related topics

- [Setting up MWS security on page 1410](#)

## Securing the LDAP connection

All connections from MWS to the LDAP server should be secured with SSL or StartTLS to ensure passwords and other sensitive information are encrypted as they pass to and from the LDAP server. If the LDAP server does not support SSL or StartTLS, the rest of this section is irrelevant.

### Determine whether the LDAP server's certificate is trusted

If the LDAP server's X.509 certificate has been signed by a trusted certificate authority such as Verisign, Thawte, GeoTrust, and so on, Java will trust the certificate automatically and you won't need to add the certificate to Java's keystore. Consult your IT department to determine whether the LDAP server certificate has been signed by a trusted certificate authority. If the LDAP server certificate is signed by a trusted certificate authority, skip ahead to [Configure MWS to connect to LDAP server using SSL or](#)

[StartTLS on page 1417](#). Otherwise, follow the instructions in [Trusting servers in Java on page 77](#) to add the certificate to Java's keystore.

## Configure MWS to connect to LDAP server using SSL or StartTLS

### To configure MWS to connect to LDAP using SSL/TLS

1. Update the `ldap.port` and `ldap.security.type` parameters in `/opt/mws/etc/mws-config.groovy`.

```
ldap.port = 636
ldap.security.type = "SSL"
```

### To configure MWS to connect to LDAP using StartTLS

1. Update the `ldap.port` and `ldap.security.type` parameters in `/opt/mws/etc/mws-config.groovy`.

```
ldap.port = 389
ldap.security.type = "StartTLS"
```

The table below lists the possible values for `ldap.security.type`:

ldap.security.type	Default port	Notes
<b>None</b>	389	This is the default if no security type is configured. All data is sent in plain text.
<b>SSL</b>	636	Requires server certificate. All data is encrypted.
<b>StartTLS</b>	389	Starts as an insecure connection and is upgraded to an SSL/TLS connection. Requires server certificate. After upgrade all data is encrypted.

## Securing the connection with the message queue

MWS supports message queue security with AES. If the `moab.messageQueue.secretKey` property is set, then all messages MWS publishes on the message queue will be encrypted. Additionally, MWS can read messages from Moab Workload Manager that are encrypted with the same key using the `MESSAGEQUEUESECRETKEY` parameter. For more information, see [Configuration on page 1772](#).

Encryption is done with AES in CBC mode where inputs are padded with PKCS5 padding. Only 128-bit (16-byte) keys are supported. Keys should be encoded in [Base64](#).

For example:

```
moab.messageQueue.secretKey = "1r6RvfqJa6voezy5wAx0hw==" //must be a Base64-encoded 128-bit key
```

**i** Important: If MWS is configured to encrypt the message queue and Moab is not (or vice versa) then the messages from Moab will be ignored. Furthermore, all attempts to access the MWS service resource will fail.

## Version and build information

To get detailed version information about MWS, use one of the following three methods:

- [Browser](#) on page 1418
- [REST request](#) on page 1419
- [MANIFEST.MF file](#) on page 1419

### Browser

Using a browser, visit the MWS home page (for example, <http://localhost:8080/mws/>). At the bottom of the page is the MWS version information. See the screenshot below:

**Migrate a VM:**

VM:

```
{ "node": { "id": "hv1" } }
```

Moab Web Services 7.0.0-beta-3, Build 993 (2012-02-04\_16-15-33), Revision 79f9da5b00e8a36e5cf40b5c96b61a04e9813fe9

**REST request**

Using a REST client or other HTTP client software, send a GET request to the `rest/diag/about` resource. Here is an example:

```
curl -u username:password http://localhost:8080/mws/rest/diag/about?api-version=3
```

This resource is also described under [Diagnostics on page 1521](#).

**MANIFEST.MF file**

If MWS fails to start, version and build information can be found in the `META-INF/MANIFEST.MF` file inside the MWS WAR file. The version properties begin with **Implementation**. Below is an excerpt of a `MANIFEST.MF` file:

```
Implementation-Build: 26
Implementation-Build-Date: 2012-06-19 14-18-59
Implementation-Revision: 376079a5e5f552f2fe25e6070fd2e84c646a98fd

Name: Grails Application
Implementation-Title: mws
Implementation-Version: 7.1.0-rc2
Grails-Version: 2.0.3
```

# Access control

## About access control

### Access control

This section describes how to manage access control in MWS. Applications are the consumers of MWS. They include Moab Viewpoint and other applications that need the resources provided by MWS. An application account consists of four editable fields and resource-specific access control settings:

Table 4-1: Field information

Field	Required	Default value	Value type	Maximum length	Description
<b>Application Name</b>	Yes	--	String	32	The name of the application. Must start with a letter and may contain letters, digits, underscores, periods, hyphens, apostrophes, and spaces.
<b>Username</b>	Yes	--	String	32	Used for authentication. Must start with a letter and may contain letters, digits, underscores, periods, and hyphens.
<b>Description</b>	No	--	String	1000	The description of the application.
<b>Enabled</b>	--	true	Boolean	--	Controls whether the application is allowed to access MWS.
<b>Access Control Settings</b>	Yes	All Per-missions	--	--	The permissions granted to the application. This is controlled by selecting specific check boxes in a grid.

An application account also contains an auto-generated password that is visible only when creating the account or when resetting its password. Whenever an application sends a REST request to MWS, it needs to pass its credentials (username and password) in a Basic Authentication header. For more information, see [Authentication on page 1443](#).

The **Application Name** is a human-friendly way to identify an application account, but MWS does not use it during authentication (or at any other time, for that matter).

The **Enabled** field is set to true automatically when an application account is created. To change the value of this field, see [Modifying an application account on page 1422](#).

Here is an example of how you might set the fields when creating an application account:

- **Application Name:** Moab Viewpoint
- **Username:** viewpoint
- **Description:** This application account grants access to Moab Viewpoint for Moab Cloud Suite.

The permissions granted to an application account may be customized while creating or modifying the account. For more information, see [Creating an application account on page 1421](#) and [Modifying an application account on page 1422](#).

## Managing application accounts

Application accounts are used to grant access to MWS. Every application with an application account must be granted at least one access control permission to a resource in MWS. To manage application accounts, see [Listing application accounts on page 1421](#).

## Listing application accounts

To list all applications accounts, browse to the MWS home page (for example, <https://servername/mws>). Log in as the admin user, click **Admin** and then **Application Accounts**.

Each column (except **Password**) can be sorted in ascending or descending order by clicking on the column heading.

## Creating an application account

To create an application account, go to the **Application List** page and click **Add Application**. The "Application Name" and "Username" are required fields. For more details, see [Field information on page 1420](#).

Access to specific resources and plugin custom web services is granted or revoked by checking or unchecking the check boxes in the respective resources or plugin web services access control sections. For each resource, access may be granted to a resource for each method supported by MWS, including GET, POST, PUT, and DELETE. See the figure below for an example.

<input type="checkbox"/> Select All	<input checked="" type="checkbox"/> GET	<input type="checkbox"/> POST	<input checked="" type="checkbox"/> PUT	<input checked="" type="checkbox"/> DELETE
<input checked="" type="checkbox"/> <b>Access Control Lists</b>			<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
<input checked="" type="checkbox"/> <b>Accounts</b>	<input checked="" type="checkbox"/>			
<input type="checkbox"/> <b>Events</b>	<input checked="" type="checkbox"/>	<input type="checkbox"/>		

In this example, the application has access to all available methods for the **Access Control Lists** and **Accounts** resources as well as to retrieve the **Events** resource through the GET method, but is denied the permission to create new events through the POST method.

Access may also be granted to each plugin type's custom web service(s). When new plugin types or plugin web services are added to MWS, applications must be updated with the new access control settings. See below for an example.

Plugin Type	<input checked="" type="checkbox"/> Can Access
<input checked="" type="checkbox"/> <b>Test</b>	
customService	<input checked="" type="checkbox"/>
unsecuredService (Unsecured)	

In this example, the application has access to all the custom web services defined for the **Test** plugin type. Note that though unsecured web services are listed, access to them cannot be denied (for more information, see [Exposing web services on page 1696](#)).

## Displaying an application account

To show information about an application account, go to the **Application List** page and click the desired application name.

In addition to displaying the values for fields, grids are also displayed which represent the application's access control permissions defined for resources and plugin custom web services. Examples of the resources and the plugin web services access control displays are shown below:

	GET	POST	PUT	DELETE
<b>Access Control Lists</b>				
<b>Accounts</b>				
<b>Events</b>				

Plugin Type	Can Access
<b>Test</b>	
customService	
unsecuredService (Unsecured)	

## Modifying an application account

To modify an application account, go to the **Application List** page, click the desired application name, and then click **Edit**. See [Creating an application account on page 1421](#) for more information on available fields and access control settings.

## Resetting an application password

To reset an application password, go to the **Application List** page and click the **Reset** link for the desired application. Alternatively, go to the **Display Application** page for the desired application and click the **Reset** link.

## Deleting an application account

To delete an application account, go to the **Application List** page, click the desired application name, and then click **Delete**. A confirmation message is shown. If the **OK** button is clicked, the application account is deleted from the system and cannot be recovered.

# API documentation

## About the API

Moab Web Services provide a set of RESTful resources that can be used to create, read, update, and delete various objects in the Moab Workload Manager. This section describes how to use RESTful web services, explains the JSON data format used for all communications with MWS, describes global URL parameters used in MWS calls, and contains other helpful information for using the Moab Web Services API.

This section contains these topics:

- [RESTful web services on page 1423](#)
- [Data format on page 1425](#)
- [Global URL parameters on page 1425](#)
- [Requesting specific API versions on page 1428](#)
- [Responses and return codes on page 1429](#)
- [Error messages on page 1432](#)
- [Pre and post-processing hooks on page 1434](#)
- [Authentication on page 1443](#)

Related topics

- [Resources introduction on page 1446](#)
- [About Moab Web Services plugins on page 1672](#)

## RESTful web services

In order to understand how to use MWS, it is first necessary to give a brief introduction to REST. REST (Representational State Transfer) is a set of guidelines which utilizes the full HTTP (Hypertext Transfer

Protocol) specification along with endpoint URLs that describe resources. The HTTP methods used in REST are comprised of the following:

Method	Description
<b>GET</b>	Query for a list or a single resource.
<b>POST</b>	Creating a resource.
<b>PUT</b>	Modifying a resource.
<b>DELETE</b>	Deleting a resource.

In comparison to other architectures of web services which use a single HTTP method and service endpoint to perform multiple types of operations (such as a POST operation to a URL), REST utilizes all of the available HTTP methods and URLs that directly correlate to resources. For example, RESTful web services for books in a library may expose many URL endpoints and the HTTP methods available for each such as GET, POST, PUT, and DELETE. The list below gives the methods, URLs, and descriptions for a sample set of services. The number 1 represents a unique identifier for books in each case.

Method	URL	Description
<b>GET</b>	/books	Retrieves a list of all books in the library.
<b>POST</b>	/books	Creates a new book.
<b>GET</b>	/books/1	Retrieves a single book.
<b>PUT</b>	/books/1	Modifies a single books.
<b>DELETE</b>	/books/1	Deletes a single book.

**i** Note that in the cases of the POST and PUT operations, additional information may be needed to describe the resource to be created or the fields that should be modified.

Moab Web Services provides RESTful web services for many resources. The methods and URLs available are documented in [Resources introduction on page 1446](#).

- [About the API on page 1423](#)

## Data format

JSON (JavaScript Object Notation) is the data format used for all communication with MWS. This format makes use of two main structures: collections of key/value pairs called *objects* and ordered lists of values called *arrays*. Objects are defined by using curly braces ({}), and arrays are defined by using square brackets ([]). A JSON object or array may contain several different types of values including numbers, booleans (true/false), strings, objects, arrays, or the keyword 'null' representing no value. For example, a simple JSON object might be defined as:

```
{
  "number": 1,
  "decimalNumber": 1.2,
  "boolean": true,
  "string": "Any string",
  "dateString": "2013-05-23 17:32:02 UTC",
  "object": {
    "key": "value"
  },
  "array": [
    "value1",
    "value2"
  ],
  "nullValue": null
}
```

Dates in MWS, for both input and output, use the pattern "yyyy-MM-dd HH:mm:ss ZZZ". For more details on that pattern, see [Joda-Time DateTimeFormat](#). For a list of valid time zone IDs, see [Joda-Time Available Time Zones](#).

For more information on JSON, see [json.org](http://json.org).

The data format of MWS is defined as follows:

- Input for a POST or PUT must be in JSON format. Set the Content-Type header to application/json.
- Output is in JSON format and always consists of an object with zero or more key/value pairs.
- The output may also be "pretty-printed" or formatted for human viewing by sending a URL parameter. For more information, see [Global URL parameters on page 1425](#).

Related topics

- [About the API on page 1423](#)

## Global URL parameters

 All URL parameters are optional.

Parameter	Valid values	Description
<b>api-version</b>	Integer	Requests a specific API version
<b>pretty</b>	<i>true</i>	Controls pretty printing of output
<b>fields</b>	Comma-separated string	Includes only specified fields in output
<b>exclude-fields</b>	Comma-separated string	Excludes specified fields from output
<b>max</b>	Integer	The maximum number of items to return
<b>offset</b>	Integer	The index of the first item to return

## API version (api-version)

See [Requesting specific API versions on page 1428](#) for information on this parameter and how it should be used.

## Pretty (pretty)

By default, the output is easy for a machine to read but difficult for humans to read. The **pretty** parameter formats the output so that it is easier to read.

## Field selection (fields)

The **fields** parameter will include *only* the specified fields in the output. For list queries, the field selection acts on the objects in **results** and not on the **totalCount** or **results** properties themselves.

The format of the **fields** parameter is a comma-separated list of properties that should be included, as in `id, state`. Using periods, sub-objects may also be specified, and fields of these objects may be included as well. This is done with the same syntax for both single sub-objects and lists of sub-objects, as in `id, requirements.requiredNodeCountMinimum, blockReason.message`.

*Example 4-1: Example for a job query*

Request

```
GET /rest/jobs?api-
version=3&fields=name, flags, requirements.taskCount, dates.createdDate
```

## Response

```

-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "dates": {"createdDate": "2012-10-17 01:11:54 UTC"},
    "flags": ["GLOBALQUEUE"],
    "name": "Moab.24",
    "requirements": [{"taskCount": 1}]
  } ]
}

```

## Field exclusion (exclude-fields)

The **exclude-fields** parameter is the opposite of the **fields** parameter. All fields will be included in the output *except* those that are specified. For list queries, the field exclusion acts on the objects in **results** and not on the **totalCount** or **results** properties themselves.

The format of the **exclude-fields** parameter is a comma-separated list of properties that should be excluded from the output, as in `id,state`. Using periods, sub-objects may also be specified, and fields of these objects may be excluded as well. This is done with the same syntax for both single sub-objects and lists of sub-objects, as in

`id,requirements.requiredNodeCountMinimum,blockReason.message`.

### Example 4-2:

Suppose a query returns the following JSON:

## Request with No Field Exclusion

```
GET /objects
```

## Response

```

-----
{
  "id": "1",
  "listOfStrings": [
    "string1",
    "string2"
  ],
  "listOfObjects": [ {
    "item1": "value1",
    "item2": "value2"
  } ],
  "singleObject": {
    "id": "obj1",
    "field1": "value1"
  }
}

```

The same query with `exclude-fields` would return the following output:

```
Request with No Field Exclusion
```

```
GET /objects?exclude-fields=id,listOfObjects.item2,singleObject.field1,listOfStrings
```

```
Response
```

```
{
  "listOfObjects": [{"item1": "value1"}],
  "singleObject": {"id": "obj1"}
}
```

## Sorting (sort)

[Images on page 1536](#) and [Events on page 1528](#) support sorting based on [MongoDB syntax](#) by using the sort parameter. To sort in ascending order, specify a 1 for the sorting field. To sort in descending order, specify a -1. Objects can also be sorted on nested fields by using dot notation to separate the sub-fields, such as field.subfield1.subfield2.

### Related topics

- [About the API on page 1423](#)

## Requesting specific API versions

Because of significant changes in the API introduced in release version 7.2.0, MWS possesses a versioned API. The `api-version` URL parameter may be used to change the requested API version for any call to MWS. The current valid API versions with their corresponding MWS versions are shown in the table below:

API version	MWS version	Documentation	Additional notes
2 (deprecated)	7.2.x	7.2.x documentation on <a href="http://docs.adaptivecomputing.com/">http://docs.adaptivecomputing.com/</a>	As of the 8.0.0 release, API version 2 is <b>officially deprecated</b> and will be removed from Moab Web Services in the next major release.
3	8.0	Contained within this document	--
latest	Latest	Contained within this document	When the <code>latest</code> API version is requested, it resolves to the latest API version of MWS, such as <code>api-version=3</code> for MWS 8.0.0.

If no API version is specified, the request is rejected. An API version must be specified with every call in Moab Web Services 8.0.0 and later.

[Resources introduction on page 1446](#) and [Resources reference on page 1782](#) contain information for the latest API version. For documentation of previous API versions, please see the table above.

## Examples

```
GET http://localhost:8080/mws/rest/nodes?api-version=2
// Data returned uses API version 2

GET http://localhost:8080/mws/rest/nodes?api-version=latest
// Data returned uses API version 3
```

### Related topics

- [About the API on page 1423](#)

## Responses and return codes

Various HTTP responses and return codes are generated from MWS operations. These are documented below according to the operation that they are associated with.

- [Listing and showing resources on page 1429](#)
- [Creating resources on page 1430](#)
- [Modifying resources on page 1431](#)
- [Deleting resources on page 1431](#)
- [Moab response headers on page 1432](#)

### Listing and showing resources

For any successful list or show operation (GET), a 200 OK response code is always returned. No additional headers beyond those typical of a HTTP response are given in the response.

The body of this response consists of the results of the list or show operation. For a list operation, the results are wrapped in metadata giving total and result counts. The result count represents the number of resource records returned in the current request, and the total count represents the number of all records available. These differ when querying or the `max` and `offset` parameters are used. The following is an example of a list operation response:

## JSON List Response Body

```

{
  "resultCount":1,
  "totalCount":5,
  "results":[
    {
      "id":"Moab.1",
      ...
    }
  ]
}

```

For a show operation, the result is given as a single object:

## JSON Show Response Body

```

{
  "id":"Moab.1",
  ...
}

```

## Creating resources

A successful creation (POST) of a resource has two potential response codes:

- If the resource was created immediately, a 201 Created response code is returned.
- If the resource is still being created, a 202 Accepted response code is returned.

In either case, a `Location` header is added to the response with the full URL which can be used to get more information about the newly created resource or the task associated with creating the resource (if a 202 is returned).

Additionally, the body of the response will contain the unique identifier of the newly created resource or the unique identifier for the task associated with creating the resource (if a 202 is returned).

For example, during creation or submission of a job, a 201 response code is returned with the following response headers and body:

## Job Creation Response Headers

```

HTTP/1.1 201 Created
Server: Apache-Coyote/1.1
Location: /mws/rest/jobs/Moab.21
X-Moab-Status: Success
X-Moab-Code: 000
Content-Type: application/json;charset=utf-8
Content-Length: 16
Date: Wed, 21 Dec 2011 23:04:47 GMT

```

## Job Creation Response Body

```

{"id":"Moab.21"}

```

## Modifying resources

For any successful resource modification operation (`PUT`), a `200 OK` or `202 Accepted` response code is returned. A `200` response code signifies that the modification was immediately completed. No additional headers are returned in this case. A `202` response code is used again to signify that the modification is not yet complete and additional actions are taking place. In this case, a `Location` header is also returned with the full URL of the resource describing the additional actions.

In the case of a `200` response code, the body of this response typically consists of an object with a single `messages` property containing a list of statuses or results of the modification(s). However, a few exceptions to this rule exist as documented in [Resources introduction on page 1446](#). In the case of a `202` response code, the format is the same as for a `202` during a creation operation, in that the body consists of an object with the unique identifier for the task associated with the additional action(s).

For example, when modifying a job, several messages may be returned as follows with the associated `200` response code.

### Job Modification Response Headers

```
HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
X-Moab-Status: Success
X-Moab-Code: 000
X-Moab-Message:
Content-Type: application/json;charset=utf-8
Content-Length: ...
Date: Thu, 22 Dec 2011 16:49:43 GMT
```

### JSON Modify Response Body

```
{
  "messages": [
    "gevent processed",
    "variables successfully modified"
  ]
}
```

## Deleting resources

For any successful resource deletion operation (`DELETE`), a `200 OK` or `202 Accepted` response code is returned. A `200` response code signifies that the deletion was immediately completed. No additional headers are returned in this case. A `202` response code is used again to signify that the deletion is not yet complete and additional actions are taking place. In this case, a `Location` header is also returned with the full URL of the resource describing the additional actions.

In the case of a `200` response code, the body of this response is empty. In the case of a `202` response code, the format is the same as for a `202` during a creation operation, in that the body consists of an object with the unique identifier for the task associated with the additional action(s).

For example, when deleting a job, a `200` response code is returned with an empty body as shown below.

```

Job Deletion Response
-----
HTTP/1.1 200 OK
Server: Apache-Coyote/1.1
X-Moab-Status: Success
X-Moab-Code: 000
X-Moab-Message:
Content-Type: application/json;charset=utf-8
Content-Length: 0
Date: Thu, 22 Dec 2011 16:49:43 GMT

```

## Moab response headers

In addition to the typical HTTP headers and the Location header described above, several headers are returned if the operations directly interact with Moab. These headers are described in the following table:

Name	Description
<b>X-Moab-Status</b>	One of Success, Warning, or Failure. Describes the overall status of the Moab request.
<b>X-Moab-Code</b>	A three digit code specifying the exact error encountered, used only in debugging.
<b>X-Moab-Message</b>	An optional message returned by Moab during the request.

## Error messages

Below is an explanation of what error message format to expect when an HTTP status code other than 20x is returned. All error codes have a response code of 400 or greater.

- [400 Bad request on page 1433](#)
- [401 Unauthorized on page 1433](#)
- [403 Forbidden on page 1433](#)
- [404 Not found on page 1433](#)
- [405 Method Not Allowed on page 1433](#)
- [500 Internal server error on page 1434](#)

## 400 Bad request

This response code is returned when the request itself is at fault, such as when trying to modify a resource with an empty `PUT` request body or when trying to create a new resource with invalid parameters. The response body is as follows:

```
{
  "messages": [
    "Message describing error",
    "Possible prompt to take action"
  ]
}
```

## 401 Unauthorized

This response code is returned when authentication credentials are not supplied or are invalid. The response body is as follows:

```
{
  "messages": [
    "You must be authenticated to access this area"
  ]
}
```

## 403 Forbidden

This response code is returned when the credentials supplied are valid, but the permissions granted are insufficient for the operation. This occurs when using application accounts (see [Access control on page 1420](#)) with limited access.

```
{
  "messages": [
    "You are not authorized to access this area"
  ]
}
```

## 404 Not found

This response code is returned when the request specifies a resource that does not exist. The response body is as follows:

```
{
  "messages": [
    "The resource with id 'uniqueId' was not found"
  ]
}
```

## 405 Method Not Allowed

This response code is returned when a resource does not support the specified HTTP method as an operation. The response body is as follows:

```
{
  "messages": [
    "The specified HTTP method is not allowed for the requested resource"
  ]
}
```

## 500 Internal server error

This indicates that there was an internal server error while performing the request, or that an operation failed in an unexpected manner. These are the most serious errors returned by MWS. If additional information is needed, the MWS log may contain further error data. The response body is as follows:

```
{
  "messages": [
    "A problem occurred while processing the request",
    "A message describing the error"
  ]
}
```

## Pre and post-processing hooks

MWS provides functionality to intercept and modify data sent to and returned from web services for all available resources. This is done by creating hooks in Groovy files located in a sub-directory of the `MWS_HOME` directory (by default, `/opt/mws/hooks`).

Please see [Reference on page 1438](#) in this topic for the full reference for available hooks and methods available to them.

- [Configuring hooks on page 1434](#)
- [Defining hooks for a resource on page 1435](#)
- [Before hooks on page 1436](#)
- [After hooks on page 1437](#)
- [Error handling on page 1437](#)
- [Defining common hooks on page 1437](#)
- [Reference on page 1438](#)

## Configuring hooks

The directory of the `hooks` folder may be changed by providing a value for `mws.hooks.location` in the configuration file. If the directory starts with a path separator (ie `/path/to/hooks`), it will be treated as an absolute path. Otherwise, it will be used relative to the location of the MWS home directory (for more information, see [Configuring Moab Web Services on page 1395](#)).

For example, if the MWS home directory is set to `/opt/mws`, the hooks directory by default would be in `/opt/mws/hooks`. Changing the `mws.hooks.location` property to `myhooks` would result in the hooks directory being located at `/opt/mws/myhooks`. Due to the default location of the MWS home directory, the default directory of the hooks directory is `/opt/mws/hooks`.

On startup, if the `hooks` directory does not exist, it will be created with a simple `README.txt` file with instructions on how to create hooks, the objects available, and the hooks available. If the folder or file is unable to be created, a message will be printed on the log with the full location of a `README` file, copied into a temporary directory.

## Defining hooks for a resource

Hooks are defined for resources by creating groovy class files in the hooks directory (`MWS_HOME/hooks` by default). Each groovy file must be named by the resource URL it is associated with and end in ".groovy". The following table shows some possible hook files that may be created. Notice that the virtual machines hook file is abbreviated as `vms`, just as the URL for virtual machines is `/rest/vms`. In most cases, the hook file names will exactly match the URLs. However, in cases of nested URLs—such as with "accounting/users"—the hook file name must replace slashes with periods. For example:

Resource	Hook filename
<b>Jobs</b>	<code>jobs.groovy</code>
<b>Nodes</b>	<code>nodes.groovy</code>
<b>Virtual Machines</b>	<code>vms.groovy</code>
<b>Accounting Users</b>	<code>accounting.users.groovy</code>
<b>Accounting Funds Reports Statement</b>	<code>accounting.funds.reports.statement.groovy</code>
<b>Accounting Charge Rates</b>	<code>accounting.charge-rates.groovy</code>
<i>url</i>	<i>url.groovy</i>

**i** `plugins.rm.groovy` is a valid hook filename. It works for the following URL:  
`/rest/plugins/<pluginID or all>/rm/<query or action>` (for example,  
`/rest/plugins/plugin1/rm/cluster-query`).

A complete example of a hook file is as follows:

## Complete Hook File

```

// Example before hook
def beforeList = {
  // Perform actions here
  // Return true to allow the API call to execute normally
  return true
}

def beforeShow = {
  // Perform actions here
  // Render messages to the user with a 405 Method Not Allowed
  // HTTP response code
  renderMessages("Custom message here", 405)
  // Return false to stop normal execution of the API call
  return false
}

// Example after hook
def afterList = { o ->
  if (!isSuccess()) {
    // Handle error here
    return false
  }
  // Perform actions here
  return o
}

```

**i** You must convert all actions or queries that are separated by dashes to a camel case. For example, the hooks called for "cluster-query" should be `beforeClusterQuery` and `afterClusterQuery`.

As the specific format for the hooks for `before` and `after` are different, each will be explained separately.

## Before hooks

As shown above, before hooks require no arguments. They can directly act on several properties, objects, and methods as described in [Reference on page 1438](#). The return value is one of the most important aspects of a before hook. If it is false, a `renderMessages`, `renderObject`, `renderList`, `render`, or `redirect` method *must* first be called. This signifies that the API call should be interrupted and the render or redirect action specified within the hook is to be completed immediately.

A return value of `true` signifies that the API call should continue normally. Parameters, session variables, request and response variables may all be modified within a `before` hook.

**i** If no return value is explicitly given, the result of the last statement in the `before` hook to be executed will be returned. This may cause unexpected behavior if the last statement resolves to `false`.

For all methods available to `before` hooks as well as specific examples, see [beforeSave on page 1438](#).

## After hooks

`After` hooks are always passed one argument: the object or list that is to be rendered as JSON. This may be modified as desired, but note that the object or list value is either a [JSONArray](#) or [JSONObject](#). Therefore, it may not be accessed and modified as a typical groovy Map.

Unlike `before` hooks, `after` hooks should not call the `render*` methods directly. This method will automatically be called on the resulting object or list returned. The `redirect` and `render` methods should also not be called at this point. Instead, if a custom object or list is desired to be used, the `serializeObject` and `serializeList` methods are available to create suitable results to return.

The return value of an `after` hook may be one of two possibilities:

- The potentially modified object or list passed as the first argument to the hook. In this case, this value will override the output object or list unless it is null.
- Null or false. In this case, the original, unmodified object or list will be used in the output.

The return value of the `after` hook, if not null or false, *must* be the modified object passed into the hook or an object or list created with the `serialize*` methods.

For all methods available to `after` hooks as well as specific examples, see [afterSave on page 1438](#).

## Error handling

`After` hooks, unlike the `before` hooks, have the possibility of handling errors encountered during the course of the request. Handling errors is as simple as adding a one-line check to the hook as shown above or in the following code:

```
if (!isSuccess()) {
    // Handle error
    return false
}
```

It is recommended that each `after` hook contain at least these lines of code to prevent confusion on what the input object or list represents or should look like.

The `isSuccess()` function is false if and only if the HTTP response code is 400 or higher, such as a 404 Not Found, 400 Bad Request, or 500 Internal Server Error and the cause of the error state was not in the associated `before` hook. In other words, objects and lists rendered in the `before` hook with any HTTP response code will never run the associated `after` hook.

When handling errors, the passed in object will always contain a `messages` property containing a list of strings describing the error(s) encountered.

## Defining common hooks

Sometimes it is beneficial to create hooks which are executed for all calls of a certain type, such as a `beforeList` hook that is executed during the course of listing any resource. These are possible using an `all.groovy` file. The format of this file is exactly the same as other hook files. The order of execution is as follows:

1. Before common hook executed.
2. Before resource-specific hook executed.
3. Normal API call executed.
4. After resource-specific hook executed.
5. After common hook executed.

## Reference

This page gives specific examples and reference for implementing hooks in MWS.

### [Available hooks](#)

The following table lists the available hooks for each resource with their associated HTTP method and description.

Name	HTTP method	Description
<b>beforeList</b>	GET	Runs before an API call that lists resources (for example, GET /rest/jobs).
<b>afterList</b>	GET	Runs after an API call that lists resources.
<b>beforeShow</b>	GET	Runs before an API call that returns a single resource (for example, GET /rest/jobs/job.1).
<b>afterShow</b>	GET	Runs after an API call that returns a single resource.
<b>beforeSave</b>	POST	Runs before an API call that saves a new resource (for example, POST /rest/-jobs).
<b>afterSave</b>	POST	Runs after an API call that returns a single resource.
<b>beforeUpdate</b>	PUT	Runs before an API call that returns a single resource (for example, PUT /rest/jobs/job.1).
<b>afterUpdate</b>	PUT	Runs after an API call that returns a single resource.
<b>beforeDelete</b>	DELETE	Runs before an API call that returns a single resource (for example, DELETE /rest/jobs/job.1).
<b>afterDelete</b>	DELETE	Runs after an API call that returns a single resource.

**i** If a resource does not support a certain operation, any hooks for that operation will simply be ignored—such as [beforeSave](#) and [afterSave](#) hooks for the Node resource, where saving is not supported.

### Available properties

The following table lists the properties, objects, and methods available in all hooks. Note that although it is possible to directly call the `render*` methods in the `after` hooks, it is not recommended.

Name	Type	Description
<b>params</b>	Map	Contains all URL parameters as well as the body of the request as parsed JSON.
<b>request</b>	<a href="#">HttpServletRequest</a>	Contains properties of the HTTP request.
<b>response</b>	<a href="#">HttpServletResponse</a>	Contains properties of the HTTP response which can be modified directly.
<b>session</b>	<a href="#">HttpSession</a>	Contains the session parameters which can be modified directly.
<b>flash</b>	Map	Temporary storage that stores objects within the session for the next request only.
<b>controllerName</b>	String	The name of the controller responding to the request. Only available in <code>before</code> hooks.
<b>actionName</b>	String	The name of the action to be run on the controller. Only available in <code>before</code> hooks.
<b>apiVersion</b>	String	The API version for the current request (for example, 1 for 7.0 and 7.1, 2 for 7.2).

**i** The parsed JSON may be accessed in `before` hooks as a simple groovy Map with `params[controllerName]`.

In addition, several methods are available to the hooks. These are described in the following sections.

### Redirect

The `redirect` method may be used to redirect the request to another API call or an arbitrary URL.

```
redirect(uri:'/rest/jobs')           // uri is used for internal redirection within MWS
redirect(url:'http://adaptivecomputing.com') // url is used for external redirection
redirect(uri:'http://adaptivecomputing.com', params:[lang:'en']) // params may be used
for URL parameters
```

**i** The `redirect` method will use the GET HTTP method for the resulting redirected request.

See the `redirect` method's [documentation](#) for more information.

### Rendering objects, lists, or messages

There are several `render*` methods available to handle any case where objects or lists are desired to be rendered directly from the hook without continuing to the API call. Three different methods may be used depending on the desired output object type:

#### Render object

---

```
// Object that should be rendered as JSON
def objectToRender = ...
// HTTP response code (bad request)
def responseCode = 400
// Render a simple object
renderObject(objectToRender)
// Render a simple object with a custom response code
renderObject(objectToRender, responseCode)
```

#### Render list

---

```
// List that should be rendered as JSON
def listToRender = ...
// If the totalCount property differs from resultCount, use this value instead
def totalCount = ...
// HTTP response code (bad request)
def responseCode = 400
// Render a simple list
//   Dynamically adds "resultCount" and "totalCount" properties based on the size of
//   the input list
renderList(listToRender)
// Render a simple list with a custom "totalCount"
renderList(listToRender, totalCount)
// Render a simple list without changing the "totalCount" but with a custom response
//   code
renderList(listToRender, null, responseCode)
// Render a simple list with a custom "totalCount" and response code
renderList(listToRender, totalCount, responseCode)
```

#### Render message(s)

---

```
// Messages
def messageToRender = "Single message"
def messagesListToRender = ["Message 1", "Message 2"]
// HTTP response code (bad request)
def responseCode = 400
// Render messages as an object with a property of "messages" containing a list of the
//   messages passed in
renderMessages(messageToRender)
renderMessages(messageToRender, responseCode)
// Supports either a single String or list of Strings
renderMessages(messagesListToRender)
renderMessages(messagesListToRender, responseCode)
```

**i** It is not recommended to call any of these methods from an `after` hook.

### Render

Less commonly used, the `render` method is also available directly. This may be used to render text directly, change the content-type of the output, and many other functions. See the `render` method's [documentation](#) for more information.

**i** It is not recommended to call this method from an `after` hook.

### Serialize objects

The `serializeObject` and `serializeList` methods may be used to convert a custom object or list respectively into a format usable for returning in the `after` hooks. Simply pass in the object or list and a serialized version will be returned from the method.

```
def afterShow = {
    def objectToRender = ...
    def serializedObject = serializeObject(objectToRender)
    return serializedObject
}
```

```
def afterShow = {
    def listToRender = [...]
    def serializedList = serializeList(listToRender)
    return serializedList
}
```

### Error handling

Error handling is only available in `after` hooks by using the following check:

```
if (!isSuccess()) {
    // Handle error
    return ... // False or modified object/list to render
}
```

### Usage examples

#### **Override an API call**

The following hook would serve to override an entire API call, the list call in this case, and return a `messages` list containing a single element of "Action is not supported" and a HTTP response code of 405 (Method Not Allowed):

```
def beforeList = {
    renderMessages("Action is not supported", 405)
    return false
}
```

To be even more specific and disallow the deletion of virtual machines, the following may be used as the `vms.groovy` file:

```
def beforeDelete = {
    renderMessages("Virtual Machine deletion is not allowed", 405)
    return false
}
```

### Add an additional property during job creation

To add an additional property to a job definition during creation, create a `beforeSave` hook in the `jobs.groovy` file as follows:

```
def beforeSave = {
    // params[controllerName] is equivalent to params["job"] or params.job
    params[controllerName].user = "myuser"
}
```

This would cause the created job to have a user of `myuser`.

### Redirect based on URL parameter

To redirect an API call if a certain URL parameter exists, create a `beforeSave` hook in the `jobs.groovy` file as follows:

```
def beforeSave = {
    if (params.external) {
        redirect(url:'http://example.com/create-job')
        return false; // Stop API call
    }
}
```

This would cause an API call of `PUT /rest/jobs?external=1` to redirect to `GET http://example.com/create-job`.

### Remove a property from getting a single job

To remove a property from the output of getting a single job, create an `afterShow` hook in the `jobs.groovy` file as follows:

```
def afterShow = { o ->
    o.discard("group")
    return o
}
```

This will cause the resulting JSON to be missing the `group` property of the job resource. Note again that these calls must use the [JSONArray](#) and [JSONObject](#) classes as mentioned in [After hooks on page 1437](#).

### Filter list items

To filter the items in a list nodes request based on user provided query parameter in the URL, use the following in the `nodes.groovy` file. A sample request that would activate the filter is `http://localhost:8080/mws/rest/nodes?api-version=3&filter-power=On`.

```

def afterList = { o ->
    // Do not filter if the user did not ask for it
    if (!params['filter-power'])
        return o
    // o = {resultCount: x, totalCount: x, results:[...]}

    // Using a built-in groovy method findAll to return all
    // list items that return true from the block
    def results = o.results.findAll { node ->
        // Includes the node only if the power equals the user input
        return params['filter-power'].equalsIgnoreCase(node.power)
    }

    // Sets the results on the return object and updates the counts
    o.element("results", results)
    o.element("resultCount", results.size())
    return o
}

```

To filter the items in a list nodes request based on values within the list itself, such as variable values, use the following in the `nodes.groovy` file.

```

def afterList = { o ->
    // o = {resultCount: x, totalCount: x, results:[...]}
    // Using a built-in groovy method findAll to return all
    // list items that return true from the block
    def results = o.results.findAll { node ->
        // Includes the node only if the variable "included" is set to "true"
        return node.variables?.included=="true"
    }

    // Sets the results on the return object and updates the counts
    o.element("results", results)
    o.element("resultCount", results.size())
    return o
}

```

## Authentication

MWS uses Basic Authentication for all REST API requests. This means that a username and password must be provided for each call to resources. There are two types of accounts that can be granted access: **Users** and **Applications**.

- For instructions on how to set the credentials for the default **User** account, see [Setting up MWS security on page 1410](#).
- For instructions on how to manage **Application** accounts, see [Access control on page 1420](#).

To use Basic Authentication, each client request must contain a header that looks like this:

```
Authorization: Basic YWRhcHRpdmU6YzNVU3R1bkU=
```

The string after the word `Basic` is the base64 encoding of `username : password`. In the example above, `YWRhcHRpdmU6YzNVU3R1bkU=` is the base64 encoding of `adaptive:c3UStunE`. For more details, see section 2 of [RFC 2617](#).

 The username and password in the Basic Authentication header are encoded but not encrypted. Therefore, it is *strongly* recommended that MWS be run behind a proxy (like Apache) with SSL enabled. For more information, see [Setting up MWS security on page 1410](#).

## System events

The broad category of system events may be broken down into two subcategories: events and notification conditions.

- [Events on page 1444](#)
- [Notification conditions on page 1445](#)

### Events

[Events on page 1528](#) are created by many components in the system, but most events originate from Moab Workload Manager and Moab Web Services. Events can be [created via the MWS interface](#) or by being placed on the message queue. The ZeroMQ™ message queue libraries were introduced in Moab and MWS 7.5.0. The message queue is critical to service lifecycle functionality (see "Service lifecycle" in the *Moab Cloud Suite Installation Guide*).

In a typical system, Moab will communicate events to MWS via a "private" message queue, and then MWS will replicate the events on the "public" message queue, or the message queue that is available to subscribers with the correct secret keys. In some cases, such as those related to the MWS service lifecycle, MWS uses events to determine activities or capabilities that are available.

A typical message on the message queue may look like the following (sent with a topic of `system.moab`):

Sample message on message queue

```
{
  "body" : {
    "associatedObjects" : [
      {
        "id" : "Moab",
        "type" : "scheduler"
      }
    ],
    "code" : 16777619,
    "eventDate" : "2014-02-28T10:57:21.000-0700",
    "message" : "A scheduler iteration is ending.",
    "origin" : "MSysMainLoop.c, MSysMainLoop, line 959"
  },
  "messageId" : "843269550",
  "messageType" : "event",
  "senderId" : "mwm@mwm-server",
  "sentDate" : "2014-02-28T10:57:21.000-0700",
  "ttl" : 3000
}
```

## Notification conditions

[Notification conditions on page 1580](#) are related to an event, but differ in three distinct areas:

1. Notification conditions are a persistent condition of the system or a component rather than a single occurrence.
  - They are ongoing rather than reoccurring, which is why they are generated from NotificationConditions.
  - They may be observed many times, but the condition is always the same.
  - A good test for this is if something "is" wrong rather than something "went" wrong.
2. Notification conditions can be acted on to result in a resolved state, mean the administrator or user can and must take actions to "fix" the condition or problem.
3. Notification conditions contain state information based on administrator or user input, meaning that they contain information about the condition (similar to events), but also contain the "status" of the administrator's view of the notification, whether it is currently open, dismissed, or ignored.

In general, questions may be asked to ascertain whether an event or a notification condition is the right fit for an occurrence. These questions, along with some sample situations, are provided below.

- Is the occurrence the root cause of a potentially ongoing condition?
  - A VM migration failed because the VM's state was unknown. The root cause was that the state was unknown, not that the VM migration failed. Therefore, VM migration failed would be an event, while the unknown state would be a notification condition.
  - A VM service provision fails because there are no hypervisors that satisfy the requirements. This would be an event. Note that there may be a notification related to this failure, such as a service template requires a feature that does not exist on any

hypervisors in the system, but this would be distinctly detected and managed from the provision failure event.

- A request to MWS failed because the connection between Moab and MongoDB was misconfigured. The failed request may be represented as an event, but a notification condition should exist that the connection between Moab and MongoDB was down.
- Can an administrator or user affect the outcome of the occurrence?
  - The outcome of a VM migration failing in the past and cannot be changed by the administrator. However, the outcome of a future VM migration may be changed when the administrator resolves the root problem (such as VM state is unknown).

## Resources

### Resources introduction

The sections in this chapter show the MWS resources and the HTTP methods defined on them. The prefix for these resources depends on how the `mws.war` file is deployed. A typical prefix would be `http://localhost:8080/mws`. Using this example, one absolute resource URI would be `http://localhost:8080/mws/rest/jobs`.

This section only contains documentation for the latest API version. Please see the table in [Requesting specific API versions on page 1428](#) for links to documentation for previous versions.

This chapter contains these sections:

- [Access control lists \(ACLs\) on page 1448](#)
- [Accounting Accounts on page 1451](#)
- [Accounting Allocations on page 1455](#)
- [Accounting Charge rates on page 1459](#)
- [Accounting Funds on page 1463](#)
- [Accounting Liens on page 1473](#)
- [Accounting Organizations on page 1477](#)

# Access control lists (ACLs)

This topic describes behavior of the ACL Rules (Access Control List Rules) object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Access Control Lists \(ACLs\)](#) reference contains the type and description of all fields in the **ACL Rules** object. It also contains details regarding which fields are valid during PUT and POST actions.

## Supported methods

**i** ACLs are not directly manipulated through a single URL, but with sub-URLs of the other objects such as Virtual Containers and Reservations.

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/reservations/&lt;rsvid&gt;/acl-rules/&lt;aclId&gt;</a>	--	<a href="#">Create or update ACL</a>	--	<a href="#">Delete ACL</a>
<a href="#">/rest/vcs/&lt;vcId&gt;/acl-rules/&lt;aclId&gt;</a>	--	<a href="#">Create or update ACL</a>	--	<a href="#">Delete ACL</a>

This topic contains these sections:

- [Getting ACLs on page 1448](#)
- [Creating or updating ACLs on page 1449](#)
  - [Create or update ACL on page 1449](#)
- [Deleting ACLs on page 1450](#)
  - [Delete ACL on page 1450](#)

## Getting ACLs

Although **ACL Rules** cannot be retrieved directly using the GET method on any of the `acl-rules` resources, **ACL Rules** are attached to supported objects when querying for them. Each supported object contains a field named `aclRules`, which is a collection of the **ACL Rules** defined on that object.

## Supported objects

The following is a list of objects that will return **ACL Rules** when queried:

- [Reservations on page 1646](#)
- [Standing reservations on page 1661](#)

## Creating or updating ACLs

The HTTP PUT method is used to create or update **ACL Rules**. The request body can contain one or more **ACL Rules**. If an **ACL Rule** with the same `type` and `value` exists, then it will be overwritten.

### Quick reference

```
PUT http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-version=3
```

## Create or update ACL

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>objectId</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

The request body below shows all the fields that are available for the PUT method, along with some sample values.

JSON Request Body

```
{
  "aclRules": [
    {
      "affinity": "POSITIVE",
      "comparator": "LEXIGRAPHIC_EQUAL",
      "type": "USER",
      "value": "ted"
    }
  ]
}
```

### Sample response

This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON Request Body

```
{"messages":["Reservation 'rsv1' successfully modified"]}
```

### Samples

Create or update multiple ACLs on a single object:

```

CPUT http://localhost:8080/mws/rest/reservations/system.21/acl-rules?api-version=3
-----
{"aclRules": [
  {
    "affinity": "POSITIVE",
    "comparator": "LESS_THAN_OR_EQUAL",
    "type": "DURATION",
    "value": "3600"
  },
  {
    "affinity": "POSITIVE",
    "comparator": "LEXIGRAPHIC_EQUAL",
    "type": "USER",
    "value": "ted"
  }
]}

```

Restrictions

- **ACL Rules** cannot be added to or updated on **Standing Reservations**.

## Deleting ACLs

The HTTP DELETE method is used to remove **ACL Rules**.

Quick reference

**i** **ACL Rules** cannot be removed from **Standing Reservations**.

```

DELETE http://localhost:8080/mws/rest/reservations/<rsvId>/acl-rules?api-
version=3/<aclId>

```

## Delete ACL

URLs and parameters

```

DELETE http://localhost:8080/mws/rest/reservations/<objectId>/acl-rules?api-
version=3/<aclId>

```

Parameter	Required	Type	Valid values	Description
<b>objectId</b>	Yes	String	--	The unique identifier of the object from which to remove the <b>ACL Rule</b> .
<b>aclId</b>	Yes	String	--	A string representing the <b>ACL Rule</b> , with the format type:value.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

**i** This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

```
JSON Response
-----
{"messages":["Successfully modified reservation 'rsv1'"]}
```

Restrictions

- **ACL Rules** cannot be removed from **Standing Reservations**.

# Accounting

## Accounting Accounts

This section describes the services available through Moab Web Services for interacting with the **Account** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Accounts](#) reference contains the type and description of the default fields for the **Accounts** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/accounts</a>	<a href="#">Get all accounts</a>	--	--	--
<a href="#">/rest/accounting/accounts/&lt;id&gt;</a>	<a href="#">Get single account</a>	--	--	--

This topic contains these sections:

- [Getting accounts on page 1452](#)
  - [Get all accounts on page 1452](#)
  - [Get single account on page 1454](#)

## Getting accounts

The HTTP GET method is used to retrieve **Accounts** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3
GET http://localhost:8080/mws/rest/accounting/accounts/<id>?api-version=3
```

## Get all accounts

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3&proxy-user=<user>
[&query=<query_conditions>][&fields=<fields_to_display>][&sort=<fields_to_sort>]|&show-
all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>query</b>	No	JSON	--	Results are restricted to those having the specified field values.	query={"organization":"sciences"}

**i** The **query** parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.

Parameter	Required	Type	Valid values	Description	Example
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,organization
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	sort={"organization":1}
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/accounts?api-version=3&proxy-user=amy&fields=id,organization&pretty=true
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "organization": "sciences",
      "id": "biology"
    },
    {
      "organization": "sciences",
      "id": "chemistry"
    }
  ]
}
```

## Get single account

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/accounts/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object.	--
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,organization
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/accounts/chemistry?api-version=3&proxy-user=amy&pretty=true
-----
{
  "id": "chemistry",
  "active": true,
  "organization": "",
  "description": "Chemistry Dept",
  "users": [
    {
      "id": "amy",
      "active": true,
      "admin": false
    },
    {
      "id": "bob",
      "active": true,
      "admin": false
    },
    {
      "id": "dave",
      "active": true,
      "admin": false
    }
  ]
}
```

## Accounting Allocations

This section describes the services available through Moab Web Services for interacting with the **Allocation** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Allocations](#) reference contains the type and description of the default fields for the **Allocation** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/accounting/allocations</code>	<a href="#">Get all allocations</a>	--	--	--
<code>/rest/accounting/allocations/&lt;id&gt;</code>	<a href="#">Get single allocation</a>	--	--	--

This topic contains these sections:

- [Getting allocations on page 1456](#)
  - [Get all allocations on page 1456](#)
  - [Get single allocation on page 1458](#)

## Getting allocations

The HTTP GET method is used to retrieve **Allocation** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3
GET http://localhost:8080/mws/rest/accounting/allocations/<id>?api-version=3
```

### Get all allocations

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>query</b>	No	JSON	--	Results are restricted to those having the specified field values. <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.                 </div>	query={"active":true}
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,fund,amount

Parameter	Required	Type	Valid values	Description	Example
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	<code>sort={"fund":1}</code>
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/accounting/allocations?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "totalCount": 5,
  "resultCount": 5,
  "results": [
    {
      "id": 1,
      "fund": 1,
      "startTime": "2013-07-12 22:16:33 UTC",

## Accounting Charge rates

This section describes the services available through Moab Web Services for interacting with the **ChargeRate** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

The [Fields: Charge Rates](#) reference contains the type and description of the default fields for the **ChargeRates** object.

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/charge-rates</a>	<a href="#">Get all charge rates</a>	--	--	--
<a href="#">/rest/accounting/charge-rates/&lt;name&gt;/&lt;value&gt;</a>	<a href="#">Get single charge rate</a>	--	--	--
<a href="#">/rest/accounting/charge-rates/&lt;name&gt;</a>	<a href="#">Get single charge rate</a>	--	--	--

This topic contains these sections:

- [Getting charge rates on page 1460](#)
  - [Get all charge rates on page 1460](#)
  - [Get single charge rate on page 1462](#)

## Getting charge rates

The HTTP GET method is used to retrieve **ChargeRate** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3/<name>
[/<value>]
```

## Get all charge rates

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3&proxy-
user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_
sort>]|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
<b>query</b>	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div style="border: 1px solid #0056b3; padding: 5px; margin-top: 10px;"> <p><b>i</b> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	<code>query={"name":"QualityOfService"}</code>
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	<code>fields=id,organization</code>
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	<code>sort={"organization":1}</code>

Parameter	Required	Type	Valid values	Description	Example
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3&proxy-user=moab&pretty=true
```

```
-----
{
  "totalCount": 4,
  "resultCount": 4,
  "results": [
    {
      "name": "Processors",
      "value": "",
      "amount": "1/s",
      "description": "1 credit per processor-second"
    },
    {
      "name": "QualityOfService",
      "value": "high",
      "amount": "*2",
      "description": "Charge double for high QOS"
    },
    {
      "name": "QualityOfService",
      "value": "low",
      "amount": "*.5",
      "description": "Charge half for low QOS"
    },
    {
      "name": "QualityOfService",
      "value": "",
      "amount": "*1",
      "description": "No extra charge for \"normal\" QOSes"
    }
  ]
}
```

### Get single charge rate

**i** A regular charge rate is uniquely specified by both its name and its value. A default charge rate has a null value and is uniquely specified by only its name.

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/charge-rates?api-version=3/<name>
[/<value>]?proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>name</b>	Yes	String	--	The name of the charge rate.	--
<b>value</b>	No	String	--	The value of the charge rate.	--
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=name,value,amount
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/charge-rates/QualityOfService/high?api-version=3&proxy-user=moab&pretty=true
-----
{
  "name": "QualityOfService",
  "value": "high",
  "amount": "*2",
  "description": "Charge double for high QOS"
}
```

## Accounting Funds

This section describes the services available through Moab Web Services for interacting with the **Fund** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Funds](#), [Fields: Fund Balances](#), [Fields: Fund Statements](#), and [Fields: Fund Statement Summary](#) reference sections contain the type and description of the default fields in the **Fund** object as well as related objects and reports given in the URLs below.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/funds</a>	<a href="#">Get all funds</a>	--	--	--
<a href="#">/rest/accounting/funds/&lt;id&gt;</a>	<a href="#">Get single fund</a>	--	--	--
<a href="#">/rest/accounting/funds/balances</a>	<a href="#">Get all fund balances</a>	--	--	--
<a href="#">/rest/accounting/funds/reports/statement</a>	<a href="#">Get fund statement</a>	--	--	--
<a href="#">/rest/accounting/funds/reports/statement/summary</a>	<a href="#">Get fund statement summary</a>	--	--	--

This topic contains these sections:

- [Getting funds on page 1464](#)
  - [Get all funds on page 1465](#)
  - [Get single fund on page 1467](#)
  - [Get all fund balances on page 1469](#)
  - [Get fund statement on page 1471](#)
  - [Get fund statement summary on page 1472](#)

## Getting funds

The HTTP GET method is used to retrieve **Fund** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/<id>?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/balances?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-version=3
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-version=3
```

## Get all funds

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3&proxy-user=<user>
[&active=true][&filter=<filter_options>[&filter-type=<filter_type>]][&query=<query_
conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=
(true|false)]
```

Parameter	Required	Type	Description	Example
<b>proxy-user</b>	Yes	String	Perform action as defined MAM user.	proxy-user=amy
<b>active</b>	No	Boolean	Lists only active or non-active allocations of the fund. The fund amount becomes the sum of the active/inactive allocations.	active=true
<b>filter</b>	No	JSON	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
<b>filter-type</b>	No	String	Query funds based on defined MAM filter type.	filter-type=NonExclusive

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	<p>Results are restricted to those having the specified field values.</p> <div style="border: 1px solid #004a7c; padding: 5px; margin-top: 10px;"> <p> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	<pre>query={"priority":"2","allocation.active":"false"}</pre>
<b>fields</b>	No	String	Comma-separated list of field names to display.	<pre>fields=id,name,amount</pre>
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	<pre>sort={"id":1}</pre>

Parameter	Required	Type	Description	Example
<b>show-all</b>	No	Boolean (true or false)	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/funds?api-version=3&proxy-user=amy&fields=id,name,amount&pretty=true
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "id": 1,
      "name": "biology",
      "amount": 50000000
    },
    {
      "id": 2,
      "name": "chemistry",
      "amount": 99727
    }
  ]
}
```

**Get single fund**

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds/<id>?api-version=3&proxy-user=<user>[&active=(true|false)] [&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Description	Example
<b>id</b>	Yes	String	The unique identifier of the object	--
<b>proxy-user</b>	Yes	String	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Description	Example
<b>active</b>	No	Boolean	Lists only active or non-active allocations of the fund. The fund amount becomes the sum of the active/inactive allocations.	active=true
<b>fields</b>	No	String	Comma-separated list of field names to display.	fields=id,name,amount
<b>show-all</b>	No	Boolean (true or false)	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
GET http://localhost:8080/mws/rest/accounting/funds/1?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": 1,
  "name": "biology",

## Get all fund balances

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds/balances?api-version=3&proxy-user=<user>[&filter=<filter_options>][&filter-type=<filter_type>]
```

Parameter	Required	Type	Description	Example
<b>proxy-user</b>	Yes	String	Perform action as defined MAM user.	proxy-user=amy
<b>filter</b>	No	JSON	Query funds based on defined MAM filter.	filter={"account": "chemistry"}
<b>filter-type</b>	No	String	Query funds based on defined MAM filter type.	filter-type-e=NonExclusive

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

The fund balances resource is an aggregation of fund data. For more information, see the [Fields: Fund Balances on page 1809](#) reference section.

```
GET http://localhost:8080/mws/rest/accounting/funds/balances?api-version=3&proxy-user=amy&pretty=true
```

```
{

## Get fund statement

### URLs and parameters

```

GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-
version=3&proxy-user=<user>[&filter=<filter_options>][&filter-type=<filter_type>]
[&start-time=<date_string>][&end-time=<date_string>][&context=<context>]

```

Parameter	Required	Type	Description	Example
<b>proxy-user</b>	Yes	String	Perform action as defined MAM user.	proxy-user=amy
<b>filter</b>	No	JSON	Query funds based on defined MAM filter.	filter={"account": "chemistry"}
<b>filter-type</b>	No	String	Query funds based on defined MAM filter type.	filter-type=e=NonExclusive
<b>start-time</b>	No	Date, -infinity, or now	Filter allocations and transaction after a start time.	start-time=2012-04-03 15:24:39 UTC
<b>end-time</b>	No	Date, -infinity, or now	Filter allocations and transactions before an end time.	end-time=2012-04-03 15:24:39 UTC
<b>context</b>	No	hpc or cloud	The context to use in Moab Accounting Manager.	context=hpc

**i** The **context** parameter overrides the default context set for MAM using the `mam.context` configuration parameter. For more information about this parameter, see [Configuration on page 1772](#).

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

The fund statement report provides a snapshot of the current funds. For more information, see [Fields: Fund Statements on page 1835](#).

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement?api-version=3&proxy-user=amy&fields=startBalance,endBalance&pretty=true

{
  "startBalance":1234.01,
  "endBalance":1000
}
```

**Get fund statement summary**

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-version=3&proxy-user=<user>[&filter=<filter_options>] [&filter-type=<filter_type>] [&start-time=<date_string>] [&end-time=<date_string>]
```

Parameter	Required	Type	Description	Example
<b>proxy-user</b>	Yes	String	Perform action as defined MAM user.	proxy-user=amy
<b>filter</b>	No	JSON	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
<b>filter-type</b>	No	String	Query funds based on defined MAM filter type.	filter-type-e=NonExclusive
<b>start-time</b>	No	Date, -infinity, or now	Filter allocations and transaction after a start time.	start-time=2012-04-03 15:24:39 UTC
<b>end-time</b>	No	Date, -infinity, or now	Filter allocations and transactions before an end time.	end-time=2012-04-03 15:24:39 UTC

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

The fund statement summary is slightly different from the typical fund statement in that the transactions are provided as summaries grouped by object and action. For more information, see [Fields: Fund Statement Summary on page 1819](#).

```
GET http://localhost:8080/mws/rest/accounting/funds/reports/statement/summary?api-
version=3&proxy-
user=amy&fields=totalCredits,totalDebits,transactions.action,transactions.amount,trans
actions.count&pretty=true
-----
{
  "totalCredits":200.02,
  "totalDebits":-100,
  "transactions":[ {
    "action":"Deposit",
    "amount":200.02,
    "count":2
  }, {
    "action":"Charge",
    "amount":-100,
    "count":1
  }
]
}
```

## Accounting Liens

This section describes the services available through Moab Web Services for interacting with the Lien object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

 The [Fields: Liens](#) reference contains the type and description of the default fields for the **Liens** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/liens</a>	<a href="#">Get all liens</a>	--	--	--
<a href="#">/rest/accounting/liens/&lt;id&gt;</a>	<a href="#">Get single lien</a>	--	--	--

This topic contains these sections:

- [Getting liens on page 1474](#)
  - [Get single lien on page 1476](#)
  - [Get all liens on page 1474](#)

## Getting liens

The HTTP GET method is used to retrieve **Lien** information.

### [Quick reference](#)

```
GET http://localhost:8080/mws/rest/accounting/liens?api-version=3
GET http://localhost:8080/mws/rest/accounting/liens/<id>?api-version=3
```

## Get all liens

### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/accounting/liens?api-version=3&proxy-user=<user>
[&active=true] [&filter=<filter_options> [&filter-type=<filter_type>]] [&query=<query_
conditions>] [&fields=<fields_to_display> [&sort=<fields_to_sort>] |&show-all=
(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>active</b>	No	Boolean	--	Lists only active or non-active liens.	active=true
<b>filter</b>	No	JSON	--	Query funds based on defined MAM filter.	filter={"account": "chemistry"}
<b>filter-type</b>	No	String	--	Query funds based on defined MAM filter type.	filter-type=NonExclusive

Parameter	Required	Type	Valid values	Description	Example
<b>query</b>	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div style="border: 1px solid #0056b3; padding: 5px; margin-top: 10px;"> <p><b>i</b> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	<code>query={"allocations.fund":2}</code>
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	<code>fields=id,instance,amount</code>
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	<code>sort={"instance":1}</code>
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/liens?api-version=3&proxy-user=amy&filter={"account":"chemistry"}&fields=instance,amount&active=true&pretty=true
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "instance": "job.1",
      "amount": 57600
    },
    {
      "instance": "job.2",
      "amount": 40762
    }
  ]
}
```

**Get single lien**

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/liens/<id>?api-version=3&proxy-user=<user>[&active=(true|false)][&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object	--
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>active</b>	No	Boolean	--	Lists only active or non-active liens.	active=true
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,name,amount
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/accounting/liens/1?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": 1,
  "instance": "job.1",
  "usageRecord": 1,
  "startTime": "2013-08-21 16:45:57 UTC",
  "endTime": "2013-08-21 17:45:57 UTC",
  "duration": 3600,
  "description": "",
  "amount": 57600,
  "allocations": [ {
    "id": 2,
    "fund": 2,
    "amount": 57600
  } ]
}
```

## Accounting Organizations

This section describes the services available through Moab Web Services for interacting with the **Organization** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

The [Fields: Organizations](#) reference contains the type and description of the default fields for the **Organization** object.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/organizations</a>	<a href="#">Get all organizations</a>	--	--	--
<a href="#">/rest/accounting/organizations/&lt;id&gt;</a>	<a href="#">Get single organization</a>	--	--	--

This topic contains these sections:

- [Getting organizations on page 1478](#)
  - [Get all organizations on page 1478](#)
  - [Get single organization on page 1479](#)

## Getting organizations

The HTTP GET method is used to retrieve **Organizations** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3
GET http://localhost:8080/mws/rest/accounting/organizations/<id>?api-version=3
```

## Get all organizations

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]][&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>query</b>	No	JSON	--	Results are restricted to those having the specified field values. <div style="border: 1px solid gray; padding: 5px; margin-top: 10px;">  The query parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.                 </div>	query={"deleted": -false}
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	sort={"requestedId": -1}
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/organizations?api-version=3&proxy-user=moab&fields=id,description&sort={"id":1}&pretty=true
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "description": "Arts College",
      "id": "arts"
    },
    {
      "description": "Sciences College",
      "id": "sciences"
    }
  ]
}
```

**Get single organization**

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/organizations/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object.	--
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all-1=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/organizations/sciences?api-version=3&proxy-user=moab&pretty=true
-----
{
  "description": "Sciences College",
  "id": "sciences"
}
```

## Accounting Quotes

This section describes the services available through Moab Web Services for interacting with the **Quote** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Quotes](#) reference contains the type and description of the default fields for the **Quotes** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/quotes</a>	<a href="#">Get all quotes</a>	--	--	--
<a href="#">/rest/accounting/quotes/&lt;id&gt;</a>	<a href="#">Get single quote</a>	--	--	--

This topic contains these sections:

- [Getting quotes](#) on page 1480
  - [Get all quotes](#) on page 1480
  - [Get single quote](#) on page 1482

## Getting quotes

The HTTP GET method is used to retrieve **Quote** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3
GET http://localhost:8080/mws/rest/accounting/quotes/<id>?api-version=3
```

### Get all quotes

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3&proxy-user=<user>
[&active=true][&filter=<filter_options>[&filter-type=<filter_type>]][&query=<query_
conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=
(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform actions as defined MAM user.	proxy-user=amy
<b>active</b>	No	Boolean	true or false	Lists only active or non-active quotes.	active=true
<b>filter</b>	No	JSON	--	Query funds based on defined MAM filter.	filter={"account":"chemistry"}
<b>filter-type</b>	No	String	--	Query funds based on defined MAM filter type.	filter-type=NonExclusive
<b>query</b>	No	JSON	--	Results are restricted to those having the specified field values.  <div style="border: 1px solid black; padding: 5px; background-color: #e6f2ff;"> <p><b>i</b> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	query={"instance":"-job.1"}
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,instance,amount

Parameter	Required	Type	Valid values	Description	Example
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	sort={"instance":1}
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/quotes?api-version=3&proxy-user=amy&filter={"account":"chemistry"}&fields=usageRecord,amount&active=true&pretty=true
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "usageRecord": 1,
    "amount": 57600
  } ]
}
```

**Get single quote**

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/quotes/<id>?api-version=3&proxy-user=<user>[&active=(true|false)] [&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object.	--

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>active</b>	No	Boolean	true or false	Lists only active or non-active quotes.	active=true
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=id,name,amount
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
GET http://localhost:8080/mws/rest/accounting/quotes/1?api-version=3&proxy-user=amy&pretty=true
```

```
{
  "id": 1,
  "amount": 57600,

## Accounting Transactions

This section describes the services available through Moab Web Services for interacting with the **Transaction** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses

delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Transactions](#) reference contains the type and description of the default fields for the **Transaction** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/accounting/transactions</a>	<a href="#">Get all transactions</a>	--	--	--
<a href="#">/rest/accounting/transactions/&lt;id&gt;</a>	<a href="#">Get single transaction</a>	--	--	--

This topic contains these sections:

- [Getting transactions on page 1484](#)
  - [Get all transactions on page 1484](#)
  - [Get single transaction on page 1487](#)

## Getting transactions

The HTTP GET method is used to retrieve **Transaction** information.

Quick reference

```
GET http://localhost:8080/mws/rest/accounting/transactions?api-version=3
GET http://localhost:8080/mws/rest/accounting/transactions/<id>?api-version=3
```

## Get all transactions

URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/transactions?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>][&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
<b>query</b>	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div style="border: 1px solid #004a7c; padding: 5px; background-color: #e6f2ff;"> <p> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	<code>query={"action":"Charge","account":"chemistry"}</code>
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	<code>fields=id</code>

Parameter	Required	Type	Valid values	Description	Example
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">Accounting Transactions</a> parameter.	<code>sort={"id":1}</code>
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/transactions?api-version=3&proxy-user=moab&query={"instance":"job.1"}&fields=object,action,instance,amount&pretty=true
-----

## Accounting Usage records

This section describes the services available through Moab Web Services for interacting with the **Usage Record** object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Usage Records](#) reference section contains the type and description of all fields in the **Usage Record** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/accounting/usage-records</b>	<a href="#">Get all usage records</a>	--	--	--
<b>/rest/accounting/usage-records/&lt;id&gt;</b>	<a href="#">Get single usage record</a>	--	--	--
<b>/rest/accounting/usage-records/quote</b>	--	--	<a href="#">Obtain a quote for resource usage</a>	--

This topic contains these sections:

- [Getting usage records on page 1489](#)
  - [Get all usage records on page 1489](#)
  - [Get single usage record on page 1492](#)
  - [Obtain a quote for resource usage on page 1493](#)

## Getting usage records

The HTTP GET method is used to retrieve **Usage Record** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3
GET http://localhost:8080/mws/rest/accounting/usage-records/<id>?api-version=3
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-version=3
```

### Get all usage records

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3&proxy-user=<user>[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy

Parameter	Required	Type	Valid values	Description	Example
<b>query</b>	No	JSON	--	<p>Results are restricted to those having the specified field values.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin-top: 10px;"> <p> The <b>query</b> parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.</p> </div>	<code>query={"account":"query"}</code>
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	<code>fields=id,instance,charge,user,account</code>

Parameter	Required	Type	Valid values	Description	Example
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	sort={"user":1}
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
GET http://localhost:8080/mws/rest/accounting/usage-records?api-version=3&proxy-user=amy&fields=id,instance,charge,user,account&pretty=true
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "id": 1,
      "instance": "job.1",
      "charge": 31,
      "user": "amy",
      "account": "chemistry"
    },
    {
      "id": 2,
      "instance": "job.2",
      "charge": 30,
      "user": "amy",
      "account": "biology"
    }
  ]
}
```

## Get single usage record

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/usage-records/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object.	code
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	field-s=id,instance,charge,user,account
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/usage-records/1?api-version=3&proxy-user=amy&pretty=true
-----
{
  "id": 1,
  "type": "Job",
  "instance": "job.1",
  "charge": 31,
  "stage": "Charge",
  "user": "amy",
  "group": "faculty",
  "account": "chemistry",
  "organization": "sciences",
  "qualityOfService": "",
  "machine": "colony",
  "nodes": "",
  "processors": 16,
  "memory": "",
  "disk": "",
  "network": "",
  "duration": 720,
  "startTime": "",
  "endTime": "",
  "description": ""
}
```

**Obtain a quote for resource usage**

URLs and parameters

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-version=3&object-type=<object>&proxy-user=<user>&charge-duration=<seconds>
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>charge-duration</b>	Yes	Integer	--	The quote duration of the job in seconds.	charge-duration=6400

Parameter	Required	Type	Valid values	Description	Example
<b>object-type</b>	Yes	String	--	The object to quote. It can be job or service.	<code>object-type=job</code>
<b>itemize</b>	No	Boolean	true or false	Returns the composite charge information in the response data.	<code>itemize=true</code>
<b>rate</b>	No	JSONArray	--	Uses the specified charge rates in the quote. The specified rates override the standard and quote rates. If the guarantee field is set to true, these charge rates will be saved and used when this quote is referenced in a charge action.	<code>rate=[{"type":"VBR","name":"Memory","rate":1}, {"type":"VBR","name":"Processors","rate":1}]</code>

Parameter	Required	Type	Valid values	Description	Example
<b>guarantee</b>	No	Boolean	true or false	Guarantees the quote and returns a quote id to secure the current charge rates. This results in the creation of a quote record and a permanent usage record. This parameter is mutually exclusive with the cost-only parameter.	guarantee=true

Parameter	Required	Type	Valid values	Description	Example
<b>grace-duration</b>	No	Integer	--	The guaranteed quote grace period in seconds. If the quote duration is specified but not the quote end time, the quote endtime will be calculated as the quote start time plus the quote duration plus the grace duration.	grace-duration=6400
<b>cost-only</b>	No	Integer	--	Returns the cost, ignoring all balance and validity checks. This parameter is mutually exclusive with the guarantee parameter.	cost-only=true

Parameter	Required	Type	Valid values	Description	Example
<b>description</b>	No	String	--	The guaranteed quote description.	description="ABC Coupon Rate"
<b>start-time</b>	No	Date	--	The guaranteed quote start time in the format yyyy-MM-dd HH:m-m:ss z,-Infinity,Infinity, or Now.	start-time="2012-04-09 13:49:40 UTC"
<b>end-time</b>	No	Date	--	The guaranteed quote end time in the format yyyy-MM-dd HH:m-m:ss z,-Infinity,Infinity, or Now.	end-time="2012-04-09 14:49:40 UTC"

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

The request body below shows all of the fields in a job that could affect the quote.

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-  
version=3&object-type=job&charge-duration=300
```

```
{  
  "id": "Moab.1",  
  "user": "amy",  
  "group": "group",  
  "rmName": "machine1",  
  "templateList": [  
    "genericVm"  
  ],  
  "account": "biology",  
  "qosRequested": "QOS1",  
  "variables": {  
    "imageName": "centos5.5-stateless",  
    "topLevelServiceId": "myService.1",  
    "serviceId": "vmService.1",  
    "vmid": "VmService.1",  
    "pmid": "VmService.1"  
  },  
  "requirements": [  
    {  
      "requiredProcessorsPerTask": 2,  
      "genericResources": {  
        "gold": 100,  
        "os": 500  
      },  
      "requiredNodeCountMinimum": 1,  
      "requiredMemoryPerTask": 1024,  
      "requiredClass": "batch"  
    }  
  ]  
}
```

The request body below shows all of the fields in a service that affect the quote in a default MAM installation.

```
POST http://localhost:8080/mws/rest/accounting/usage-records/quote?api-
version=3&object-type=service&charge-duration=300
```

```
{
  "name": "service.1",
  "user": "amy",
  "account": "chemistry"
  "attributes": {
    "moab": {
      "job": {
        "resources": {
          "procs": 1,
          "mem": 2048,
          "OS": 500,
          "gold": 100
        },
        "variables": {
          "Var1": 1524
        },
        "image": "centos5.5-stateless",
        "template": "genericVM",
      }
    }
  }
}
```

### Sample response

- If the quote is not guaranteed:

JSON response

```
{
  "instance": "Moab.1",
  "amount": 600
}
```

- If the quote is guaranteed:

JSON response

```
{
  "id": 1,
  "usageRecord": 2,
  "instance": "Moab.1",
  "amount": 600
}
```

- If the quote is guaranteed and itemized:

JSON response

```
{
  "details": [
    {
      "name": "Processors",
      "value": "2",
      "duration": 300,
      "rate": 1,
      "scalingFactor": 1,
      "amount": 600,
      "details": "2 [Processors] * 1 [ChargeRate{VBR}{Processors}] * 300
[Duration]"
    },
    {
      "name": "Memory",
      "value": "1024",
      "duration": 300,
      "rate": 1,
      "scalingFactor": 1,
      "amount": 307200,
      "details": "1024 [Memory] * 1 [ChargeRate{VBR}{Memory}] * 300 [Duration]"
    }
  ],
  "id": 20,
  "instance": "Moab.1",
  "usageRecord": 20,
  "amount": 307800
}
```

- If the quote is on a service:

JSON response

```

{
  "services": [
    {
      "details": [
        {
          "name": "Processors",
          "value": "22",
          "duration": 30,
          "rate": 1,
          "scalingFactor": 1,
          "amount": 660,
          "details": "22 [Processors] * 1 [ChargeRate{VBR}{Processors}] * 30
[Duration]"
        },
        {
          "name": "Memory",
          "value": "32343242",
          "duration": 30,
          "rate": 1,
          "scalingFactor": 1,
          "amount": 970297260,
          "details": "32343242 [Memory] * 1 [ChargeRate{VBR}{Memory}] * 30
[Duration]"
        }
      ],
      "id": 120,
      "instance": "myVmWorkflow",
      "usageRecord": 157,
      "amount": 970297920
    },
    {
      "details": [
        {
          "name": "Storage",
          "value": "2500",
          "duration": 30,
          "rate": 1.157E-7,
          "scalingFactor": 1,
          "amount": 0,
          "details": "2500 [Storage] * 1.157e-07 [ChargeRate{VBR}{Storage}] * 30
[Duration]"
        }
      ],
      "id": 122,
      "instance": "myExtraStorageWorkflow",
      "usageRecord": 159,
      "amount": 0
    },
    {
      "details": [
        {
          "name": "Processors",
          "value": "0",
          "duration": 30,
          "rate": 1,
          "scalingFactor": 1,
          "amount": 0,
          "details": "0 [Processors] * 1 [ChargeRate{VBR}{Processors}] * 30
[Duration]"
        }
      ],
    }
  ]
}

```

```

    "name": "Memory",
    "value": "0",
    "duration": 30,
    "rate": 1,
    "scalingFactor": 1,
    "amount": 0,
    "details": "0 [Memory] * 1 [ChargeRate{VBR}{Memory}] * 30 [Duration]"
  }
],
"id": 123,
"instance": "myPmWorkflow",
"usageRecord": 160,
"amount": 0
}
],
"amount": 970297920
}

```

### Restrictions

The `details` field is only available with MAM version 7.1.0 or later.

### Related topics

- [Resources introduction on page 1446](#)

## Accounting Users

This section describes the services available through Moab Web Services for interacting with the User object in Moab Accounting Manager. It contains the URLs, request bodies, and responses delivered to and from MWS as an intermediary for MAM.

**i** The [Fields: Users](#) reference contains the type and description of all fields in the **User** object.

### Supported methods

Resource	GET	PUT	POST	DELETE
<code>rest/accounting/users</code>	<a href="#">Get all users</a>	--	--	--
<code>rest/accounting/users/&lt;id&gt;</code>	<a href="#">Get single user</a>	--	--	--

This topic contains these sections:

- [Getting users on page 1503](#)
  - [Get all users on page 1503](#)
  - [Get single user on page 1505](#)

## Getting users

The HTTP GET method is used to retrieve **User** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3
GET http://localhost:8080/mws/rest/accounting/users/<id>?api-version=3
```

## Get all users

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3&proxy-user=<user>
[&query=<query_conditions>][&fields=<fields_to_display>[&sort=<fields_to_sort>]|&show-
all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>proxy-user</b>	Yes	String	--	Perform action as defined MAM user.	proxy-user=amy
<b>query</b>	No	JSON	--	Results are restricted to those having the specified field values.	query={"active":true}

**i** The **query** parameter does not support the full Mongo query syntax. Only querying for a simple, non-nested JSON object is allowed.

Parameter	Required	Type	Valid values	Description	Example
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	<code>fields=name,defaultAccount</code>
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending. Should be used in conjunction with the <a href="#">fields</a> parameter.	<code>sort={"defaultAccount":1}</code>
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	<code>show-all=true</code>

See [Global URL parameters on page 1425](#) for available URL parameters.

## Sample response

```
GET http://localhost:8080/mws/rest/accounting/users?api-version=3&proxy-user=moab&query={"active":true}&pretty=true
```

```
{
  "totalCount": 6,
  "resultCount": 4,
  "results": [
    {
      "active": true,
      "commonName": "",
      "phoneNumber": "",
      "emailAddress": "",
      "defaultAccount": "",
      "description": "Accounting Admin",
      "id": "scottmo"
    },
    {
      "active": true,
      "commonName": "Amy Miller",
      "phoneNumber": "(801) 555-1437",
      "emailAddress": "amy@hpc.com",
      "defaultAccount": "chemistry",
      "description": "",
      "id": "amy"
    },
    {
      "active": true,
      "commonName": "Robert Taylor",
      "phoneNumber": "(801) 555-1474",

      "defaultAccount": "film",
      "description": "",
      "id": "dave"
    }
  ]
}
```

## Get single user

### URLs and parameters

```
GET http://localhost:8080/mws/rest/accounting/users/<id>?api-version=3&proxy-user=<user>[&fields=<fields_to_display>|&show-all=(true|false)]
```

Parameter	Required	Type	Valid values	Description	Example
<b>id</b>	Yes	String	--	The unique identifier of the object	--
<b>fields</b>	No	String	--	Comma-separated list of field names to display.	fields=name,defaultAccount
<b>show-all</b>	No	Boolean	true or false	true shows all fields including metadata and hidden fields. Default is false.	show-all=true

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/accounting/users/amy?api-version=3&proxy-user=moab&pretty=true
-----
{
  "active": true,
  "commonName": "Amy Miller",
  "phoneNumber": "(801) 555-1437",
  "emailAddress": "amy@hpc.com",
  "defaultAccount": "chemistry",
  "description": "",
  "id": "amy"
}
```

## Credentials

This section describes behavior of the **Credential** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

 The Credential API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting specific API versions on page 1428](#).

**i** The [Fields: Credentials](#) reference contains the type and description of all fields in the **Credential** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/credentials/accounts</a>	<a href="#">Get all account credentials</a> <a href="#">Get single account credential</a>	<a href="#">Modify account credentials on page 1519</a>	--	--
<a href="#">/rest/credentials/classes</a>	<a href="#">Get all class credentials</a> <a href="#">Get single class credential</a>	<a href="#">Modify class credentials on page 1519</a>	--	--
<a href="#">/rest/credentials/groups</a>	<a href="#">Get all group credentials</a> <a href="#">Get single group credential</a>	<a href="#">Modify group credentials on page 1520</a>	--	--

      "email": "root@root.com"
    }
  ]
}

```

## Get single user credential

### URLs and parameters

```
GET http://localhost:8080/mws/rest/credentials/users/<name>?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/credentials/users/root?api-version=3
```

```
{
  "name": "root",
  "account_access_list": ["Administration"],
  "default_account": "Administration",
  "qos_access_list": [
    "qos1",
    "qos2"
  ],
  "default_qos": "qos1",
  "partition_access_list": [
    "partition1",
    "SHARED"
  ],
  "default_partition": "partition1",
  "target_type": "CEILING",
  "target": 18.43,
  "priority": 53,
  "max_job_duration_in_seconds": 234,
  "max_idle_jobs": 42,
  "max_jobs": 523,
  "max_processors": 4,
  "max_processor_seconds": 525,
  "max_nodes": 75,
  "email": "root@root.com"
}
```

## Modifying credentials

The HTTP PUT method is used to modify **credentials**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/credentials/accounts/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/classes/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/groups/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/qoses/<name>?api-version=3 [&change-
mode=<add|remove|set>]
PUT http://localhost:8080/mws/rest/credentials/users/<name>?api-version=3 [&change-
mode=<add|remove|set>]
```

### URL parameters

URL parameters for modifying a credential.

Credentials parameter	Required	Type	Valid values	Description
<b>change-mode</b>	No	String	set (default) add remove	If <b>set</b> , replace existing list with the given one. If <b>add</b> , add the given field(s) to the existing list. If <b>remove</b> , remove the given field(s) from the existing list.

**i** Moab Workload Manager will automatically add SHARED and the value of default\_partition to the partition\_access\_list.

## Modify account credentials

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/accounts/<name>?api-version=3 [&change-mode=<add|remove|set>]
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample body

```
PUT http://localhost:8080/mws/rest/credentials/accounts/biology?api-version=3&change-mode=add
-----
{
  "qos_access_list": [
    "qos3",
    "qos4"
  ],
  "max_job_duration_in_seconds": 234
}
```

## Modify class credentials

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/classes/<name>?api-version=3 [&change-mode=<add|remove|set>]
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample body

```
PUT http://localhost:8080/mws/rest/credentials/classes/highprio?api-version=3
-----
{
  "max_idle_jobs": 50,
  "max_jobs": 300
}
```

## Modify group credentials

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/groups/<name>?api-version=3 [&change-
mode=<add|remove|set>]
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample body

```
PUT http://localhost:8080/mws/rest/credentials/groups/students?api-version=3&change-
mode=set
-----
{
  "reservation": "system.2",
  "user_access_list": ["tom"]
}
```

## Modify QoS credentials

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/qoses/<name>?api-version=3 [&change-
mode=<add|remove|set>]
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample body

```
PUT http://localhost:8080/mws/rest/credentials/qoses/special?api-version=3
-----
{
  "max_processors": 5,
  "max_processor_seconds": 500
}
```

## Modify User credentials

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/credentials/users/<name>?api-version=3 [&change-
mode=<add|remove|set>]
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample body

```
PUT http://localhost:8080/mws/rest/credentials/users/tom?api-version=3
```

```
{
  "email": "tom@root.com"
}
```

## Diagnostics

This section describes additional REST calls that are available for performing diagnostics on Moab Web Services.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/diag/about</a>	<a href="#">Get version information</a>	--	--	--
<a href="#">/rest/diag/auth</a>	<a href="#">Diagnose authentication</a>	--	--	--
<a href="#">/rest/diag/health/summary</a>	<a href="#">Get health summary</a>	--	--	--
<a href="#">/rest/diag/health/detail</a>	<a href="#">Get health detail</a>	--	--	--

**i** [/rest/diag/ldap](#) is deprecated. All information that was available in that resource is now available in [/rest/diag/health/detail](#).

This topic contains these sections:

- [Get version information on page 1522](#)
- [Diagnose authentication on page 1522](#)
- [Connection health information on page 1522](#)
  - [Get health summary on page 1523](#)
  - [Get health detail on page 1523](#)
- [Diagnostics on page 1521](#)

## Get version information

The HTTP GET method is used to retrieve version and build information.

### [Quick reference](#)

```
GET http://localhost:8080/mws/rest/diag/about?api-version=3
```

### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/diag/about?api-version=3
```

### [Sample response](#)

The response contains the application suite, version, build date, and revision.

```
{
  "suite": "CLOUD",
  "version": "7.2.2",
  "buildDate": "2013.03.15_13.12.45",
  "revision": "302238e24e327f4aa45ab4c91834216a7fc19d63"
}
```

## Diagnose authentication

The HTTP GET method is used to test for proper authentication. This resource is designed to be used as a simple validation of credentials and gives no output besides the response code.

### [Quick reference](#)

```
GET http://localhost:8080/mws/rest/diag/auth?api-version=3
```

### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/diag/auth?api-version=3
```

### [Sample response](#)

 A successful result is indicated by the 200 response code while a failure is indicated by a 401 response code.

```
{}
```

## Connection health information

The HTTP GET method is used to retrieve health or status information for connections to external systems or software. There are two available resources for health, one that returns simple summary information and another that returns detailed information.

### Quick reference

```
GET http://localhost:8080/mws/rest/diag/health/summary?api-version=3
GET http://localhost:8080/mws/rest/diag/health/detail?api-version=3
```

## Get health summary

### URLs and parameters

```
GET http://localhost:8080/mws/rest/diag/health/summary?api-version=3
```

**i** If the MongoDB connection is down, authenticated resources are not available. While this resource does not possess much detail beyond that of simple connection information, it is still useful as it does not require authentication and therefore can be used to determine connection problems with MongoDB.

### Sample response

The response contains the connection health for Moab Workload Manager (MWM), Moab Accounting Manager (MAM), MongoDB, LDAP, ZeroMQ, PAM. A `true` response value indicates that the connection is healthy and available, and a `false` response indicates that the connection is currently down. Likewise, the `mongoConnected` property for Moab signifies the state of the Moab to MongoDB connection. The possible values of this state are `UP`, `DOWN`, `NOT_CONFIGURED` (when the MongoDB server is not configured in Moab), `NOT_SUPPORTED` (when Moab is not compiled with MongoDB support), and `UNKNOWN` (when MWS cannot communicate with Moab).

```
{
  "mam": {"connected": true},
  "mongo": {"connected": true},
  "mwm": {
    "connected": true,
    "mongoConnected": "UP",
    "zmqConnected": true
  },
  "ldap": {"connected": true},
  "pam": {"connected": true},
  "zmq": {"connected": true},
}
```

## Get health detail

### URLs and parameters

```
GET http://localhost:8080/mws/rest/diag/health/detail?api-version=3
```

**i** If the MongoDB connection is down, authenticated resources such as this are not available. In this case, using the [Get health summary](#) instead may be required.

### Sample response

The response contains the connection health and information for Moab Workload Manager (MWM), Moab Accounting Manager (MAM), MongoDB, LDAP, ZeroMQ, PAM. A "connected": true response value indicates that the connection is healthy and available, and a false response indicates that the connection is currently down. Likewise, the mongoConnected property for Moab signifies the state of the Moab to MongoDB connection. The possible values of this state are UP, DOWN, NOT\_CONFIGURED (when the MongoDB server is not configured in Moab), NOT\_SUPPORTED (when Moab is not compiled with MongoDB support), and UNKNOWN (when MWS cannot communicate with Moab). A message is also present for all down connections except Moab to MongoDB giving a reason for the error state.

```

{
  "mam": {
    "connected": true,
    "adminUser": "root",
    "host": "mamhost",
    "port": 7741,
    "version": "7.5",

- [Resources introduction on page 1446](#)

## Distinct

The **Distinct** resource enables clients to retrieve distinct (unique) values from another MWS resource. For example, a client can request the list of all `featuresReported` across all nodes like this:

```
GET http://localhost:8080/mws/rest/distinct/nodes/featuresReported/?api-version=3
```

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/distinct/&lt;resource&gt;/&lt;field&gt;</code>	<a href="#">Get distinct values</a>	--	--	--

This topic contains these sections:

- [Get distinct values on page 1526](#)

### Get distinct values

The HTTP GET method is used to retrieve **distinct** values from another MWS resource.

## URLs and parameters

```
GET http://localhost:8080/mws/rest/distinct/<resource>/<field>?api-version=3
```

Parameter	Required	Type	Valid values	Example
<b>resource</b>	Yes	String	The MWS resource to query.	nodes
<b>field</b>	Yes	String	The field for which to return the distinct values.	featuresReported
<b>query</b>	No	JSON	Determines the subset of objects from which to retrieve the distinct values.	query={"states.-powerState": "On"}

**i** The **Distinct** resource has no access control of its own. Rather, it depends on the access control of the MWS resource being queried.

For example, for a client to run a query like `/rest/distinct/nodes/featuresReported`, it must have GET rights on the Nodes resource. For more information, see [Access control on page 1420](#).

## Examples

*Example 4-3: Get all featuresReported across all nodes*

```
http://localhost:8080/mws/rest/distinct/nodes/featuresReported?api-version=3
```

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": ["vlan1"]
}
```

*Example 4-4: Get all available operating system images across all nodes that are powered on*

```
http://localhost:8080/mws/rest/distinct/nodes/operatingSystem.imagesAvailable?api-version=3&query={"states.powerState": "On"}
```

```
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    "linux",
    "windows"
  ]
}
```

## Related topics

# Events

This section describes the URLs, request bodies, and responses delivered to and from Moab Web Services for handling events.

 The Event API is new with API version 3. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting specific API versions on page 1428](#).

 The [Fields: Events](#) reference contains the type and description of all fields in the **Event** object. It also contains details regarding which fields are valid during POST actions.

## Important changes

- The following fields have been renamed in API version 3:

Name in version 1 & 2	Name in version 3
eventTime	eventDate
sourceComponent	origin
errorMessage.message	message
relatedObjects	associatedObjects

- The following fields have been removed in API version 3.

 MWS will no longer report these fields, even if there are existing events in the database with these fields.

- eventCategory
- status
- facility
- initiatedBy
- primaryObject (Primary objects are now reported in associatedObjects.)
- errorMessage.originator
- errorMessage.errorCode
- details

- The following fields are new in API version 3 (see [Fields: Events on page 1894](#)):
  - arguments
  - code

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/events</a>	<a href="#">Get all events</a>	--	<a href="#">Create event</a>	--
<a href="#">/rest/events/&lt;id&gt;</a>	<a href="#">Get single event</a>	--	--	--

This topic contains these sections:

- [Getting events on page 1529](#)
  - [Get all events on page 1529](#)
  - [Get single event on page 1533](#)
- [Creating events on page 1534](#)
  - [Create event on page 1534](#)

## Getting events

The HTTP GET method is used to retrieve **Event** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/events?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/events/<id>?api-version=3
```

## Get all events

URLs and parameters

```
GET http://localhost:8080/mws/rest/events?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Valid values	Example
<b>query</b>	No	JSON	Query for specific results. It is possible to query events by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"severity":"ERROR"}

Parameter	Required	Type	Valid values	Example
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	<code>sort={"id":-1}</code>

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/events?api-version=3
```

```
{
  "totalCount":2,
  "resultCount":2,
  "results":[
    {
      "arguments":[
      ],
      "associatedObjects":[
        {
          "type":"VM",
          "id":"vml"
        }
      ],
      "tenant":
        {
          "id":"1234567890abcdef12345678",
          "name":"Research"
        },
      "code":234881023,
      "eventDate":"2013-06-10 17:13:31 UTC",
      "eventType":"VM Provision",
      "message":null,
      "origin":"CSA Plugin",
      "severity":"INFO",
      "id":"51b6093bc4aa708a5bebb6ae"
    },
    {
      "arguments":[
        "51b608ddc4aa708a5bebb684"
      ],
      "associatedObjects":[
        {
          "type":"Service",
          "id":"51b608ddc4aa708a5bebb684"
        }
      ],
      "tenant":
        {
          "id":"1234567890abcdef12345678",
          "name":"Research"
        },
      "code":33554944,
      "eventDate":"2013-06-10 17:11:59 UTC",
      "eventType":"Service Create",
      "message":"The service '51b608ddc4aa708a5bebb684' was created",
      "origin":"MWS/ServiceEvents/CREATE_1ID",
      "severity":"INFO",
      "id":"51b608dfc4aa708a5bebb686"
    }
  ]
}
```

Querying events

It is possible to query events by one or more fields based on [MongoDB query syntax](#). The following contains examples of simple and complex event queries and event queries by date.

**Simple queries:**

- To see only events that are of type "Service Create":

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"Service Create"}
```

- To see only events of type "Service Create" with the severity of "INFO":

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"Service Create","severity":"INFO"}
```

- To see only events with a code of 33554946

```
http://localhost:8080/mws/rest/events?api-version=3&query={code:33554946}
```

**More complex queries:**

- You can query on embedded JSON objects within the event JSON. For example, to see events associated with service 51b608ddc4aa708a5bebb684:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"associatedObjects.id":"51b608ddc4aa708a5bebb684"}
```

- To see only events that are NOT associated with service 51b608ddc4aa708a5bebb684:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"associatedObjects.id":{"$ne":"51b608ddc4aa708a5bebb684"}}
```

- When the field values of the desired events are a finite set, you can use the \$in operator. For example, to see events that have a severity of either WARN or ERROR:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"severity":{"$in":["ERROR","WARN"]}}
```

**Querying events by date**

- To see events created before January 27, 2012 at 12:08 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$lt":"2012-01-27 12:08:00 UTC"}}
```

- To see events created before or on January 27, 2012 at 12:08 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$lte":"2012-01-27 12:08:00 UTC"}}
```

- To see all events created after January 27, 2012 at 12:04 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$gt":"2012-01-27 12:04:00 UTC"}}
```

- To see all events created after or on January 27, 2012 at 12:04 a.m. UTC:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$gte":"2012-01-27 12:04:00 UTC"}}
```

- To see events created between 12:04 a.m. and 12:08 a.m. UTC inclusive:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventDate":{"$gte":"2012-01-27 12:04:00 UTC","$lte":"2012-01-27 12:08:00 UTC"}}
```

- To see events created between 12:04 a.m. and 12:08 a.m. UTC inclusive that have a severity of ERROR:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"severity":"ERROR","eventDate":{"$gte":"2012-01-27 12:04:00 UTC","$lte":"2012-01-27 12:08:00 UTC"}}
```

### Sorting

See the sorting section of [Global URL parameters on page 1425](#).

### Limiting the number of results

- If you want to limit the number of results of events, you can use the max parameter. For example, to see only 10 "VM Provision" events:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"VM Provision"}&sort={"eventDate":1}&max=10
```

- To see "VM Provision" events 51-60 when sorted by eventDate in descending order, you can combine max with offset, as follows:

```
http://localhost:8080/mws/rest/events?api-version=3&query={"eventType":"VM Provision"}&sort={"eventDate":-1}&max=10&offset=50
```

## Get single event

### URLs and parameters

```
GET http://localhost:8080/mws/rest/events/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/events/51b608dfc4aa708a5bebb686?api-version=3
```

```
{
  "arguments": ["51b608ddc4aa708a5bebb684"],
  "associatedObjects": [ {
    "type": "Service",
    "id": "51b608ddc4aa708a5bebb684"
  } ],
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "code": 33554944,
  "eventDate": "2013-06-10 17:11:59 UTC",
  "eventType": "Service Create",
  "message": "The service '51b608ddc4aa708a5bebb684' was created",
  "origin": "MWS/ServiceEvents/CREATE_1ID",
  "severity": "INFO",
  "id": "51b608dfc4aa708a5bebb686"
}
```

## Creating events

The HTTP POST method is used to create an **Event**.

### Quick reference

```
POST http://localhost:8080/mws/rest/events?api-version=3
```

### Create event

#### URLs and parameters

```
POST http://localhost:8080/mws/rest/events?api-version=3
```

#### Request body

```
POST http://localhost:8080/mws/rest/events?api-version=3 Content-Type:application/json
```

```
{
  "arguments": ["vm1"],
  "associatedObjects": [ {
    "type": "VM",
    "id": "vm1"
  } ],
  "code": 234881023,
  "eventDate": "2013-06-10 17:13:31 UTC",
  "eventType": "VM Provision",
  "message": "The virtual machine \"vm1\" was provisioned",
  "origin": "CSA Plugin",
  "severity": "INFO"
}
```

**i** An event's `tenant` is automatically inherited from the `associatedObjects`.

### Sample response

If the request was successful, the response will be an object with an `id` property containing the ID of the newly created events. On failure, the response is an error message.

JSON response

```
{ "arguments": ["vm1"], "associatedObjects": [{"_id": "vm1", "id": "vm1", "type": "VM", "version": 0}], "code": 234881023, "eventDate": "2013-06-10 17:13:31 UTC", "eventType": "VM Provision", "id": "51b62046c4aa708a5bebc018", "message": "The virtual machine vm1 was provisioned", "origin": "CSA Plugin", "severity": "INFO", "version": 0 }
```

Below is an example of `events.log` output for a successful event request:

```
2013-06-10T11:13:31.000-06:00 severity="INFO" code="0x0dffffff" type="VM Provision" origin="CSA Plugin" associatedObject.0.type="VM" associatedObject.0.id="vm1" arguments=["vm1"] message="The virtual machine \"vm1\" was provisioned"
```

**i** Note that " (double quote) characters in the input have been replaced by \ " characters in the output. (For other character restrictions, see [Restrictions on page 1535](#).)

### Restrictions

Special characters—such as newline, carriage return, and " (double quote) characters—are encoded in the output of `events.log` to make `events.log` easy to parse with scripts and third party tools. For example, if the input XML contains:

```
<ErrorMessage>RM says, "Cannot provision vm21"</ErrorMessage>
```

Then the following will be output to `events.log`:

```
error.message="RM says, \"Cannot provision vm21\""
```

(Notice that " has been replaced with \ ".)

This table contains the most common encodings. (For more information, see [escape sequences for Java Strings](#).)

Character	Escape sequence
" (double quote)	\ "
\ (backslash)	\\
newline	\n

Character	Escape sequence
carriage return	\r
tab	\t

Other restrictions include:

- **origin**, **eventType**, **associatedObject.id**, and **associatedObject.type** cannot contain single quotes (') or double quotes (").

## Images

This section describes behavior of the **Image** object in Moab Web Services. An image resource is used to track the different types of operating systems and hypervisors available in the data center. It also tracks which virtual machines are available on the hypervisors. This section describes the URLs, request bodies, and responses delivered to and from MWS.

 The [Fields: Images](#) reference contains the type and description of all fields in the **Image** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
/rest/images	<a href="#">Get all images</a>	--	<a href="#">Create single image</a>	--

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/images/&lt;id&gt;</a>	<a href="#">Get single image</a>	<a href="#">Modify single image</a>	--	<a href="#">Delete single image</a>
<a href="#">/rest/images/&lt;name&gt;</a>	<a href="#">Get single image</a>	<a href="#">Modify single image</a>	--	<a href="#">Delete single image</a>

This topic contains these sections:

- [Getting images on page 1537](#)
  - [Get all images on page 1537](#)
  - [Get single image on page 1538](#)
- [Creating images on page 1540](#)
  - [Create single image on page 1540](#)

  - [Delete single image on page 1544](#)

## Getting images

The HTTP GET method is used to retrieve **Image** information. You can query all objects or a single object.

### Quick reference

```
GET http://localhost:8080/mws/rest/images?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/images/<id>?api-version=3
GET http://localhost:8080/mws/rest/images/<name>?api-version=3
```

## Get all images

### URLs and parameters

```
GET http://localhost:8080/mws/rest/images?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query images by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"type":"stateful","osType":"linux"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/images?api-version=3&fields=id,name
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "4fa197e68ca30fc605dd1cf0",
    "name": "centos5-stateful"
  } ]
}
```

Sorting and querying

See the sorting and querying sections of [Global URL parameters on page 1425](#).

**Get single image**

URLs and parameters

```
GET http://localhost:8080/mws/rest/images/<id>?api-version=3
GET http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Image.
<b>name</b>	Yes	String	--	The name of the Image.

**i** You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

#### Virtual machine image example:

```
GET http://localhost:8080/mws/rest/images/centos5-compute-stateful?api-version=3
```

```
{
  "active":true,
  "extensions":{
    "xcat":{
      "os":"centos",
      "architecture":"x86_64",
      "profile":"compute"
    }
  },
  "features":[],
  "hypervisor":false,
  "hypervisorType": null,
  "id":"4fa197e68ca30fc605dd1cf0",
  "name":"centos5-compute-stateful",
  "osType":"linux",
  "supportsPhysicalMachine":false,
  "supportsVirtualMachine":true,
  "templateName":null,
  "type":"stateful",
  "version":0,
  "virtualizedImages":[]
}
```

#### Hypervisor image example:

```
GET http://localhost:8080/mws/rest/images/esxi-4.1-stateful?api-version=3
```

```
{
  "active":true,
  "extensions":{
    "xcat":{
      "hvGroupName":"hvGroup",
      "vmGroupName":"vmGroup",
      "os":"esxi-4.1",
      "architecture":"x86_64",
      "profile":"hv"
    }
  },
  "features":[],
  "hypervisor":true,
  "hypervisorType":"ESX",
  "id":"4fa197e68ca30fc605dd1cf0",
  "name":"centos5-compute-stateful",
  "osType":"linux",
  "supportsPhysicalMachine":true,
  "supportsVirtualMachine":false,
  "templateName":null,
  "type":"stateful",
  "version":0,
  "virtualizedImages":[]
}
```

**i** The `version` field contains the current version of the database entry and does not reflect the version of the operating system. For more information, see [Modify single image](#) on page 1543.

## Creating images

The HTTP POST method is used to submit **Images**.

### Quick reference

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

### Create single image

#### URLs and parameters

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

See [Global URL parameters](#) on page 1425 for available URL parameters.

#### Request body

Three fields are required to submit an image: **name**, **hypervisor**, and **osType**. Each image must also support provisioning to either a physical machine or a virtual machine by using the **supportsPhysicalMachine** or **supportsVirtualMachine** fields.

**i** The **name** field must contain only letters, digits, periods, dashes, and underscores.

The array of virtualized images are themselves objects that contain image IDs or names. For more information on available fields and types, see [Fields: Images on page 1903](#).

The following is an example of the most basic image that can be created:

```
POST http://localhost:8080/mws/rest/images?api-version=3
```

```
{
  "name": "centos5-stateful",
  "osType": "linux",
  "hypervisor": false,
  "supportsVirtualMachine": true
}
```

Note that this example does not provide any information for a provisioning manager (such as xCAT) to actually provision the machine. In order to provide this, you must add an entry to the **extensions** field that contains provisioning manager-specific information. Each key in the extensions field corresponds to the provisioning manager, and certain properties are required based on this key. For example, the xCAT extension key must be named `xcat` and must contain certain fields. These extension keys are documented in [Fields: Images on page 1903](#). See the following examples of creating images with xCAT-specific provisioning information below.

#### Sample response

If the request was successful, the response body is the new image that was created exactly as shown in [Get single image](#). On failure, the response is an error message.

#### Samples

The **virtualizedImages** field only accepts input when the image is a hypervisor and expects an array of image IDs *or* names, as shown in the following example:

```
Example payload of hypervisor with 2 vms
```

```
{
  "hypervisor": true,
  "name": "esx5-stateful",
  "osType": "linux",
  "supportsPhysicalMachine": true,
  "type": "stateful",
  "hypervisorType": "ESX",
  "virtualizedImages": [
    {"id": "4fa197e68ca30fc605dd1cf0"},
    {"name": "centos5-stateful"}
  ]
}
```

The following example shows how to create an image that utilizes a cloned template for a virtual machine. (Note that the **type** must be set to `linkedclone` in order to set the **templateName** field.)

## VM Utilizing a Cloned Template

```
{
  "active": true,
  "hypervisor": false,
  "name": "centos5-compute-stateful",
  "osType": "linux",
  "type": "linkedclone",
  "supportsVirtualMachine": true,
  "templateName": "centos5-compute"
}
```

The following are samples of a virtual machine and a hypervisor image that can be provisioned with xCAT:

## xCAT Virtual Machine Image

```
{
  "active": true,
  "features": [],
  "hypervisor": false,
  "name": "centos5-compute-stateful",
  "osType": "linux",
  "type": "stateful",
  "supportsVirtualMachine": true,
  "extensions": {
    "xcat": {
      "os": "centos",
      "architecture": "x86_64",
      "profile": "compute"
    }
  }
}
```

```
xCAT Hypervisor Image
-----
{
  "active": true,
  "features": [],
  "hypervisor": true,
  "name": "esxi5-base-stateless",
  "osType": "linux",
  "virtualizedImages": [
    {"name": "centos5-compute-stateless"}
  ],
  "type": "stateless",
  "hypervisorType": "ESX",
  "supportsPhysicalMachine": true,
  "extensions": {
    "xcat": {
      "os": "esxi5",
      "architecture": "x86_64",
      "profile": "base",
      "hvType": "esx",
      "hvGroupName": "esx5hv",
      "vmGroupName": "esx5vm"
    }
  }
}
```

## Modifying images

The HTTP PUT method is used to modify **Images**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/images/<id>?api-version=3
PUT http://localhost:8080/mws/rest/images/<name>?api-version=3
```

## Modify single image

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/images/<id>?api-version=3
PUT http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Image.
<b>name</b>	Yes	String	--	The name of the Image.

**i** You must specify either **id** or **name**, but you do not have to specify both. The **name** field must contain only letters, digits, periods, dashes, and underscores.

See [Global URL parameters on page 1425](#) for available URL parameters.

Example request

```
PUT http://localhost/mws/rest/images/centos5-stateful?api-version=3
{
  "name": "centos5-stateful",
  "type": "stateful",
  "hypervisor": false,
  "osType": "linux",
  "virtualizedImages": []
}
```

**i** The **version** field contains the current version of the database entry and does not reflect the version of the operating system. This field cannot be updated directly. However, if **version** is included in the modify request, it will be used to verify that another client did not update the object in between the time the data was retrieved and the modify request was delivered.

Sample response

If the request was successful, the response body is the modified image as shown in [Get single image](#). On failure, the response is an error message.

## Deleting images

The HTTP DELETE method is used to delete **Images**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/images/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/images/<name>?api-version=3
```

### Delete single image

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/images/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/images/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Image.
<b>name</b>	Yes	String	--	The name of the Image.

**i** Only one of **id** or **name** are required.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON Response

```
{}
```

## Job arrays

This section describes behavior of the **Job Array** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The [Fields: Job Arrays](#) reference section contains the type and description of all fields in the **Job Array** object.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/job-arrays</a>	--	--	<a href="#">Submit job array</a>	--

This topic contains these sections:

- [Submitting job arrays on page 1545](#)
  - [Submit job array on page 1546](#)

## Submitting job arrays

The HTTP POST method is used to submit **Job Arrays**.

### Quick reference

```
POST http://localhost:8080/mws/rest/job-arrays?api-version=3[&proxy-user=<username>]
```

While the **Job Array** resource only gives access to create job arrays, job arrays are retrieved using the operations in [Getting job information on page 1548](#).

### Restrictions

All restrictions present for [Submitting jobs](#) are present for job arrays. In addition, job arrays are *only* supported if the `ENABLEJOBARRAYS` parameter is set to `TRUE` in the `moab.cfg` file. For example:

```
ENABLEJOBARRAYS      TRUE
```

## Submit job array

### URLs and parameters

```
POST http://localhost:8080/mws/rest/job-arrays?api-version=3 [&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
<b>proxy-user</b>	No	String	--	Perform this action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

To submit a job array, only two fields are required: `jobPrototype` and one of `indexValues` or `indexRanges`. Both index ranges and values may be specified if desired.

The request body below shows all the fields that are available during job array submission, although the `jobPrototype` shown is a simple example and does not utilize all fields of a job submission.

**i** The `jobPrototype` field has the same properties as a typical job submission. Consequently the `api-version` of the job array will apply to the `jobPrototype` like it does when you submit jobs, so the `api-version` in the call must match the `api-version` of the job. Examples of this can be seen in [Submitting jobs on page 1555](#).

JSON request body

```
{
  "name": "myarray",
  "indexRanges": [ {
    "startIndex": 11,
    "endIndex": 25,
    "increment": 2
  } ],
  "indexValues": [ 2, 4, 6, 8, 10 ],
  "slotLimit": 2,
  "cancellationPolicy": {
    "firstJob": "FAILURE",
    "anyJob": "SUCCESS"
  },
  "jobPrototype": {
    "commandFile": "/tmp/test.sh",
    "initialWorkingDirectory": "/tmp",
    "requirements": [{"taskCount": 4}]
  }
}
```

### Sample response

The response of this task is the same as submitting a job (see [Submit job on page 1556](#)).

## Jobs

This section describes behavior of the **Job** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Job API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting specific API versions](#) on page 1428.

The [Fields: Jobs](#) reference contains the type and description of all fields in the **Job** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/jobs</code>	<a href="#">Get all jobs</a>	--	<a href="#">Submit job</a>	--
<code>/rest/jobs/&lt;name&gt;</code>	<a href="#">Get single job</a>	<a href="#">Modify job attributes</a>	--	<a href="#">Cancel job</a>
<code>/rest/jobs/&lt;name&gt;/&lt;modifyAction&gt;</code>	--	<a href="#">Perform actions on job</a>	--	--

This topic contains these sections:

- [Getting job information](#) on page 1548
  - [Get all jobs](#) on page 1548
  - [Get single job](#) on page 1549
- [Submitting jobs](#) on page 1555
  - [Submit job](#) on page 1556

- [Modifying jobs on page 1562](#)
  - [Modify job attributes on page 1562](#)
  - [Generic resources on page 1565](#)
  - [Perform actions on job on page 1567](#)
- [Deleting \(canceling\) jobs on page 1568](#)
  - [Cancel job on page 1568](#)

## Getting job information

The HTTP GET method is used to retrieve **Job** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/jobs/<name>?api-version=3
```

### Get all jobs

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/jobs?api-version=3
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"isActive":true}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

### How to get all jobs

```
GET http://localhost:8080/mws/rest/jobs?api-version=3&fields=name,flags&max=3
```

```
{
  "totalCount": 8,
  "resultCount": 3,
  "results": [
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.1"
    },
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.2"
    },
    {
      "flags": ["GLOBALQUEUE"],
      "name": "Moab.4"
    }
  ]
}
```

### How to get a subset of jobs

Get active jobs

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"isActive":true}
```

Get completed jobs

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"isActive":false}
```

Get jobs owned by a particular user

```
http://localhost:8080/mws/rest/jobs?api-version=3&query={"credentials.user":"fred"}
```

### Known issues

Some jobs are not returned if `DisplayFlags UseBlocking` is set in the `moab.cfg` file.

## Get single job

### URLs and parameters

```
GET http://localhost:8080/mws/rest/jobs/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

**i** The `attributes` field is only applicable in API version 2 and later, and the `MOAB_TENANT` field only applies if the job is attached to a tenant.

### Job arrays

- If a job is the master of a job array, the response will have some additional fields set as shown in the following example. The **name** field is chosen by the Moab, and the **customName** field comes from the [Fields: Job Arrays](#) name field.

```

Job array master
-----
{
  "name": "Moab.5",
  "customName": "myarray",
  "flags": [
    "ARRAYMASTER",
    "GLOBALQUEUE",
    "CANCELONFIRSTFAILURE",
    "CANCELONANYSUCCESS"
  ]
}

```

- If a job is a sub-job of an array, the response will have other fields set as shown in the following example.

```

Array sub-job
-----
{
  "name": "Moab.5[21]",
  "customName": "myarray",
  "arrayIndex": 21,
  "arrayMasterName": "Moab.5",
  "flags": [
    "ARRAYJOB",
    "GLOBALQUEUE",
    "CANCELONFIRSTFAILURE",
    "CANCELONANYSUCCESS"
  ]
}

```

## Submitting jobs

The HTTP POST method is used to submit **Jobs**.

### Quick reference

```
POST http://localhost:8080/mws/rest/jobs?api-version=3[&proxy-user=<username>]
```

### Restrictions

- No more than one virtual container can be specified in the request. The virtual container must already exist.
- The `credentials.user` and `credentials.group` properties are used to submit a job as the specified user belonging to the specified group.

- Job variables have the following restrictions:
  - Variable names cannot contain equals (=), semicolon (;), colon (:), plus (+), question mark (?), caret (^), backslash (\), or white space.
  - Variable values cannot contain semicolon (;), colon (:), plus (+), or caret (^).
- When submitting jobs, the only supported hold type is `User`.
- The proxy-user parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

## Submit job

### URLs and parameters

```
POST http://localhost:8080/mws/rest/jobs?api-version=3 [&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
<b>proxy-user</b>	No	String	--	Perform the action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

JSON request body (specified host list)

```
{
  "attributes": [
    "attr1",
    "attr2"
  ],
  "commandFile": "/tmp/test.sh",
  "commandScript": "c2xlZXAgNjAK",
  "commandLineArguments": "-x -v",
  "credentials": {

  "processors": {"dedicated": 2},
  "swap": {"dedicated": 4096},
  "matlab": {"dedicated": 6},
  "intellij": {"dedicated": 2}
},
"taskCount": 4,
"tasksPerNode": 14
}],
"reservationRequested": {"name": "rsv.1"},
"resourceFailPolicy": "RETRY",
"resourceManagerExtension": "x=PROC=4",
"standardErrorFilePath": "/tmp/error",

```

```

"standardOutputFilePath": "/tmp/out",
"submitHost": "admin-node",
"templates": [
  {"name": "template1"},
  {"name": "template2"}
],
"variables": {
  "var1": "val1",
  "var2": "val2"
},
"virtualContainers": [{"name": "vc1"}],
"vmUsagePolicy": "CREATEVM"
}

```

### Sample response

The response of this task is one of three possibilities:

- An object with a single **messages** property containing a list of error messages on failure.

```

{"messages":["Could not create job - invalid requirements"]}

```

- An object with a **name** property containing the name of the newly created job.

```

{"name":"Moab.1"}

```

- An object with a **name** property and a **virtualContainers** list containing the name of the newly created virtual container.

```

{ "name": "Moab.1", "virtualContainers": [{"name": "vc1"}] }

```

The virtual container will only be reported when a *new* virtual container has been created by Moab for the job.

### Examples of job submission

This section includes some sample job submission requests.

#### Example 4-5: Submit job to run on node2 and node3

```

POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/tmp",
  "nodesRequested": [
    {"name": "node2"},
    {"name": "node3"}
  ]
}

```

**Example 4-6: Submit job that requires 20 processors**

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/tmp",
  "requirements": [{"taskCount": 20}]
}
```

**Example 4-7: Submit job to run after a certain time**

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "commandFile": "/tmp/test.sh",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "dates": {"earliestRequestedStartDate": "2012-10-11 18:36:35 UTC"},
  "initialWorkingDirectory": "/tmp",
  "requirements": [{"taskCount": 20}]
}
```

**Example 4-8: Submit job based on *msub* example**

Given this *msub* command:

```
msub -l nodes=3:ppn=2,walltime=1:00:00,pmem=100 script2.pbs.cmd
```

Here is an equivalent MWS request:

```
POST http://localhost:8080/mws/rest/jobs?api-version=3
-----
{
  "duration": 3600,
  "commandFile": "/home/adaptive/script2.pbs.cmd",
  "credentials": {
    "group": "adaptive",
    "user": "adaptive"
  },
  "initialWorkingDirectory": "/home/adaptive",
  "requirements": [ {
    "resourcesPerTask": {"memory": {"dedicated": 100}},
    "taskCount": 6,
    "tasksPerNode": 2
  } ]
}
```

**i** To emulate what `msub` does, make `commandFile` an absolute path, and add `credentials.user`, `credentials.group`, and `initialWorkingDirectory`.

As shown above, `nodes=3:ppn=2` is equivalent to setting `taskCount` to 6 and `tasksPerNode` to 2.

Example 4-9: Submit a job array

For information on how to submit a job array, see [Submitting job arrays on page 1545](#).

## Modifying jobs

The HTTP PUT method is used to modify **Jobs**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/jobs/<name>[/<modifyAction>]?api-version=3 [&proxy-user=<username>]
```

### Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

## Modify job attributes

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/jobs/<name>?api-version=3 [&proxy-user=<username>] [&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.
<b>proxy-user</b>	No	String	--	Perform the action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Additional URL parameters

Parameter	Required	Valid values	Description
<b>change-mode</b>	No	set (default) add remove	If <b>set</b> , replace all fields with the fields specified. If <b>add</b> , add the specified fields to existing fields. If <b>remove</b> , remove the specified fields from existing fields.

Request body

The request body below shows all the fields that are available when modifying a job, along with some sample values.

JSON request body

```
{
  "credentials": {
    "account": "account",
    "jobClass": "BATCH",
    "qosRequested": "QOS1"
  },
  "customName": "custom name for job",
  "dates": {"earliestRequestedStartDate": "2012-11-08 13:18:47 UTC"},
  "duration": 600,
  "flags": [
    "RESTARTABLE",
    "SUSPENDABLE"
  ],
  "holds": ["User"],
  "messages": [
    {"message": "Message one"},
    {"message": "Message two"}
  ],
  "nodesRequested": [
    {
      "name": "n015"},
    {
      "name": "n016"
    },
    {
      "name": "n017"
    },
    {
      "name": "n018"
    }
  ],
  "partitionAccessListRequested": [
    "p1",
    "p2"
  ],
  "priorities": {
    "system": 3,
    "user": 5
  },
  "requirements": [
    {
      "features": [
        "vlan1",
        "vlan2"
      ],
      "resourcesPerTask": [
        "matlab": {
          "dedicated": 1
        },
        "tape": {
          "dedicated": 2
        }
      ]
    }
  ],
  "reservationRequested": {"name": "rsv.1"},
  "variables": {
    "var1": "val1",
    "var2": "val2"
  }
}
```

```
}
}
```

### Sample response

**i** These messages may not match the messages returned from Moab exactly, but are given as an example of the structure of the response.

**i** Not all messages are shown for the above request body.

JSON response

```
-----
{"messages": [
  "Account modified successfully",
  "Messages modified successfully",
  "Variables modified successfully"
]}
```

### Restrictions

- Old messages are not removed from jobs; only new messages are added.
- Job variables have the restrictions documented in [Submitting jobs on page 1555](#).
- Although the client can modify `features` and `resourcesPerTask`, Moab only considers these elements when they appear in the first element of the `requirements` array. If the `requirements` array contains two or more elements, all elements but the first are silently ignored.

### Generic resources

Jobs can require configurable, site-specific consumable resources called generic resources. For example, some jobs may require a matlab license. Only one job at a time may legally consume this license. Matlab is not a standard resource and may only be available on some sites. Nevertheless Moab allows this to be configured and tracked as is explained in [Managing Consumable Generic Resources on page 573](#).

You must specify generic resources in the `requirements.resourcesPerTask` portion of the JSON document. Any resource in `requirement.resourcesPerTask` that is not a standard resource is considered a generic resource. Standard resources include disk, memory, processors, and swap. Assume a job has the following in `requirement.resourcesPerTask`:

```
{
  "resourcesPerTask":{
    "processors":{
      "dedicated":4,
      "utilized":0
    },
    "memory":{
      "dedicated":2048,
      "utilized":0
    },
    "disk":{
      "dedicated":4096,
      "utilized":0
    },
    "swap":{
      "dedicated":1024,
      "utilized":0
    },
    "tape":{
      "dedicated":1,
      "utilized":0
    },
    "matlab":{
      "dedicated":2,
      "utilized":0
    }
  }
}
```

The standard resources the job requires are:

- 4 processors
- 2048 MB of memory
- 4096 MB of disk
- 1024 MB of swap

The generic resources the job requires are

- 1 tape
- 2 matlab

To modify a job so that it requires 1 matlab license, run the following:

```
PUT http://localhost:8080/mws/rest/jobs/Moab.2?api-version=3
{
  "requirements":[
    {
      "resourcesPerTask":{
        "matlab":{
          "dedicated":1
        }
      }
    }
  ]
}
```

## Perform actions on job

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/jobs/<name>/<modifyAction>?api-version=3 [&proxy-user=<username>]
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.
<b>modifyAction</b>	Yes	String	cancel checkpoint execute hold requeue rerun resume suspend unhold	<p>If <b>cancel</b>, attempts to cancel the job (equivalent to deleting a job).</p> <p>If <b>checkpoint</b>, attempts to checkpoint the job. Note that the OS must support checkpointing for this to work.</p> <p>If <b>execute</b>, executes the job (if possible).</p> <p>If <b>hold</b>, attempts to hold the job using the holds set in the request body.</p> <p>If <b>requeue</b>, attempts to requeue the job.</p> <p>If <b>rerun</b>, attempts to rerun the job.</p> <p>If <b>resume</b>, attempts to resume the job.</p> <p>If <b>suspend</b>, attempts to suspend the job.</p> <p>If <b>unhold</b>, attempts to release the holds set in the request body.</p>
<b>proxy-user</b>	No	String	--	Perform the action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

Request bodies are only required for holding or unholding jobs. All other actions do not require request bodies of any kind.

JSON request body to add holds to a job

```
{"holds": ["User"]}
```

JSON request body to remove holds from a job

```
{"holds": ["User"]}
```

If no holds are specified when unholding a job, all holds will be removed. This is equivalent to specifying holds as a list with a single element of `All`.

Sample response

**i** This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```
-----
{"messages": ["Job modified successfully"]}
```

## Deleting (canceling) jobs

The HTTP DELETE method is used to cancel **Jobs**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/jobs/<name>?api-version=3[&proxy-
user=<username>]
```

Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

## Cancel job

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/jobs/<name>?api-version=3[&proxy-
user=<username>]
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.
<b>proxy-user</b>	No	String	--	Perform the action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

JSON response for successful DELETE

```
-----
{}
```

**i** Additional information about the DELETE can be found in the HTTP response header X-MWS-Message.

## Job templates

This section describes behavior of the **Job Template** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Job Templates](#) reference section contains the type and description of all fields in the **Job Template** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/job-templates</a>	<a href="#">Get all job templates</a>	--	--	--
<a href="#">/rest/job-templates/&lt;id&gt;</a>	<a href="#">Get single job template</a>	--	--	--

This topic contains these sections:

- [Getting job templates](#) on page 1569
  - [Get all job templates](#) on page 1570
  - [Get single job template](#) on page 1570

### Getting job templates

The HTTP GET method is used to retrieve **Job Template** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/job-templates/<id>?api-version=3
```

## Get all job templates

### URLs and parameters

```
GET http://localhost:8080/mws/rest/job-templates?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/job-templates?api-version=3&fields=id
{
  "totalCount": 14,
  "resultCount": 14,
  "results": [
    {"id": "DEFAULT"},
    {"id": "genericVM"},
    {"id": "genericVM-setup"},
    {"id": "genericVM-destroy"},
    {"id": "genericVM-migrate"},
    {"id": "genericPM"},
    {"id": "genericPM-setup"},
    {"id": "genericPM-destroy"},
    {"id": "OSStorage"},
    {"id": "OSStorage-setup"},
    {"id": "OSStorage-destroy"},
    {"id": "extraStorage"},
    {"id": "extraStorage-setup"},
    {"id": "extraStorage-destroy"}
  ]
}
```

## Get single job template

### URLs and parameters

```
GET http://localhost:8080/mws/rest/job-templates/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
id	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

## Sample response

JSON response

```

{
  "account": "account",
  "args": "arg1 arg2",
  "commandFile": "/tmp/script",
  "description": "description",
  "genericSystemJob": true,
  "id": "genericVM",
  "inheritResources": false,
  "jobDependencies": [ {
    "name": "genericVM-setup",
    "type": "JOBSUCCESSFULCOMPLETE"
  } ],
  "jobFlags": ["VMTRACKING"],
  "jobTemplateFlags": ["SELECT"],
  "jobTemplateRequirements": [ {
    "architecture": "x86_64",

## Metric types

This section describes behavior of the **Metric Type** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The [Fields: Metric Types](#) reference section contains the type and description of all fields in the **Metric Type** object.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/metric-types</a>	<a href="#">Get all metric types</a>	--	--	--

This topic contains these sections:

- [Getting metric types on page 1572](#)
  - [Get all metric types on page 1572](#)

## Getting metric types

The HTTP GET method is used to retrieve **Metric Type** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3
```

### Get all metric types

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
GET http://localhost:8080/mws/rest/metric-types?api-version=3&fields=id
```

```
{
  "totalCount": 9,
  "resultCount": 9,
  "results": [
    {"id": "vmcount"},
    {"id": "watts"},
    {"id": "pwatts"},
    {"id": "temp"},
    {"id": "cpu"},
    {"id": "mem"},
    {"id": "io"},
    {"id": "ccores"},
    {"id": "threads"}
  ]
}
```

## Nodes

This section describes behavior of the **Node** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Node API is new with *API version 2*. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3` in order to behave as documented.

For more information, see [Requesting specific API versions on page 1428](#).

The **Fields: Nodes** reference contains the type and description of all fields in the **Node** object. It also contains details regarding which fields are valid during PUT and POST actions.

### Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/nodes</code>	<a href="#">Get all nodes</a>	--	--	--
<code>/rest/nodes/&lt;name&gt;</code>	<a href="#">Get single node</a>	<a href="#">Modify node</a>	--	--

This topic contains these sections:

- [Getting nodes on page 1573](#)
  - [Get all nodes on page 1573](#)
  - [Get single node on page 1574](#)
- [Modifying nodes on page 1578](#)
  - [Modify node on page 1579](#)

## Getting nodes

The HTTP GET method is used to retrieve **Node** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/nodes/<name>?api-version=3
```

### Get all nodes

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/nodes?api-version=3
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"type":"-compute"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

**i** This query will not return the `DEFAULT` or `GLOBAL` nodes from Moab. However, the [Get single node](#) task may be used to retrieve them individually if desired.

Sample response

```
GET http://localhost:8080/mws/rest/nodes?api-version=3&fields=name
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"name": "node1"},
    {"name": "node2"},
    {"name": "node3"}
  ]
}
```

**Get single node**

URLs and parameters

```
GET http://localhost:8080/mws/rest/nodes/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

**i** The `attributes` field is only applicable in API version 2 and later, and the `MOAB_TENANT` field only applies if the node is attached to a tenant.

Sample response

JSON response

```
{
  "name": "126.csa",
  "architecture": null,
  "classes": ["class1"],
  "attributes": {
    "MOAB_TENANT": {
      "value": "1234567890abcdef12345678",
      "displayValue": "ResearchGroup"
    },
    "MOAB_DATACENTER": {
      "value": "vcenter-datacenter-401",

## Modifying nodes

The HTTP PUT method is used to modify **Nodes**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/nodes/<name>?api-version=3 [&proxy-user=<username>]
```

### Restrictions

The **proxy-user** parameter is ignored unless you set `ENABLEPROXY=TRUE` in the `moab.cfg` file. For example:

```
ADMINCFG[1]          USERS=root,ted ENABLEPROXY=TRUE
```

## Modify node

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/nodes/<name>?api-version=3 [&proxy-user=<username>]
[&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the object.
<b>proxy-user</b>	No	String	--	Perform the action as this user.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Additional URL parameters

Parameter	Required	Valid values	Description
<b>change-mode</b>	No	set (default) add remove	If <b>set</b> , replace all features with the features specified. If <b>add</b> , add the specified features to existing features. If <b>remove</b> , remove the specified features from existing features.

### Request body

The request body below shows all the fields that are available when modifying a node, along with some sample values.

Sample JSON request body to modify a node

```
{
  "featuresCustom": ["feature1", "feature2"],
  "messages": [
    {"message": "Message one"},
    {"message": "Message two"}
  ],
  "metrics": {"pwatts": 211},
  "operatingSystem": {"image": "esx4.1"},
  "partition": "part1",
  "states": {
    "powerState": "On",
    "state": "Running"
  },
  "variables": {
    "key": "value",
    "arbitrary text key": "more value"
  }
}
```

Sample response

**i** This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```

{
  "messages": [
    "Successfully modified os to 'linux'",
    "Successfully powered node off"
  ]
}
    
```

## Notification conditions

This section describes behavior of the **Notification Conditions** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**!** The Notification Conditions API is new with *API version 3*, and is not available with older API versions. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting specific API versions on page 1428](#).

**i** The [Fields: Notification Conditions](#) reference contains the type and description of all fields in the **Notification Conditions** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/notification-conditions</b>	<a href="#">Get all notification conditions</a>	<a href="#">Update notification condition</a>	--	--
<b>/rest/notification-conditions/&lt;id&gt;</b>	<a href="#">Get single notification condition</a>	--	--	--

This topic contains these sections:

- [Getting notification conditions on page 1581](#)
  - [Get all notification conditions on page 1581](#)
  - [Get single notification condition on page 1583](#)
- [Updating notification conditions on page 1583](#)
  - [Update notification condition on page 1584](#)

## Getting notification conditions

The HTTP GET method is used to retrieve **Notification Condition** information.

### [Quick reference](#)

```
GET http://localhost:8080/mws/rest/notification-conditions?api-version=3
GET http://localhost:8080/mws/rest/notification-conditions/<id>?api-version=3
```

### Get all notification conditions

#### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/notification-conditions?api-version=3[&query=
{"escalationLevel":"ADMIN"}][&sort={"observedDate":-1}]
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Query for specific results. It is possible to query notifications by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"escalationLevel":"ADMIN"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"observedDate":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```

GET http://localhost:8080/mws/rest/notification-conditions?api-version=3&query=
{"escalationLevel":"ADMIN"}&sort={"observedDate":-1}
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "createdDate": "2013-09-10 23:13:33 UTC",
      "details": {
        "pluginType": "NodeUtilizationReport",
        "pluginId": "node-report"
      },
      "escalationLevel": "ADMIN",
      "expirationDate": null,
      "expirationDuration": null,
      "message": "The node 'testnode' has not been updated since the last poll,
which is likely due to a misconfiguration.",
      "objectId": "testnode",
      "objectType": "Node",
      "observedDate": "2013-09-10 23:13:33 UTC",
      "origin": "MWS/plugins/NodeUtilizationReport/node-report",
      "tenant": {
        "id": "1234567890abcdef12345678",
        "name": "Research"
      },
      "id": "522fa79de4b0cafeaec6f83e"
    },
    {
      "createdDate": "2013-09-11 17:19:35 UTC",
      "details": {
        "pluginType": "VCenter",
        "pluginId": "vcenter42"
      },
      "escalationLevel": "ADMIN",
      "expirationDate": null,
      "expirationDuration": null,
      "message": "The node 'node1' does not have vcenter tools installed,
therefore the state is unknown and migrations may not work correctly",
      "objectId": null,
      "objectType": "System",
      "observedDate": "2013-09-11 17:19:35 UTC",
      "origin": "MWS/plugins/VCenter/vcenter42",
      "tenant": {
        "id": "1234567890abcdef12345678",
        "name": "Research"
      },
      "id": "5230a627e4b0d51bef490e86"
    }
  ]
}

```

**i** A notification's `tenant` is automatically inherited from the `objectId` and `objectType` fields. If no object is associated with the notification condition, the notification is visible to all tenants.

## Get single notification condition

### URLs and parameters

```
GET http://localhost:8080/mws/rest/notification-conditions/<id>?api-version=3
```

Parameter	Required	Type	Description
<b>id</b>	Yes	String	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/notification-conditions/521a1f18e4b0e3f9031f47f5?api-version=3
```

```
{
  "createdDate": "2013-09-10 23:13:33 UTC",
  "details": {
    "pluginType": "NodeUtilizationReport",
    "pluginId": "node-report"
  },
  "escalationLevel": "ADMIN",
  "expirationDate": null,
  "expirationDuration": null,
  "message": "The node 'testnode' has not been updated since the last poll, which is likely due to a misconfiguration.",
  "objectId": "testnode",
  "objectType": "Node",
  "observedDate": "2013-09-10 23:13:33 UTC",
  "origin": "MWS/plugins/NodeUtilizationReport/node-report",
  "tenant": {
    "id": "1234567890abcdef12345678",
    "name": "Research"
  },
  "id": "522fa79de4b0cafeaec6f83e"
}
```

**i** A notification's tenant is automatically inherited from the `objectId` and `objectType` fields. If no object is associated with the notification condition, the notification is visible to all tenants.

## Updating notification conditions

The HTTP PUT method is used to update **Notification Condition** information. The PUT operation is idempotent, meaning that is used for both creating new notification conditions and updating existing ones. If the `escalationLevel`, `origin`, `message`, `objectType`, and `objectId` fields match an existing notification condition, it will be updated. Otherwise, a new condition will be created.

### Quick reference

```
PUT http://localhost:8080/mws/rest/notification-conditions?api-version=3
```

## Update notification condition

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notification-conditions?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

The request body below shows some fields that are available when updating a notification condition, along with some sample values.

Sample JSON request body to update a notification condition

```
{
  "details": {
    "pluginType": "NodeTester",
    "pluginId": "my-tester1"
  },
  "escalationLevel": "ADMIN",
  "expirationDuration": 30,

## Notifications

This section describes behavior of the **Notifications** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

The Notifications API is new with *API version 3*, and is not available with older API versions. The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting specific API versions](#) on page 1428.

The [Fields: Notifications](#) reference contains the type and description of all fields in the **Notifications** object.

### Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/notifications/</code>	<a href="#">Get all notifications</a>	--	--	--
<code>/rest/notifications/&lt;id&gt;</code>	<a href="#">Get single notification</a>	--	--	--
<code>/rest/notifications/ignore</code>	--	<a href="#">Ignore all notifications</a>	--	--
<code>/rest/notifications/&lt;id&gt;/ignore</code>	--	<a href="#">Ignore single notification</a>	--	--
<code>/rest/notifications/unignore</code>	--	<a href="#">Unignore all notifications</a>	--	--

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/notifications/&lt;id&gt;/unignore</a>	--	<a href="#">Unignore single notification</a>	--	--
<a href="#">/rest/notifications/dismiss</a>	--	<a href="#">Dismiss all notifications</a>	--	--
<a href="#">/rest/notifications/&lt;id&gt;/dismiss</a>	--	<a href="#">Dismiss single notification</a>	--	--

This topic contains these sections:

## Getting notifications

The HTTP GET method is used to retrieve **Notification** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/notifications?api-version=3
GET http://localhost:8080/mws/rest/notifications/<id>?api-version=3
```

## Get all notifications

### URLs and parameters

```
GET http://localhost:8080/mws/rest/notifications?api-version=3[&proxy-user=<username>]
[&query={"ignoredDate":null,"dismissedDate":null}][&sort={"observedDate":-1}]
```

Parameter	Required	Type	Description	Example
<b>proxy-user</b>	No	String	Perform the action as this user. <div style="border: 1px solid #0070c0; padding: 5px; margin-top: 10px;">  Notifications cannot be created directly. Instead, they are automatically created for the current user or <code>proxy-user</code> specified in the request from non-expired notification conditions (see <a href="#">Notification conditions</a> on page 1580). This is true no matter the query specified.                     </div>	--
<b>query</b>	No	JSON	Query for specific results. It is possible to query notifications by one or more fields based on <a href="#">MongoDB query syntax</a> . However, typically you will want to query on <code>{"ignoredDate":null,"dismissedDate":null}</code> .	<pre>query= {"ignoredDate":null,"dismissedDate":null}</pre>
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	<pre>sort={"observedDate":-1}</pre>

See [Global URL parameters](#) on page 1425 for available URL parameters.

**Sample response**

```
GET http://localhost:8080/mws/rest/notifications?api-version=3&proxy-user=<username>&query={"ignoredDate":null,"dismissedDate":null} [&sort={"observedDate":-1}]
-----
{
  "totalCount": 2,

  "origin": "MWS/HealthNotificationJob",
  "user": "admin",
  "id": "5230ed82e4b065347016d60d"
}
```

## Ignoring notifications

The HTTP PUT method is used to ignore **Notifications**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/ignore?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/ignore?api-version=3
```

## Ignore all notifications

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/ignore?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
JSON response
-----
{"messages":["Updated 10 Notification objects"]}
```

## Ignore single notification

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/ignore?api-
version=3
```

Parameter	Required	Type	Description
<b>id</b>	Yes	String	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/ignore?api-version=3
-----
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",

  "user": "admin",
  "id": "5230ed82e4b065347016d60d"
}
```

## Unignoring notifications

The HTTP PUT method is used to unignore **Notifications**.

#### Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/unignore?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/unignore?api-version=3
```

### Unignore all notifications

#### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/unignore?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
JSON response
-----
{"messages":["Updated 10 Notification objects"]}
```

## Unignore single notification

```
PUT
http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/unignore?api-
version=3
```

Parameter	Required	Type	Description
<b>id</b>	Yes	String	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
PUT
http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/unignore?api-
version=3
```

```
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",
  "createdDate": "2013-08-25 15:13:28 UTC",
  "details": {},
  "dismissedDate": "null",
  "ignoredDate": null,
  "message": "A health check failed for the 'LDAP' connection, please see the MWS
health details page for more information.",

  "id": "5230ed82e4b065347016d60d"
}
```

## Dismissing notifications

The HTTP PUT method is used to dismiss **Notifications**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/notifications/dismiss?api-version=3
PUT http://localhost:8080/mws/rest/notifications/<id>/dismiss?api-version=3
```

### Dismiss all notifications

#### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/dismiss?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response

```
{"messages":["Updated 10 Notification objects"]}
```

### Dismiss single notification

#### URLs and parameters

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/dismiss?api-version=3
```

Parameter	Required	Type	Description
<b>id</b>	Yes	String	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
PUT http://localhost:8080/mws/rest/notifications/5230ed82e4b065347016d60d/dismiss?api-version=3
```

```
{
  "conditionId": "521a1f18e4b0e3f9031f47f5",

## Permissions

This section describes behavior of the **Permissions** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

 The [Fields: User's Permissions](#) reference section contains the type and description of fields that all **Permissions** have in common.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/permissions</a>	<a href="#">Get all permissions</a>	--	<a href="#">Create single permission</a>	--
<a href="#">/rest/permissions/&lt;id&gt;</a>	<a href="#">Get single permission</a>	--	--	<a href="#">Delete single permission</a>
<a href="#">/rest/permissions/users/&lt;id&gt;</a>	<a href="#">Get a user's permissions</a>	--	--	--
<a href="#">/rest/permissions/users</a>	<a href="#">Get a current user's permissions</a>	--	--	--

This topic contains these sections:

- [Getting permissions](#) on page 1594
  - [Get all permissions](#) on page 1594
  - [Get single permission](#) on page 1595
  - [Get a user's permissions](#) on page 1595
  - [Get a current user's permissions](#) on page 1596
- [Creating permissions](#) on page 1597
  - [Create single permission](#) on page 1597
- [Deleting permissions](#) on page 1598
  - [Delete single permission](#) on page 1598

## Getting permissions

The HTTP GET method is used to retrieve **Permission** information. You can query all objects or a single object.

### Quick reference

```
GET http://localhost:8080/mws/rest/permissions?api-version=3
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

## Get all permissions

### URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query permissions by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={ "type": "CUSTOM"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name": -1}

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/permissions?api-
version=3&fields=resource,action,description
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [{
    "resource" : "chart",
    "action" : "read",
    "description" : "The permission to view all charts."
  } ]
}
```

### Sorting and querying

See the sorting and querying sections of [Global URL parameters on page 1425](#).

## Get single permission

### URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the permission.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

```
{
  "action" : "create",
  "description" : "The permission to create all charts.",
  "id" : "50296335e4b0011b0f8394ec",
  "label" : "Create Chart",
  "resource" : "chart",
  "resourceFilter" : null,
  "type" : "custom",
  "scope" : "NONE",
  "version" : 0
}
```

For permissions with type "domain", scope must be GLOBAL or TENANT. All other permissions should have scope NONE.

## Get a user's permissions

### URLs and parameters

```
GET http://localhost:8080/mws/rest/permissions/users/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the user.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/permissions/users/bob?api-version=3
```

```
[
  {
    "action": "read",
    "description": "The permission to read all charts",
    "id": "5033b842e4b09cc61bedb818",
    "label": "",
    "resource": "chart",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "read",
    "description": "The permission to read all pages",
    "id": "5033b8a5e4b09cc61bedb82d",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "update",
    "description": "The permission to update all pages",
    "id": "5033b8a5e4b09cc61bedb82f",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  }
]
```

## Get a current user's permissions

### URLs and parameters

```
GET http://localhost/mws/rest/permissions/users/?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost/mws/rest/permissions/users/?api-version=3
```

```
[
  {
    "action": "read",
    "description": "The permission to read all charts",
    "id": "5033b842e4b09cc61bedb818",
    "label": "",
    "resource": "chart",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "read",
    "description": "The permission to read all pages",
    "id": "5033b8a5e4b09cc61bedb82d",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  },
  {
    "action": "update",
    "description": "The permission to update all pages",
    "id": "5033b8a5e4b09cc61bedb82f",
    "label": "",
    "resource": "page",
    "resourceFilter": null,
    "type": "custom",
    "scope": "NONE",
    "version": 1
  }
]
```

## Creating permissions

The HTTP POST method is used to create **Permissions**.

### Quick reference

```
POST http://localhost:8080/mws/rest/permissions?api-version=3
```

### Create single permission

#### URLs and parameters

```
POST http://localhost:8080/mws/rest/permissions?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

**i** The **resource**, **action**, and **type** are required on each permission.

Api permissions are permissions with the type 'api' and are the only permissions enforced by MWS.

Api permissions must map to a valid resource. For example, "services" is valid because there is a resource `/mws/rest/services`.

Api permissions must have `create`, `read`, `update`, or `delete` as the action.

The following is an example request body to create a permission:

```
POST http://localhost:8080/mws/rest/permissions?api-version=3
-----
{
    "resource" : "Chart",
    "action" : "read",
    "type" : "custom",
    "scope" : "NONE",
    "label" : "Read all charts",
    "description" : "The permissions to view all charts."
}
```

Sample response

If the request was successful, the response body is the new permission that was created exactly as shown in [Get single permission](#). On failure, the response is an error message.

## Deleting permissions

The HTTP DELETE method is used to delete **Permissions**.

Quick reference

```
DELETE http://localhost:8080/mws/rest/permissions/<id>?api-version=3
```

### Delete single permission

URLs and parameters

```
DELETE http://localhost:8080/mws/rest/permission/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the permission.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
JSON response
-----
{}

```

## Plugins

This section describes behavior of the **Plugins** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Plugins](#) reference contains the type and description of all fields in the **Plugin** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/plugins</b>	<a href="#">Get all plugins</a>	--	<a href="#">Create plugin</a>	--
<b>/rest/plugins/reporting-jobs/&lt;jobName&gt;?api-version=3</b>	<a href="#">Get all plugins reporting object</a>	--	--	--
<b>/rest/plugins/reporting-nodes/&lt;nodeName&gt;?api-version=3</b>	<a href="#">Get all plugins reporting object</a>	--	--	--
<b>/rest/plugins/reporting-vms/&lt;vmName&gt;?api-version=3</b>	<a href="#">Get all plugins reporting object</a>	--	--	--
<b>/rest/plugins/&lt;id&gt;</b>	<a href="#">Get single plugin</a>	<a href="#">Modify plugin</a>	--	<a href="#">Delete plugin</a>
<b>/rest/plugins/&lt;id&gt;/poll</b>	--	--	<a href="#">Trigger plugin poll</a>	--

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/plugins/&lt;id&gt;/services/&lt;serviceName&gt;</a>	<a href="#">Access a plugin web service</a>			

This topic contains these sections:

  - [Access a plugin web service on page 1606](#)

## Getting plugins

The HTTP GET method is used to retrieve **Plugin** information. Queries for all objects, a single object, and query by reported object are available.

### Quick reference

```
GET http://localhost:8080/mws/rest/plugins?api-version=3
GET http://localhost:8080/mws/rest/plugins/<id>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-jobs/<jobName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/<nodeName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-vm/<vmName>?api-version=3
```

## Get all plugins

### URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/plugins?api-version=3&fields=id
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "plugin1"},
    {"id": "plugin2"},
    {"id": "plugin3"}
  ]
}
```

## Get all plugins reporting object

### URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins/reporting-jobs/<jobName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/<nodeName>?api-version=3
GET http://localhost:8080/mws/rest/plugins/reporting-vm/<vmName>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>jobName</b>	Yes	String	--	The name of the job to query by.
<b>nodeName</b>	Yes	String	--	The name of the node to query by.
<b>vmName</b>	Yes	String	--	The name of the VM to query by.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

This built-in query returns the same information as [Get all plugins](#), but filters the items to only plugins that are currently reporting the specified job, node, or VM (see [Reporting state data on page 1698](#)). The list is sorted ascending by the `precedence` field. In other words, the most authoritative plugin for the report is listed first. For more information, see [Data consolidation on page 1677](#).

```
GET http://localhost:8080/mws/rest/plugins/reporting-nodes/node1?api-
version=3&fields=id
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "plugin1"},
    {"id": "plugin2"},
    {"id": "plugin3"}
  ]
}
```

## Get single plugin

### URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response

```
{
  "id": "plugin1",
  "pluginType": "Native",
  "pollInterval": 30,
  "autoStart": true,
  "config": {
    "getJobs": "exec:///opt/moab/tools/workload.query.pl"
  },
  "state": "STARTED",
  "nextPollDate": "2011-12-02 17:28:52 UTC",
  "lastPollDate": "2011-12-02 17:28:22 UTC"
}
```

## Creating plugins

The HTTP POST method is used to create **Plugins**.

### Quick reference

```
POST http://localhost:8080/mws/rest/plugins?api-version=3
```

## Create plugin

### URLs and parameters

```
POST http://localhost:8080/mws/rest/plugins?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

When creating a plugin, the `id` and `pluginType` fields are required. The request body below shows all fields that are available when creating a plugin, along with some sample values.

JSON request body

```

{
  "id": "plugin1",
  "pluginType": "Native",
  "pollInterval": 30,
  "autoStart": true,
  "config": {
    "getJobs": "exec:///opt/moab/tools/workload.query.pl"
  }
}

```

### Sample response

JSON response for successful POST

```

{"id": "plugin1"}

```

### Restrictions

While it is possible to create a plugin with arbitrary nested configuration, such as:

```

...
"config": {
  "nestedObject": {
    "property1": "value1",
    "property2": "value2"
  },
  "nestedList": ["listItem1", "listItem2"]
}

```

It is *not* recommended, because the user interface (see [Plugin management on page 1742](#)) does not support editing or viewing any configuration data values other than strings.

## Modifying plugins

The HTTP PUT method is used to modify **Plugins**. Additionally, the POST method may be used to trigger an immediate poll of a **Plugin**.

### Quick reference

```

PUT http://localhost:8080/mws/rest/plugins/<id>?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/poll?api-version=3

```

## Modify plugin

### URLs and parameters

```

PUT http://localhost:8080/mws/rest/plugins/<id>?api-version=3

```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

The request body below shows all the fields that are available when modifying a **Plugin**, along with some sample values.

```

JSON request body for plugin modification
-----
{
  "state":"STARTED",
  "pollInterval":30,
  "autoStart":true,
  "config":{
    "getJobs":"exec:///opt/moab/tools/workload.query.pl"
  },
  "state":"STARTED"
}
    
```

Sample response

```

JSON response
-----
{"messages":["Plugin plugin1 updated", "Started Plugin 'plugin1'"]}
    
```

**Trigger plugin poll**

URLs and parameters

```

POST http://localhost:8080/mws/rest/plugins/<id>/poll?api-version=3
    
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

Trigger poll

This resource call will trigger an immediate poll of the specified plugin. It is equivalent to the same operation on [Monitoring and lifecycle controls on page 1745](#).

Request body

No request body is required.

### Sample response

JSON response

```
-----  
{"messages":["Polled Plugin with ID 'myPlugin'"]}
```

## Deleting plugins

The HTTP DELETE method is used to delete **Plugins**.

### Quick reference

```
DELETE http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

### Delete plugin

#### URLs and parameters

```
DELETE http://localhost:8080/mws/rest/plugins/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response for successful DELETE

```
-----  
{}
```

Additional information about a successful DELETE can be found in the HTTP response header `X-MWS-Message`.

JSON response for an unsuccessful DELETE

```
-----  
{"messages":["Plugin plugin1 could not be deleted", "Error message describing the problem"]}
```

## Accessing Plugin Web Services

All HTTP methods can be used to access **Plugin Web Services**. However, some services only support specific methods. Check the specific plugin type documentation for more information.

Quick reference

```
GET http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
PUT http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
DELETE http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
```

**Access a plugin web service**

URLs and parameters

```
GET http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
POST http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
PUT http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
DELETE http://localhost:8080/mws/rest/plugins/<id>/services/<serviceName>
[</objectId>]?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.
<b>objectId</b>	No	String	--	An arbitrary ID parameter that will be passed to the web service.
<b>serviceName</b>	Yes	String	--	The name of the web service, either in CamelCase or hyphenated.

See [Global URL parameters on page 1425](#) for available URL parameters.

Web service IDs

Translation is done to map [CamelCase](#) web service names to hyphenated names in the URL. For example, a web service method named `notifyEvent` on a plugin with a name of `notifications` may be called with the following URLs:

```
// CamelCase
/rest/plugins/notifications/services/notifyEvent

// Hyphenated
/rest/plugins/notifications/services/notify-event
```

HTTP method and request body

Because plugin custom web services do not need to distinguish which HTTP method is used (see [Custom web services on page 1676](#)), it is recommended to use GET and POST when making requests to access

web services unless documented otherwise. The request body and output may vary for each web service called. See [Plugin types on page 1607](#) for the requested plugin for available web services, request parameters, and expected output.

- [Plugin types on page 1607](#)

## Plugin types

This section describes behavior of the **Plugin Type** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Plugin Types](#) reference section contains the type and description of all fields in the **Plugin Type** object. It also contains details regarding which fields are valid during PUT and POST actions.

#### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/plugin-types</a>	<a href="#">Get all plugin types</a>	<a href="#">Creating or updating plugin types</a>	--	--
<a href="#">/rest/plugin-types/&lt;id&gt;</a>	<a href="#">Get single plugin type</a>	--	--	--

This topic contains these sections:

- [Getting plugin types on page 1607](#)
  - [Get all plugin types on page 1608](#)
  - [Get single plugin type on page 1608](#)
- [Creating or updating plugin types on page 1609](#)
  - [Update plugin type \(file\) on page 1609](#)
  - [Update plugin type \(JAR\) on page 1611](#)

### Getting plugin types

The HTTP GET method is used to retrieve **Plugin Type** information. Queries for all objects and a single object are available.

### [Quick reference](#)

```
GET http://localhost:8080/mws/rest/plugin-types/<id>?api-version=3
```

## Get all plugin types

### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/plugin-types?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### [Sample response](#)

```
GET http://localhost:8080/mws/rest/plugin-types?api-version=3&fields=id
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {"id": "vCenter"},
    {"id": "Native"}
  ]
}
```

## Get single plugin type

### [URLs and parameters](#)

```
GET http://localhost:8080/mws/rest/plugin-types/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response

```

{
  "author": "Adaptive Computing Enterprises, Inc.",
  "commonsVersion": "0.9.3 > *",
  "description": "Polls a VMware® vCenter™ Server for information on the hypervisors
and virtual machines it manages.",
  "documentationLink": "",
  "email": "",
  "eventComponent": 1,
  "realizedEventComponent": 513,
  "id": "VCenter",
  "initialPlugins": { },
  "instances": [
    {"id":"vcenter"}
  ],
  "issueManagementLink": "",
  "license": "APACHE",
  "mwsVersion": "7.1.2 > *",
  "pollMethod": true,
  "scmLink": "",
  "title": "VCenter",
  "version": "1.0",
  "webServices": [ ],
  "website": "http://www.adaptivecomputing.com"
}

```

## Creating or updating plugin types

The HTTP PUT method is used to create or update **Plugin Types**. The Content-Type HTTP header is used to determine if the request contains a single class file as plaintext or the binary data of a JAR file. Each request is explained in the following sections.

### Quick reference

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3[&reload-plugins=false]
```

There is a known issue with dynamically updating plugin types with typed field injection. For more information, see [Add or update plugin types on page 1739](#).

## Update plugin type (file)

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3[&reload-plugins=false]
```

Parameter	Required	Type	Valid values	Description
<b>reload-plugins</b>	No	String	true or false	Reloads all plugins of this type on successful update. Defaults to true.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

This function is idempotent, meaning it will create the **Plugin Type** if it does not exist or update it if it does. The request body is the actual contents of the class file to upload. This web service is an exception to most as it *requires* a content type of `application/x-groovy` or `text/plain`.

If the `application/x-groovy` or `text/plain` content types are not used in the request, it will be interpreted as JSON, resulting in a failure.

Plaintext upload

```

package test

import com.adaptc.mws.plugins.*

class UploadPlugin {
    static author = "Adaptive Computing"
    static description = "A sample plugin class"
    String id

    public void configure() throws InvalidPluginConfigurationException {
        def myConfig = config
        def errors = []
        if (!myConfig.arbitraryKey)
            errors << "Missing arbitraryKey!"
        if (errors)
            throw new InvalidPluginConfigurationException(errors)
    }

    public def customService(Map params) {
        return params
    }
}

```

If using the [curl](#) library to perform plugin type uploading, the equivalent of the command-line option `--data-binary` must be used to send the request body. Otherwise compilation errors may be encountered when uploading the plugin type.

### Sample response

The response of this task is the same as the [Get all plugin types](#) task. The reason that the return of this task is a list is to accommodate the possibility of uploading multiple plugin types in a single JAR file as explained in the next section.

## Update plugin type (JAR)

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/plugin-types?api-version=3&jar-
filename=<filename.jar>[&reload-plugins=false]
```

Parameter	Required	Type	Valid values	Description
<b>jar-file-name</b>	Yes	String	--	The filename of the JAR file that is being uploaded.
<b>reload-plugins</b>	No	String	true or false	Reloads all plugins of this type on successful update. Defaults to true.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

This function is idempotent, meaning it will create the **Plugin Types** if they do not exist or update them if they do. The request body is the binary contents of the JAR file to upload. This web service is an exception to most as it *requires* a content type of `application/x-jar`.

If the `application/x-jar` content type is not used in the request, it will be interpreted as JSON, resulting in a failure.

If using the [curl](#) library to perform plugin type uploading, the equivalent of the command-line option `--data-binary` must be used to send the request body. Otherwise compilation errors may be encountered when uploading the plugin type.

### Sample response

The response of this task is the same as the [Get all plugin types](#) task. Note that when using a JAR file, multiple plugin types may be uploaded in the same request.

### Related topics

## Policies

This section describes behavior of the **Policies** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The **Fields: Policies** reference section contains the type and description of fields of all **Policies**.

### Supported policies

Name	ID
Automatic VM Migration	auto-vm-migration
Fairshare	fairshare
Hypervisor Allocation Overcommit	hv-allocation-overcommit
Migration Exclusion List	migration-exclusion-list
Node Allocation	node-allocation

### Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/policies</b>	<a href="#">Get all policies</a>	--	--	--
<b>/rest/policies/&lt;id&gt;</b>	<a href="#">Get single policy</a>	<a href="#">Modify policy</a>	--	--

This topic contains these sections:

- [Getting policies on page 1612](#)
  - [Get all policies on page 1613](#)
  - [Get single policy on page 1613](#)
- [Modifying policies on page 1615](#)
  - [Modify policy on page 1616](#)

## Getting policies

The HTTP GET method is used to retrieve **Policies** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/policies?api-version=3
```

## Get all policies

### URLs and parameters

```
GET http://localhost:8080/mws/rest/policies?api-version=3
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Query for specific results.	query={"state":"DISABLED","-conflicted":"false"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"id":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/policies?api-version=3&fields=id,state,conflicted
```

```
{
  "totalCount": 4,
  "resultCount": 4,
  "results": [ {
    "conflicted": false,
    "state": "DISABLED",
    "id": "auto-vm-migration"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "hv-allocation-overcommit"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "node-allocation"
  }, {
    "conflicted": false,
    "state": "DISABLED",
    "id": "migration-exclusion-list"
  }
]
```

## Get single policy

### URLs and parameters

```
GET http://localhost:8080/mws/rest/policies/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample responses

#### Auto VM Migration

```
{
  "conflicted": false,
  "description": "Controls how virtual machines are automatically migrated.",
  "id": "auto-vm-migration",
  "name": "Auto VM Migration",
  "potentialConflicts": [],
  "priority": 1,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "genericMetricThresholds": {
    "GMETRIC1": 1.3
  },
  "processorUtilizationThreshold": 0.5,
  "memoryUtilizationThreshold": 0.4
}
```

#### Fairshare

```
{
  "conflicted": false,
  "decayFactor": 0.44,
  "depth": 4,
  "description": "Control job feasibility and priority decisions based on system utilization targets for users, groups, accounts, classes, and QoS levels.",
  "intervalSeconds": 600,
  "name": "Fairshare",
  "potentialConflicts": [],
  "priority": 16,
  "state": "ENABLED",
  "tags": [],
  "types": [],
  "usageMetric": "DEDICATED_PROCESSOR_SECONDS_DELIVERED",
  "version": 3,
  "id": "fairshare"
}
```

## Hypervisor Allocation Overcommit

```

{
  "conflicted": false,
  "description": "Controls how hypervisors are overallocated with regards to
processors and memory.",
  "id": "hv-allocation-overcommit",
  "name": "Hypervisor Allocation Overcommit",
  "potentialConflicts": [],
  "priority": 2,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "processorAllocationLimit":29.5,
  "memoryAllocationLimit":1.2
}

```

## Migration Exclusion List

```

{
  "conflicted": false,
  "description": "Controls which machines are excluded from automatic live migration
operations.",
  "hvExclusionList": ["blade05", "blade02"],
  "name": "Migration Exclusion List",
  "potentialConflicts": [],
  "priority": 100,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 1,
  "vmExclusionList": ["vm1", "vm5"],
  "id": "migration-exclusion-list"
}

```

## Node Allocation

```

{
  "conflicted": false,
  "description": "Controls how nodes are selected for workload placement.",
  "id": "node-allocation",
  "name": "Node Allocation",
  "potentialConflicts": [],
  "priority": 3,
  "state": "DISABLED",
  "tags": [],
  "types": [],
  "version": 0,
  "nodeAllocationAlgorithm": "CustomPriority",
  "customPriorityFunction": "-100*GMETRIC[vmcount]"
}

```

## Modifying policies

The HTTP PUT method is used to modify **Policies**.

[Quick reference](#)

```
PUT http://localhost:8080/mws/rest/policies/<id>?api-version=3
```

**Modify policy**

[URLs and parameters](#)

```
PUT http://localhost:8080/mws/rest/policies/<id>?api-version=3 [&change-mode=set]
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

[Additional URL parameters](#)

URL parameters for modifying a Migration Exclusion Lists Policy.

Migration Exclusion Lists parameter	Required	Type	Valid values	Description
<b>change-mode</b>	No	String	set (default) add remove	If <b>set</b> , replace existing exclusion list(s) with the given one. If <b>add</b> , add the given VMs/HVs to the existing exclusion list(s). If <b>remove</b> , remove the given VMs/HVs from the existing exclusion list(s).

[Request body](#)

In general, the fields shown in the [Fields: Policies](#) reference section are *not* available for modification. However, the `state` field may be modified to a valid `PolicyState`. All other fields listed in the specific policy type sections (i.e. `AutoVMMigrationPolicy`) may be modified unless documented otherwise.

- The request body below shows all the fields that are available when modifying a Auto VM Migration Policy, along with some sample values.

```
JSON request body for Auto VM Migration Policy
{
  "genericMetricThresholds": {
    "GENERICTHRESHOLD": 5
  },
  "memoryUtilizationThreshold": 0.5,
  "processorUtilizationThreshold": 0.4
}
```

- The request body below shows all the fields that are available when modifying a Fairshare Policy, along with some sample values.

```
JSON request body for Fairshare Policy
-----
{
  "decayFactor": 0.44,
  "depth": 4,
  "intervalSeconds": 600,
  "usageMetric": "DEDICATED_PROCESSOR_SECONDS_DELIVERED",
}
```

- The request body below shows all the fields that are available when modifying a Hypervisor Allocation Overcommit Policy, along with some sample values.

```
JSON request body for Hypervisor Allocation Overcommit Policy
-----
{
  "processorAllocationLimit":29.5,
  "memoryAllocationLimit":1.2
}
```

- The request body below shows all the fields that are available when modifying a Migration Exclusion Lists Policy, along with some sample values.

```
JSON request body for Migration Exclusion Lists Policy
-----
{
  "vmExclusionList" : ["vm1","vm3","vm5"],
  "hvExclusionList" : ["hv2","hv3","hv6"]
}
```

- The request body below shows all the fields that are available when modifying a Node Allocation Policy, along with some sample values.

```
JSON request body for Node Allocation Policy
-----
{
  "nodeAllocationAlgorithm" : "CustomPriority",
  "customPriorityFunction" : "-100*GMETRIC[vmcount]"
}
```

### Sample response

```
JSON response
-----
{
  "messages": ["Policy auto-vm-migration updated"]
}
```

### Samples

Enable the Auto VM Migration Policy and set values.

```
PUT http://localhost:8080/mws/rest/policies/auto-vm-migration?api-version=3
```

```
{
  "state": "enabled",
  "migrationAlgorithmType": "overcommit",
  "processorUtilizationThreshold": 0.5,
  "memoryUtilizationThreshold": 0.4
}
```

 As noted in the [Fields: Policies](#) reference section documentation for `AutoVMMigrationPolicy`, if the `state` is set to `ENABLED`, then the `migrationAlgorithmType` must *not* be set to `NONE`.

### Restrictions

All policies:

- Fields cannot be modified while the policy is disabled. Enable the policy to modify the field.

Auto VM Migration

- Arbitrary metrics can be added to **genericMetricThresholds**, but they cannot be removed once added.
- The **migrationAlgorithmType** field cannot be modified while the policy is disabled. Enable the policy to modify the field.
- Moab is configured with a default limit of 10 generic metrics. If this limit is reached, such as when arbitrary metrics are added to **genericMetricThresholds**, the metric will not be reported. To increase this limit, set the `MAXGMETRIC` property in the Moab configuration file.

Fairshare

- Updating the **usageMetric** field will clear all credential-based fairshare interval data.

## Fairshare

This section describes behavior of the **Fairshare** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

 The supported methods table below requires each resource to be accessed with a URL parameter of `api-version=3`.

For more information, see [Requesting specific API versions on page 1428](#).

Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/policies/fairshare</b>	<a href="#">Get all fairshare interval data on page 1620</a>	--	--	--
<b>/rest/policies/fairshare/&lt;credentialType&gt;</b>	<a href="#">Get all fairshare interval data for a single credential type on page 1623</a>	--	--	--
<b>/rest/policies/fairshare/&lt;credentialType&gt;/&lt;name&gt;</b>	<a href="#">Get all fairshare interval data for a single credential on page 1626</a>	--	--	--

This topic contains these sections:

- [Getting credential-based fairshare interval data on page 1619](#)
  - [Get all fairshare interval data on page 1620](#)

## Getting credential-based fairshare interval data

The HTTP GET method is used to retrieve **Policies** information.

### Quick reference

```
GET http://localhost:8080/mws/rest/policies/fairshare/credentials?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/accounts?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/classes?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/groups?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/qoses?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/users?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/accounts/<name>?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/classes/<name>?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/groups/<name>?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/qoses/<name>?api-version=3
GET http://localhost:8080/mws/rest/policies/fairshare/credentials/users/<name>?api-version=3
```

## Get all fairshare interval data

### URLs and parameters

```
GET http://localhost:8080/mws/rest/policies/fairshare/credentials?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/policies/fairshare/credentials?api-version=3
```

```

### Get all fairshare interval data for a single credential

#### URLs and parameters

```

GET
http://localhost:8080/mws/rest/policies/fairshare/credentials/<accounts|classes|groups|qoses|users>/<name>?api-version=3

```

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The unique name of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```

GET
http://localhost:8080/mws/rest/policies/fairshare/credentials/accounts/DEFAULT?api-version=3
-----
{
  "name": "DEFAULT",
  "target_type": null,
  "target": null,
  "interval_data": [
    0,
    0,
    0,
    0
  ],
  "credential_type": "ACCOUNT"
}

```

## Principals

This section describes behavior of the **Principal** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Principals](#) reference contains the type and description of all fields in the **Principal** object. It also contains details regarding which fields are valid during PUT and POST actions.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/principals</a>	<a href="#">Get all principals</a>	--	<a href="#">Create single principal</a>	--
<a href="#">/rest/principals/&lt;id&gt;</a>	<a href="#">Get single principal</a>	<a href="#">Modify single principal</a>	--	<a href="#">Delete single principal</a>
<a href="#">/rest/principals/&lt;name&gt;</a>	<a href="#">Get single principal</a>	<a href="#">Modify single principal</a>	--	<a href="#">Delete single principal</a>

This topic contains these sections:

- [Getting principals on page 1627](#)
  - [Get all principals on page 1628](#)
  - [Get single principal on page 1629](#)
- [Creating principals on page 1630](#)
  - [Create single principal on page 1630](#)
- [Modifying principals on page 1631](#)
  - [Modify single principal on page 1631](#)
- [Deleting principals on page 1633](#)
  - [Delete single principal on page 1633](#)

## Getting principals

The HTTP GET method is used to retrieve **Principal** information. You can query all objects or a single object.

Quick reference

```
GET http://localhost:8080/mws/rest/principals?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/principals/<id>?api-version=3
GET http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

**Get all principals**

URLs and parameters

```
GET http://localhost:8080/mws/rest/principals?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query principals by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={ "name":"Acme Principal"}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":- 1}

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/principals?api-version=3&fields=name,group
-----
{
  "totalCount": 2,
  "resultCount": 2,
  "results": [
    {
      "groups": [
        {
          "name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
          "type": "LDAPGROUP"
        }
      ],
      "name": "Engineering-Principal"
    },
    {
      "groups": [
        {
          "name": "CN=Marketing,CN=Users,DC=corp,DC=cloud,DC=dev",
          "type": "LDAPGROUP"
        }
      ],
      "name": "Marketing-Principal"
    }
  ]
}
```

Sorting and Querying

See the sorting and querying sections of [Global URL parameters on page 1425](#).

## Get single principal

### URLs and parameters

```
GET http://localhost:8080/mws/rest/principals/<id>?api-version=3
GET http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the principal.
<b>name</b>	Yes	String	--	The name of the principal.

 You must specify either id or name, but you do not have to specify both.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/principals/principal8?api-version=3

{
  "attachedRoles": [ {
    "description": "This is a role for normal users in the Acme BU Group.",
    "id": "5033b8eae4b09cc61bedb895",
    "name": "Acme-User-Role",
    "permissions": [
      {
        "action": "read",
        "description": "The permission to read all nodes",
        "id": "5033b842e4b09cc61bedb818",
        "label": "",
        "resource": "nodes",
        "resourceFilter": null,
        "type": "api",
        "version": 1
      }
    ],
    "version": 2
  } ],
  "description": "Principal 8",
  "groups": [ {
    "name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
    "type": "LDAPGROUP"
  } ],
  "id": "5033d33fe4b018b28745fecb",
  "name": "principal8",
  "users": [
    {
      "name": "jhammon",
      "type": "LDAP"
    },
    {
      "name": "bjones",
      "type": "LDAP"
    }
  ],
  "version": 0
}
```

## Creating principals

The HTTP POST method is used to submit **Principals**.

### Quick reference

```
POST http://localhost:8080/mws/rest/principals?api-version=3
```

### Create single principal

#### URLs and parameters

```
POST http://localhost:8080/mws/rest/principals?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

**i** The **name** field is required and must contain only letters, digits, periods, dashes, and underscores. The **attachedRoles** field expects an array of Role IDs *or* names:

The following is an example request body to create a principal:

```
POST http://localhost:8080/mws/rest/principals?api-version=3
-----
{
  "name" : "Acme-Principal",
  "attachedRoles" : [{"name":"Acme-User-Role"}],
  "description" : "A cool principal",
  "groups" : [{"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev",
"type":"LDAPGROUP"}],
  "users" : [{
    "name" : "john",
    "type" : "LDAP"
  } ]
}
```

Sample response

If the request was successful, the response body is the new principal that was created, exactly as shown in [Get single principal](#). On failure, the response is an error message.

## Modifying principals

The HTTP PUT method is used to modify **Principals**.

Quick reference

```
PUT http://localhost:8080/mws/rest/principals/<id>?api-version=3
PUT http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

### Modify single principal

URLs and parameters

```
PUT http://localhost:8080/mws/rest/principals/<id>?api-version=3
PUT http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Principal.

Parameter	Required	Type	Valid values	Description
<b>name</b>	Yes	String	--	The name of the Principal. <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; margin-top: 5px;">  The <b>name</b> field must contain only letters, digits, periods, dashes, and underscores.                 </div>
<b>change-mode</b>	Yes	String	add remove set (default)	If <b>add</b> , add the given objects (ldapGroups, ldapOUs, etc.) to the objects that already exist. If <b>remove</b> , delete the given objects from the objects that already exist. If <b>set</b> , add the given objects (ldapGroups, ldapOUs, etc.) and remove the objects that already exist.

See [Global URL parameters on page 1425](#) for available URL parameters.

 You must specify either **id** or **name**, but you do not have to specify both.  
 The **attachedRoles** field expects an array of Role IDs *or* names:

Example request

```
PUT http://localhost/mws/rest/principals/Acme-Principal?api-version=3
{
  "groups" : [ {
    "name" : "CN=Marketing,CN=Users,DC=mycompany,DC=com",
    "type" : "LDAPGROUP"
  }, {
    "name" : "CN=Sales,CN=Users,DC=mycompany,DC=com",
    "type" : "LDAPGROUP"
  } ],
  "users" : [ {
    "name" : "jhammon",
    "type" : "LDAP"
  } ]
}
```

 The **version** field contains the current version of the database entry. This field cannot be updated directly. However, if **version** is included in the modify request, it will be used to verify that another client did not update the object between the time that the data was retrieved and the modify request was delivered.

Sample response

If the request was successful, the response body is the modified principal as shown in [Get single principal](#). On failure, the response is an error message.

## Deleting principals

The HTTP DELETE method is used to delete **Principals**.

### Quick reference

```
DELETE http://localhost:8080/mws/rest/principals/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

## Delete single principal

### URLs and parameters

```
DELETE http://localhost:8080/mws/rest/principals/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/principals/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the principal.
<b>name</b>	Yes	String	--	The name of the principal.

See [Global URL parameters on page 1425](#) for available URL parameters.

You must specify either **id** or **name**, but you do not have to specify both.

### Sample response

JSON response

```
{}
```

## Getting reports

The HTTP GET method is used to retrieve **Report** information. Queries for all reports with no attached data and a single report with associated data are available.

### Quick reference

```
GET http://localhost:8080/mws/rest/reports?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<id>?api-version=3
GET http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

## Get all reports (no data)

### URLs and parameters

```
GET http://localhost:8080/mws/rest/reports?api-version=3[&query={"field":"value"}
&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
<b>query</b>	No	JSON	Queries for specific results. It is possible to query reports by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"reportSize":4}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response

```
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "3efe5c670be86ba8560397ff",
    "name": "cpu-util"
    ...
  } ]
}
```

Samples

```
GET http://localhost:8080/mws/rest/reports?api-version=3&fields=id,name

{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {
      "id": "3efe5c670be86ba8560397ff",
      "name": "cpu-util"
    },
    {
      "id": "3efe5c670be86ba856039800",
      "name": "cpu-temp"
    },
    {
      "id": "3efe5c670be86ba856039801",
      "name": "cpu-load"
    }
  ]
}
```

**Get single report (with data)**

URLs and parameters

```
GET http://localhost:8080/mws/rest/reports/<id>?api-version=3
GET http://localhost:8080/mws/rest/reports/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the report.
<b>name</b>	Yes	String	--	The name of the report.

**i** Only one of **id** or **name** are required.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

In the example below, the first datapoint has a null data element, which means that the `minimumSampleSize` configured for the report was not met when consolidating the datapoint. The second datapoint contains actual data.

```

JSON response
-----
{
  "consolidationFunction": "average",
  "datapointDuration": 15,
  "datapoints": [
    {
      "endDate": "2011-12-02 17:28:22 UTC",
      "startDate": "2011-12-02 17:28:22 UTC",
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null
    },
    {
      "endDate": "2011-12-02 17:28:23 UTC",
      "startDate": "2011-12-02 17:28:37 UTC",
      "firstSampleDate": "2011-12-02 17:28:23 UTC",
      "lastSampleDate": "2011-12-02 17:28:30 UTC",
      "data": {
        "utilization": 99.89,
        "time": 27.433333333333337
      }
    }
  ],
  "description": "Example of CPU utilization reporting",
  "id": "3efe5c670be86ba8560397ff",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 2
}

```

### Get datapoints for single report

URLs and parameters

```

GET http://localhost:8080/mws/rest/reports/<id>/datapoints?api-version=3 [&query=
{"field": "value"}&sort={"field": <1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/datapoints?api-version=3 [&query=
{"field": "value"}&sort={"field": <1|-1>}]

```

Parameter	Required	Type	Description	Example
<b>id</b>	Yes	String	The unique identifier of the report.	--
<b>name</b>	Yes	String	The name of the report.	--
<b>query</b>	No	JSON	Queries for specific results.	query={"reportSize":4}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

**i** Only one of **id** or **name** are required.

It is possible to query reports by one or more fields based on [MongoDB query syntax](#).

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

This function is exactly the same as [Get single report \(with data\)](#). No report metadata (i.e. description, minimumSampleSize, etc.) is returned.

JSON response

```

{
  "resultCount":1,
  "totalCount":1,
  "results":[
    {
      "endDate": "2011-12-02 17:28:22 UTC",
      "startDate": "2011-12-02 17:28:22 UTC",
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null
    },
    {
      "endDate": "2011-12-02 17:28:37 UTC",
      "startDate": "2011-12-02 17:28:37 UTC",
      "firstSampleDate": "2011-12-02 17:28:23 UTC",
      "lastSampleDate": "2011-12-02 17:28:23 UTC",
      "data": {
        "utilization": 99.89,
        "time": 27.433333333333337
      }
    }
  ]
}

```

## Getting samples for reports

The HTTP GET method is used to retrieve **Sample** information.

### Quick reference

```

GET http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]

```

## Get samples for report

### URLs and parameters

```
GET http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3[&query=
{"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Description	Example
<b>id</b>	Yes	String	The unique identifier of the report.	--
<b>name</b>	Yes	String	The name of the report.	--
<b>query</b>	No	JSON	Queries for specific results.	query={"reports-ize":4}
<b>sort</b>	No	JSON	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

**i** Only one of **id** or **name** are required.

It is possible to query reports by one or more fields based on [MongoDB query syntax](#).

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
JSON response
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "timestamp": "2011-12-02 17:28:37 UTC"
    "data":{
      "cpu1":2.3,
      "cpu2":1.2,
      "cpu3":0.0,
      "cpu4":12.1
    }
  },
  ...
  ]
}
```

## Creating reports

The HTTP POST method is used to create **Reports**. Operations are available to create reports with or without historical datapoints.

### Quick reference

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

## Create report

### URLs and parameters

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

To create a report, several fields are required as documented in [Fields: Reports on page 2261](#).

The request body below shows all the fields that are available during report creation.

JSON request body

```
{
  "name": "cpu-util",
  "description": "An example report on cpu utilization",
  "consolidationFunction": "average",
  "datapointDuration": 15,
  "minimumSampleSize": 1,
  "reportSize": 2,
  "keepSamples": true,
  "reportDocumentSize": 1024,
  "datapoints": [
    {
      "startDate": "2011-12-01 19:16:57 UTC",
      "endDate": "2011-12-01 19:16:57 UTC",
      "data": {
        "time": 30,
        "util": 99.98
      }
    }
  ]
}
```

### Sample response

```
{
  "messages": ["Report cpu-util created"],
  "id": "3efe5c670be86ba8560397ff",
  "name": "cpu-util"
}
```

Samples

```
POST http://localhost:8080/mws/rest/reports?api-version=3 (Minimal report without datapoints)
-----
{
    "name": "cpu-util",
    "datapointDuration": 15,
    "reportSize": 2
}
```

## Creating samples

The HTTP POST method is used to create samples for **Reports**.

Quick reference

```
POST http://localhost:8080/mws/rest/reports?api-version=3
```

## Create samples for report

URLs and parameters

```
POST http://localhost:8080/mws/rest/reports/<id>/samples?api-version=3
POST http://localhost:8080/mws/rest/reports/<name>/samples?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the report.
<b>name</b>	Yes	String	--	The name of the report.

 Only one of **id** or **name** are required.

See [Global URL parameters on page 1425](#) for available URL parameters.

Request body

To create samples for a report, simply send data and an optional timestamp to the URL above. The request body below shows all the fields that are available during sample creation. Note that the `data` field can contain arbitrary JSON.

JSON request body

```

{
  "timestamp": "2011-12-01 19:16:57 UTC",
  "agent": "my agent",
  "data": {
    "cpu1": 2.3,
    "cpu2": 1.2,
    "cpu3": 0.0,
    "cpu4": 12.1
  }
}

```

### Sample response

```
{"messages": ["1 sample(s) created for report cpu-util"]}
```

## Deleting reports

The HTTP DELETE method is used to delete **Reports**.

### Quick reference

```

DELETE http://localhost:8080/mws/rest/reports/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/reports/<name>?api-version=3

```

## Delete report

### URLs and parameters

```

DELETE http://localhost:8080/mws/rest/reports/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/reports/<name>?api-version=3

```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the report.
<b>name</b>	Yes	String	--	The name of the report.

 Only one of **id** or **name** are required.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

JSON response

```
{"messages": ["Report cpu-util deleted"]}
```

## Reservations

This section describes behavior of the **Reservations** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Reservations](#) reference contains the type and description of all fields in the **Reservations** object. It also contains details regarding which fields are valid during PUT and POST actions.

Supported methods

Resource	GET	PUT	POST	DELETE
<b>/rest/reservations</b>	<a href="#">Get all reservations</a>	--	<a href="#">Create reservation</a>	--
<b>/rest/reservations/&lt;id&gt;</b>	<a href="#">Get single reservation</a>	<a href="#">Modify reservation</a>	--	<a href="#">Release reservation</a>

This topic contains these sections:

- [Getting reservations](#) on page 1646
  - [Get all reservations](#) on page 1647
  - [Get single reservation](#) on page 1647
- [Creating reservations](#) on page 1650
  - [Create reservation](#) on page 1650
- [Modifying reservations](#) on page 1652
  - [Modify reservation](#) on page 1652
- [Releasing reservations](#) on page 1653
  - [Release reservation](#) on page 1653

### Getting reservations

The HTTP GET method is used to retrieve **Reservation** information. Queries for all objects and a single object are available.

Quick reference

```
GET http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Restrictions

Only admin or user reservations are returned with this call.

**Get all reservations**

URLs and parameters

```
GET http://localhost:8080/mws/rest/reservations?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
GET http://localhost:8080/mws/rest/reservations?api-version=3&fields=id
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "system.1"},
    {"id": "system.2"},
    {"id": "system.3"}
  ]
}
```

**Get single reservation**

URLs and parameters

```
GET http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

JSON response

```

{

## Creating reservations

The HTTP POST method is used to create **Reservations**.

### Quick reference

```
POST http://localhost:8080/mws/rest/reservations?api-version=3
```

### Create reservation

#### URLs and parameters

```
POST http://localhost:8080/mws/rest/reservations?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Request body

The request body below shows all the fields that are available when creating a **Reservation**, along with some sample values.

JSON request body

```
{
  "accountingAccount": "",
  "accountingGroup": "",
  "accountingQOS": "",
  "accountingUser": "root",
  "aclRules": [ {
    "affinity": "POSITIVE",
    "comparator": "LEXIGRAPHIC_EQUAL",
    "type": "GROUP",
    "value": "staff"
  } ],
  "comments": "",
  "duration": 200000000,
  "endDate": "2018-03-17 16:49:10 UTC",
  "excludeJobs": [
    "job1",
    "job2"
  ],
  "flags": [
    "SPACEFLEX",
    "ACLOVERLAP",
    "SINGLEUSE"
  ],
  "hostListExpression": "",
  "idPrefix": "",
  "label": "myreservation",
  "owner": {
    "name": "adaptive",
    "type": "USER"
  },
  "partitionId": "",
  "profile": "",
  "requirements": {
    "architecture": "",
    "featureList": [
      "feature1",
      "feature2"
    ],
    "memory": 0,
    "os": "",
    "taskCount": 1
  },
  "reservationGroup": "",
  "resources": {
    "PROCS": 2,
    "MEM": 1024,
    "DISK": 1024,
    "SWAP": 1024,
    "other1": 17,
    "other2": 42
  },
  "startDate": "2011-11-14 20:15:50 UTC",
  "subType": "Other",
  "trigger": {
    "eventType": "START",
    "actionType": "EXEC",
    "action": "date"
  },
  "variables": {
```

```

    "var1": "val1",
    "var2": "val2"
  }
}

```

This example is to create a reservation if no conflicting reservations are found. (This is the equivalent to `mrsvctl -c -h node01 -E`.)

```

JSON request body
-----
{
  "flags": [
    "DEDICATEDRESOURCE"
  ],
  "hostListExpression": "node01"
}

```

Sample response

```

JSON Response for successful POST
-----
{"id": "system.44"}

```

## Modifying reservations

The HTTP PUT method is used to modify **Reservations**.

Quick reference

```

PUT http://localhost:8080/mws/rest/reservations/<id>?api-version=3&change-
mode=<add|remove|set>

```

### Modify reservation

URLs and parameters

```

PUT http://localhost:8080/mws/rest/reservations/<id>?api-version=3&change-
mode=<add|remove|set>

```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.
<b>change-mode</b>	Yes	String	add remove set	<p>If <b>add</b>, add the given variables to the variables that already exist.</p> <p>If <b>remove</b>, delete the given variables from the variables that already exist.</p> <p>If <b>set</b>, replace all existing variables with the given variables.</p>

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

The request body below shows all the fields that are available when modifying a **Reservation**, along with some sample values.

JSON request body for reservation modify

```
{
  "variables": {
    "var1": "val1",
    "var2": "val2"
  }
}
```

### Sample response

**i** This message may not match the message returned from Moab exactly, but is given as an example of the structure of the response.

JSON response

```
{"messages":["reservation 'system.43' attribute 'Variable' changed."]}
```

### Restrictions

You can change the ACL Rules on a reservation, but not using this resource. See [Create or update ACL on page 1449](#).

## Releasing reservations

The HTTP DELETE method is used to release **Reservations**.

### Quick reference

```
DELETE http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

## Release reservation

### URLs and parameters

```
DELETE http://localhost:8080/mws/rest/reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

```
JSON Response for successful DELETE
{}

```

## Resource types

This section describes behavior of the **Resource Type** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The [Fields: Resource Types](#) reference contains the type and description of all fields in the **Resource Type** object.

Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/resource-types</a>	<a href="#">Get all resource types</a>	--	--	--

This topic contains these sections:

- [Getting resource types on page 1654](#)
  - [Get all resource types on page 1654](#)

### Getting resource types

The HTTP GET method is used to retrieve **Resource Type** information.

Quick reference

```
GET http://localhost:8080/mws/rest/resource-types?api-version=3

```

### Get all resource types

URLs and parameters

```
GET http://localhost:8080/mws/rest/resource-types?api-version=3

```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/resource-types?api-version=3&fields=id
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [
    {"id": "throttle_migrate"}
  ]
}
```

### Related topics

## Roles

This section describes behavior of the **Role** resource in Moab Web Services. The role resource is used to control access to MWS resources based on the proxy-user. Each role is attached to a principal and contains a list of proxy-user permissions that the group can use in MWS. This section describes the URLs, request bodies, and responses delivered to and from MWS.

The [Fields: Roles](#) reference section contains the type and description of all fields in the **Role** object. It also contains details regarding which fields are valid during PUT and POST actions.

### Supported methods

Resource	GET	PUT	POST	DELETE
<a href="#">/rest/roles</a>	<a href="#">Get all roles</a>	--	<a href="#">Create single role</a>	--
<a href="#">/rest/roles/&lt;id&gt;</a>	<a href="#">Get single role</a>	<a href="#">Modify single role</a>	--	<a href="#">Deleting roles</a>
<a href="#">/rest/roles/&lt;name&gt;</a>	<a href="#">Get single role</a>	<a href="#">Modify single role</a>	--	<a href="#">Delete single role</a>

This topic contains these sections:

- [Getting roles on page 1656](#)
  - [Get all roles on page 1656](#)
  - [Get single role on page 1657](#)
- [Creating roles on page 1658](#)
  - [Create single role on page 1659](#)

- [Modifying roles on page 1660](#)
  - [Modify single role on page 1660](#)
- [Deleting roles on page 1661](#)
  - [Delete single role on page 1661](#)

## Getting roles

The HTTP GET method is used to retrieve **Role** information. You can query all objects or a single object.

### Quick reference

```
GET http://localhost:8080/mws/rest/roles?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
GET http://localhost:8080/mws/rest/roles/<id>?api-version=3
GET http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

## Get all roles

### URLs and parameters

```
GET http://localhost:8080/mws/rest/roles?api-version=3[&query={"field":"value"}&sort={"field":<1|-1>}]
```

Parameter	Required	Type	Valid values	Description	Example
<b>query</b>	No	JSON	--	Queries for specific results. It is possible to query roles by one or more fields based on <a href="#">MongoDB query syntax</a> .	query={"name":"Acme-User-Role"}
<b>sort</b>	No	JSON	--	Sort the results. Use 1 for ascending and -1 for descending.	sort={"name":-1}

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
GET http://localhost:8080/mws/rest/roles?api-version=3&fields=id,name
-----
{
  "totalCount": 1,
  "resultCount": 1,
  "results": [ {
    "id": "4fa197e68ca30fc605dd1cf0",
    "name": "Acme-User-Role"
  } ]
}
```

### Sorting and querying

See the sorting and querying sections of [Global URL parameters on page 1425](#).

## Get single role

### URLs and parameters

```
GET http://localhost:8080/mws/rest/roles/<id>?api-version=3
GET http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Role.
<b>name</b>	Yes	String	--	The name of the Role.

You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```

GET http://localhost:8080/mws/rest/roles/Acme-User-Role?api-version=3
-----
{
  "description" : "This is a role for normal users in the Acme BU Group.",
  "id" : "5022e695e4b073f54e47c28d",
  "name" : "Acme-User-Role",

    "action" : "create",
    "description" : "The permission to create all charts.",
    "id" : "5022e695e4b073f54e47c28e",
    "label" : "Create Chart",
    "resource" : "chart",
    "resourceFilter" : null,
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "read",
    "description" : "The permission to view all charts.",
    "id" : "5022e695e4b073f54e47c28f",
    "label" : "View Chart",
    "resource" : "chart",
    "resourceFilter" : null,
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "update",
    "description" : "The permission to modify the africa chart.",
    "id" : "5022e695e4b073f54e47c290",
    "label" : "Modify Africa Chart",
    "resource" : "chart",
    "resourceFilter" : {
      "name" : "africa"
    },
    "type" : "custom",
    "scope" : "GLOBAL",
    "version" : 0
  }, {
    "action" : "read",
    "description" : "The permissions to view John's services.",
    "id" : "5022e695e4b073f54e47c291",
    "label" : "Read John's services",
    "resource" : "services",
    "resourceFilter" : {
      "user": "john"
    },
    "type" : "api",
    "scope" : "GLOBAL",
    "version" : 0
  } ],
  "version" : 2
}

```

## Creating roles

The HTTP POST method is used to submit **Roles**.

### Quick reference

```
POST http://localhost:8080/mws/rest/roles?api-version=3
```

## Create single role

### URLs and parameters

```
POST http://localhost:8080/mws/rest/roles?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

### Request body

**i** The **name** field is required and must contain only letters, digits, periods, dashes, and underscores.

The following is an example of a request body to create a role:

```
POST http://localhost:8080/mws/rest/roles?api-version=3
-----
{
  "name" : "Acme-User-Role",
  "description" : "This is a role for normal users in the Acme BU Group.",
  "permissions" :
  [
    {
      "id" : "4fa197e68ca30fc605dd1cf0"
    },
    {
      "id" : "4fa197e68ca30fc605dd1df2"
    }
  ]
}
```

### Sample response

If the request was successful, the response body is the new role that was created, exactly as shown in [Get single role](#). On failure, the response is an error message.

### Samples

The **permissions** field only expects an array of permission IDs, as shown in the following example:

```
Example payload of role with 2 permissions
-----
{
  "name" : "Acme-User-Role",
  "description" : "This is a role for normal users in the Acme BU Group.",
  "permissions" :
  [
    {
      "id" : "4fa197e68ca30fc605dd1cf0"
    }
  ]
}
```

## Modifying roles

The HTTP PUT method is used to modify **Roles**.

### Quick reference

```
PUT http://localhost:8080/mws/rest/roles/<id>?api-version=3
PUT http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

## Modify single role

### URLs and parameters

```
PUT http://localhost:8080/mws/rest/roles/<id>?api-version=3
PUT http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Role.
<b>name</b>	Yes	String	--	The name of the Role.  <div style="border: 1px solid #0070C0; padding: 5px; border-radius: 5px;">  The <b>name</b> field must contain only letters, digits, periods, dashes, and underscores.                 </div>
<b>change-mode</b>	No	String	add remove set (default)	If <b>add</b> , adds the given permissions to the permissions that already exist. If <b>remove</b> , deletes the given permissions from the permissions that already exist. If <b>set</b> , adds the given permissions and deletes the permissions that already exist.

 You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Example request

```
PUT http://localhost/mws/rest/role/Acme-User-Role?change-mode=add?api-version=3
{
  "permissions": [{"id": "4fa197e68ca30fc605dd1cf0"} ]
}
```

### Sample response

If the request was successful, the response body is the modified role as shown in [Get single role](#). On failure, the response is an error message.

## Deleting roles

The HTTP DELETE method is used to delete **Roles**.

### Quick reference

```
DELETE http://localhost:8080/mws/rest/roles/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

### Delete single role

#### URLs and parameters

```
DELETE http://localhost:8080/mws/rest/roles/<id>?api-version=3
DELETE http://localhost:8080/mws/rest/roles/<name>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the Role.
<b>name</b>	Yes	String	--	The name of the Role.

You must specify either **id** or **name**, but you do not have to specify both.

See [Global URL parameters on page 1425](#) for available URL parameters.

### Sample response

```
JSON response
```

```
{}
```

## Standing reservations

This section describes behavior of the **Standing Reservation** object in Moab Web Services. It contains the URLs, request bodies, and responses delivered to and from MWS.

**i** The **Fields: Standing Reservations** reference section contains the type and description of all fields in the **Standing Reservation** object. It also contains details regarding which fields are valid during PUT and POST actions.

### Supported methods

Resource	GET	PUT	POST	DELETE
<code>/rest/standing-reservations</code>	<a href="#">Get all standing reservations</a>	--	--	--
<code>/rest/standing-reservations/&lt;id&gt;</code>	<a href="#">Get single standing reservation</a>	--	--	--

This topic contains these sections:

- [Getting standing reservations on page 1662](#)
  - [Get all standing reservations on page 1662](#)
  - [Get single standing reservation on page 1663](#)

## Getting standing reservations

The HTTP GET method is used to retrieve **Standing Reservation** information. Queries for all objects and a single object are available.

### Quick reference

```
GET http://localhost:8080/mws/rest/standing-reservations/<id>?api-version=3
```

### Get all standing reservations

#### URLs and parameters

```
GET http://localhost:8080/mws/rest/standing-reservations?api-version=3
```

See [Global URL parameters on page 1425](#) for available URL parameters.

#### Sample response

```
GET http://localhost:8080/mws/rest/standing-reservations?api-version=3&fields=id
-----
{
  "totalCount": 3,
  "resultCount": 3,
  "results": [
    {"id": "sr1"},
    {"id": "sr2"},
    {"id": "sr3"}
  ]
}
```

## Get single standing reservation

### URLs and parameters

```
GET http://localhost:8080/mws/rest/standing-reservations/<id>?api-version=3
```

Parameter	Required	Type	Valid values	Description
<b>id</b>	Yes	String	--	The unique identifier of the object.

See [Global URL parameters on page 1425](#) for available URL parameters.

Sample response

# Reporting framework

## Overview of reporting framework

The reporting framework is a set of tools to make time-based reports from numerical data. The following sections will (1) provide an overview of the framework and the concepts related to it, and (2) work through an example report (CPU Utilization) with details regarding which web services to use and with what data.

The REST API reference is located in the Report resource section (see [Reports on page 1636](#)).

## Concepts

The reporting framework uses 3 core concepts: reports, datapoints, and samples.

- Reports (see [Fields: Reports on page 2261](#)): A report is a time-based view of numerical data.
- Report Datapoints (see [Fields: Report Datapoints on page 2259](#)): A datapoint is a consolidated set of data for a certain time period.
- Report Samples (see [Fields: Report Samples on page 2341](#)): A sample is a snapshot of a certain set of data at a particular point in time.

To illustrate, consider the memory utilization of a virtual machine: at any given point in time, you can get the memory utilization by using your operating system's performance utilities (top for Linux, Task Manager for Windows):

2400/12040MB

By recording the memory utilization and time constantly for 1 minute, you could gather the following data:

Time	Memory utilization
3:53:55 PM	2400/12040 MB
3:54:13 PM	2410/12040 MB
3:54:27 PM	2406/12040 MB
3:54:39 PM	2402/12040 MB

Time	Memory utilization
3:54:50 PM	2409/12040 MB

Each of the rows in the table above represent a **sample** of data. By averaging the rows we can consolidate them into one or more **datapoints**:

Start time	End time	Memory utilization
3:53:30 PM	3:54:00 PM	2400/12040 MB
3:54:00 PM	3:54:30 PM	2408/12040 MB
3:54:30 PM	3:55:00 PM	2406/12040 MB

**i** Note that each datapoint covers exactly the same amount of time, and averages all samples within that period of time.

A **report**, then, is simply a list of datapoints with some additional configuration information:

Field	Value
<b>Name</b>	Memory Utilization Report
<b>Datapoint Duration</b>	30 seconds
<b>Report Size</b>	3 datapoints

Datapoints:

Start time	End time	Memory utilization
3:53:30 PM	3:54:00 PM	2400/12040 MB
3:54:00 PM	3:54:30 PM	2408/12040 MB
3:54:30 PM	3:55:00 PM	2406/12040 MB

## Capabilities

While storing simple information like memory utilization is nice, the reporting framework is built to automatically handle much more complex information.

### Consolidating Samples

Samples are JSON documents which are pushed into the report using the Samples API (see [Creating samples on page 1644](#)). Samples are then stored until the consolidation operation creates a datapoint out of them. The table below shows how different data types are handled in this operation:

Type	Consolidation function handling
<b>Numbers</b>	Numerical data is averaged.
<b>Strings</b>	Strings are aggregated into an array.
<b>Objects</b>	The consolidation function recursively consolidates sub-objects.
<b>Lists</b>	Lists are combined into a single flat list containing all elements.
<b>Mixed</b>	If samples have different types of data for the same field, the values are aggregated into an array.
<b>Null</b>	These values will be ignored unless all values for a sample field are set to null, resulting in a null result.

**i** If the mixed data types contains at least one number, it will be treated as numerical data. The non-numerical data will be ignored and the result will be averaged.

Below is an example of how the consolidation function works:

- Samples:

Time	NumberEx	StringEx	ListEx	MixedEx	MixedNumberEx
3:53:55 PM	2400	"str1"	["elem1"]	"str1"	"str1"
3:54:13 PM	2410	"str2"	["elem2", "elem3"]	["elem1"]	["elem1"]
3:54:27 PM	2405	"str3"	["elem4"]	null	5

- Resulting Datapoint after consolidation:

Time	NumberEx	StringEx	ListEx	MixedEx	MixedNumberEx
3:55:00 PM	2405	["str1", "str2", "str3"]	["elem1", "elem2", "elem3", "elem4"]	["str1", "elem1"]	5

### Minimum number of samples

If your dataset is highly variable (i.e. values contained in samples are not very close together), converting a single sample into a datapoint may provide misleading information. It may be better to have a datapoint with an "Unknown" value. This can be accomplished by setting the minimum number of samples for a datapoint in the report.

The `minimumSampleSize` field in the Reports reference section (see [Reports on page 1636](#)) explains that if the specified size of samples is not met when the consolidation function is performed, the datapoint is considered "null" and no data is available for it. When this occurs, the sample data is discarded and the `data` field of the datapoint is set to "null".

For information on how to set this option, see the REST API Report Resource section (see [Reports on page 1636](#)).

### Report size

Reports have a predetermined number of datapoints, or size, which sets a limit on the amount of data that can be stored. After the report size has been reached, as newly created datapoints are pushed into the report, the oldest datapoints will automatically be deleted. This is to aid in managing the storage capacity of the server hosting MWS.

On report creation, a Mongo collection will be initialized that is the configured report document size multiplied by the report size. Be careful in setting a large report size or report document size as this may quickly allocate the entire disk. See the `reportDocumentSize` and `reportSize` fields in [Fields: Reports on page 2261](#) for more information.

### Related topics

- [Example report \(CPU Utilization\) on page 1668](#)

## Example report (CPU Utilization)

To understand how the behavior and usage of the reporting framework, a sample report covering CPU Utilization will be shown in this section. It will not cover how to gather or display data for reports, but will cover some basic operations that are available with Moab Web Services to facilitate reporting.

### Creating a report

Before any data is sent to Moab Web Services, a report must first be created. A JSON request body with a HTTP method of POST must be used to do this.

```

POST /rest/reports
-----
{
  "name": "cpu-util",
  "description": "An example report for cpu utilization",
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "reportSize": 288
}

```

This will result in a report being created which can then be retrieved by sending a GET request to `/rest/reports/cpu-util`. The `datapointDuration` of 600 signifies that the datapoint consolidation should occur once every 10 minutes, while the `reportSize` (i.e. number of the datapoints) shows that the report will retain up to 2 days worth of the latest datapoints.

```

GET /rest/reports/cpu-util
-----
{
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "datapoints": [],
  "description": "An example report for cpu utilization",
  "id": "aef6f6a3a0bz7bf6449537c9d",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 288,
  "version": 0
}

```

(Note that an ID has been automatically generated and that no datapoints are associated with the report.)

## Adding samples

Until samples are added and associated with the report, datapoint consolidation will generate datapoints with a `data` field equal to `null`. Once samples are added, however, they will be averaged and inserted into the next datapoint.

Create samples for the `cpu-util` by sending a POST request as follows:

```
POST /rest/reports/cpu-util/samples
```

```
[
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:00:00 UTC",
    "data": {
      "minutes1": 0.5,
      "minutes5": 0,
      "minutes15": 0
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:01:00 UTC",
    "data": {
      "minutes1": 1,
      "minutes5": 0.5,
      "minutes15": 0.05
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:02:00 UTC",
    "data": {
      "minutes1": 1,
      "minutes5": 0.5,
      "minutes15": 0.1
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:03:00 UTC",
    "data": {
      "minutes1": 0.75,
      "minutes5": 1,
      "minutes15": 0.25
    }
  },
  {
    "agent": "cpu-monitor",
    "timestamp": "2012-01-01 12:04:00 UTC",
    "data": {
      "minutes1": 0,
      "minutes5": 1,
      "minutes15": 0.85
    }
  }
]
```

This sample data contains average load for the last 1, 5, and 15 minute intervals. The samples were recorded at one-minute intervals starting at noon on January 1st, 2012.

## Consolidating data

A consolidation function must run to generate datapoints from the given samples. This scheduled consolidation will occur at intervals of `datapointDuration` seconds. For each field in the `data` object in samples, all values will be averaged. If non-numeric values are included, the following strategies will be followed:

1. All fields which contain a single numeric value in any included sample will be averaged and the non-numeric or null values will be ignored.
2. All fields which contain a list will be consolidated into a single, flat list.
3. All fields which contain only non-numeric or null values will be consolidated into a single, flat list.

If no historical datapoints are provided in the creation of a report as in this example, the next consolidation will be scheduled for the current time plus the `datapointDuration`. In this example, the scheduled consolidation is at 10 minutes from the creation date. If historical datapoints are included in the report creation, the latest datapoint's `endDate` plus the `datapointDuration` will be used as the scheduled time. If this date was in the past, the next scheduled consolidation will occur at the appropriate interval from the last `endDate`.

## Retrieving report data

To retrieve the consolidated datapoints, simply perform a GET request on the report once again. Alternatively, the GET for a report's datapoints (see [Get datapoints for single report on page 1640](#)) may be used.

```
GET /rest/reports/cpu-util
-----
{
  "consolidationFunction": "average",
  "datapointDuration": 600,
  "datapoints": [
    {
      "firstSampleDate": null,
      "lastSampleDate": null,
      "data": null,
      "startDate": "2012-01-01 11:49:00 UTC",
      "endDate": "2012-01-01 11:59:00 UTC"
    },
    {
      "firstSampleDate": "2012-01-01 12:00:00 UTC",
      "lastSampleDate": "2012-01-01 12:04:00 UTC",
      "data": {
        "minutes1": 0.65,
        "minutes15": 0.25,
        "minutes5": 0.6
      },
      "startDate": "2012-01-01 11:59:00 UTC",
      "endDate": "2012-01-01 12:09:00 UTC"
    }
  ],
  "description": "An example report for cpu utilization",
  "id": "aef6f6a3a0bz7bf6449537c9d",
  "keepSamples": false,
  "minimumSampleSize": 1,
  "name": "cpu-util",
  "reportSize": 288,
  "version": 0
}
```

Note that of the two datapoints above, only the second actually contains data, while the other is set to null. Only samples lying within the datapoint's duration, or from the `startDate` to the `endDate`, are included in the consolidation. Therefore the first datapoint, which covered the 10 minute period just

before the samples' recorded timestamps, contained no data. The second, which covers the 10 minute period matching that of the samples, contains the averaged sample data. This data could be used to display consolidated report data in a custom interface.

## Possible configurations

Configuration options may be changed to affect the process of report generation. These are documented in [Fields: Reports on page 2261](#) and [Fields: Report Samples on page 2341](#).

# Plugins

## About Moab Web Services plugins

This chapter describes MWS plugins, their use, and their creation in Moab Workload Manager. The sections in this chapter provide you with the following information:

- An introduction to the concept of MWS plugins (see [Plugin introduction on page 1673](#)).
- A description of the plugin lifecycle (see [Lifecycle states on page 1675](#)).
- How plugins are driven by events ([Handling events on page 1711](#)).
- How to expose web services from a plugin ([Exposing web services on page 1696](#)).
- How plugin utility services may be used ([Utility services on page 1677](#)).
- How data report collisions between plugins are consolidated ([Data consolidation on page 1677](#)).
- How calls from Moab are routed to MWS plugins ([Routing on page 1679](#)).

It contains the following sections:

- [Plugin overview on page 1673](#)
- [Plugin developer's guide on page 1679](#)
- [Plugin type management on page 1737](#)
- [Plugin management on page 1742](#)
- [Plugin services on page 1747](#)

Related topics

- [Configuring Moab Web Services on page 1395](#)

## Plugin overview

This section provides an overview of the plugin layer in web services. It contains these topics:

- [Plugin introduction on page 1673](#)
- [Lifecycle states on page 1675](#)
- [Events on page 1676](#)
- [Custom web services on page 1676](#)
- [Utility services on page 1677](#)
- [Data consolidation on page 1677](#)
- [Routing on page 1679](#)

Related topics

- [About Moab Web Services plugins on page 1672](#)

## Plugin introduction

Moab Web Services plugins provide a highly extensible interface to interact with Moab, MWS, and external resources. Plugins can perform some of the same functions as Moab resource managers (RMs), while also providing many other features not available to RMs. This section will discuss the main features of plugins, some basic terminology, and how MWS plugins can interact with Moab.

### Features

Plugins can:

- Be created, modified, and deleted without restarting Moab Workload Manager or MWS.
- Be defined in Groovy and uploaded to MWS without restarting.
- Have individual data storage space and configuration.
- Access MWS configuration and RESTful web services.
- Log to a standard location configured in MWS.
- Be polled at a regular interval (configured on a per-plugin basis).
- Be informed of important system events.
- Be individually stopped, started, paused, and resumed.
- Expose secured and unsecured custom web services for external use.
- Be manipulated via a full RESTful API (for more information, see [Resources introduction on page 1446](#)).
- Be manipulated via a full user interface in a web browser.

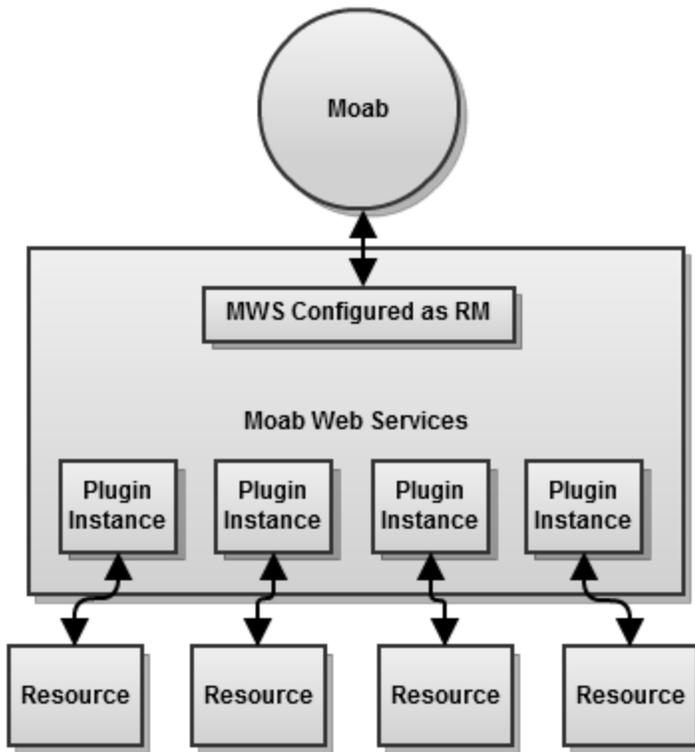

### Terminology

There are two distinct terms in the plugin layer: [plugin types](#) and [plugins \(instances\)](#).

Term	Description
<b>plugin types</b>	<p>Plugin types can be considered plugin templates with built-in logic. In object-oriented programming languages, this relates to the concept of a class. They possess certain abilities, or methods, that can be called by Moab Web Services to query or update information about certain resources. They also can define methods which will be exposed to external clients as web services. They do not contain any configuration or current data, but they are often tied to a <i>type</i> of component, such as components that communicate with Moab's WIKI Protocol, or those that are built on a certain product.</p> <p>They can define several types of methods:</p> <ul style="list-style-type: none"> <li>• <b>Instance methods</b> that return information about the current plugin, such as <code>getState</code>. (While these are defined in the plugin type, the plugin type itself does not have a state.)</li> <li>• The <b>poll event method</b> that is called at a configured interval.</li> <li>• <b>Lifecycle event methods</b> of plugins created from the plugin type, such as <code>beforeStart</code> and <code>afterStart</code>.</li> <li>• <b>RM event methods</b> that are called by Moab when certain events occur.</li> <li>• <b>Web service methods</b> that expose custom functionality as public web services.</li> </ul> <p>Some examples of plugin types include the Native and vCenter plugin types.</p>
<b>plugins (instances)</b>	<p>Plugins (also called plugin instances) are created from plugin types. They contain current data or configuration and use the plugin type methods to interact with resources.</p>

#### Interactions with Moab as a resource manager

The plugin layer in MWS is integrated with Moab Workload Manager via the Native Resource Manager (RM) interface. When utilizing plugins, MWS is configured as a RM in Moab, as explained in the next section. Events from Moab are pushed through the RM interface to MWS, which is then pushed to each plugin in turn. The relationship between MWS, Moab, and plugins is shown in the following image:

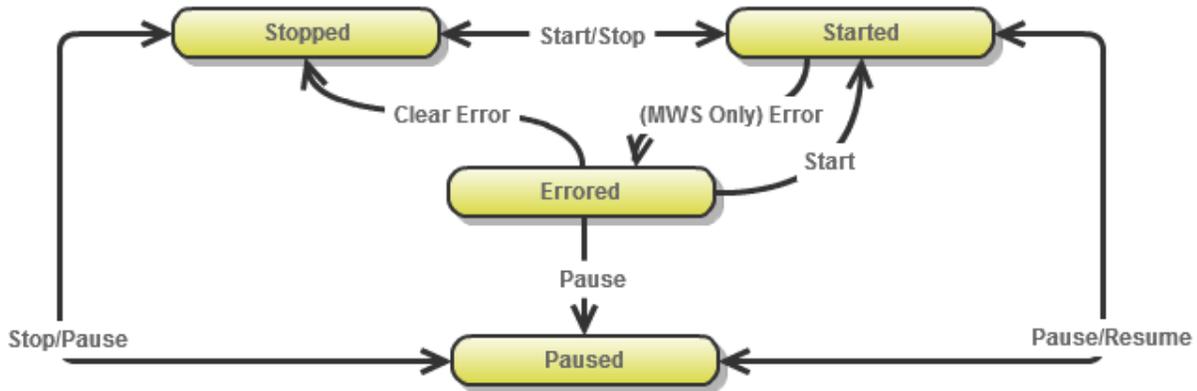

For more information, see [Data consolidation](#) on page 1677 and [Reporting state data](#) on page 1698.

Related topics

- [About Moab Web Services plugins](#) on page 1672

## Lifecycle states

During the course of a plugin's use, the state of the plugin may change many times. Plugins have four possible states: **Stopped**, **Started**, **Paused**, and **Errored**. For the descriptions of each state, see the [Fields: Plugins](#) reference section. The flow of a plugin through the states is shown in the following image:

**i** You can see [Handling events](#) on page 1711 for information about the events that occur during lifecycle state changes.

Related topics

- [Plugin introduction](#) on page 1673

Events

Plugins use an event-based model, meaning that methods are called on the plugin when certain criteria are met or situations arise. Events currently exist for polling, lifecycle state changes, and RM events from Moab. For more information, see [Handling events](#) on page 1711.

Related topics

- [Handling events](#) on page 1711
- [Plugin introduction](#) on page 1673

Custom web services

Although the events interface typically serves most cases, there are some instances where an event is not supported that is desired. This is especially true when an external resource is the source of the event. To address these issues, plugins can expose custom web services to external resources. These web services may be named freely and do anything they wish within the plugin framework.

For example, suppose a resource needs to notify a plugin that provisioning of a virtual machine has been completed. Instead of having the plugin poll the resource to verify that the provisioning was finished, the plugin could expose a custom web service to handle notification from the resource itself.

```

Sample custom web service
-----

def vmProvisionFinished(Map params) {
    // Handle event
    return [messages:["Event successfully processed"]]
}

```

Additionally, plugin types may define web services which are unsecured, meaning that a user or application account is not required to access it. A full explanation of the syntax and creation of custom secured and unsecured web services may be seen on [Exposing web services on page 1696](#).

For information how resources can access plugin web services, see [Accessing Plugin Web Services on page 1605](#).

Related topics

- [Plugin introduction on page 1673](#)

## Utility services

Several features of plugins are only available by utilizing bundled services. These include:

- Accessing the individual datastore (see [Individual datastore on page 1694](#)).
- Reporting state data to Moab through the Resource Manager interface (see [Reporting state data on page 1698](#)).
- Manipulating other plugins and controlling their lifecycle (see [Controlling lifecycle on page 1701](#)).
- Accessing REST resources from Moab Web Services ([Accessing MWS REST resources on page 1702](#)).

It may also be necessary or desired to create additional utility services when creating new plugin types. The easiest way to do this is to create a utility service which is called by convention a translator (see [Using translators on page 1716](#)), because it can typically "translate" from a specific resource or API to data which can be used by the plugin type.

Finally, custom components (see [Registering custom components on page 1717](#)) may be used to fulfill use cases not covered by bundled services or custom translators.

## Data consolidation

At times, plugins can report differing or even contradictory data for nodes, virtual machines, and jobs. This is called a data "collision". The act of resolving these collisions is called "Consolidation." Plugins also have the concept of "precedence," where the plugins with the lowest precedence value are considered more authoritative than the greater precedence values plugins. For example, a plugin with a precedence value of 1 has a higher precedence and is considered more authoritative than a plugin with a precedence value of 5. If no precedence is provided when creating plugins, the plugin is automatically assigned to the

lowest precedence, or 1 greater than the highest precedence value. The precedence value may not be less than 1.

When data from one plugin "collides" with another, the data from the highest precedence plugin will be considered the authoritative source for information. If multiple sets of data (reports) are provided by the same plugin, the latest set of data will take precedence. Additionally, MWS supports the concept of treating node and virtual machine data with state information **optimistically**, **pessimistically**, or **neither**. This is configured using the `plugins.stateConsolidationPolicy` configuration property in the MWS configuration file. If this property is set to `optimistic` and *any* plugin reports the state for a node or VM as "Up," the consolidated state will be "Up." Inversely, if the property is set to `pessimistic` and *any* plugin reports the state as "Down," the consolidated state will be "Down." If it is set to `null` (neither), consolidation will occur for the state field just as with any other field, with higher precedence and later reports being considered authoritative.

**i** When MWS is upgraded to a version that supports plugin precedence from an older version, existing plugins will not have the precedence field set. The administrator should assign precedence to each plugin manually through the API (see [Modifying plugins on page 1603](#)) or through the user interface (see [Modifying a plugin on page 1744](#)) to ensure that the consolidation will occur as expected. By default, data from a plugin without a precedence defaults to a precedence of 1, or the highest precedence.

Consolidation examples

Suppose two plugins exist, `pluginA` and `pluginB`. Plugin "A" has a precedence of 1, and plugin "B" has a precedence of 2, meaning that plugin "A" is more authoritative. These plugins both report data for a node with an ID of `node1`. However, each reports a different node power state. Plugin "A" reports the power as `ON`, while plugin "B" reports the power as `OFF`. The data collision that occurs due to these two contradictory reports is resolved by the precedence of the plugins. Since plugin A has a higher precedence (lower number), it is considered authoritative and the node will be reported as `ON`.

Now suppose that the plugins also report differing node state for `node1`. In this case, the node state would depend on the `plugins.stateConsolidationPolicy` property. The different combinations of report values compared to the state consolidation policy and the final reported state are shown in the table below.

Plugin "A" node state	Plugin "B" node state	State consolidation policy	Consolidated node state
ON	OFF	null (neither)	ON
OFF	ON	null (neither)	OFF
ON	OFF	optimistic	ON
OFF	ON	optimistic	ON

Plugin "A" node state	Plugin "B" node state	State consolidation policy	Consolidated node state
ON	OFF	pessimistic	OFF
OFF	ON	pessimistic	OFF

In general, it is recommended that no two plugins report the same resource or that they report different properties of the same resource. For example, if plugin "A" only modified the power state and plugin "B" only modified the available disk resource, these two plugins would work in harmony to provide a consistent view of the node resource.

For more information, see [Reporting state data on page 1698](#) and [Resource manager queries on page 1735](#).

## Routing

 Plugin routing is currently in *Beta*. Interfaces may change significantly in future releases.

Because Moab Web Services is configured as a Resource Manager (RM) in Moab Workload Manager, events are sometimes triggered by Moab through the RM interface. These actions could be migrating a virtual machine, starting a job, submitting a job, modifying a node, and so forth. The decisions regarding which plugins are affected and notified is termed **routing**.

Currently all plugins receive all commands from Moab. This means that each plugin will receive the command to start a job if sent from Moab, even if that plugin does not handle the job. This means that plugins must ensure they handle actions or commands only for resources which they report or handle.

## Plugin developer's guide

Plugin types comprise the methods by which Moab may communicate with resource managers or other external components. They define all operations that can be performed for a "type" or "class" of plugins, hence the name "plugin type."

Several plugin types are provided with Moab Web Services, but it is easy to create additional plugin types and add their functionality to web services. This involves using [Groovy](#), which is based on the [Java](#) programming language. This section describes the general guidelines and specifics of implementing new plugin types.

## API classes and interfaces

There are several packages and classes available to assist in creating plugin types. These can all be found in the [API documentation](#).

This section contains these topics:

- [Requirements](#) on page 1680
- [Dynamic methods](#) on page 1681
- [Logging](#) on page 1682
- [i18n messaging](#) on page 1683

## Requirements

This section discusses the requirements to create a basic functional plugin. The `com.adaptc.mws.plugins` package contains the abstract class [AbstractPlugin](#) that should form the basis of any new plugin type. However, this class need not be extended to create a functional plugin type. Only two requirements must be fulfilled for this:

1. The class name must end in `Plugin`.
2. There must exist `id` field getter and setter methods:

```
* public String getId();  
* public void setId(String id);
```

The `id` field may be stored in whichever way desired as long as the getter and setter are available as shown above, but will most likely be implemented as follows:

```
class BasicPlugin {
    String id
}
```

In this case, `String id` will be expanded by the Groovy compiler to the full getter and setter method definitions given above. In other words, no explicit method definitions are actually needed. Note that the `BasicPlugin` shown above is able to be uploaded as a plugin type to MWS, but does not actually do anything.

It must also be noted that the `AbstractPlugin` class already implements an `id` field. Therefore, a plugin type that extends this class does not need to define the field as shown in the following example.

```
import com.adaptc.mws.plugins.AbstractPlugin

class BasicPlugin extends AbstractPlugin {
    // No ID field is needed since it exists in AbstractPlugin
}
```

- [Plugin developer's guide on page 1679](#)

## Dynamic methods

 These methods are currently in *Beta*. Interfaces may change significantly in future releases.

Several methods are dynamically inserted onto each plugin. These methods do not need to be included in the plugin class, and will be overwritten if included. Additionally, a logger is inserted into each plugin as discussed in the next section. The inserted methods are shown below (full definitions can be found in [AbstractPlugin](#) and [AbstractPluginInfo](#)):

- `public void start() throws PluginStartException;` (Equivalent to the start method in the [Plugin control service on page 1750](#).)
- `public void stop() throws PluginStopException;` (Equivalent to the stop method in the [Plugin control service on page 1750](#).)
- `public Log getLog();` (See [Logging on page 1682](#).)
- `public ConfigObject getAppConfig();` (See [Configuration on page 1685](#).)
- `public String message(Map parameters);` (See [i18n messaging on page 1683](#).)
- `public String getPluginType();`
- `public PluginState getState();`
- `public Integer getPollInterval();`
- `public Boolean getAutoStart();`
- `public Map<String, Object> getConfig();` (See [Configuration on page 1685](#).)

Many of these methods are provided for convenience and are discussed in the linked pages or the following sections.

## Logging

Logging in plugin types uses the [Apache Commons Logging](#) and [log4j](#) libraries. Each plugin is injected with a method called `getLog` which can be used to access the configured logger. It returns an instance of [org.apache.commons.logging.Log](#). Examples of using the logger are shown below.

The logger may be used to register messages to the MWS log at several levels (in order of severity):

1. trace
2. debug
3. info
4. warn
5. error
6. fatal

Each of these levels is available as a method on the logger, for example:

```
public void poll() {
    getLog().debug("getLog() is equivalent to just using 'log' in Groovy")
    log.debug("This is a debug message and is used for debugging purposes only")
    log.info("This is a informational message")
    log.warn("This is a warning")
    log.error("This is an error message")
}
```

### Logger name

Each logger in the MWS logging configuration has a name. In the case of plugins, it is comprised of the full class name, including the package, prepended by "plugins.". For example, a plugin class of "example.LoggingPlugin" will have access to a logger configured as `plugins.example.LoggingPlugin`.

### Logging configuration

The logging configuration is done through the MWS configuration file. For more information on configuring loggers, see [Configuring Moab Web Services on page 1395](#). A good configuration for developing plugin types may be to add "plugins" at the debug level. Be sure to set the log level threshold down for the desired appender.

```
log4j = {
  ...
  // Appender configuration
  ...
  debug "plugins"
}
```

## i18n messaging

Plugins, translators, and custom components all have access to [i18n](#) messages. Utilizing messages requires the two following steps:

1. Including a file (or multiple files) that ends in "messages.properties" in the plugin JAR file.
2. Using the message method on a plugin type, translator, or custom component.

### [Including messages in plugin JAR file](#)

Messages are defined using property files. These may be named anything as long as they end with "messages.properties" and must be placed at the root or top level of the plugin JAR file. If they are present, they will be loaded automatically. Multiple property files may be used within a single plugin JAR file.

Each property file consists of an arbitrary amount of lines that define a message property (also called a code) with letters, numbers, and periods, associated with a human-readable message that can span multiple lines, have quotes, or contain arguments. These are demonstrated in the following example.

```
first.message.code=This is the first message
second.message=This message can span multiple lines, \\
  and will not show the linebreaks when retrieved
message.with.arguments=This message has arguments: first - {0}, second - {1}, third -
{2}, etc.
message.with.quotes=This message uses single quotes around 'this phrase'.
```

It is recommended to namespace the messages by using the property definitions and multiple property files if necessary. For example, suppose a plugin JAR existed which actually contained two plugin types: Message1Plugin and Message2Plugin. The first suggestion is to namespace the messages for each plugin by the property definition, such as the following:

```
message1Plugin.first.message=This is a message for Message1Plugin
message2Plugin.first.message=This is a message for Message2Plugin
```

These messages could be stored in a file named "messages.properties" in the root of the plugin JAR file. If there are many messages contained for each plugin type, it may be necessary to split each plugin type's messages into a separate file, such as "message1-messages.properties" and "message2-messages.properties". Note that it is essential that each property file ends with "messages.properties" so that it is registered correctly.

It is important that no two message codes are identical within a single plugin JAR file, even if they are defined in separate property files. If this is done, a conflict will exist with the messages and behavior is undefined.

### Using the message method

Each plugin, translator, and custom component is injected with a method named `message`. This method takes a `Map` as its parameter, which can contain one or several of the following properties:

Parameter	Type	Description
<b>code</b>	String	The message property definition (everything before the equals sign in the property file for a single message), for example, <code>first.message.code</code> .
<b>args</b>	List<Object>	A list of arguments to insert into the message.
<b>default</b>	String	A default message to be used when the message code cannot be resolved.
<b>error</b>	org.springframework.context.MessageSourceResolvable	An object that represents a hierarchy of message codes. This is typically used to display errors.

The most utilized parameters are `code` and `args`, as these combined provide great flexibility in generating messages. If a message cannot be resolved, or in other words the message definition does not exist, the code will simply be returned as the resolved message. Below are several examples of messages resolved using the property files given above. While these are contained in the polling method, the message may be used anywhere within a plugin type.

```
package example
import com.adaptc.mws.plugins.AbstractPlugin

class MessagingPlugin extends AbstractPlugin {
  def poll() {
    assert message(code:"first.message.code")== "This is the first message"
    assert message(code:"message.with.arguments", args:[
      "1st", 2, true
   ])== "This message has arguments: first - 1st, second - 2, third - true, etc."
    assert message(code:"message.with.quotes")== "This message uses single quotes around
    'this phrase'."
    assert message(code:"invalid.message.code")== "invalid.message.code"
  }
}
```

### Related topics

- [Plugin developer's guide on page 1679](#)

## Configuration

Plugin types can access two different kinds of configuration: an individual plugin's configuration, and the global MWS application configuration.

### Individual plugin configuration

The individual plugin configuration is separate for each instance of a plugin. This may be used to store current configuration information such as access information for linked resources. It should not be used to store cached information or non-configuration related data. The individual datastore should be used instead for these cases (for more information, see [Individual datastore on page 1694](#)).

It is accessed by using the `getConfig` method discussed in [Dynamic methods on page 1681](#).

```
public void poll() {
    def configFromMethod = getConfig()
    // OR an even simpler method...
    def configFromMethod = config
}
```

A common case is to retrieve the configuration in the `configure` method, verify that it matches predetermined criteria, and utilize it perform initial setup of the plugin (e.g. initialize libraries needed to communicate with external resources). For example, to verify that the configuration contains the keys "username" and "password," the following code may be used.

```
public void configure() throws InvalidPluginConfigurationException {
    def myConfig = config
    // This checks to make sure the key exists in the configuration Map and that the
    // value is not empty or null
    if (!myConfig.containsKey("username") || !myConfig.username)
        throw new InvalidPluginConfigurationException("The username configuration parameter
        must be provided")
    if (!myConfig.containsKey("password") || !myConfig.password)
        throw new InvalidPluginConfigurationException("The password configuration
        parameter must be provided")
}
```

### Access MWS configuration

The MWS application configuration can also be accessed in plugin types. This configuration is global for the entire application and can be modified by the administrator as shown in [Configuring Moab Web Services on page 1395](#).

It is accessed by using the `getAppConfig` method discussed in [Dynamic methods on page 1681](#). This is demonstrated below:

```
public void poll() {
    // Retrieve the current MWS_HOME location
    def mwsHome = appConfig.mws.home.location
    // OR an even simpler method...
    def mwsHome = getAppConfig().mws.home.location
}
```

Any of the properties shown in the [Configuration](#) reference may be accessed. Custom properties may also be registered and accessed:

```
mws-config.groovy
-----
plugins.custom.property = "This is my custom property"
```

```
CustomAppPropertyPlugin
-----
public void poll() {
    assert appConfig.plugins.custom.property=="This is my custom property"
}
```

## Related topics

- [Plugin developer's guide on page 1679](#)

## Configuration constraints

Plugin types can optionally define validation constraints for the polling interval and plugin configuration. These parameters are then checked against the defined constraints during the creation of a new plugin. If the validation fails, meaning the configuration provided does not pass the constraints defined by the plugin type, the plugin will fail to be created with error messages based on the parameters and constraints defined.

### Defining constraints

To define constraints for a plugin type and therefore for all plugins created using it, use the following syntax:

```
import com.adaptc.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
    static constraints = {
        // Set plugin's default polling interval
        pollInterval defaultValue:60
        // The "myParam" configuration parameter is automatically required and cannot be
blank
        myParam blank:false
        // The "myEnum" configuration parameter is not required and must set to one of the
values in the list
        myEnum required:false, inList:["val1", "val2", "val3"]
        // Insert additional constraints here...
    }
}
```

In the table below, all available constraints are shown, as well as the expected value type, an example, the default message code, and the message suffix. The message columns are described in greater detail in the [Messaging](#) section below.

Constraint	Default value	Type	Example value	Default message code	Message suffix	Description
<b>blank</b>	--	Boolean	true	default.blank.message	blank	If false, the parameter (if present) cannot be a blank string.
<b>creditCard</b>	--	Boolean	true	default.invalid.creditCard.message	creditCard.invalid	If <b>true</b> , uses <code>org.apache.commons.validator.CreditCardValidator</code> to determine if the parameter (if present) is a valid credit card number.
<b>defaultValue</b>	--	Object or Closure	60	--	--	If the parameter is not present, it will be set to this default value. Does not return any error messages. See <a href="#">Default value</a> below for more information.
<b>email</b>	--	Boolean	true	default.invalid.email.message	email.invalid	If <b>true</b> , the parameter (if present) must be a valid email address.
<b>inList</b>	--	List	["first", "second"]	default.notinlist.message	notinList	The parameter (if present) must be set to one of the values specified.
<b>matches</b>	--	String	"[a-z][A-Z]+"	default.doesnt.match.message	matches.invalid	The parameter (if present) must match the specified regular expression.

Constraint	Default value	Type	Example value	Default message code	Message suffix	Description
<b>max</b>	--	Integer	10	default.invalid.max.message	max.exceeded	The parameter (if present) must not be greater than the defined value.
<b>*max-Size</b>	--	Integer	10	default.invalid.max.size.message	maxSize.exceeded	The parameter's (if present) size must not be greater than the defined value.
<b>min</b>	--	Integer	1	default.invalid.min.message	min.notmet	The parameter (if present) must not be less than the defined value.
<b>*min-Size</b>	--	Integer	1	default.invalid.min.size.message	minSize.notmet	The parameter's (if present) size must not be less than the defined value.
<b>notEqual</b>	--	Object	"Invalid Value"	default.not.equal.message	notEqual	The parameter (if present) must <i>not</i> be set to the defined value.
<b>nullable</b>	true	Boolean	false	default.null.message	nullable	If <b>true</b> , the parameter (if present) must be non-null value. See <a href="#">required</a> for how to enforce the parameter to be present.
<b>password</b>	--	Boolean	true	--	--	If <b>true</b> , the parameter (if present) is hidden from the user both on input and display when managing plugin configuration. It is not, however, hidden in the REST API. Does not return any error messages.

Constraint	Default value	Type	Example value	Default message code	Message suffix	Description
<b>range</b>	--	Range	1..10	default.invalid.range.message	range.toosmall/range.toobig	Uses a groovy range to validate that the value is within a specified range.
<b>required</b>	true	Boolean	false	default.required.message	required	If <b>true</b> , the parameter must be present and non-null for the plugin to be created successfully. Implies the <code>nullable:false</code> constraint.
<b>scale</b>	--	Integer	2	--	--	Only valid for Double parameters. Rounds the parameter (if present) to the specified number of digits. Does not return any error messages.
<b>*size</b>	--	Range	2	default.invalid.size.message	size.toosmall/size.toobig	Uses a groovy range to restrict the size of a collection, string, or a number.
<b>*type</b>	--	Classes	Integer.class	typeMismatch	typeMismatch	See <a href="#">Type inferencing and conversion</a> below.
<b>url</b>	--	Boolean	true	default.invalid.url.message	url.invalid	If <b>true</b> , uses <code>org.apache.commons.validator.UrlValidator</code> to determine if the parameter (if present) is a valid URL. Does not support <code>exec</code> or <code>file</code> scheme URLs.
<b>scriptable-Url</b>	--	Boolean	true	default.invalid.scriptable.url.message	scriptableUrl.invalid	Identical to the <a href="#">url</a> validator, but adds support for <code>exec</code> and <code>file</code> scheme URLs.

Constraint	Default value	Type	Example value	Default message code	Message suffix	Description
<b>validator</b>	--	Closure	(See <a href="#">Custom validator</a> )	default.invalid.validator.message	validator.error	See <a href="#">Custom validator</a> below.

\* The user interface (see [Plugin management on page 1742](#)) does not support parameters whose type is a subclass of Collection (a List, for example). Such parameters are therefore not recommended.

 The polling interval constraints must always apply to Integer types. If this specification is violated, the plugin type cannot be added or updated.

Messaging

When defined constraints are violated for a plugin, error messages are retrieved based on the configuration parameters and the applied constraints using i18n Messaging codes (see [i18n messaging on page 1683](#)). First, the most specific error message will be attempted to be resolved from a message code generated from the plugin type name, the configuration parameter, and the constraint. This code takes the format of `pluginTypeName.parameterName.suffix` where the plugin type's name has a lowercase first letter and the suffix is shown in the table above. If this message code is not defined, the default message code (as shown in the table above) will be used.

For example, if the [url](#) constraint validation failed for the "ExamplePlugin" plugin type's "endpoint" configuration parameter, the following message codes would be resolved in order:

- `examplePlugin.endpoint.url.invalid`
- `default.invalid.url.message`

 Plugin types that have two or more uppercase letters at the start of the name will not be converted to have a lowercase first letter for error message codes. In other words, for the example just given using "VCenterPlugin" instead of "ExamplePlugin", the following message codes would be resolved in order:

```
VCenterPlugin.endpoint.url.invalid
default.invalid.url.message
```

Default messages

Default messages may be contained in any `messages.properties` file included in the plugin JAR file as explained in i18n Messaging (see [i18n messaging on page 1683](#)). Arguments for each constraint vary, but they always include these argument indices:

- {0}: The configuration parameter name (for example, endpoint).
- {1}: The plugin type class name (for example, my.package.ExamplePlugin).
- {2}: The value of the configuration parameter.

If default messages are not defined in the plugin project, the following messages will be used:

```
default.doesnt.match.message=The '{0}' configuration parameter value ({2}) does not
match the required pattern '{3}'
default.invalid.url.message=The '{0}' configuration parameter value ({2}) is not a
valid URL
default.invalid.scriptable.url.message=The '{0}' configuration parameter value ({2})
is not a valid scriptable URL
default.invalid.creditCard.message=The '{0}' configuration parameter value ({2}) is
not a valid credit card number
default.invalid.email.message=The '{0}' configuration parameter value ({2}) is not a
valid e-mail address
default.invalid.range.message=The '{0}' configuration parameter value ({2}) does not
fall within the valid range from {3} to {4}
default.invalid.size.message=The '{0}' configuration parameter value ({2}) does not
fall within the valid size range from {3} to {4}
default.invalid.max.message=The '{0}' configuration parameter value ({2}) is greater
than the maximum value of {3}
default.invalid.min.message=The '{0}' configuration parameter value ({2}) is less
than the minimum value of {3}
default.invalid.max.size.message=The '{0}' configuration parameter value ({2})
exceeds the maximum size of {3}
default.invalid.min.size.message=The '{0}' configuration parameter value ({2}) is
less than the minimum size of {3}
default.invalid.validator.message=The '{0}' configuration parameter value ({2}) does
not pass custom validation
default.not.inlist.message=The '{0}' configuration parameter value ({2}) is not
contained within the list [{3}]
default.blank.message=The '{0}' configuration parameter cannot be blank
default.not.equal.message=The '{0}' configuration parameter value ({2}) cannot be
equal to '{3}'
default.null.message=The '{0}' configuration parameter cannot be null
default.required.message=The '{0}' configuration parameter is required and cannot be
null
typeMismatch=The '{0}' configuration parameter value ({2}) does not match the
required type '{3}'
```

### Labels and help messages

Message codes may also be provided for configuration parameters to aid the admin user with human readable property labels and help messages. Similar to the validation error message codes, labels and help message codes may be defined using the `pluginTypeName.parameterName.label` and `pluginTypeName.parameterName.help` message codes. These values are used only in plugin type management (see [Plugin type management on page 1737](#)) and are not exposed through the REST API.

### Type inferencing and conversion

Due to the dynamic nature of configuration parameters, the expected type or class of values for each parameter are inferred from constraints. The following rules govern how type is inferred, in priority order:

- If the **\*type** constraint is applied to a parameter, the constraint value will be used as the expected type.

**i** Only the `String`, `Date`, `Double`, `Integer`, and `Boolean` classes are supported for the **\*type** constraint. If `Float` or `Long` is desired, use `Double` and `Integer` respectively as the type.

- If the **inList** or **range** constraints are applied to a parameter, the class of the first element in the constraint value array is used as the expected type.
- If the **\*minSize** or **\*maxSize** constraints are applied to a parameter, `java.lang.Collection` is used as the expected type.
- If the **max**, **min**, or **notEqual** constraints are applied to a parameter, the class of the constraint value is used as the expected type.
- If none of the above apply, `java.lang.String` is used as the expected type.

If the configuration parameter values can be converted to the expected types, this will occur automatically. Otherwise, the **\*type** constraint is violated and the applicable error messages will be generated.

#### Custom validator

In cases where the built-in constraints prove inadequate for validation, custom validators may be used. The **validator** constraint expects a Groovy Closure parameter which has one or (optionally) two arguments: the value of the configuration parameter and the plugin object. With these parameters, complex validation logic may be defined. Additionally, custom message codes and arguments may be defined by validator constraints and these will be used in generating error messages when validation fails.

For example, suppose that the parameter "user" cannot be set to the same value as parameter "creator." Additionally, the "creator" parameter must not be equal to either "bob" or "joe." The existing constraints are inadequate to fulfill this use case, but the following code using validators would perform exactly as expected:

```
import com.adaptc.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
    static constraints = {
        user validator:{ val, obj ->
            if (val==obj.config.creator)
                return "invalid.equal.to.creator"
        }
        creator validator:{ val ->
            if ("val"=="joe")
                return ["invalid.equal", "joe"]
            if (val=="bob")
                return ["invalid.equal", "bob"]
        }
    }
}
```

In the examples above, the message codes and output on validation failure is shown below:

```
Message codes
-----
```

```
constrainedPlugin.user.invalid.equal.to.creator=The user configuration parameter value
({2}) must not be equal to the creator parameter.
constrainedPlugin.creator.invalid.equal=The creator configuration parameter must not
be equal to {3}.
```

```
Output error messages
-----
```

```
For user = "jill", creator = "jill"
"The user configuration parameter value (jill) must not be equal to the creator
parameter."
For user = "jill", creator = "bob"
"The creator configuration parameter must not be equal to bob."

For user = "jill", creator = "joe"
"The creator configuration parameter must not be equal to joe."
```

The validator Closure may return:

- `Nothing` (`null`) or `true` if the validation succeeded without errors.
- `false` if a validation error occurred (in this case the default validator message suffix would be used).
- A string which will be used as the message code suffix in the `pluginTypeName.propertyName.suffix` format.
- A list with the first element being the message code suffix, and all other elements being arguments for the message indexed starting at 3 (as shown in the example above).

All validator constraints automatically have the `appConfig` property available, which contains the application configuration as discussed in the Configuration section (see [Configuration on page 1685](#)). The `suite` property contains the value of the configured MWS suite. Additionally, services may be retrieved as explained in the next section.

### Retrieving services

At times it may be necessary to use Bundled Services in custom validators. A method named `getService` which takes a single string parameter of the name of the service (as used during injection) is provided to be used in these cases. For example, if a plugin needs a valid server certificate file, the SSL Service may be used as follows:

```
import com.adaptc.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
  static constraints = {
    certificateFile validator:{ val ->
      ISSLService sslService = getService("sslService")
      try {
        sslService.getSocketFactory(val)
      } catch(Exception e) {
        // Certificate file is invalid, return an error
        return ["invalid", e.message]
      }
    }
  }
}
```

**i** The `getService` method does not work with [translators](#), [custom components](#), [RM services](#), or the [Individual datastore](#) on page 1694.

### Default value

The default value for a configuration parameter might depend on the MWS configuration or other properties. Therefore, the [defaultValue](#) constraint can be set to a closure. The `defaultValue` closure does not take any parameters and must return the object to be used as the default value.

For example, if the default value of a parameter must be true if and only if MWS is configured for the Cloud suite, then the following constraints would satisfy these conditions:

```
import com.adaptc.mws.plugins.*
class ConstrainedPlugin extends AbstractPlugin {
  static constraints = {
    myParameter required: true, type: Boolean, defaultValue: {
      return suite == Suite.CLOUD
    }
  }
}
```

As with [validator](#) closures, `defaultValue` closures have access to `appConfig`, `suite`, and `getService`.

## Individual datastore

Each plugin has access to an individual, persistent datastore which may be used for a variety of reasons. The datastore is not designed to store Moab data such as nodes, jobs, or virtual machines, but custom, arbitrary data pertinent only to the individual plugin. This may include storing objects in a persistent cache, state information for currently running processes, or any other arbitrary data. The individual datastore has the following properties:

- Data is persisted to the Mongo database and will be available even if the plugin or MWS is restarted.

- The data must be stored in groups of data called **collections**. These correspond directly to MongoDB collections.
- Each plugin may have an arbitrary number of collections.
- Collections are guaranteed not to collide if there are identically named collections between two plugin types or even two plugin instances.
- Each collection contains multiple objects or **entries**. These correspond directly to MongoDB documents.
- The values of entries may be any object which can be serialized to MongoDB: simple types (int or Integer), Maps, and Lists.
- A collection is automatically created whenever an entry is added to it, it does not need to be specifically initialized.

To utilize the datastore, the [Plugin datastore service](#) must be used. Operations are provided to add, query, and remove data from each collection.

**i** Simple key/value storage is not currently provided with the datastore. It may easily be done, however, by storing data in the format of `{name:"key", value:"value"}` and then retrieving this entry later by querying on name equals "key."

### Example

The example below demonstrates two web services (see [Exposing web services on page 1696](#)). The first adds multiple entries containing various types of data to an arbitrarily named collection. The second retrieves the data and returns it to the user.

```
package example
import com.adaptc.mws.plugins.*

class DatastorePlugin extends AbstractPlugin {
  IPluginDatastoreService pluginDatastoreService

  def storeData(Map params) {
    def collectionName = params.collectionName
    def data = [[boolVal:true], [stringVal:"String"], [intVal:1], [nullVal:null]]
    if (pluginDatastoreService.addData(collectionName, data))
      log.info("Data successfully added")
    else
      log.info("There was an error adding the data")
    return [success:true]
  }

  def retrieveData(Map params) {
    def collectionName = params.collectionName
    return pluginDatastoreService.getCollection(collectionName)
  }
}
```

## Exposing web services

Any number of methods may be exposed as public, custom web services by satisfying several criteria:

- The method must declare that it returns `Object` or `def`.
- The method must define a single argument of type `Map`.
- The method must actually return a `List` or `Map`.
- The method must not be declared as private or protected; only public or unscoped methods will be recognized as web services.

### Parameters and request body

The `Map` argument will contain all parameters passed into the web service by the client. See [Accessing Plugin Web Services on page 1605](#) for additional details.

Parameters may be passed into the web service call as normal URL parameters such as `?param=value&param2=value2`, as key-value pairs in the POST body of a request, or as JSON in the body.

For the first two cases, the parameters will be available on the `Map` argument passed into the web service call as key value pairs matching those of the request. Note that in these cases all keys and values will be interpreted as strings. However, the parameters object has several helper methods to convert from Strings to simple types, such as Booleans, integers, doubles, floats, and lists. If the value is not a valid simple type, null is returned.

Finally, note that the client may optionally include an `objectId` as the last part of the URL. When this is done, the `id` field will be set to this value in the `Map` argument to the web service.

```
GET <webServiceUrl>?key=value&key2=true&key3=5&list=1&list=2

def serviceMethod(Map params) {
    assert params.key=="value"
    assert params.key2=="true"
    assert params.bool('key2')==true
    assert params.key3=="5"
    assert params.int('key3')==5
    assert params.list('list')==[1, 2]

    // Null is returned if the conversion is invalid
    assert params.int('key')==null
}
```

When the body possesses JSON, the parsed JSON object or array will be available within a parameter called **body** in the `Map` argument. In this scenario, the types of the values are preserved by the JSON format.

```
POST <webServiceUrl> with JSON body of
{"key":"value","key2":true,"key3":5}

def serviceMethod(Map params) {
    assert params.body.key=="value"
    assert params.body.key2==true
    assert params.body.key3==5
}
```

### Unsecured web services

There are times when it is desirable to create a plugin with a publicly available web service that does not require a valid application account in order to access it (for details, see [Access control on page 1420](#)). In these cases, the [Unsecured](#) annotation may be used on the plugin web service method. No authentication will be performed on Unsecured web services. An example of using the annotation is given below.

```
Sample unsecured custom web service
-----
@Unsecured
def retrievePublicData(Map params) {
    return [data:["data item 1", "data item 2"]]
}
```

Be cautious in using this annotation as it may potentially present a security risk if sensitive data is returned from the web service.

### Returning errors

In order to signify an error occurred or invalid data was provided, the [WebServiceException](#) class may be thrown from any custom web service. This exception contains constructors and fields for a list of messages and a HTTP response code. For example, suppose that the user provided inadequate information. The web service could use the following code to notify the user and prompt them to take action with custom messages.

```
def service(Map params) {
    // Handle invalid input
    if (!params.int('a'))
        throw new WebServiceException("Invalid parameter 'a' specified, please specify an
integer!", 400)
    // Use params.a correctly ...
}
```

For the example above, a 400 response code (bad request) would be returned with a response body as follows:

```
{
  "messages":[
    "Invalid parameter 'a' specified, please specify an integer!"
  ]
}
```

If any other exception is thrown from a web service (ie Exception, IllegalArgumentException, etc.), a 500 response code will be returned with the following response body:

```
{
  "messages":[
    "A problem occurred while processing the request",
    "Message provided in the exception constructor"
  ]
}
```

See [Responses and return codes on page 1429](#) for more information on error formats in MWS.

### Accessing the HTTP Request Method

The HTTP method used for the request is available from the Map parameters argument. The key used to access it is stored as a static field in [PluginConstants](#) called `WEB_SERVICES_METHOD`. The value is a string which can be GET, POST, PUT, or DELETE. The following example demonstrates how this could be used with the `WebServiceException` to create a REST API with a plugin.

```
def serviceMethod(Map params) {
    // Check to make sure that this request used the HTTP GET method
    // Throw a 405 error (method not supported) if not
    if (params[PluginConstants.WEB_SERVICES_METHOD]!="GET")
        throw new WebServiceException("Method is not supported", 405)
}
```

## Reporting state data

As long as Moab Workload Manager is configured with MWS as a Resource Manager (RM), plugins may report state information on jobs, nodes, storage, and virtual machines to Moab. This is done through **Reports** that are generated by the plugin and passed to the bundled RM services ([Job RM service](#), [Node RM service](#), [Storage RM service](#), and [Virtual machine RM service](#)). Each report is for a specific type of object: job, node, storage, or virtual machine. Each contains current state information on the specific attributes of the type it is for.

 Note that storage is a sub-type of node, meaning that it is a specialized node.

### Generating reports

To generate a report, simply create a new instance of a report depending on the type of object to be reported:

Object type	Report type
<b>Job</b>	<a href="#">JobReport</a>
<b>Node</b>	<a href="#">NodeReport</a>
<b>Storage</b>	<a href="#">StorageReport</a>
<b>Virtual Machine</b>	<a href="#">VirtualMachineReport</a>

Each report has a single required parameter for creating a new instance—the ID of the object which is being reported. Once the report instance has been created, any property may be modified as shown in the API documentation links in the table above. The following example shows the creation of a simple node report and modification of a few properties:

```

public void poll() {
    NodeReport node = new NodeReport("node1")
    node.timestamp = new Date()
    node.image = "centos-5.4-stateless"
    ... // Set other properties and persist the report
}

```

### Master and slave reports

At times, you may want to report some additional attributes on objects *only if* the objects are being reported by other plugins. For example, you may want to report the power state of a VM, but sometimes the plugin reporting this data can receive data even after the VM has been destroyed. In this case, you can set the `slaveReport` field on any report to `true`, signifying that the report should only be used if another plugin is reporting on the same object (in other words, creating "master" reports).

**i** If all reports for an object are "slave" reports, and no "master" reports exist, then the object will not report to Moab Workload Manager.

### Special cases in field values

All complex types, such as Lists, Maps, and objects (not including Enumerated values such as [NodeReportState](#) and [JobReportState](#)) have default values set for them and are not required to be instantiated before use. For example, the metrics property of a node report may be modified as follows:

```

public void poll() {
    NodeReport node = new NodeReport("node1")
    // The following assignments are equivalent in their functionality
    node.features.add("FEAT1")
    node.features << "FEAT2"
    // The following assignments are equivalent in their functionality
    node.metrics.METRIC1 = 4d
    node.metrics["METRIC2"] = 125.5
    ... // Set other properties and persist the report
}

```

For the resources and requirements (jobs only) properties, assignments may be made easily without checking for previously existing values or null objects. For example, resources may be added to the resources property simply by accessing it as a Map:

```

public void poll() {
    NodeReport node = new NodeReport("node1")
    node.resources.RES1.total = 10
    node.resources.RES1.available = 3
    node.resources["RES2"].total = 10
    node.resources["RES2"].available = 10
    ... // Set other properties and persist the report
}

```

The job report's requirements property has some additional handling to allow it to be accessed as a single [JobReportRequirement](#) object, such as in the following example:

```
public void poll() {
    JobReport job = new JobReport("job.1")
    job.nodeCountMinimum = 4
    job.processorCountMinimum = 2
    job.requiredNodeFeatures << "FEAT1"
    job.preferredNodeFeatures << "FEAT2"
    ... // Set other properties and persist the report
}
```

**i** Although multiple requirements may be added to the `requirements` list to provide consistency with the MWS Job resource (see [Jobs on page 1547](#)), only the first requirement object's properties will be reported to Moab through the RM interface.

Managing images for nodes

In order to have Moab Workload Manager recognize a node as a virtual machine hypervisor, it must have a valid associated Image (see [Images on page 1536](#)). In particular, the `image` property on a node report must set to a valid image name. The image's `hypervisorType` and `virtualizedImages` properties are then used to report the correct hypervisor type and supported virtual machine images to Moab.

If the `image` is invalid, it will be ignored and the node will not be recognized as a hypervisor. If the image is valid, but no `hypervisorType` value is present, the `extensions.xcat.hvType` field value will be used. If that is also not present, the configuration parameter for default hypervisor type (see [Configuration on page 1772](#)) will be used instead.

Persisting a Report

After a report has been generated and all desired fields have been updated, the report must be sent to one of the three bundled RM services for persisting. If this is not done, the report will be discarded and will not be considered when reporting state information to Moab. The RM services are shown below according to the object type that they handle:

Object type	RM service
<b>Job</b>	<a href="#">Job RM service</a>
<b>Node</b>	<a href="#">Node RM service</a>
<b>Storage</b>	<a href="#">Storage RM service</a>
<b>Virtual Machine</b>	<a href="#">Virtual machine RM service</a>

Each service has two methods: `save` and `update`. The difference between these is that the `save` method first removes all previous reports from the plugin calling the method, and then persists the new reports, thereby only persisting the latest reports, while the `update` method does not remove any reports before persisting the new reports. Typically, the `save` method will be used while a plugin is being polled, while the `update` method will be used in incremental event based reporting. An example of using the `save` method is shown below.

```
INodeRMService nodeRMService

public void poll() {
    NodeReport node = new NodeReport("node1")
    // Change the state
    node.state = NodeReportState.BUSY
    // Persist
    nodeRMService.save([node])
}
```

Once this is done, the reports will be persisted to MongoDB and will be included in RM queries (see [Resource manager queries on page 1735](#)) from Moab Workload Manager or users.

## Controlling lifecycle

 Plugin control is currently in Beta. Interfaces may change significantly in future releases.

At times a plugin developer may wish to modify the current state of a plugin or even create plugins programmatically. This may be done with the [Plugin control service](#). Operations exist on the service to:

- create plugin instances dynamically with specific configuration.
- retrieve plugin instances by ID or based on configuration properties.
- start or stop plugin instances.
- verify plugin instance configuration.

#### Creating plugins

Several methods are provided to allow on-the-fly creation of new plugins. Generally, they allow a plugin with a specific ID and plugin type (as a string or as a Groovy Class) to be created with optional configuration properties. These properties should match the fields in [Plugins on page 1599](#).

If any configuration properties are omitted, the defaults will be used as described in [Setting default plugin configuration on page 1747](#). A boolean value is also returned indicating whether the creation succeeded or not.

Note that the `createPlugin` methods will initialize the plugin for retrieval or usage and attempt to start the plugin if the `autoStart` property is true.

#### Retrieving plugins

Plugins may be retrieved by using an ID, querying by plugin type, or even querying based on configuration parameters. Several methods are provided to perform these functions as shown on [Plugin control service on page 1750](#).

#### Starting and stopping plugins

Plugins may also be started or stopped on demand. These two methods are exposed directly as `start` and `stop` on the plugin control service. Although each method does not return any data, exceptions are

thrown if errors are encountered.

### Verifying plugin configuration

Finally, the plugin control service may be used to verify plugin configuration at any point instead of just when the plugin is started or modified. This may be useful to attempt to modify plugin configuration directly through the `setConfig` dynamic method (see [Dynamic methods on page 1681](#)) and then verify that the new configuration is valid for the plugin. Exceptions are thrown if the plugin or the configuration is invalid.

### Examples

If an error state is detected it may be necessary to stop the current plugin instance until corrective action can be taken. This may be done using the following code:

```
package example

import com.adaptc.mws.plugins.*

class ErrorPlugin {
    IPluginControlService pluginControlService

    public void poll() {
        // Error is detected, stop plugin instance!
        try {
            log.warn("An error was detected, trying to stop the plugin ${id}")
            pluginControlService.stop(id)
            log.warn("The plugin was successfully stopped")
        } catch (PluginStopException e) {
            log.error("Plugin instance ${id} could not be stopped", e)
        }
    }
}
```

### Related topics

- [Plugin developer's guide on page 1679](#)

## Accessing MWS REST resources

Often a plugin type may need to access existing MWS REST Resources in order to extend or complement default MWS functionality. This may be done with the [Moab REST service](#), which allows a plugin type developer to utilize the existing Resources documentation see [Resources introduction on page 1446](#)) to perform these tasks.

All accesses to resources require a HTTP method to use (such as GET, POST, PUT, or DELETE) and a relative URL (such as `/rest/jobs`). Although it mimics the REST resource interface, no actual requests are made and no data is transmitted through the network.

### Authentication

All resources are available to the Moab REST Service, and no authentication or Application Accounts are needed.

**i** Caution must be used when developing plugin types, as there are no restrictions to what may be done with the Moab REST Service. This is especially true when not utilizing hooks as discussed below.

### Hooks

If pre and post-processing hooks are utilized in MWS ([Pre and post-processing hooks on page 1434](#)), the plugin type developer may choose whether or not they are executed when performing a "request" through the Moab REST service. This is done through the hooks option as documented in [Moab REST service on page 1748](#).

### Verifying API version support

The Moab REST Service provides a method for easily determining which API versions are supported by the current version of MWS. This method includes checks to make sure that the API version will work as expected, including verifying any configuration or external services are running.

```
moabRestService.isAPIVersionSupported(1)
moabRestService.isAPIVersionSupported(2)
```

### Converting string dates

Because the Moab REST Service returns data exactly as given to an external consumer of MWS, including dates converted to strings, the service provides a method for converting MWS date strings to actual Date objects.

```
moabRestService.convertDateString("2011-11-08 13:18:47 MST")
```

### URL parameters

URL parameters, such as `query`, `sort`, `proxy-user`, and others should be not be appended directly to the URL. Instead, these may be specified with the `params` option:

```
// Query images that are hypervisors
moabRestService.get("/rest/images", params:[query: '{"hypervisor":true}'])
// Sort images by osType
moabRestService.get("/rest/images", params:[sort: '{"osType":1}'])
```

### Examples

This code retrieves a list of all nodes, and is equivalent to the [Get all nodes](#) task.

```

package example

import com.adaptc.mws.plugins.*
import net.sf.json.*

class RestPlugin {
    IMoabRestService moabRestService

    public void poll() {
        def result = moabRestService.get("/rest/nodes")
        // OR with the hook enabled..
        def result = moabRestService.get("/rest/nodes", hooks:true)

        assert result instanceof MoabRestResponse
        assert nodes instanceof List

        log.debug("Nodes list:")
        nodes.each { JSON node ->
            log.debug(node.id)
        }
    }
}

```

This code adds a flag to a job, and is equivalent to the [Modify job attributes](#) task. This request also enables the hook (if one is configured) for the "request" and uses a URL parameter. This is the equivalent of making a call to `/rest/jobs/job.1?proxy-user=adaptive`.

```

package example

import com.adaptc.mws.plugins.*
import net.sf.json.*

class RestPlugin {
    IMoabRestService moabRestService

    public void poll() {
        def jobId = "job.1"
        def result = moabRestService.put("/rest/jobs/"+jobId, hooks:true, params:['proxy-
user':'adaptive']) {
            [flags:["RESTARTABLE"]]
        }
        assert result.isSuccess()
    }
}

```

### Related topics

- [Plugin developer's guide on page 1679](#)

## Creating events and notifications

Plugins may easily create new events and create or update notification conditions using the [Plugin event service](#). Previously, this was only possible by utilizing the MWS REST resources. The event service eases this burden from plugin developers. There are several operations that are available using the service:

- Create an event with or without specifying an event date.
- Create an event from an enumeration annotated with `EventEnumeration` (see [Plugin event service on page 1755](#)) with or without specifying an event date.
- Create or update a notification condition with or without specifying an observed date or expiration duration.

## Creating events

Events are composed of several properties such as arguments, associated objects, origin, message, severity, escalation level, and a unique event code. The plugin event service removes the need for magic strings such as those for event severity ("INFO", "WARN", "FATAL") and also handles creating unique event codes. In other words, no bitwise manipulation is required to create new events.

The event code is comprised of several elements:

Code element	Description
Severity	If the event is informational, a warning, an error, or fatal.
Escalation level	Who cares about the event, or who should act on the event.
Component code	Internally made up of the MWS component code (stored internally) and the plugin event component code (see <a href="#">Plugin event component code on page 1705</a> ).
Entry code	The code representing a unique event for the component (for each plugin event component code).

The plugin event service handles the severity, escalation level, and entry code portions of the code by the values passed as parameters to the `createEvent` method. The plugin event component code is described in the next section.

### [Plugin event component code](#)

The plugin event component code should be a unique number across all plugin types or projects from 1–254. This number is combined with the MWS component code to represent each plugin as a unique component code across all Adaptive Computing products. 0 is reserved for MWS itself and should not be used. 255 is reserved for plugin types that do not define an event component code and represents an "unknown" plugin component. Additionally, codes 1–150 are reserved for Adaptive Computing plugins, while 151–254 are reserved for Professional Services and/or customer-specific plugins.

This code may be specified by setting an `eventComponent` property (see [Fields: Plugin Types on page 2204](#)) on the plugin project file or as a static property on the plugin type. As with all other project properties, the plugin type value overrides the project value. For example:

```

class MyExampleProject {
    ...
    Integer eventComponent = 2
    ...
}
ExamplePlugin {
    static final eventComponent = 1
    ...
}
Example2Plugin {
    // no eventComponent property
    ...
}

```

In this case, the plugin type `ExamplePlugin` has a plugin event component code of 1, while the `Example2Plugin` has a code of 2 since it inherits it from the project properties.

### Origin suffix

The origin of an event created through the plugin event service is automatically set by the plugin framework to `MWS/plugins/<plugin type>/<plugin id>`. For example, an event created by the plugin created from the "ExamplePlugin" plugin type with an ID of "plugin1" would generate events with an origin of `MWS/plugins/Example/plugin1`.

While this origin is sufficient for an administrator to determine the plugin where the event came from, the plugin developer may want this to be more specific to a class name or method name. This may be done using the optional `originSuffix` parameter to the `createEvent` method. The origin suffix, as its name implies, is appended to the end of the generated origin. For the example above, suppose the plugin developer passed `myMethod/switch1` as the origin suffix parameter when creating a new event. The event would then have an origin of `MWS/plugins/Example/plugin1/myMethod/switch1`.

### Event enumerations

While creating events using the plugin event service is quite simple, often there are related events that have properties in common, such as the event type prefix or the origin suffix. Additionally, [i18n messages](#) (see [i18n messaging on page 1683](#)) are typically used for the event's message. Using the `EventEnumeration` annotation (see [Plugin event service on page 1755](#)) in combination with an enumeration simplifies this process. When this is done, each message is pulled from the `messages.properties` files using a standard convention, and the event type prefix and the origin suffix may optionally added as static properties on the enumeration. Using `EventEnumeration` requires:

- The annotated element is an `enum`, not a class or interface.
- Each enumeration value must use the constructor with three arguments: the event name, the severity, and the escalation level.
- If an event type prefix is specified, it must be defined as `"static String EVENT_TYPE_PREFIX = ..."`, otherwise the property should not be defined.
- If an origin suffix is specified, it must be defined as `"static String ORIGIN_SUFFIX = ..."`, otherwise the property should not be defined.

If any of these conditions are not fulfilled, using the `EventEnumeration` annotation will result in compilation errors.

Enumeration values are automatically marked as implementing the `IPluginEvent` interface and may be used as the first parameter of the `createEvent` method on the plugin event service. For example:

```
package example

import com.adaptc.mws.plugins.EventEnumeration
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject
import static com.adaptc.mws.plugins.IPluginEventService.Severity.*
import static com.adaptc.mws.plugins.IPluginEventService.EscalationLevel.*

public class ExamplePlugin {
    void poll() {
        // Event 1 takes no arguments
        pluginEventService.createEvent(ExampleEvents.EVENT1, null, null)
        // Event 2 takes one argument and has an associated object
        pluginEventService.createEvent(ExampleEvents.EVENT2, ["arg1"], [new AssociatedObject
(type:"type1", id:"id1")])
    }
}

@EventEnumeration
enum ExampleEvents {
    EVENT1("Example One", INFO, USER), // Entry code is 0
    EVENT2("Example Two", INFO, USER) // Entry code is 1
}
```

It may be noted that several key properties of events are missing from the enumeration definition and create event call parameters:

- Message: retrieved automatically from `i18n` messages (see [Messages for event enumerations on page 1707](#))
- Event type: generated from the enumeration constructor and optional event type prefix property (see [Event type for event enumerations on page 1708](#))
- Entry code: generated from the return value of `ordinal()` on the enumeration value; in other words, this is generated from the order of the enumeration values

### Messages for event enumerations

The message for events created from enumerations is generated using `i18n` messages (see [i18n messaging on page 1683](#)) with codes in the following format:

- `<enumeration type name>.<enumeration value name>.message`
- `<enumeration type name>.<enumeration value name>.comment`

Considering the example in the section above, the message for `ExampleEvents.EVENT1` would be generated using the argument list passed to the `createEvent` method with the `"ExampleEvents.EVENT1.message"` message from `messages.properties`. This message should contain arguments if needed, such as `"My example with ID {0} was created"` and is used as the `"message"` property in the created event. The comment, on the other hand, is not persisted with the event and should be text (typically in paragraph format) describing why the event typically occurs or what actions should be taken when it does occur. Consider the message to contain instance specific information for the event (passed as arguments to the message) and the comment to be general documentation concerning the event.

As a best practice, name event enumeration values using the number and short name of each argument to the message. This makes it easy for the consumer to know which arguments are expected and what each means. For example, if an event is for connection errors and needs two arguments to the message, the URL and the error message, the enumeration value should be named "CONNECT\_FAILURE\_1URL\_2ERROR" or even "CONNECT\_TO\_1URL\_FAILURE\_2ERROR". In this way, the consumer knows that the first argument represents the URL and the second is the error message.

### Event type for event enumerations

As described above, the static string field `EVENT_TYPE_PREFIX` may be defined on the enumeration. This value is optional and, when present, is prepended with a space to the event name parameter from the constructor to generate the event type. For example, consider the following enumeration:

```
package example

import com.adaptc.mws.plugins.EventEnumeration
import static com.adaptc.mws.plugins.IPluginEventService.Severity.*
import static com.adaptc.mws.plugins.IPluginEventService.EscalationLevel.*

@EventEnumeration
enum MyPluginEvents {
    CONNECT("Connect", INFO, ADMIN),
    DISCONNECT("Disconnect", INFO, ADMIN)

    static String EVENT_TYPE_PREFIX = "My Plugin"
}
```

If `MyPluginEvents.CONNECT` and `MyPluginEvents.DISCONNECT` were used with the plugin event service, the generated event types would be "My Plugin Connect" and "My Plugin Disconnect" respectively.

### Origin for event enumerations

The origin for event enumeration values automatically contains more information than those for non-enumerated events, such as those described above. The enumeration type name and value are appended to the origin. For example, consider the following enumeration and plugin fragment:

```
...
class ExamplePlugin {
    ...
    assert id=="example1" // plugin ID is example1
    pluginEventService.createEvent(ExampleEvents.EVENT1, null, null)
    ...
}
...
@EventEnumeration
enum ExampleEvents {
    EVENT1("Event One", INFO, ADMIN)
    ...
}
```

The origin generated for the created event would be `MWS/plugins/Example/example1/ExampleEvents/EVENT1`. The static string field `ORIGIN_SUFFIX` may also be defined on the enumeration. This value is optional and, when present, is appended to the end of the generated origin as described above with the origin suffix parameter to the `createEvent` method.

Example

In order to understand all interactions when event enumerations are used, the following is a complete example.

## Plugin type

```

package example
import com.adaptc.mws.plugins.*

class ConnectPlugin extends AbstractPlugin {
    static eventComponent = 1

    IPluginEventService pluginEventService

    void poll() {
        def errorMessage = connect()
        if (errorMessage)
            pluginEventService.createEvent(ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR,
[config.url, errorMessage], null)
        else
            pluginEventService.createEvent(ConnectEvents.CONNECT_SUCCESS, null, null)
    }

    // Returns the error message or null/empty on success
    private String connect() {
        String errorMessage
        ...
        return errorMessage
    }
}

```

## Event enumeration

```

package example
import com.adaptc.mws.plugins.EventEnumeration
import static com.adaptc.mws.plugins.IPluginEventService.Severity.*
import static com.adaptc.mws.plugins.IPluginEventService.EscalationLevel.*

@EventEnumeration
enum ConnectEvents {
    CONNECT_SUCCESS("Success", INFO, ADMIN),
    CONNECT_TO_1URL_FAILURE_2ERROR("Failure", ERROR, ADMIN)

    static String EVENT_TYPE_PREFIX = "Connect"
}

```

```

messages.properties
-----
ConnectEvents.CONNECT_SUCCESS.message=The plugin was successfully connected!
ConnectEvents.CONNECT_SUCCESS.comment=This occurs when the plugin successfully
connects to the configured URL and
    is informational only.
ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR.message=The plugin failed to connect to
{0}: {1}
ConnectEvents.CONNECT_TO_1URL_FAILURE_2ERROR.comment=This occurs when the plugin fails
to connect to the configured
    URL for any reason. The most common reason is that the service is not running and
needs to be started.
    
```

The following are examples of the events created in MWS:

```

Created events
-----
{"totalCount": 2, "resultCount": 2, "results": [
  {
    "arguments": ["http://localhost:1000", "The service is not running!"],

    "associatedObjects": []
  }
]}
    
```

Unique event codes

The last topic that must be covered in creating events from plugins is that all efforts should be made to make sure that event codes are unique throughout all Adaptive Computing product suites. Additionally, the codes should be static, meaning they do not change once established. In order to do this, adhere the following recommendations:

- Use a unique (across all plugin types) plugin event component code for each plugin type.
- Follow the guidelines for plugin event component codes established above (see [Plugin event component code on page 1705](#)) and ensure it is a number 1-254.

- Use event enumerations where possible, otherwise ensure (through testing if possible) that all entry codes are unique for each plugin type.
- Ensure (through testing if possible) that the ordinal value of the event enumeration values do not change.

## Creating or updating notification conditions

The plugin event service also makes it easy to create or update notification conditions. Simply use the `updateNotificationCondition` method. Just as the MWS notification condition resource, this is an idempotent operation, meaning it can be called multiple times with the same result. If the notification condition does not exist, it will be created automatically. If it does exist, the observed date and details will be updated accordingly.

## Examples

Examples are available on [Plugin event service on page 1755](#).

### Related topics

## Handling events

**i** Plugin events (excepting the poll event) are currently in Beta. Interfaces may change significantly in future releases.

Plugin types may handle specific events by containing methods defined by the conventions below. All events are optional.

### The polling event

To maintain current information, each plugin is polled at a specified time interval. The following method definition is required to utilize the polling event.

```
void poll() { ... }
```

Typically this polling method is used to report node and virtual machine information. By default, the polling interval is set to 30 seconds, but can be modified for all or individual plugins as explained in [Plugin management on page 1742](#).

When a polling event occurs, the `poll` method on the target plugin is called. This method may perform any function desired and should typically make calls to the [Node RM service](#), the [Virtual machine RM service](#), and the [Job RM service](#) services to report the current state of nodes and virtual machines. For example, the `poll` method in the Native plugin type is implemented as follows:

**i** This is an extremely simplified version of what is actually implemented in the Native plugin type.

```
INodeRMService nodeRMService;
IVirtualMachineRMService virtualMachineRMService;

public void poll() {
    nodeRMService.save(getNodes());
    virtualMachineRMService.save(getVirtualMachines());
}
```

This simple poll method calls two other helper methods called `getNodes` and `getVirtualMachines` to retrieve node and virtual machine reports. These reports are then sent to the appropriate RM service. See [Reporting state data on page 1698](#) for more information on the RM services; however, the objective of this example is to demonstrate one possible use of the poll event handler. Other plugin types, on the other hand, may use the poll event to update internal data from pertinent resources or make calls to external APIs.

[Lifecycle events](#)

Events are also triggered for certain lifecycle state changes. The following method definitions are required to receive lifecycle events.

```
public void configure() throws InvalidPluginConfigurationException { ... }
public void beforeStart() { ... }
public void afterStart() { ... }
public void beforeStop() { ... }
public void afterStop() { ... }
```

Each event is described in the table below with the associated state change when the event is triggered.

State change	Event	Description
<b>configure</b>	Configure	Triggered before <code>beforeStart</code> and after the plugin has been configured. May be used to verify configuration and perform any setup needed any time configuration is loaded or modified.
<b>beforeStart</b>	Start	Triggered just before starting a plugin.
<b>afterStart</b>	Start	Triggered just after a plugin has been started.

State change	Event	Description
<b>beforeStop</b>	Stop	Triggered just before stopping a plugin.
<b>afterStop</b>	Stop	Triggered just after stopping a plugin.

Currently, no events are triggered for pausing, resuming, erroring, or clearing errors for plugins.

### RM events

When MWS is configured as a Moab Resource Manager (see [Moab Workload Manager resource manager integration on page 1730](#), and more specifically, [Configuring Moab Workload Manager on page 1731](#)), RM events are sent from Moab to each plugin according to the routing specification (see [Routing on page 1679](#)). The following method definitions are required to receive these events.

```
public boolean jobCancel(String jobName) { ... }
public boolean jobModify(String jobName, Map<String, Object> attributes, ModifyMode
modifyMode) { ... }
public boolean jobRequeue(String jobName) { ... }
public boolean jobResume(String jobName) { ... }
public boolean jobStart(String jobName, List<String> nodes, String username) { ... }
public boolean jobSubmit(Map<String, Object> job, String submissionString, String
submissionFlags) { ... }
public boolean jobSuspend(String jobName) { ... }
public boolean nodeModify(List<String> nodes, Map<String, String> attributes,
ModifyMode modifyMode) { ... }
public boolean nodePower(List<String> nodes, NodeReportPower state) { ... }
public boolean virtualMachinePower(List<String> virtualMachines, NodeReportPower
state) { ... }
```

## Handling exceptions

Plugin exceptions are currently in Beta. Interfaces may change significantly in future releases.

The `com.adaptc.mws.plugins` package contains several exceptions that may be used and in some cases, should be caught. All exceptions end with "Exception", as in [PluginStartException](#).

There are several specific cases where Exceptions should or can be used:

- The `reload` method on the [Plugin control service](#) can throw the [InvalidPluginConfigurationException](#) to signify that the configuration contains errors.
- Various methods on the [Plugin control service](#) throw plugin exceptions which must be caught to diagnose errors when creating plugin types.
- Any exception (including the Exception class) can be thrown from a custom web service to display a 500 Internal Server Error to the client requesting the service with the given error message.

## Managing SSL connections

At times it is desirable to load and use self-signed certificates, certificates generated from a single trusted certificate authority (CA), or even simple server certificates. It may also be necessary to use client certificates to communicate with external resources. To ease this process, the [SSL service](#) may be utilized. This service provides methods to load client and server certificates from the filesystem. Methods are also present to aid in creating connections which automatically trust all server certificates and connections.

Several points should be noted when using the SSL Service:

- Certificate files may be in the PEM file format and do not need to be in the DER format (as is typical of Java security).
- Each method returns an instance of `SSLSocketFactory`, which may then be used to create simple sockets or, in combination with another client library of choice, create a connection.
- If the client certificate password is non-null, it will be used to decrypt the protected client certificate.
- This service is *not* needed when performing SSL communications with trusted certificates, such as those for HTTPS enabled websites that do not have a self-signed certificate.
- If the file name of the certificate file (client or server) is relative (no leading '/' character), it will be loaded from the `mws.certificates.location` configuration parameter (see [Configuration on page 1772](#)).
  - The default value of `mws.certificates.location` is `MWS_HOME/etc/ssl.crt`.
- Both the client certificate alias and password may be `null`. In this case, the client certificate must not be encrypted and the client certificate's default alias (the first subject CN) will be used.
- The lenient socket factory and hostname verifier automatically trust all server certificates. Because of this, they present a large security hole. Only use these methods in development or in fully trusted environments.

#### Example

To create a socket to a server that requires a client certificate, the following code may be used.

```

package example

import com.adaptc.mws.plugins.*

class SSLConnectionPlugin extends AbstractPlugin {
  ISslService sslService

  public void poll() {
    // This certificate is not encrypted and will be the only certificate presented to
    the
    // connecting end of the socket.
    // This file will be loaded from MWS_HOME + mws.certificates.location + my-cert.pem.
    String clientCert = "my-cert.pem"

    def socketFactory = sslService.getSocketFactory(clientCert, null, null)
    def socket = socketFactory.createSocket("hostname.com", 443)
    // Write and read from the socket as desired..
  }
}

```

To create a HTTPS URL connection to a server that has a self-signed certificate, the following code may be used. Note that this is very typical of client libraries – they have a method to set the SSL socket factory used when creating connections.

```

package example

import com.adaptc.mws.plugins.*

class SSLConnectionPlugin extends AbstractPlugin {
  ISslService sslService

  public void poll() {
    // This certificate represents either the server public certificate or the CA's
    certificate.
    // Since the path is absolute it will not be loaded from the MWS_HOME directory.
    String serverCert = "/etc/ssl/certs/server-cert.pem"

    def socketFactory = sslService.getSocketFactory(serverCert)

    // Open connection to URL
    HttpURLConnection conn = "https://hostname.com:443/test".toURL().openConnection()
    conn.setSSLSocketFactory(socketFactory)

    // Retrieve page content and do with as desired..
    def pageContent = conn.getInputStream().text
  }
}

```

## Utilizing services or custom "helper" classes

There are three general types of services available for use in plugins:

- Bundled services such as the [Moab REST service](#).
- Custom built translators loaded by convention of their name.

- Other custom built helper classes registered with Annotations.

These will each be described in this section.

## Bundled services

Bundled services are utility classes that are included and injected by default onto all plugin types. It is not required to use any of these services, but they enable several core features of plugin types as discussed in [Utility services on page 1677](#).

More information may be found on each bundled service in [Plugin services on page 1747](#).

## Using translators

Often a plugin type class file becomes so complex that it is desirable to split some of its logic into separate utility service classes. The most typical use case for this is to split out the logic for "translating" from a specific resource API to a format of data that the plugin type can natively understand and utilize. For this reason, there is a convention defined to easily add these helper classes called "Translators."

Simply end any class name with "Translator," and it will be automatically injected just as bundled services onto plugin types, other translators, or even custom registered components. The injection occurs only if a field exists on the class matching the name of the translator with the first letter lower-cased. For example, a translator class called "MyTranslator" would be injected on plugin types, other translators, and custom components that define a field called "myTranslator" as `def myTranslator` or `MyTranslator myTranslator`.

 Do not use two upper-case letters to start the class name of a Translator. Doing this may cause injection to work improperly. For example, use `RmTranslator` instead of `RMTranslator` as the class name.

 Be careful not to declare translator and custom component injection such that a cyclic dependency is created.

### [Logging in translators](#)

All translators automatically have a "getLog" method injected on them which can be used to access the configured logger. It returns an instance of [org.apache.commons.logging.Log](#).

```
package example

class ExampleTranslator {
    public void myMethod() {
        // log will be translated to getLog() by the groovy compiler
        log.info("Starting my method")
    }
}
```

See [Logging on page 1682](#) for more information on logging configuration and usage.

### Example

Suppose that a translator needs to be created to handle a connection to access an external REST resource. The translator could be defined as follows:

```
package example

class ExampleTranslator {
    public int getExternalNumber() {
        def number = ... // Make call to external resource
        return number
    }
}
```

A plugin type can then use the translator by defining a field called "exampleTranslator". Note that an instance does not need to be explicitly created.

```
package example

class ExamplePlugin {
    def exampleTranslator
    // OR ...
    //ExampleTranslator exampleTranslator

    public void poll() {
        // Use the translator
        log.info("The current number is "+exampleTranslator.getExternalNumber())
    }
}
```

To extend the example, the translator may also be injected into another translator:

```
package example

class AnotherTranslator {
    def exampleTranslator

    public int modifyNumber(int number) {
        return number + exampleTranslator.getExternalNumber()
    }
}
```

This translator may be used in the plugin type just as the other translator.

## Registering custom components

There are cases where the concept of a "Translator" does not fit the desired use of a utility class. In these cases, it is possible to register any arbitrary class as a component to be injected just as a translator would be. This is done using the Spring Framework's annotation `org.springframework.stereotype.Component`. When this annotation is used, the class is automatically registered to be injected just as translators onto plugin types and translators.

All annotations are available in the dependencies declared by the plugins-commons artifact.

**i** Do not use two upper-case letters to start the class name of a custom component. Doing this may cause injection to work improperly. For example, use `RmUtility` instead of `RMUtility` as the class name.

### Changing scope

By default, when a custom component is injected, only a single instance is created for all classes which inject it. This is referred to as the 'singleton' scope. Another scope that is available is 'prototype', which creates a new instance every time it is injected. This is useful when the class contains state data or fields that are modified by multiple methods. To change the scope, use the `org.springframework.context.annotation.Scope` on the class with a single `String` parameter specifying "singleton" or "prototype."

### Injecting translators or components

The need may arise to inject translators or other custom components onto custom components. This is done using the `org.springframework.beans.factory.annotation.Autowired` or `javax.annotation.Resource` annotations. The `Autowired` annotation is used to inject class instances by the type (i.e. `MyTranslator myTranslator`) while the `Resource` annotation is used to inject class instances by the name (i.e. `def myTranslator`). Add the desired annotation to the field that needs to be injected.

**i** Note that using the `Autowired` annotation does injection by type which differs from translator and plugin type injection. These are done by name just as the `Resource` annotation allows. Due to this fact, a type of "def" cannot be used when doing injection onto custom components using the `Autowired` annotation. See the example below.

Injection of custom components *onto* translators and plugin types are still done by name, only fields injected using the `Autowired` annotation are affected.

**!** Be careful not to declare translator and custom component injection such that a cyclic dependency is created.

### Logging in custom components

Unlike plugins and translators, custom components do *not* automatically have a "getLog" method injected on them. In order to log with custom components, you must use the Apache Commons Logging classes to retrieve a new log. The `PluginConstants` class contains the value of the logger prefix that is used for all plugins and translators. The following is an example of how to retrieve and use a logger correctly in a custom component.

```

package example

import com.adaptc.mws.plugins.PluginConstants
import org.apache.commons.logging.Log
import org.apache.commons.logging.LogFactory
import org.springframework.stereotype.Component

@Component
class ExampleComponent {
    private static final Log log = LogFactory.getLog(PluginConstants.LOGGER_
PREFIX+this.name)

    public void myMethod() {
        log.info("Starting my method")
    }
}

```

See [Logging on page 1682](#) for more information on logging configuration and usage.

### Example

Suppose that a custom utility class is needed to perform complex logic. A custom component could be defined as follows (notice the optional use of the Scope annotation):

```

package example

import org.springframework.stereotype.Component
import org.springframework.context.annotation.Scope

@Component
@Scope("prototype")
class ComplexLogicHandler {
    def handleLogic() {
        ... // Perform complex logic and return
    }
}

```

A plugin type or translator could then be defined to inject this component:

```

package example

class CustomPlugin {
    def complexLogicHandler

    public void poll() {
        complexLogicHandler.handleLogic()
    }
}

```

Now suppose another custom component needs to use the ComplexLogicHandler in its code. It can inject it using the Autowired annotation:

```

package example

import org.springframework.stereotype.Component
import org.springframework.beans.factory.annotation.Autowired

@Component
class AnotherHandler {
    // Note that this is injected by type, so 'def' may not be used
    @Autowired
    ComplexLogicHandler complexLogicHandler

    def wrapLogic() {
        complexLogicHandler.handleLogic()
    }
}

```

To perform the same injection but by name (as translators and plugin types are injected), use the `Resource` annotation:

```

package example

import org.springframework.stereotype.Component
import javax.annotation.Resource

@Component
class AnotherHandler {
    // Note that this is injected by name based solely on the name defined in
    // the annotation. The name of the field itself does not affect the injection.
    @Resource(name="complexLogicHandler")
    def complexLogicHandler

    def wrapLogic() {
        complexLogicHandler.handleLogic()
    }
}

```

## Packaging plugins

Plugin types may be packaged in two different ways to upload to MWS:

- A simple Groovy file containing a single plugin type definition.
- A JAR file containing one or more plugin types, translators, and custom components.

While each may be uploaded to MWS using the REST API or the User Interface as described in [Add or update plugin types on page 1739](#), using a JAR file is recommended. Using a simple Groovy file is useful for testing and generating proof of concept work, but does not allow the use of several features of plugins.

The principles of packaging a plugin type or set of plugin types in a JAR file are very simple. Simply compile the classes and package in a typical JAR file. All classes ending in "Plugin" are automatically attempted to be loaded as a plugin type, all classes ending in "Translator" are attempted to be loaded as a translator, and all classes annotated as a custom component will be attempted to be loaded. It is recommended that a build framework is used to help with compiling and packaging the JAR file, such as

[Gradle](#). This makes it easy to declare a dependency on the necessary JAR files used in plugin development and to debug, compile, and test plugin code.

In addition to using utility services such as translators, packaging plugin types in JAR files allows the creation of a single project for multiple related plugin types and bundling of external dependencies. These two features are discussed in the following sections.

## Plugin projects and metadata

Each plugin type has information attached to it, called metadata, which describes the origin and purpose of the plugin type. Additionally, a JAR file may also contain a project file which defines default metadata attributes for all plugin types in the JAR. Initial plugins, or plugins that will be created on loading of the JAR file if they do not exist, are also able to be defined on a project file. In all cases, metadata declared on a plugin type will override the metadata defined on the project file.

To define a project file, simply add a class to JAR file that ends in "Project." This file will attempted to be loaded as the project file. Every field on a project file, and even the file itself, is optional. All available fields are shown in the example below.

```

class SampleProject {
    // Plugin information
    String title = "Sample"
    String description = "Sample plugin types"
    String author = "Our Company."
    String website = "http://example.com"
    String email = "sample@example.com"
    Integer eventComponent = 1
    // Versioning properties
    String version = "0.1"
    String mwsVersion = "7.1 > *"
    String commonsVersion = "0.9 > *"
    String license = "APACHE"

    // Documentation properties
    String issueManagementLink = "http://example.com/ticket-system/sample-plugins"
    String documentationLink = "http://example.com/docs/sample-plugins"
    String scmLink = "http://example.com/git/sample-plugins"

    // Plugins that are to be created with these properties only when they do NOT exist
    // This does not override any existing plugin instance configuration
    def initialPlugins = {
        /*
         * Multiple instances of plugins may be defined here.
         * In this case, 'sample' is the id of the plugin
         */
        sample {
            pluginType = "Sample"
            // All properties except for "pluginType" are optional
            pollInterval = 30
            autoStart = true
            // Although it is possible to set plugin precedence, it is not recommended
            // may already be taken and plugin creation will fail in this case
            precedence = 5
            config {
                configParam = "value"
            }
        }
        // Another plugin with an ID of 'sample2'
        sample2 {
            ...
        }
    }
}

```

As can be seen, metadata information about the plugin type(s), versions, and documentation are available. These are displayed when viewing plugin information in the User Interface or through the REST API.

Any of these properties except for `initialPlugins`, `mwsVersion`, and `commonsVersion` may be overwritten by the plugin type class itself by using static properties. A simple example is shown below.

```

package example

class SamplePlugin {
    // Properties may be typed, untyped, final, or otherwise,
    // but they MUST be static
    static version = "0.2"
    static title = "Sample plugin"
    static description = "This sample plugin is used to demonstrate metadata information"
    static author = "Separate Division"
    static eventComponent = 1

    ... // Rest of the plugin type definition
}

```

### Event component

The `eventComponent` field is explored in [Creating events and notifications on page 1704](#).

### MWS and commons versions

The `mwsVersion` and `commonsVersion` fields are used to restrict the versions of MWS and plugin framework with which the plugin project may be used. Each field is of the format `FIRST_VERSION > LAST_VERSION`, where `FIRST_VERSION` is the first supported MWS or plugin framework version (inclusive), and `LAST_VERSION` is the last supported MWS or plugin framework version (inclusive). Each version must take the format of `##` or `##.##`, as in `7.1`, or `7.1.2`. An asterisk (`*`) is used to denote any version, and may be used for the first or the last version.

Although support for restricting both the MWS and commons versions are provided, it is recommended to use the commons version restriction always and the MWS version restriction where necessary. Restrictions on the commons version prevent plugin loading errors while restrictions on the MWS version prevent runtime errors such as missing support for certain MWS API versions.

Typically the `mwsVersion` and `commonsVersion` fields are set as shown above, with the first version set to a specific number, and the last version set to any (an asterisk). This is the recommended approach for setting both fields. It is not recommended to use any version (asterisk) for the first version. Some examples of `mwsVersion` and `commonsVersion` values are shown below with explanations of how they behave.

```

String mwsVersion = "7.1 > *" // Any MWS version 7.1.0 and greater is supported
(including 7.2, etc)
String mwsVersion = "7.1.3 > *" // Any MWS version 7.1.3 and greater is supported
(including 7.2, etc)
String mwsVersion = "7.1 > 7.1.3" // Any MWS version between 7.1.0 and 7.1.3 is
supported
String mwsVersion = "*" > "*" // Any MWS version is supported (not recommended!)
String mwsVersion = "*" > 7.2" // Any MWS version up to 7.2 is supported (not
recommended!)

String commonsVersion = "0.9 > *" // Any framework version 0.9.0 and greater is
supported (including 1.0, etc)
String commonsVersion = "0.9.3 > *" // Any framework version 0.9.3 and greater is
supported (including 1.0, etc)
String commonsVersion = "0.9 > 0.9.3" // Any framework version between 0.9.0 and 0.9.3
is supported
String commonsVersion = "*" > "*" // Any framework version is supported (not
recommended!)
String commonsVersion = "*" > 1.0" // Any framework version up to 1.0 is supported (not
recommended!)

```

If the `mwsVersion` or `commonsVersion` fields are formatted incorrectly, the plugin project will fail to load. If a plugin project is uploaded to MWS and the version check fails, the project will fail to load with an error message about the `mwsVersion` or `commonsVersion`.

 The `mwsVersion` and `commonsVersion` fields cannot be overridden by a single plugin type, but can be set only at the plugin project level. This prevents mixing of MWS and commons version requirements within a single project.

### Initial plugins

The initial plugins closure provides the flexibility to insert plugin instances when the JAR is loaded. This occurs at two points: when the plugin JAR is first uploaded to MWS, and when MWS is restarted. As shown in the example above, the ID, `pluginType`, and other properties may be configured for multiple plugins.

The nature of Groovy closures means that programmatic definition of initial plugins is possible. This may even be based on the MWS application configuration. Two properties are automatically available in the `initialPlugins` closure:

- `appConfig` – Contains the MWS application configuration. Any configuration parameter is available for access as documented on [Configuration on page 1772](#).
- `suite` – Contains the currently configured suite that MWS is running in. This is equivalent to the `mws.suite` configuration parameter, and is an instance of [Suite](#).

### Native plugin case study

The Native JAR file utilizes many of the features discussed above. In the root of the JAR file, a compiled class called `NativeProject` exists which defines all of the metadata fields, including `initialPlugins`. Trying to create an initial plugin presents two distinct problems:

- The plugin should be initialized only if the suite is CLOUD.
- The plugin type configuration must contain an entry referencing the configured `mws.home.location` parameter, or the configured `MWS_HOME` location.

The `initialPlugins` closure is defined as follows:

```

import com.adaptc.mws.plugins.Suite

class NativeProject {
  ... // Metadata fields

  def initialPlugins = {
    // Initialize the cloud-native plugin only if the suite is CLOUD
    if (suite==Suite.CLOUD) {
      'cloud-native' {
        pluginType = "Native"
        pollInterval = 30
        config {
          // Use the appConfig property to retrieve the current MWS HOME
          getCluster = "file://${appConfig.mws.home.location}/etc/nodes
        }
      }
    }
  }
}

```

## Managing external dependencies

External dependencies (e.g. JAR files) may be included and referenced in JAR files. Certain rules must also be followed in order to have the dependencies loaded from the JAR file correctly:

The plugin type must bundle all external dependency JARs in the root of the plugin type JAR file.

An entry must be included in the `MANIFEST.MF` file that references each of these bundled JAR files as a space separated list:

```
Class-Path: dependency1.jar dependency2.jar dependency3.jar
```

Assuming that these rules are followed and that the plugin type is uploaded using the REST API or the User Interface, the dependent JARs will first be loaded and then the new plugin type and associated files will be loaded.

## Documenting plugin types

Documentation may also be included in JAR files by placing one or more [Markdown](#) formatted files in the root of the project JAR file. These files will be processed dynamically by MWS and presented as documentation pages for the respective plugin types within the MWS plugin user interface pages. Markdown is a simple text-to-HTML format used in some of the most popular open-source repositories such as [GitHub](#) and [BitBucket](#). To help provide plugin developers use a single place or file for documentation, the conventional use of "README.md" as documentation was followed within MWS.

### Documentation file naming

Each documentation filename must start with "README" and end with ".md". If only one documentation file is needed for bundled plugin type(s), it is recommended to call the file "README.md". For multiple plugin types, the file name must contain the plugin type name without the "Plugin" suffix in the format of "README-<PluginName>.md". For example, if a plugin project JAR file contained the plugin type classes "MyPlugin", "ABTestPlugin", and "ImportantPlugin", the documentation files would be located in the root of the JAR file and would be called "README-My.md", "README-ABTest.md", and "README-Important.md"

respectively. If a "README" file does not exist for a certain plugin type, the main "README.md" file (if provided) will be used as documentation for that plugin type.

### Markdown syntax

The Markdown syntax supported by MWS is very close to [GitHub Flavored Markdown](#). Internally, the [pegdown](#) Markdown processor is used to generate the HTML with the TABLES, ABBREVIATIONS, FENCED\_CODE\_BLOCKS, SMARTYPANTS, DEFINITIONS, and QUOTES extensions enabled. HTML tags may also be used directly in order to create more refined formatting of the documentation, but this is discouraged with the exception of inserting the configuration reference table discussed below.

For example, the TABLES extension may be used to easily create HTML tables:

```
Name | Notes
-----|-----
Bob   | Knows how to use MWS plugins but has never created one
George | Writes MWS plugins in his spare time
```

The only main difference from standard Markdown processors is that block quotes (marked by lines prepended with '> ') are shown as highlighted information boxes when displayed in MWS. This may be used to draw more attention to informational or warning messages without writing custom HTML.

```
> Warning: The use of this plugin type requires that MWS and MWM are configured
correctly as described in
> the MWS user guide.
```

### Configuration reference table

A table of available configuration parameters is often constructed in documentation for each plugin type. To ease the burden on the plugin developer of maintaining this documentation and the constraints on the plugin type, a table generated from the constraints (see [Configuration constraints on page 1686](#)) and included messages is available by using the following HTML in the README file(s):

```
<div class="configuration-table">This section will be replaced by MWS with the
configuration parameters table</div>
```

The text within the div container may be anything, but should state something helpful such as that it is placeholder in cases where the documentation may be viewed within other contexts such as on GitHub.

The generated table includes the following columns for each configuration parameter listed in the constraints: name, key, required, type, description. The "name" and "description" values are retrieved from the "help" and "label" messages bundled in the plugin JAR (see the labels and help messages section in [Configuration constraints on page 1686](#) for more information).

### Web services reference sections

Documentation for exposed web services (see [Exposing web services on page 1696](#)) is also able to be generated automatically. Instead of a single table as done with configuration parameters, a section with several tables (possible URL access points, URL parameters, and response fields) and additional information is generated for each exposed web service. This is available by using the following HTML in the README file(s):

```
<div class="webservice-sections">This section will be replaced by MWS with the web
service documentation</div>
```

The text within the `div` container may be anything, but should state something helpful such as that it is placeholder in cases where the documentation may be viewed within other contexts such as on GitHub.

### Changing heading sizes

The generated sections each begin with an `<h2>` heading with the name of the web service. If a different heading size (`h3`, `h4`, etc.) is desired, this may be done with the following HTML:

```
<div class="webservice-sections" data-level="3">This section will be replaced by MWS
with the web service documentation</div>
```

Notice the `data-level` attribute, which contains the number used in the HTML `h` tag.

### Message codes

Just as with the configuration table, the data for the content is generated automatically from the web service method name and from `i18n` messages (see [i18n messaging on page 1683](#)) bundled in the plugin JAR file. Message codes are available to customize the label and description of the web service. Codes are also available to define an arbitrary number of URL parameters and response fields. These do not need to be defined, but are helpful. The following table defines each message used in generating the documentation for web services.

Name	Message code	Description
<b>Web Service Label</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.label</code>	The label used as the heading for the section, defaults to the naturally capitalized method name if not present.
<b>Web Service Description</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.help</code>	Paragraph text describing the web service and its functionality, outputs, etc.
<b>Parameter Key</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.parameter&lt;n&gt;.key</code>	The <code>n</code> th URL parameter, starting at 1 (example: <code>id</code> ).
<b>Parameter Label</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.parameter&lt;n&gt;.label</code>	The label for the <code>n</code> th URL parameter, defaults to the naturally capitalized key if not present.

Name	Message code	Description
<b>Parameter Type</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.parameter&lt;n&gt;.type</code>	The type for the <i>n</i> th URL parameter, defaults to <i>String</i> if not present.
<b>Parameter Description</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.parameter&lt;n&gt;.help</code>	The description or help text for the <i>n</i> th URL parameter.
<b>Response Field Key</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.return&lt;n&gt;.key</code>	The <i>n</i> th response field, starting at 1 (example: <i>success</i> ).
<b>Response Field Label</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.return&lt;n&gt;.label</code>	The label for the <i>n</i> th response field, defaults to the naturally capitalized key if not present.
<b>Response Field Type</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.return&lt;n&gt;.type</code>	The type for the <i>n</i> th response field, defaults to <i>String</i> if not present.
<b>Response Field Description</b>	<code>&lt;pluginType&gt;.webServices.&lt;webServiceMethod&gt;.return&lt;n&gt;.help</code>	The description or help text for the <i>n</i> th response field.

As an example, suppose that a web service method called "doSomething" exists on a plugin type named "MyExamplePlugin". This web service expects two URL parameters: *id*, an integer, and *action*, a string. The response body consists of a JSON object with two fields: *success*, a boolean value, and *messages*, a list of strings. The following messages would serve to generate helpful documentation:

```

messages.properties
-----

# web service messages
myExamplePlugin.webServices.doSomething.label=Do Something Important
myExamplePlugin.webServices.doSomething.help=This web service does something important
with the input parameters.
# parameters
myExamplePlugin.webServices.doSomething.parameter1.key=id
myExamplePlugin.webServices.doSomething.parameter1.label=ID
myExamplePlugin.webServices.doSomething.parameter1.type=Integer
myExamplePlugin.webServices.doSomething.parameter1.help=The identifier of an object
myExamplePlugin.webServices.doSomething.parameter2.key=action
myExamplePlugin.webServices.doSomething.parameter2.label=Action # same as the default
would be
myExamplePlugin.webServices.doSomething.parameter2.type=String # same as the default
would be
myExamplePlugin.webServices.doSomething.parameter2.help=The action to perform

# response fields
myExamplePlugin.webServices.doSomething.return1.key=success
myExamplePlugin.webServices.doSomething.return1.label=Success # same as the default
would be
myExamplePlugin.webServices.doSomething.return1.type=Boolean
myExamplePlugin.webServices.doSomething.return1.help=True if the request succeeded,
false otherwise
myExamplePlugin.webServices.doSomething.return1.key=messages
myExamplePlugin.webServices.doSomething.return1.label=Error Messages
myExamplePlugin.webServices.doSomething.return1.type=List of Strings
myExamplePlugin.webServices.doSomething.return1.help=Error messages describing the
reason why success is false.

```

Note that if the *first* URL parameter key is `id`, the listed resource URLs will include the optional URL with the `id` parameter inline, such as `/rest/plugins/<pluginId>/services/<webService>/<id>`. Therefore, it is recommended to use `id` as parameter 1 if the web service expects a parameter with that key.

## Example plugin types

Several plugin types are provided by Adaptive Computing for use in Moab Web Services. Examples of these include the Native and vCenter plugin types.

A sample plugin type in Groovy would resemble the following:

```

package sample

import com.adaptc.mws.plugins.*

class SamplePlugin extends AbstractPlugin {
    static author = "Adaptive Computing"
    static description = "A simple plugin in groovy"
    static version = "0.1"

    INodeRMService nodeRMService

    public void configure() throws InvalidPluginConfigurationException {
        def myConfig = config // "config" is equivalent to getConfig() in groovy
        def errors = []
        if (!myConfig.arbitraryKey)
            errors << "Missing arbitraryKey!"
        if (errors)
            throw new InvalidPluginConfigurationException(errors)
    }

    public void poll() {
        NodeReport node = new NodeReport("node1")
        node.resources.RES1.total = 5
        node.resources.RES1.available = 5
        node.state = NodeReportState.IDLE
        nodeRMService.save([node])
    }

    // Access at /rest/plugins/<id>/services/example-service
    public def exampleService(Map params) {
        return [success:true]
    }
}

```

## Moab Workload Manager resource manager integration

Moab Workload Manager possesses the concept of Resource Managers (RMs). While plugins can be related to RMs, they often provide greater functionality and serve more purposes than a typical RM. MWS must be represented in Moab as a RM to enable certain plugin features such as state reporting and handling RM events. This section describes the process of configuring Moab and additional details of its queries to MWS. It includes the following topics:

- [Configuring Moab Workload Manager on page 1731](#)
- [Resource manager queries on page 1735](#)

### Related topics

- [About Moab Web Services plugins on page 1672](#)

## Configuring Moab Workload Manager

During each iteration of Moab Workload Manager's cycle, it will query MWS through the RM interface to access current node, virtual machine, and job information. At this point, all reports are loaded from the database and consolidated into a single report of each object as explained in [Data consolidation on page 1677](#).

**i** All unset (or null) values for properties on reports are ignored.

In some cases it may be desired to query MWS directly for the current consolidated node, storage, virtual machine, and job reports. This may be done using the following URLs which return data in a format that is a subset of the API version 3 interface for each object (i.e. `/rest/nodes?api-version=3`, `/rest/vms?api-version=3`, `/rest/jobs?api-version=3`).

Query	Description
<code>/rest/plugins/all/rm/cluster-query?api-version=3</code>	Retrieves consolidated node, storage, and virtual machine reports from all plugins.
<code>/rest/plugins/&lt;ID&gt;/rm/cluster-query?api-version=3</code>	Retrieves consolidated node, storage, and virtual machine reports for the specified plugin ID.
<code>/rest/plugins/all/rm/workload-query?api-version=3</code>	Retrieves consolidated job reports from all plugins.
<code>/rest/plugins/&lt;ID&gt;/rm/workload-query?api-version=3</code>	Retrieves consolidated job reports for the specified plugin ID.

These queries have no effect on the data itself. In other words, reports are not removed or manipulated when RM queries are performed. These are manipulated only the RM services as described in [Reporting state data on page 1698](#).

### Examples

The following example uses cURL (see [cURL samples on page 1771](#)) to perform the query.

```

$ curl -u moab-admin:changeme! http://localhost:8080/mws/rest/plugins/all/rm/cluster-
query?api-version=3&pretty=true

- [Moab Workload Manager resource manager integration on page 1730](#)
- [Resource manager queries on page 1735](#)

## Resource manager queries

Moab Workload Manager must be configured to use MWS as a resource manager. Do the following:

- First, the following lines must be in the Moab Workload Manager configuration file or one of its included files:

```

RMCFG [mws]                TYPE=MWS
RMCFG [mws]                FLAGS=UserSpaceIsSeparate
RMCFG [mws]                BASEURL=http://localhost:8080/mws

```

*The **BASEURL** must match the configured URL of MWS.*

- The next step is to edit the MWS credential information in the Moab private configuration file (/opt/moab/etc/moab-private.cfg, by default). Here are the default values:

```

CLIENTCFG [RM:mws] USERNAME=moab-admin PASSWORD=changeme!

```

**i** **USERNAME** and **PASSWORD** must match the values of `auth.defaultUser.username` and `auth.defaultUser.password`, respectively, found in the MWS configuration file. The MWS RM contacts MWS directly using the base URL, username, and password configured.

Optionally, the **USERNAME** and **PASSWORD** configuration values may be specified directly in the Moab configuration file, though this is not recommended. Likewise, the **BASEURL** configuration value can be specified in the Moab private configuration file.

- Lastly, to enable such actions as submitting jobs as different users, the **ENABLEPROXY=TRUE** option must be present in the **ADMINCFG** configuration line, and the **OSCREDLLOOKUP** option must be set to **NEVER**, as follows:

```
ADMINCFG [1]           USERS=root           ENABLEPROXY=TRUE
OSCREDLLOOKUP        NEVER
```

- You may also want to configure SSL by using the following options (in either the **RMCFG** or **CLIENTCFG** section):
  - **SSLCACERT**: Lets you specify the absolute path to your SSL CA certificate. (This also enables the use of self-signed certificates, if desired.) It is recommended that you set this option in the Moab private configuration file. For example:

```
CLIENTCFG [RM:mws]   SSLCACERT=/path/to/cert.pem
```

- **SSLNOHOSTCHECK**: Lets you disable the SSL check to make sure that the actual server name matches the certificate's server name. For example:

```
#In moab-private.cfg
CLIENTCFG [RM:mws]   SSLNOHOSTCHECK=TRUE

#Or in moab.cfg
RMCFG [mws]         SSLNOHOSTCHECK=TRUE
```

 **WARNING:** This setting could compromise the security of the system and should not be used in production environments.

- **SSLNOPEERCHECK**: Lets you disable the SSL check to make sure that the certificate is valid.

```
#In moab-private.cfg
CLIENTCFG [RM:mws]   SSLNOPEERCHECK=TRUE

#Or in moab.cfg
RMCFG [mws]         SSLNOPEERCHECK=TRUE
```

 **WARNING:** This setting could compromise the security of the system and should not be used in production environments.

## Plugin type management

Plugin types may be managed and accessed with Moab Web Services dynamically, even while running. Operations are provided to upload (add or update) plugin types and to list or show current plugin types. The available fields that are displayed with plugin types are given in [Fields: Plugin Types on page 2204](#). For more information on how these fields are set, see [Plugin projects and metadata on page 1721](#).

Plugin Type JAR or groovy files should never be manually copied into the `MWS_HOME/plugins` directory. They must be managed using the methods shown in this section or through the REST API (see [Plugin types on page 1607](#)).

Bundled plugin types are included automatically in Moab Web Services releases and may be utilized immediately after startup. See [Plugin management on page 1742](#) for more information on how to utilize these plugin types.

The plugin type documentation is now located in the plugin type management pages. See [Plugin type documentation on page 1738](#) for more information.

This section contains these topics:

- [Listing plugin types on page 1737](#)
- [Displaying plugin types on page 1738](#)

## Displaying plugin types

To show information about a plugin type, go to the **Plugin Type List** page and click the desired plugin type.

The screenshot shows the 'Show Plugin Type' interface for a 'Native' plugin. It includes a globe icon and the title 'Show Plugin Type'. The main content area lists various attributes: ID (Native), Title (Native), Description (Basic implementation of a native plugin), Author (Adaptive Computing Enterprises, Inc.), Email (mws.plugins@adaptivecomputing.com), License (APACHE), Version (0.2), MWS Version (7.1 > \*), Issues, Documentation, Sources, Has Poll Method (Yes), and Web Services (Name). Below the Web Services section, a message states 'There are no entries at this time'. The 'Default Configuration' section contains a table with columns for ID, Poll Interval, and Auto Start, showing a single entry for 'cloud-native' with a poll interval of 30. The 'Plugins' section contains a table with columns for ID and State, showing a single entry for 'cloud-native' with a state of 'Started'. At the bottom, there are two buttons: 'Add Plugin' and 'Plugin Type List'.

## Plugin type documentation

To show the documentation for a plugin type, go to the **Plugin Type List** page and click the desired plugin type. Then, click the **Open Documentation** button. This will display any documentation bundled with the plugin type.

Related topics

- [Plugin type management on page 1737](#)

## Add or update plugin types

Plugin types can be uploaded into Moab Web Services using a Groovy file, a Java Archive ([JAR](#)) file, or pasted Groovy code. To access the plugin type upload page, navigate to the **Plugin Type List** page and click **Add or Update Plugin Type**. The default interface of this page enables the uploading of a single Groovy class file or a JAR file.

When a plugin type is updated, by default all corresponding plugins created from the plugin type will be recreated. If this behavior is not desired, clear the **Do you want to reload all plugins to use this new version?** checkbox before uploading the plugin type.

### [Single class file](#)

Groovy files containing a single plugin type may be uploaded at the `/mws/admin/plugin-types/create` URL.

**Create Plugin Type**

Do you want to reload all plugins to use this new version?

+ Add files... Start upload Cancel upload Clear files

Cancel

Type or Paste Code

If the upload failed or an error occurred during initialization of the plugin, an error message will be displayed.

**Create Plugin Type**

Plugin Type with ID 'NotAValidClass' is an invalid plugin: Class name does not end with Plugin

Do you want to reload all plugins to use this new version?

+ Add files... Start upload Cancel upload Clear files

sample.groovy	0.04 KB	<div style="width: 100%; height: 10px; background-color: orange;"></div>	<input type="button" value="Cancel"/>
---------------	---------	--------------------------------------------------------------------------	---------------------------------------

Cancel

Type or Paste Code

### [JAR file](#)

A JAR file, as described in [Packaging plugins on page 1720](#), containing one or more plugins may also be uploaded using the same process as the Groovy file.

Click **Add files...**, select the `.jar` file, and click the **Start upload** button. If the upload failed or an error occurred during initialization of the plugin(s), an error message will be displayed.

The JAR upload process differs from the single file in that if successful, the name of the JAR file itself is displayed instead of the plugin name(s).

### Create Plugin Type

Do you want to reload all plugins to use this new version?

+ Add files...			Start upload	Cancel upload	Clear files
samples.jar	28.16 KB				

Cancel

Type or Paste Code

### Code

To paste or type code directly into MWS and have it be loaded as a single class file, click **Type or Paste Code**, and type or paste the code into the presented text box.

## Create Plugin Type

Upload File(s)

Do you want to reload all plugins to use this new version?

## Create Plugin Type

Upload File(s)

Do you want to reload all plugins to use this new version?

Code

```
package sample.polling;

import com.ace.mws.plugins.*

public class PollingPlugin extends AbstractPlugin {
    static final title = "Polling Sample"
    public void poll() {
```

Save

Cancel

When the code is in the box, click **Create**. If the upload succeeded and the code was able to be compiled as Groovy, the browser will be redirected to the **Show Plugin Type** page. If the upload failed or an error occurred during compilation or initialization of the plugin, an error message will be displayed.

You may need to refer to the MWS [log](#) file for additional details and error messages in the case of a failure.

## Monitoring and lifecycle controls

To monitor and control the lifecycle of plugins, browse to the MWS home page (for example, <https://servername/mws>). Log in as the admin user, then click **Plugins > Plugin Monitoring**. This page displays the current state of all plugins as well as their polling status.

### Plugin Monitoring

This page monitors the status of all plugins in Moab Web Services.

Tuesday, June 12, 2012

11:28:11 AM

Reload when poll occurs

#### Active Plugins

ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:08	00:00:21	  
no-polling	Logging			 

#### Disabled Plugins

ID	Plugin Type	State	Actions
There are no Disabled Plugins set up at this time			

**i** If plugins are created from plugin types which do not have a `poll` method, their lifecycle controls will be limited. Any information below which mentions polling does not apply to the 'no-polling' plugin shown in the screenshots.

Active plugins

Active plugins are those which are in the Started or Paused states. These are available to receive events such as polling. If paused, a plugin will not receive events but is not actually stopped, therefore no stop events are triggered.

The following images demonstrate the status of plugins in the active states.

**Active Plugins**

ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:08	00:00:21	⏹️ ⏸️ ▶️
no-polling	Logging			⏹️ ⏸️

Started plugins which can include the relative time of the last poll as well as the time of the next poll in a countdown format. Action buttons are available to stop or pause the plugin as well as trigger an immediate poll event.

**Active Plugins**

ID	Plugin Type	Last Poll	Next Poll	Actions
cloud-native	Native	00:00:26		⏹️ ▶️ ▶️
no-polling	Logging			⏹️ ▶️

Paused plugins which can include only the last polling time. Action buttons are available to stop or resume the plugin, as well as trigger an immediate poll event.

Disabled plugins

Disabled plugins are those which are in the Stopped or Errored states. These plugins do not receive events such as polling. If errored, a plugin may either be stopped, which represents a "clearing" of the error, or started normally. However, if no action is taken on an errored plugin, it likely will not start due to the fact that most plugins are put into the errored state during startup of the plugin.

The following images demonstrate the representation of plugins in the disabled states.

**Disabled Plugins**

ID	Plugin Type	State	Actions
no-polling	Logging	Stopped	▶️

Stopped plugins. A single action button is available to attempt to start the plugin.

Disabled Plugins			
ID	Plugin Type	State	Actions
with-error	Logging	Errored	 

An errored plugin. As mentioned previously, action buttons are available to stop the plugin or clear the error as well as attempt to start the plugin. If the start fails, an error message will be displayed.

- [Plugin management on page 1742](#)

## Setting default plugin configuration

Configuration of default values for plugin configuration parameters involves setting fields in the MWS configuration file. These values are used if no values are provided when creating a new plugin. Additionally, the default values will be displayed to the user on the **Create Plugin** page.

The parameters to configure are documented on [Configuration on page 1772](#) and comprise most values starting with plugins.

Related topics

- [Plugin management on page 1742](#)

## Plugin services

To use the built-in services, declare a variable with the correct name as a property in the plugin class.

The convention for each service name is to remove the leading "I" and lower case the resulting first letter. For example, the property to use the `IMoabRestService` would be called `moabRestService`. The following is an example of using the `IPluginControlService` in this manner.

```
Using the IPluginControlService
-----
package example;
import com.adaptc.mws.plugins.*;

class ExamplePlugin {
    IPluginControlService pluginControlService;

    public poll() {
        // Use service...
        pluginControlService.stop("pluginId");
    }
}
```

**i** Use of the Groovy anonymous type "def" may also be used. For example, the service definition above would use `def pluginControlService` instead of `IPluginControlService pluginControlService`.

**⚠** Do *not* attempt to create a new instance of the services before use, such as in a constructor. The services will be automatically injected before any methods are called on the plugin.

#### API documentation

The `com.adaptc.mws.plugins` package contains interfaces for all bundled services available to plugin types. These may be used as discussed above. All services begin with "I" and end with "Service", as in [IMoabRestService](#) ([Moab REST service on page 1748](#)).

#### Related topics

- [About Moab Web Services plugins on page 1672](#)

## Job RM service

The job RM service may be used to report job state data to Moab Workload Manager through the RM interface. See [Reporting state data on page 1698](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation (see [Data consolidation on page 1677](#)), old job reports may no longer exist in the database by the time the query is done.

The `jobRMService` property will be injected with a class of type [IJobRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

#### Related topics

- [Plugin services on page 1747](#)

## Moab REST service

The Moab REST service may be used to access the MWS RESTful API (see [Resources introduction on page 1446](#)) in plugins. All "requests" made through this service are internal only and no data is actually transmitted over the network. See [Accessing MWS REST resources on page 1702](#) for more information.

The `moabRestService` property will be injected with a class of type [IMoabRestService](#) in all plugin types.

#### Accessing resources

In order to access a resource, a relative URL matching that in the documentation must be used along with a HTTP method, such as GET, POST, PUT, or DELETE. The method names on [IMoabRestService](#) match the HTTP methods directly. For example, to call a GET operation on `/rest/jobs`, use the following code:

```
moabRestService.get("/rest/jobs")
```

### Using parameters correctly

Although the ordering of the parameters for each method on `IMoabRestService` may seem confusing at first glance, this is to allow for easy use with Groovy. Examples are given below for each combination of parameters:

```
String URL
-----
moabRestService.get("/rest/jobs")
```

```
Map options, String URL
-----
moabRestService.get("/rest/jobs", hooks:true, contentType:"application/json")
```

```
String URL, Closure data
-----
moabRestService.get("/rest/jobs/job.1") {
    [flags:"RESTARTABLE"]
}
```

```
Map options, String URL, Closure data
-----
moabRestService.get("/rest/jobs/job.1", hooks:true, contentType:"application/json") {
    [flags:"RESTARTABLE"]
}
```

### Options

The following options are valid in each method call supporting the `options` parameter:

Name	Type	Default	Description
<code>data</code>	See <a href="#">Valid data types on page 1750</a>	--	Specifies the body of the "request." This can be overwritten by the <code>data</code> Closure parameter.
<code>hooks</code>	Boolean	false	Specifies whether or not hooks (see <a href="#">Pre and post-processing hooks on page 1434</a> ) are run as part of the "request."
<code>contentType</code>	String	application/json	Indicates the content type used for the request.
<code>params</code>	Map	--	Indicates URL query parameters to use for the "request," such as <code>query</code> , <code>sort</code> , <code>proxy-user</code> , or others.

### Valid data types

If the `data Closure` parameter is specified, it overwrites the `data` option. In each case, there are four valid types for the `data` option or return value of the `data closure`:

- A non-null [JSON](#) instance.
- A valid JSON string. This will be converted into a [JSON](#) instance.
- A valid Map instance. This will be converted into a [JSONObject](#) instance.
- A valid List instance. This will be converted into a [JSONArray](#) instance.

 A [JSONException](#) may be thrown if the JSON string is invalid or the Map or List contains values that cannot be serialized to JSON.

### Related topics

- [Plugin services on page 1747](#)

## Node RM service

The node RM service may be used to report node state data to Moab Workload Manager through the RM interface. See [Reporting state data on page 1698](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation (see [Data consolidation on page 1677](#)), old node reports may no longer exist in the database by the time the query is done.

The `nodeRMService` property will be injected with a class of type [INodeRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

### Related topics

- [Plugin services on page 1747](#)

## Plugin control service

 This service is currently in Beta. Interfaces may change significantly in future releases.

The control service allows lifecycle management operations to be performed on plugins. It also provides methods to create and retrieve plugins. Note that the plugin control service may be used by other plugins, allowing one plugin to dynamically create, retrieve, start, or stop plugins.

The `pluginControlService` property will be injected with a class of type [IPluginControlService](#) in all plugin types.

Examples

Create plugin with default configuration

---

```
try {
    if (pluginControlService.createPlugin("myPlugin", "Native"))
        log.info "myPlugin was created successfully!"
    else
        log.warn "There was an error creating myPlugin"
} catch(PluginStartException e) {
    log.warn "There was a problem starting the new plugin: ${e.message}"
} catch(InvalidPluginConfigurationException e) {
    log.warn "There were errors with the plugin's configuration: ${e.errors}"
}
```

Create plugin with custom configuration

---

```
if (pluginControlService.createPlugin("myPlugin", "Native", [autoStart:false,
pollInterval:600]))
    log.info "myPlugin was created successfully!"
else
    log.warn "There was an error creating myPlugin"
```

Start plugin

---

```
try {
    pluginControlService.start("myPlugin")
} catch(PluginStartException e) {
    log.warn "There was a problem starting the plugin: ${e.message}"
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
} catch(InvalidPluginConfigurationException e) {
    log.warn "The plugin has an invalid configuration: ${e.errors}"
}
```

Stop plugin

---

```
try {
    pluginControlService.stop("myPlugin")
} catch(PluginStopException e) {
    log.warn "There was a problem stopping the plugin: ${e.message}"
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
}
```

Configure plugin

---

```
try {
    pluginControlService.configure("myPlugin")
} catch(InvalidPluginException) {
    log.warn "The plugin 'myPlugin' is invalid"
} catch(InvalidPluginConfigurationException e) {
    log.warn "The plugin has an invalid configuration: ${e.errors}"
}
```

## Related topics

- [Plugin services on page 1747](#)

## Plugin datastore service

The datastore service is provided to allow a plugin to persist data to the database that is isolated from all other persistent data. In other words, this service provides access to a plugin's individual datastore (see [Individual datastore on page 1694](#)).

The `pluginDatastoreService` property will be injected with a class of type [IPluginDatastoreService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

### Examples

Adding a single custom entry

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = [:]
        ... // Add data here to the Map
        if (pluginDatastoreService.addData(collectionName, data))
            log.info("Data successfully added")
        else
            log.warn("There was an error adding the data")
    }
}
```

Adding multiple entries

```
package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def dataList = []
        dataList.add( /* Custom Map of data here */
        dataList << ... // Custom Map of data here
        if (pluginDatastoreService.addData(collectionName, dataList))
            log.info("Data entries successfully added")
        else
            log.warn("There was an error adding the data entries")
    }
}
```

## Updating a single entry

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = [:]
        ... // Add data here to the Map
        if (pluginDatastoreService.updateData(collectionName, "key", "value", data))
            log.info("Data successfully updated")
        else
            log.warn("There was an error updating the data")
    }
}

```

## Querying if a collection exists

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        if (pluginDatastoreService.exists(collectionName))
            log.info("Collection exists")
        else
            log.warn("The collection does not exist")
    }
}

```

## Querying contents of a collection

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def dataList = pluginDatastoreService.getCollection(collectionName)
        if (dataList!=null)
            log.info("Collection successfully queried")
        else
            log.warn("The collection does not exist!")
    }
}

```

## Retrieving a single entry

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = pluginDatastoreService.getData(collectionName, "key", "value")
        if (data!=null)
            log.info("Data successfully retrieved")
        else
            log.warn("The entry with key==value does not exist")
    }
}

```

## Removing a collection

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        def data = pluginDatastoreService.clearCollection(collectionName)
        // Data now contains the collection that was cleared
        if (data!=null)
            log.info("Collection successfully cleared")
        else
            log.warn("The collection does not exist!")
    }
}

```

## Removing a single entry

```

package example

public class ExamplePlugin {
    def pluginDatastoreService

    public void poll() {
        def collectionName = "collection1"
        if (pluginDatastoreService.removeData(collectionName, "key", "value"))
            log.info("Data entry successfully removed")
        else
            log.warn("The entry where key==value does not exist!")
    }
}

```

## Plugin event service

The event service is provided to ease the burden and reduce boilerplate code for creating new events and updating notification conditions. For more information on how to use this service, see [Creating events and notifications on page 1704](#).

The `pluginEventService` property will be injected with a class of type [IPluginEventService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

### Examples

#### Creating a custom event

```
package example

import com.adaptc.mws.plugins.IPluginEventService.Severity
import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Create a completely custom event
        pluginEventService.createEvent(Severity.INFO, EscalationLevel.USER, 0x4F, "Custom
Type",
                                     "poll", "My event occurred", null, null)
    }
}
```

#### Creating a custom event with messages

```
package example

import com.adaptc.mws.plugins.IPluginEventService.Severity
import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Use i18n messages for another event
        def args = ["arg1", "arg2"]
        pluginEventService.createEvent(Severity.WARN, EscalationLevel.POWER_USER, 0x5F,
"Custom Type",
                                     "poll", message
(code:"examplePlugin.customEvent.message", args:args), args,
                                     // AssociatedObjects or simple maps may be
used
                                     [new AssociatedObject(type:"type1", id:"id1"),
                                     [type:"type2", id:"id2"]])
    }
}
```

Creating an event from EventEnumeration

```

package example

import com.adaptc.mws.plugins.EventEnumeration
import com.adaptc.mws.plugins.IPluginEventService.Severity
import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        // Messages are pulled for messages.properties file(s) and the arguments are used
        def args = ["arg1", "arg2"]
        pluginEventService.createEvent(MyEvents.EVENT_INFO, args, [[type:"type1", id:"id1]])
        pluginEventService.createEvent(MyEvents.EVENT_WARN, args, [[type:"type2", id:"id2]])
    }
}

@EventEnumeration
enum MyEvents {
    EVENT_INFO("Information", INFO, USER),
    EVENT_ERROR("Warning", WARN, USER)

    static final String EVENT_TYPE_PREFIX = "Example Plugin"
    static final String ORIGIN_SUFFIX = "poll"
}

```

Create or update a notification

```

package example

import com.adaptc.mws.plugins.IPluginEventService.EscalationLevel
import com.adaptc.mws.plugins.IPluginEventService.AssociatedObject

public class ExamplePlugin {
    def pluginEventService

    public void poll() {
        pluginEventService.updateNotification(EscalationLevel.POWER_USER, "There is an error
with node1",
// If non-null, this must always be an associated object, never null
new AssociatedObject(id:"node1", type:"node"), null)
    }
}

```

## SSL service

The SSL service may be used to manage and load certificates or keys from disk and create socket connections. See [Managing SSL connections on page 1714](#) for more information.

The `sslService` property will be injected with a class of type [ISslService](#) in all plugin types.

## Storage RM service

The storage RM service may be used to report storage state data to Moab Workload Manager through the RM interface. See [Reporting state data on page 1698](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation (see [Data consolidation on page 1677](#)), old storage reports may no longer exist in the database by the time the query is done.

The `storageRMService` property will be injected with a class of type [IStorageRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

## Virtual machine RM service

The virtual machine RM service may be used to report virtual machine state data to Moab Workload Manager through the RM interface. See [Reporting state data on page 1698](#) for more information. It may also be used to retrieve previous reports made by a plugin. Please note that due to data consolidation [Data consolidation on page 1677](#), old virtual machine reports may no longer exist in the database by the time the query is done.

The `virtualMachineRMService` property will be injected with a class of type [IVirtualMachineRMService](#) in all plugin types. Note that it is not available for injection in translators or custom components.

# Plugin types

## Power Management Plugin

The Power Management plugin is used as a resource manager to Moab to report and manipulate the power state (On or Off) for each node. Moab considers nodes in the power state On or Off; however, through TORQUE and scripts, we are able to separate the Off state into those controlled through the operating system (Standby, Suspend, Hibernate, Shutdown) and those controlled through hardware (Off). This plugin provides an easy way to integrate with Moab to translate Moab's Off action into the desired TORQUE or script action for each node. A cluster will have multiple instances of this plugin when it has varied hardware integration and/or credentials.

### Creating a Power Management Plugin

To create a Power Management plugin, see [Creating a plugin on page 1742](#). During plugin creation, refer to the [Configuration on page 1758](#) section.

## Configuration

### Configuration Parameters

Name	Key	Required	Type	Description
Node Configuration File	nodeConfigurationFile	Yes	String	File containing list of nodes that use the scripts and credentials in this plugin instance. This is also the file to configure a particular node's off state, or an off state that will override the default off state for this instance.
Username File	usernameFile	Yes	String	File containing username issued to the scripts with the -u option.
Password File	passwordFile	Yes	String	File containing password issued to the scripts with the -p option.
Node Power Script	nodePowerScript	Yes	String	Script that powers on and off nodes and wakes them from a low power state.
Node Query Script	nodeQueryScript	Yes	String	Script that queries power state using an intelligent platform management interface.

Name	Key	Required	Type	Description
Default Power Off State	defaultPowerOffState	Yes	String	Actual state (Standby, Suspend, Hibernate, Shutdown, or Off) nodes will go into when Moab powers them off.
Max Threads	maxThreads	Yes	Integer	Thread count issued to the scripts with the -t option (defaults to 4).

## Plugin Management

For information on managing the IPMI plugin, including stopping it, starting it, and checking on its status, see the [Plugin management on page 1742](#) section of the MWS Guide.

## Web Services

### Node Power (Secured)

#### Resource URLs

Resource
/rest/plugins/<pluginId>/services/nodePower
/rest/plugins/<pluginId>/services/node-power

#### URL Parameters

Parameter	Name	Type	Description
nodes	Moab Nodes	String	A comma-delimited list of Moab node names. It is required.
power	The Power State	String	The power command Moab issues the node (On or Off).

#### Response Fields

Field	Name	Type	Description
success	Success Indicator	Boolean	True if the power script and/or <a href="#">pbsnodes on page 2705</a> was successful, otherwise false.

Field	Name	Type	Description
messages	Messages	List of Strings	Only present when the request was not successful or the node was not configured with the plugin instance. Contains error messages describing why the pbsnodes or the power script failed.

*Additional Information*

This web service was intended for Moab's use only and is exposed for debugging and testing your customized scripts.

## Reload Node Configuration (Secured)

*Resource URLs*

Resource
<code>/rest/plugins/&lt;pluginId&gt;/services/reloadNodeConfiguration</code>
<code>/rest/plugins/&lt;pluginId&gt;/services/reload-node-configuration</code>

*URL Parameters*

Parameter	Name	Type	Description
No URL parameters required			

*Response Fields*

Field	Name	Type	Description
success	Success Indicator	Boolean	True if the reload succeeded, otherwise false.
messages	Messages	List of Strings	Only present when the request failed. Contains error messages describing why the reload failed.

*Additional Information*

 The reloadNodeConfiguration web service must be run after any change to the node configuration file for it to take effect.

## Node Configuration File

The node configuration file is used when the plugin is first instantiated or the `reloadNodeConfiguration` web service is called. The plugin expects a file that is readable by the `tomcat` user and has a Moab node name on each line. If the user would like to override the default power-off state of the node, then the node name is followed by a space and the state. For example, a node configuration file might look like this:

```
node01.ac
node02.ac
node03.ac Hibernate
node04.ac Suspend
```

The valid power-off states include Standby, Suspend, Hibernate, Shutdown, and Off. If no power-off state is provided for the node in the configuration file, then the default power-off state will be used.

## The Node Power and Query Script

The plugin uses the power script to power on nodes from all power states and to power off nodes only into the Off power state. The plugin uses the power state of the node to decide whether to power on the node with `wake` or `on`. If the node is in Standby or Suspend, the plugin will call the script with the `wake` parameter. If the node is in Hibernate, Shutdown, or Off, the plugin will call the script with the `on` parameter. The plugin calls the power node script with the `off` parameter to put the node in the Off state (it uses TORQUE to put the node in the Standby, Suspend, Hibernate, and Shutdown state).

The plugin uses the query script to know if a node is in the Off power state. If the query script reports the node as Off, the plugin will report the node as Off to Moab. If the query script reports the node as On, the plugin will look to TORQUE to make sure the node is in a Running power state before it reports it as On.

The plugin passes the `usernameFile`, `passwordFile`, and `maxThreads` configuration parameters down to the scripts. The node power script is called with this syntax:

```
<nodePowerScript> -u <usernameFile> -p <passwordFile> -t <maxThreads> node01 node02
node03 ... <on|off|wake>
```

The node query script is called with this syntax:

```
<nodeQueryScript> -u <usernameFile> -p <passwordFile> -t <maxThreads> node01 node02
node03 ...
```

The plugin expects the scripts to print JSON to standard out. An example query script output would look like this:

```
[
  {
    "name": "node01.ac",
    "power": "ON",
    "Processor_2_Temp": 61,
    "Processor_1_Temp": 54
  },
  ...
]
```

Notice it is a list of nodes where each node has the required fields `name` and `power`. All the other key-value pairs will be reported to Moab as a generic resource as long as the value is a number.

The output for the node power plugin is not required; however, the output is read to give the user a detailed error message if needed. For both the node power and query scripts, if the field `error` exists, the plugin will log an error with all the strings in the list. An example error returned to the plugin would look like this:

```
[
  {
    "command": "ipmitool -I lan -H node01i -U admin -f /opt/moab/etc/power-
management/abc-plugin-password-file sdr type temperature",
    "name": "node01.ac",
    "error": [
      "big error"
    ]
  }
  ...
]
```

## Troubleshooting

The Power Management plugin logs all errors and warnings to the MWS log file, which is `/opt/mws/log/mws.log` by default. The `stacktrace.log` file, in the same directory as `mws.log`, can also be helpful in diagnosing problems. If your MWS supports notifications, they are also helpful in diagnosing the error states the plugin is in, if any. Just check for notifications from the `PowerManagement` plugin type and the instance that you are interested in. When the issue has been resolved, you can dismiss the notification. For more information, see the Notification and Notification Condition Resource in the MWS documentation.

### Set the appropriate MWS RM precedence

The Create/Edit Plugin pages give the option to set the precedence of the Moab RM plugin. The purpose of the Power Management Plugin is to report node power; however, if the precedence is too low another Moab RM plugin with a higher precedence and conflicting node might overwrite the node power. To check what MWS is reporting to Moab, go to the URL:

```
http://<MWS host>:8080/mws/rest/plugins/all/rm/cluster-query[?api-version=3]
```

To check what your plugin instance is reporting to Moab, use the URL:

```
http://<MWS host>:8080/mws/rest/plugins/<instance-name>/rm/cluster-query[?api-
version=3]
```

If the power is reported in your instance but not to Moab, please increase the precedence of the Moab RM plugin.

### Configure the MWS RM in Moab

First, the following lines must be in the Moab Workload Manager configuration file or one of its included files:

```

RMCFG [mws]          TYPE=MWS
RMCFG [mws]          FLAGS=UserSpaceIsSeparate
RMCFG [mws]          BASEURL=http://<mws host>:8080/mws

```

Next, edit the MWS credential information in the Moab private configuration file (`/opt/moab/etc/moab-private.cfg`, by default). Here are the default values:

```

CLIENTCFG [RM:mws]  USERNAME=moab-admin  PASSWORD=changeme!

```

For more information see the Resource manager queries section in the MWS documentation.

## Configure TORQUE with tomcat administrator

The plugin assumes that TORQUE is installed on the same host as MWS and that tomcat is an administrator. This can be verified with [qmgr on page 2726](#). Run the command:

```

qmgr -c 's s managers += tomcat@<mws_host>'

```

For more information see the Specifying non-root administrators section of the TORQUE documentation.

## Make sure the Node and Power scripts work first.

The default scripts are included in `/opt/moab/tools/mws/power_management` and have their own documentation with the `-h` option. They need to have a file that maps each node in the Moab cluster to the IPMI address that the script will need to call using `ipmitool`. It also needs a file that includes the IPMI password. After that is provided and `ipmitool` is installed and working, the scripts will successfully implement the interface needed for this plugin.

# References

## Client code samples

The code samples contained in this section of the reference material are provided to help quick start integration with MWS. They are provided as a convenience and not as fully developed APIs.

All examples use the default configuration of MWS, including the default username and password, and assume that MWS is deployed at `http://localhost:8080/mws`.

This section contains these topics:

- [Javascript code samples on page 1764](#)
- [PHP code samples on page 1765](#)

- [Perl code samples on page 1769](#)
- [Python code examples on page 1771](#)
- [cURL samples on page 1771](#)

#### Related topics

## Javascript code samples

When utilizing Javascript to interact with MWS, it is recommended to use libraries that provide a simple browser-independent syntax for performing REST calls. It must also be noted that it is not recommended to make calls to MWS directly from client-side Javascript, as this will contain the username and password for MWS and could potentially be retrieved and utilized by a malicious user.

Examples for specific libraries are given below.

## jQuery

The jQuery `ajax` function makes it extremely simple to perform all REST calls. There are also some shorthand methods which utilize the `ajax` method in a simple manner—such as `getJSON` and `post`—but these do not have the ability to specify authentication parameters, which is why they are not used below.

**i** In all examples given, it is assumed that the `$` variable is mapped to `jQuery`, which is the default configuration of jQuery.

### GET

```
$.ajax({
  url: "http://localhost:8080/mws/rest/jobs",
  dataType: 'json',
  username: 'admin',
  password: 'secret',
  success: new function(data) {
    $('<div class="result">').html(data);
    alert("GET was successful");
  }
});
```

## POST

```
$.ajax({
  url: "http://localhost:8080/mws/rest/jobs",
  data: {
    "commandFile":"/tmp/test.sh",
    "initialWorkingDirectory":"/tmp",
    "user":"adaptive",
    "requirements":[{"requiredNodeCountMinimum":1}]
  }
  dataType: 'json',
  username: 'admin',
  password: 'secret',
  success: new function(data) {
    $('<div class="result">').html(data);
    alert("GET was successful");
  }
});
```

## PUT

```
$.ajax({
  type: 'PUT',
  url: 'http://localhost:8080/mws/rest/jobs/Moab.1',
  data: {"holds":["user"]},
  dataType: "json",
  username: 'admin',
  password: 'secret',
  success: function(data) {
    $('<div class="result">').html(data);
    alert("PUT was successful");
  }
});
```

## DELETE

```
$.ajax({
  type: 'DELETE',
  url: 'http://localhost:8080/mws/rest/jobs/Moab.1',
  username: 'admin',
  password: 'secret',
  success: function(data) {
    $('<div class="result">').html(data);
    alert("DELETE was successful");
  }
});
```

## PHP code samples

All of these examples make use of the [cURL PHP Extension](#). While this library is easy to use for GET and POST requests, it is somewhat more difficult to use for PUT and DELETE requests. Each will be covered in this topic.

**i** Notice the use of the [JSON PHP Extension](#)'s `json_decode` and `json_encode` functions.

## GET

```
<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs";
$username = "admin";
$password = "secret";
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}
?>
```

POST

```
<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "commandFile"=>"/tmp/test.sh",
    "initialWorkingDirectory"=>"/tmp",
    "user"=>"adaptive",
    "requirements"=>array(
        array("requiredNodeCountMinimum"=>1)
    )
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup POST request
curl_setopt($ch, CURLOPT_POSTFIELDS, json_encode($requestPayload));
curl_setopt($ch, CURLOPT_POST, 1);

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}
?>
```

PUT

```

<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs/Moab.1";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "holds"=>array("user")
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup PUT request
curl_setopt($ch, CURLOPT_POSTFIELDS, json_encode($requestPayload));
curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "PUT");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {
    print_r($responseInfo);
    echo $responseBody;
} else {
    print_r(json_decode($responseBody));
}

```

DELETE

```

<?php
$baseUrl = "http://localhost:8080/mws/rest";
$resource = "/jobs/Moab.1";
$username = "admin";
$password = "secret";
$requestPayload = array(
    "holds"=>array("user")
);
$ch = curl_init();
curl_setopt($ch, CURLOPT_HTTPAUTH, CURLAUTH_BASIC);
curl_setopt($ch, CURLOPT_TIMEOUT, 10);
curl_setopt($ch, CURLOPT_RETURNTRANSFER, true);
curl_setopt($ch, CURLOPT_HTTPHEADER, array("Content-Type: application/json"));
curl_setopt($ch, CURLOPT_USERPWD, "$username:$password");
curl_setopt($ch, CURLOPT_URL, "$baseUrl$resource");
// Setup DELETE request
curl_setopt($ch, CURLOPT_CUSTOMREQUEST, "DELETE");

$responseBody = curl_exec($ch);
$responseInfo = curl_getinfo($ch);
curl_close($ch);

if ($responseInfo["http_code"]!=200 && $responseInfo["http_code"]!=201) {

## Perl code samples

These examples all utilize the `LWP::UserAgent` module, which must be installed before running them.

### GET

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(GET => 'http://localhost:8080/mws/rest/images');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

### POST

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(POST => 'http://localhost:8080/mws/rest/images');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");
$req->content('
{"profile":"compute","osVersion":"5","name":"centos5stateless","hypervisor":0,"architecture":"x86_64","osName":"centos","osType":"linux","type":"stateless"}');

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
```

PUT

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(PUT => 'http://localhost:8080/mws/rest/images/centos5-
stateless');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");
$req->content('{"osVersion":"5.5"}');

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
}
```

DELETE

```
#!/usr/bin/perl -w
use strict;
use warnings;
# Create a user agent object
use LWP::UserAgent;
my $ua = LWP::UserAgent->new;
$ua->agent("MyApp/0.1");

# Create a request
my $req = HTTP::Request->new(DELETE => 'http://localhost:8080/mws/rest/images/centos5-
stateless');
$req->content_type('application/json');
$req->authorization_basic("admin", "secret");

# Pass request to the user agent and get a response back
my $res = $ua->request($req);

# Check the outcome of the response
if ($res->is_success) {
    print $res->content;
} else {
    print $res->status_line, "n";
}
}
```

## Python code examples

Notice the use of the `json` module to build a Python object from the return JSON data. If you want, you can also use `json.dumps` to create a JSON string from a Python object.

### Simple request (GET)

```
import urllib
import base64
import string
import json
def get(base, port, url):
    conn = urllib.HTTPConnection(base, port, timeout=60)
    conn.request('GET', url, None, { 'Authorization' : 'Basic '+string.strip
(base64.encodestring('admin:secret'))})
    return conn.getresponse().read()

data = get("localhost", 8080, "/mws/rest/jobs?format=json")
print json.loads(data)
```

### Complex request (POST)

```
import urllib
import base64
import string
import json
def post(base, port, url, payload):
    conn = urllib.HTTPConnection(base, port, timeout=60)
    conn.request('POST', url, payload, { 'Authorization' : 'Basic '+string.strip
(base64.encodestring('admin:secret')), 'Content-Type' : 'application/json' })
    r = conn.getresponse()
    return r.read()

# Note that json.dumps may also be used to create the json string from a python object
data = post("localhost", 8080, "/mws/rest/jobs", '
{"commandFile":"/tmp/test.sh","initialWorkingDirectory":"/tmp","user":"adaptive","requirements":[{"requiredNodeCountMinimum":1}]}')
print json.loads(data)
```

## cURL samples

Unlike the other code samples given in this section, these samples are simple commands that can be run from any server command line with the `curl` program installed in order to communicate with MWS.

### GET

```
curl -u admin:secret -X GET -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
```

### POST

```
curl -u admin:secret -X POST -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
-d '{
  "commandFile":"/tmp/test.sh", "initialWorkingDirectory":"/tmp", "user":"adaptive", "requirements":[{"requiredNodeCountMinimum":1}]}'
```

### PUT

```
curl -u admin:secret -X PUT -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
-d '{"holds":["user"]}'
```

### DELETE

```
curl -u admin:secret -X DELETE -H "Content-Type: application/json"
http://localhost:8080/mws/rest/jobs
```

## Configuration

These properties can be modified by setting the appropriate values in the `mws-config.groovy` file. This file is located in `MWS_HOME/etc/` or `/opt/mws/etc/` by default as explained in [Configuring Moab Web Services on page 1395](#).

**i** The configuration file is read not only on startup, but also each time it is changed. Several properties, including those for Moab Workload Manager (`moab`), Moab Accounting Manager (`mam`), Mongo (`grails.mongo`), and authentication (`auth`) are processed after each change and can affect the runtime behavior of MWS.

Configuration files can also be placed in the `MWS_HOME/etc/mws.d` directory. Any configuration files here get merged with `MWS_HOME/etc/mws-config.groovy`. In case of conflict, the configuration in `MWS_HOME/etc/mws.d` takes precedence.

### Configuration reference

For all possible values that can be set, please see the Grails reference guide. For project specific settings (usually the only ones you'll need to change), you may set the following properties:

Property	Type	Default	Description
<code>auth.defaultUser.password</code>	String	changeme!	Unencoded password of the default admin user.

Property	Type	Default	Description
<code>auth.defaultUser.username</code>	String	moab-admin	Username of the default admin user (only created if no other users exist).
<code>grails.mongo.host</code>	String	127.0.0.1	The MongoDB host to use (Note that MongoDB runs on 127.0.0.1 and <i>not</i> localhost by default).
<code>dataSource.insight.password</code>	String	changeme!	The password for the username used to log in to the Insight database.
<code>dataSource.insight.url</code>	String	jdbc:postgresql://127.0.0.1:5432/n insight	The <a href="#">JDBC URL</a> for the Insight database. For more information, see <a href="#">Configuring Moab Web Services on page 1395</a> .
<code>dataSource.insight.username</code>	String	mws	The username used to log into the Insight database.
<code>grails.mongo.port</code>	Integer	27017	The MongoDB port to use.
<code>grails.mongo.replicaSet</code>	List of Strings	n/a	The MongoDB replica set servers to use (for example, ["moab1:27017", "moab2:27017"]); <b>note</b> that <code>grails.mongo.host</code> <i>must</i> be set to null to use this option.
<code>grails.mongo.databaseName</code>	String	mws	The MongoDB database name to use.

Property	Type	Default	Description
<b>grails.mongo.username</b>	String	-	(Optional) The user-name to use when connecting to MongoDB.
<b>grails.mongo.password</b>	String	-	(Optional) The password to use when connecting to MongoDB.
<b>grails.mongo.options.connectionsPerHost</b>	Integer	50	The number of connections allowed per host.
<b>grails.- mongo.- options.threadsAllowedToBlockForConnecti</b>	Integer	5	The number of threads per connection allowed to wait for an available connection.
<b>grails.mongo.options.autoConnectRetry</b>	Boolean	true	Controls whether the system retries automatically on connection errors.
<b>grails.mime.use.accept.header</b>	Boolean	false	When enabled, uses the HTTP Content-Accept header to determine the content type used for return data (JSON only for now).
<b>grails.plu- gins.springsecurity.basic.realmName</b>	String	Moab Web Services	The HTTP realm used when using basic auth.
<b>grails.plugins.springsecurity.active</b>	Boolean	true	Enables or disables security for MWS as a whole, including all providers.
<b>grails.plugins.springsecurity.useBasicAuth</b>	Boolean	true	Enables or disables basic auth with a simple user-name/password.

Property	Type	Default	Description
<b>grails.plugins.springsecurity.oauthProvider.active</b>	Boolean	true	Enables or disables the OAuth2 provider.
<b>ldap.baseDNs</b>	List of Strings	-	A list of distinguished names that are the root entries for LDAP searches.
<b>ldap.bindUser</b>	String	-	The distinguished name of the LDAP bind user.
<b>ldap.directory.type</b>	String	-	The type of LDAP directory (for example, "Microsoft Active Directory"). See <a href="#">Configuring Moab Web Services on page 1395</a> for valid values..
<b>ldap.password</b>	String	-	The password of the LDAP bind user
<b>ldap.port</b>	Integer	-	LDAP server's port
<b>ldap.security.server.certificate</b>	String	-	The filename of the LDAP server's PEM encoded X.509 certificate. See <a href="#">Setting up MWS security on page 1410</a> for more information.
<b>ldap.security.type</b>	String	-	How the connection between MWS and LDAP is secured. See <a href="#">Setting up MWS security on page 1410</a> for more information.
<b>ldap.server</b>	String	-	LDAP server hostname or IP address

Property	Type	Default	Description
<b>mam.server</b>	String	localhost	Moab Accounting Manager server hostname or IP address
<b>mam.port</b>	Integer	7112	Moab Accounting Manager server's port
<b>mam.secretKey</b>	String	mamsecret	Secret key used to communicate with Moab Accounting Manager
<b>moab.databaseName</b>	String	moab	The name of the MongoDB database to use to retrieve current Moab data; this should match the database setting in Moab.
<b>moab.messageQueue.port</b>	Integer	5563	The port on which Moab publishes ZeroMQ messages.
<b>moab.messageQueue.secretKey</b>	String	-	Used to encrypt and decrypt messages on the message queue using AES. Must be a <a href="#">Base64</a> -encoded 128-bit (16-byte) key. For example: "1r6RvfqJa6voezy5wAx0hw=="
<b>moab.port</b>	Integer	42559	Moab server's port
<b>moab.secretKey</b>	String	moabsecret	Secret key used to communicate with Moab. See Moab Configuration.
<b>moab.server</b>	String	localhost	Moab server hostname or IP address

Property	Type	Default	Description
<b>mws.cache.duration.default</b>	Integer	60	The default number of seconds to use for caching objects from Moab. This is only supported in certain objects such as policies.
<b>mws.cache.duration.policy</b>	Integer	180	The number of seconds that the cache for policies is valid. If set to null, the default is used.
<b>mws.certificates.location</b>	String	etc/ssl.crt	The directory (relative or absolute) where plugin certificates are stored. See the <a href="#">Managing SSL connections on page 1714</a> .
<b>mws.events.expireAfterSeconds</b>	Integer	2592000	Events older than this many seconds (30 days by default) will be deleted from the database. Effective only with MongoDB 2.2 or later.
<b>mws.health.check.period</b>	Integer	30	The number of seconds in between health checks. Used in creating notification conditions if problems exist in configuration or connections. For more information, see <a href="#">Notification conditions on page 1580</a> .

Property	Type	Default	Description
<b>mws.hooks.location</b>	String	hooks	The directory (relative or absolute) where Hooks are stored. See <a href="#">Pre and post-processing hooks on page 1434</a> for more information.
<b>mws.plugins.location</b>	String	plugins	The directory (relative or absolute) where Plugins are stored. See <a href="#">About Moab Web Services plugins on page 1672</a> for more information.
<b>mws.messageQueue.port</b>	Integer	5570	The port on which MWS publishes ZeroMQ messages.
<b>mws.messageQueue.address</b>	String	-	The IP address on which MWS publishes ZeroMQ messages.
<b>mws.services.hooks.syncInterval</b>	Integer	30	The number of seconds between each time MWS checks for service phase transition hooks that completed or timed out.
<b>mws.services.phases.syncInterval</b>	Integer	14400	The number of seconds between each time MWS checks with Moab Workload Manager to verify that the service phases are correctly synchronized.
<b>mws.suite</b>	String	CLOUD	The suite or context that MWS is running in (see <a href="#">Suite</a> for valid values)

Property	Type	Default	Description
<b>pam.configuration.service</b>	String	-	The name of the PAM configuration file located in <code>/etc/pam.d</code> . This parameter and specification tells MWS which PAM configuration file you want to use. For more information, see <a href="#">PAM (pluggable authentication module) configuration using mws-config.groovy</a> on page 1405.
<b>plugins.pluginType</b>	String	-	Default configuration value for the plugin <code>pluginType</code> field (see <a href="#">Setting default plugin configuration</a> on page 1747).
<b>plugins.autoStart</b>	Boolean	true	Default configuration value for the plugin <code>autoStart</code> field (see <a href="#">Setting default plugin configuration</a> on page 1747).
<b>plugins.pollInterval</b>	Integer	30	Default configuration value for the plugin <code>pollInterval</code> field (see <a href="#">Setting default plugin configuration</a> on page 1747).
<b>plugins.config</b>	Map	-	Default configuration value for the plugin <code>config</code> field (see <a href="#">Setting default plugin configuration</a> on page 1747).

Property	Type	Default	Description
<b>plugins.loadInitialPlugins</b>	Boolean	true	If true, loads the initial plugins defined for uploaded or built-in plugin types (see <a href="#">Plugin projects and metadata on page 1721</a> ).
<b>plugins.stateConsolidationPolicy</b>	NodeStatePolicy	null	If "optimistic", treats state data optimistically. If "pessimistic", treats state state pessimistically. May be null. See <a href="#">Data consolidation on page 1677</a> for more information.
<b>plugins.defaultHypervisorType</b>	String	ESX	This is reported to Moab when a node report references a hypervisor image that does not have the hypervisorType or extensions.xcat.hvType fields set. See <a href="#">Fields: Images on page 1903</a> .

### [Logging reference](#)

The following loggers are available to use for debugging purposes:

Logger	Default	Description
<b>grails.app</b>	debug	Most classes in the main MWS application.
<b>grails.app.bootstrap.BootStrap</b>	debug	Handles startup and initialization of MWS.

Logger	Default	Description
<b>com.ace.mws</b>	debug	The base logger for MWS specific functionality not included in other loggers (this comprises very few classes).
<b>grails.app.services.com.ace.mws.plugins.PluginUtilityService</b>	debug	Class for initializing and helper methods of plugins.
<b>com.ace.mws.hooks.HookUtils</b>	debug	Helper class for loading hooks during startup process.
<b>plugins</b>	debug	All MWS plugins (see <a href="#">About Moab Web Services plugins on page 1672</a> ).
<b>com.ace.mws.plugins</b>	debug	MWS plugin helper class, used to create and initialize plugins.
<b>com.ace.mws.gapi</b>	warn	Base logger for all Moab connections, requests, and responses.
<b>com.ace.mws.gapi.Connection</b>	info	Logger which controls all requests and responses from Moab.
<b>com.ace.mws.gapi.parsers</b>	info	Loggers for parsers of Moab's data.
<b>com.ace.mws.gapi.serializers</b>	info	Loggers for all serialization from MWS to Moab Wire Protocol.
<b>grails.app.service.grails.plugins.reloadconfig</b>	info	Handles dynamic reloading of configuration files.
<b>net.sf.json</b>	error	JSON and XML processing library.
<b>org.springframework.security</b>	info	Authentication/authorization logger.

Logger	Default	Description
<code>org.codehaus.groovy.grails.web.servlet</code>	error	Loggers for request handlers.
<code>org.codehaus.groovy.grails.web.mapping</code>	error	URL mapping.
<code>org.codehaus.groovy.grails.web.mapping.filter</code>	error	URL mapping.
<code>org.codehaus.groovy.grails.plugins</code>	error	All grails plugins (MWS internal).
<code>org.codehaus.groovy.grails.commons</code>	error	Core application and class-loading.

<b>Hooks filename</b>	acl-rules.groovy	<a href="#">Pre and post-processing hooks on page 1434</a>
<b>Distinct query-supported</b>	No	<a href="#">Distinct on page 1526</a>

## API version 3

AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	PUT	Description
<b>affinity</b>	<a href="#">AclAffinity</a>	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#">AclAffinity.POSITIVE</a> .
<b>comparator</b>	<a href="#">ComparisonOperator</a>	Yes	The type of comparison to make against the ACL object.  Defaults to <a href="#">ComparisonOperator.EQUAL</a> .
<b>type</b>	<a href="#">AclType</a>	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	Yes	The name of the object that is being granted (or denied) access.

AclAffinity

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds

## API version 1

AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	PUT	Description
<b>affinity</b>	<a href="#">AclAffinity</a>	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#">AclAffinity.POSITIVE</a> .
<b>comparator</b>	<a href="#">ComparisonOperator</a>	Yes	The type of comparison to make against the ACL object.  Defaults to <a href="#">ComparisonOperator.EQUAL</a> .
<b>type</b>	<a href="#">AclType</a>	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	Yes	The name of the object that is being granted (or denied) access.

AclAffinity

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported

Value	Description
QUEUE	Not supported
RACK	Not supported
SCHED	Not supported
SYSTEM	Not supported
TASK	Not supported
VC	Not supported
XFACTOR	Not supported

## API version 3

Account

Users may be designated as members of an account and may be allowed to share its allocations. The user members may be designated as active or inactive, and as an account admin or not an account admin. Default account properties include the description, the organization it is part of, and whether or not it is active. An account's user membership can also be adjusted. By default, a standard user may only query accounts they belong to.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique account identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this account is active or not
<b>creationTime</b>	<b>Date</b>	The time this account was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this account is deleted or not
<b>description</b>	<b>String</b>	The account description
<b>modificationTime</b>	<b>Date</b>	The time this account was last modified
<b>organization</b>	<b>String</b>	The organization to which the account belongs
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>users</b>	<a href="#">Set&lt;AccountUser&gt;</a>	The users associated with this account

AccountUser

An account user is a person authorized to use an account.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>admin</b>	<b>Boolean</b>	A boolean indicating wheter this user is an admin or not

API version 2

Account

Users may be designated as members of an account and may be allowed to share its allocations. The user members may be designated as active or inactive, and as an account admin or not an account admin. Default account properties include the description, the organization it is part of, and whether or not it is active. An account's user membership can also be adjusted. By default, a standard user may only query accounts they belong to.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique account identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this account is active or not
<b>creationTime</b>	<b>Date</b>	The time this account was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this account is deleted or not
<b>description</b>	<b>String</b>	The account description
<b>modificationTime</b>	<b>Date</b>	The time this account was last modified
<b>organization</b>	<b>String</b>	The organization to which the account belongs
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>users</b>	<a href="#">Set&lt;AccountUser&gt;</a>	The users associated with this account

AccountUser

An account user is a person authorized to use an account.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>admin</b>	<b>Boolean</b>	A boolean indicating wheter this user is an admin or not

## API version 1

Account

Users may be designated as members of an account and may be allowed to share its allocations. The user members may be designated as active or inactive, and as an account admin or not an account admin. Default account properties include the description, the organization it is part of, and whether or not it is active. An account's user membership can also be adjusted. By default, a standard user may only query accounts they belong to.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique account identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this account is active or not
<b>creationTime</b>	<b>Date</b>	The time this account was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this account is deleted or not
<b>description</b>	<b>String</b>	The account description
<b>modificationTime</b>	<b>Date</b>	The time this account was last modified
<b>organization</b>	<b>String</b>	The organization to which the account belongs
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>users</b>	<a href="#">Set&lt;AccountUser&gt;</a>	The users associated with this account

AccountUser

An account user is a person authorized to use an account.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>admin</b>	<b>Boolean</b>	A boolean indicating wheter this user is an admin or not

## API version 3

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified

Field Name	Type	Description
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

## API version 2

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation

## API version 3

ChargeRate

Charge rates establish how much to charge for usage. A charge rate consists of its name, an optional value and the amount. Both name and value are primary keys and a charge rate is uniquely defined by both its name and its value. A charge rate value that is null designates the default charge rate.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>amount</b>	<b>String</b>	The charge rate amount
<b>creationTime</b>	<b>Date</b>	The date this charge rate was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this charge rate is deleted or not
<b>description</b>	<b>String</b>	The charge rate description
<b>modificationTime</b>	<b>Date</b>	The date this charge rate was last modified
<b>name</b>	<b>String</b>	The charge rate name
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>value</b>	<b>String</b>	The charge rate value. This will be null for default charge rates.

## API version 2

ChargeRate

Charge rates establish how much to charge for usage. A charge rate consists of its name, an optional value and the amount. Both name and value are primary keys and a charge rate is uniquely defined by both its name and its value. A charge rate value that is null designates the default charge rate.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>amount</b>	<b>String</b>	The charge rate amount
<b>creationTime</b>	<b>Date</b>	The date this charge rate was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this charge rate is deleted or not
<b>description</b>	<b>String</b>	The charge rate description
<b>modificationTime</b>	<b>Date</b>	The date this charge rate was last modified
<b>name</b>	<b>String</b>	The charge rate name
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>value</b>	<b>String</b>	The charge rate value. This will be null for default charge rates.

## API version 1

ChargeRate

Charge rates establish how much to charge for usage. A charge rate consists of its name, an optional value and the amount. Both name and value are primary keys and a charge rate is uniquely defined by both its name and its value. A charge rate value that is null designates the default charge rate.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>amount</b>	<b>String</b>	The charge rate amount
<b>creationTime</b>	<b>Date</b>	The date this charge rate was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this charge rate is deleted or not
<b>description</b>	<b>String</b>	The charge rate description
<b>modificationTime</b>	<b>Date</b>	The date this charge rate was last modified
<b>name</b>	<b>String</b>	The charge rate name
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>value</b>	<b>String</b>	The charge rate value. This will be null for default charge rates.

## API version 3

FundBalance

Represents a report of fund balance.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	The total adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#">Set&lt;Allocation&gt;</a>	Allocations associated with this fund
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>available</b>	<b>BigDecimal</b>	The total amount available for charging. <a href="#">amount</a> - <a href="#">reserved</a> + <a href="#">creditLimit</a>
<b>balance</b>	<b>BigDecimal</b>	The allocation total not blocked by liens. <a href="#">amount</a> - <a href="#">reserved</a>
<b>capacity</b>	<b>BigDecimal</b>	The total amount allocated via deposits and credit limits. <a href="#">allocated</a> + <a href="#">creditLimit</a>
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>percentRemaining</b>	<b>Double</b>	The percentage of allocation remaining. <a href="#">amount</a> * 100 / <a href="#">allocated</a>

Field Name	Type	Description
<b>percentUsed</b>	<b>Double</b>	The percentage of allocated used. $\text{used} * 100 / \text{allocated}$
<b>reserved</b>	<b>BigDecimal</b>	The sum of active lien amounts against this fund
<b>used</b>	<b>BigDecimal</b>	The total amount used this allocation cycle. $\text{allocated} - \text{amount}$

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)

Field Name	Type	Description
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

#### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

## API version 2

FundBalance

Represents a report of fund balance.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	The total adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#">Set&lt;Allocation&gt;</a>	Allocations associated with this fund

<b>available</b>	<b>BigDecimal</b>	The total amount available for charging. <a href="#">amount</a> - <a href="#">reserved</a> + <a href="#">creditLimit</a>
<b>balance</b>	<b>BigDecimal</b>	The allocation total not blocked by liens. <a href="#">amount</a> - <a href="#">reserved</a>
<b>capacity</b>	<b>BigDecimal</b>	The total amount allocated via deposits and credit limits. <a href="#">allocated</a> + <a href="#">creditLimit</a>
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>percentRemaining</b>	<b>Double</b>	The percentage of allocation remaining. <a href="#">amount</a> * 100 / <a href="#">allocated</a>

Field Name	Type	Description
<b>percentUsed</b>	<b>Double</b>	The percentage of allocated used. $\frac{\text{used} * 100}{\text{allocated}}$
<b>reserved</b>	<b>BigDecimal</b>	The sum of active lien amounts against this fund
<b>used</b>	<b>BigDecimal</b>	The total amount used this allocation cycle. $\text{allocated} - \text{amount}$

### Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)

Field Name	Type	Description
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

#### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

## API version 1

FundBalance

Represents a report of fund balance.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	The total adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#">Set&lt;Allocation&gt;</a>	Allocations associated with this fund
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>available</b>	<b>BigDecimal</b>	The total amount available for charging. <a href="#">amount</a> - <a href="#">reserved</a> + <a href="#">creditLimit</a>
<b>balance</b>	<b>BigDecimal</b>	The allocation total not blocked by liens. <a href="#">amount</a> - <a href="#">reserved</a>
<b>capacity</b>	<b>BigDecimal</b>	The total amount allocated via deposits and credit limits. <a href="#">allocated</a> + <a href="#">creditLimit</a>
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>percentRemaining</b>	<b>Double</b>	The percentage of allocation remaining. <a href="#">amount</a> * 100 / <a href="#">allocated</a>

Field Name	Type	Description
<b>percentUsed</b>	<b>Double</b>	The percentage of allocated used. $\frac{\text{used} * 100}{\text{allocated}}$
<b>reserved</b>	<b>BigDecimal</b>	The sum of active lien amounts against this fund
<b>used</b>	<b>BigDecimal</b>	The total amount used this allocation cycle. $\text{allocated} - \text{amount}$

Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)

Field Name	Type	Description
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

## API version 3

FundStatementSummary

An fund statement summary is related to and quite similar to the [FundStatement](#) report, but differs in the [transactions](#) field by using the [FundTransactionSummary](#).

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>endBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">endTime</a> of the statement
<b>endTime</b>	<b>Date</b>	The ending time that the statement covers
<b>funds</b>	<a href="#">Set&lt;Fund&gt;</a>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
<b>generationTime</b>	<b>Date</b>	The date that the statement report was generated
<b>startBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">startTime</a> of the statement
<b>startTime</b>	<b>Date</b>	The starting time that the statement covers
<b>totalCredits</b>	<b>BigDecimal</b>	The total number of credits that occurred during the time period that the statement covers
<b>totalDebits</b>	<b>BigDecimal</b>	The total number of debits that occurred during the time period that the statement covers
<b>transactions</b>	<a href="#">Set&lt;FundTransactionSummary&gt;</a>	Summaries of the specific transactions which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such

as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into a fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with a fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#"><u>Set&lt;Allocation&gt;</u></a>	The allocations associated with this fund.
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>defaultDeposit</b>	<b>String</b>	The default deposit amount
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this fund is deleted or not
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#"><u>Set&lt;FundConstraint&gt;</u></a>	Constraints on fund usage.

Field Name	Type	Description
<b>initialDeposit</b>	<b>BigDecimal</b>	The initial deposit amount
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>priority</b>	<b>Integer</b>	The fund priority
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### Allocation

API version 3

FundStatement

An fund statement is a report generated from Moab Accounting Manager fund, allocation, and transaction data. It contains fields detailing the specific time period covered, the starting and ending balances, the total of the transactions, and fund and transaction details.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>endBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">endTime</a> of the statement
<b>endTime</b>	<b>Date</b>	The ending time that the statement covers
<b>funds</b>	<a href="#">Set&lt;Fund&gt;</a>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
<b>generationTime</b>	<b>Date</b>	The date that the statement report was generated
<b>startBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">startTime</a> of the statement
<b>startTime</b>	<b>Date</b>	The starting time that the statement covers
<b>totalCredits</b>	<b>BigDecimal</b>	The total number of credits that occurred during the time period that the statement covers
<b>totalDebits</b>	<b>BigDecimal</b>	The total number of debits that occurred during the time period that the statement covers
<b>transactions</b>	<a href="#">Set&lt;FundTransaction&gt;</a>	Details of each specific transaction which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints

may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#">Set&lt;Allocation&gt;</a>	The allocations associated with this fund.
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>defaultDeposit</b>	<b>String</b>	The default deposit amount
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this fund is deleted or not
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.
<b>initialDeposit</b>	<b>BigDecimal</b>	The initial deposit amount

<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created

Field Name	Type	Description
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

#### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

#### FundTransaction

Represents a Moab Accounting Manager transaction.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>account</b>	<b>String</b>	The account associated with the transaction. For a credit this will likely be zero
<b>action</b>	<b>String</b>	Action name for the transaction
<b>amount</b>	<b>BigDecimal</b>	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
<b>instance</b>	<b>String</b>	Instance name
<b>machine</b>	<b>String</b>	The machine associated with the transaction. For a credit this will likely be zero. This field is not available in the Cloud context.
<b>object</b>	<b>String</b>	Object's name associated with the transaction
<b>time</b>	<b>Date</b>	The date at which the transaction occurred
<b>user</b>	<b>String</b>	The user associated with the transaction. For a credit this will likely be zero

## API version 2

FundStatement

An fund statement is a report generated from Moab Accounting Manager fund, allocation, and transaction data. It contains fields detailing the specific time period covered, the starting and ending balances, the total of the transactions, and fund and transaction details.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>endBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">endTime</a> of the statement
<b>endTime</b>	<b>Date</b>	The ending time that the statement covers
<b>funds</b>	<a href="#">Set&lt;Fund&gt;</a>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
<b>generationTime</b>	<b>Date</b>	The date that the statement report was generated
<b>startBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">startTime</a> of the statement
<b>startTime</b>	<b>Date</b>	The starting time that the statement covers
<b>totalCredits</b>	<b>BigDecimal</b>	The total number of credits that occurred during the time period that the statement covers
<b>totalDebits</b>	<b>BigDecimal</b>	The total number of debits that occurred during the time period that the statement covers
<b>transactions</b>	<a href="#">Set&lt;FundTransaction&gt;</a>	Details of each specific transaction which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints

may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#"><u>Set&lt;Allocation&gt;</u></a>	The allocations associated with this fund.
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>defaultDeposit</b>	<b>String</b>	The default deposit amount
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this fund is deleted or not
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#"><u>Set&lt;FundConstraint&gt;</u></a>	Constraints on fund usage.
<b>initialDeposit</b>	<b>BigDecimal</b>	The initial deposit amount

Field Name	Type	Description
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>priority</b>	<b>Integer</b>	The fund priority
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created

Field Name	Type	Description
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

#### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

#### FundTransaction

Represents a Moab Accounting Manager transaction.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>account</b>	<b>String</b>	The account associated with the transaction. For a credit this will likely be zero
<b>action</b>	<b>String</b>	Action name for the transaction
<b>amount</b>	<b>BigDecimal</b>	Amount of the transaction. A positive or amount signifies a credit, while a negative or zero amount signifies a debit.
<b>instance</b>	<b>String</b>	Instance name
<b>machine</b>	<b>String</b>	The machine associated with the transaction. For a credit this will likely be zero. This field is not available in the Cloud context.
<b>object</b>	<b>String</b>	Object's name associated with the transaction
<b>time</b>	<b>Date</b>	The date at which the transaction occurred
<b>user</b>	<b>String</b>	The user associated with the transaction. For a credit this will likely be zero

API version 1

FundStatement

An fund statement is a report generated from Moab Accounting Manager fund, allocation, and transaction data. It contains fields detailing the specific time period covered, the starting and ending balances, the total of the transactions, and fund and transaction details.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>endBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">endTime</a> of the statement
<b>endTime</b>	<b>Date</b>	The ending time that the statement covers
<b>funds</b>	<a href="#">Set&lt;Fund&gt;</a>	The funds that this statement covers. Only a sub-set of the full fund fields are available from this property. This includes id, name, priority, description, and creationTime.
<b>generationTime</b>	<b>Date</b>	The date that the statement report was generated
<b>startBalance</b>	<b>BigDecimal</b>	The balance of the funds at the <a href="#">startTime</a> of the statement
<b>startTime</b>	<b>Date</b>	The starting time that the statement covers
<b>totalCredits</b>	<b>BigDecimal</b>	The total number of credits that occurred during the time period that the statement covers
<b>totalDebits</b>	<b>BigDecimal</b>	The total number of debits that occurred during the time period that the statement covers
<b>transactions</b>	<a href="#">Set&lt;FundTransaction&gt;</a>	Details of each specific transaction which occurred during the time period that this statement covers.

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints

may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#">Set&lt;Allocation&gt;</a>	The allocations associated with this fund.
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>defaultDeposit</b>	<b>String</b>	The default deposit amount
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this fund is deleted or not
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.

<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.

Field Name	Type	Description
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

## API version 1

Fund

A fund is a container for a time-bounded reference currency called credits for which the usage is restricted by constraints that define how the credits must be used. Much like with a bank, an fund is a repository for these resource or service credits which are added through deposits and debited through withdrawals and charges. Each fund has a set of constraints designating which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, Feature, etc.). Fund constraints may also be negated with an exclamation point leading the constraint value.

When credits are deposited into an fund, they are associated with a time period within which they are valid. These time-bounded pools of credits are known as allocations. (An allocation is a pool of billable units associated with an fund for use during a particular time period.) By using multiple allocations that expire in regular intervals it is possible to implement a use-it-or-lose-it policy and establish an allocation cycle.

Funds may be nested. Hierarchically nested funds may be useful for the delegation of management roles and responsibilities. Deposit shares may be established that assist to automate a trickle-down effect for funds deposited at higher level funds. Additionally, an optional overflow feature allows charges against lower level funds to trickle up the hierarchy.

Funds may have an arbitrary name which is not necessarily unique for the fund. Funds may also have a priority which will influence the order of fund selection when charging.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique fund identifier
<b>allocated</b>	<b>BigDecimal</b>	Total Adjusted allocations. This value is affected positively by deposits, activations and destination transfers and affected negatively by withdrawals, deactivations and source transfers that have occurred since the last reset.
<b>allocations</b>	<a href="#"><u>Set&lt;Allocation&gt;</u></a>	The allocations associated with this fund.
<b>amount</b>	<b>BigDecimal</b>	The sum of active allocation amounts within this fund. It does not take into fund current liens.
<b>creationTime</b>	<b>Date</b>	Date this fund was created
<b>creditLimit</b>	<b>BigDecimal</b>	The sum of active credit limits within this fund
<b>defaultDeposit</b>	<b>String</b>	The default deposit amount

Field Name	Type	Description
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this fund is deleted or not
<b>description</b>	<b>String</b>	The fund description
<b>fundConstraints</b>	<a href="#">Set&lt;FundConstraint&gt;</a>	Constraints on fund usage.
<b>initialDeposit</b>	<b>BigDecimal</b>	The initial deposit amount
<b>modificationTime</b>	<b>Date</b>	The date this fund was last modified
<b>name</b>	<b>String</b>	The name of this fund
<b>priority</b>	<b>Integer</b>	The fund priority
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### Allocation

An allocation is a time-bounded pool of resource or service credits associated with an fund. An fund may have multiple allocations, each for use during a different time period.

An allocation has a start time and an end time that defines the time period during which the allocation may be used. By default an allocation is created with an unbounded time period (-infinity to infinity). An active flag is automatically updated to true if the fund is within its valid timeframe or false if it is not. An allocation may also have a credit limit representing the amount by which it can go negative. Thus, by having a positive balance in the Amount field, the fund is like a debit fund, implementing a pay-first use-later model. By establishing a credit limit instead of depositing an initial balance, the fund will be like a credit fund, implementing a use-first pay-later model. These strategies can be combined by depositing some amount of funds coupled with a credit limit, implementing a form of overdraft protection where the funds will be used down to the negative of the credit limit.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this allocation
<b>active</b>	<b>Boolean</b>	Indicates whether this allocation is active or not

Field Name	Type	Description
<b>allocated</b>	<b>BigDecimal</b>	Adjusted allocation. This value stores the effective allocated amount based on the initial deposit and subsequent allocation adjustments via deposits, withdrawals or transfers.
<b>amount</b>	<b>BigDecimal</b>	The amount of this allocation
<b>creationTime</b>	<b>Date</b>	The date this allocation was created
<b>creditLimit</b>	<b>BigDecimal</b>	Determines how far in the negative this allocation is permitted to be used (enforced in quotes and liens)
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this allocation is deleted or not
<b>description</b>	<b>String</b>	The description of this allocation
<b>endTime</b>	<b>Date</b>	The date this allocation becomes inactive
<b>fund</b>	<b>String</b>	The fund Id associated with this allocation
<b>modificationTime</b>	<b>Date</b>	The date this allocation was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The date this allocation becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

### FundConstraint

Constraints designate which entities (such as Users, Accounts, Machines, Classes, Organizations, etc.) may access the encapsulated credits in a fund or for which aspects of usage the funds are intended (QualityOfService, GeographicalArea, etc.).

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier of this constraint.
<b>fund</b>	<b>String</b>	The fund ID that this constraint is associated with.

Field Name	Type	Description
<b>name</b>	<b>String</b>	The name of the constraint.
<b>value</b>	<b>String</b>	The value of the constraint. The constraint may be negated by the used of an exclamation point leading the value.

## API version 3

Lien

A lien is a reservation or hold placed against an allocation. Before usage of a resource or service begins, a lien is placed against one or more allocations within the requesting user's applicable funds. Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique lien identifier
<b>allocations</b>	<a href="#">Set&lt;LienAllocation&gt;</a>	The allocation amounts reserved with this lien.
<b>creationTime</b>	<b>Date</b>	The date this lien was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this lien is deleted or not
<b>description</b>	<b>String</b>	The lien description
<b>duration</b>	<b>Long</b>	The expected duration of the reserved usage in seconds
<b>endTime</b>	<b>Date</b>	The time the lien becomes inactive
<b>instance</b>	<b>String</b>	The lien is against the specified instance (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	The date this lien was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The time the lien becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>usageRecord</b>	<b>Long</b>	The id of the usage record associated with the lien and containing the usage properties

LienAllocation

Amounts of the allocations that the lien has holds against

Field Name	Type	Description
<b>id</b>	<b>String</b>	The child allocation id
<b>amount</b>	<b>Long</b>	The amount reserved against the allocation by this lien
<b>fund</b>	<b>Long</b>	The fund that the allocation is in
<b>lien</b>	<b>String</b>	The parent lien id

## API version 2

Lien

A lien is a reservation or hold placed against an allocation. Before usage of a resource or service begins, a lien is placed against one or more allocations within the requesting user's applicable funds. Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique lien identifier
<b>allocations</b>	<a href="#">Set&lt;LienAllocation&gt;</a>	The allocation amounts reserved with this lien.
<b>creationTime</b>	<b>Date</b>	The date this lien was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this lien is deleted or not
<b>description</b>	<b>String</b>	The lien description
<b>duration</b>	<b>Long</b>	The expected duration of the reserved usage in seconds
<b>endTime</b>	<b>Date</b>	The time the lien becomes inactive
<b>instance</b>	<b>String</b>	The lien is against the specified instance (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	The date this lien was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The time the lien becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>usageRecord</b>	<b>Long</b>	The id of the usage record associated with the lien and containing the usage properties

LienAllocation

Amounts of the allocations that the lien has holds against

Field Name	Type	Description
<b>id</b>	<b>String</b>	The child allocation id
<b>amount</b>	<b>Long</b>	The amount reserved against the allocation by this lien
<b>fund</b>	<b>Long</b>	The fund that the allocation is in
<b>lien</b>	<b>String</b>	The parent lien id

## API version 1

Lien

A lien is a reservation or hold placed against an allocation. Before usage of a resource or service begins, a lien is placed against one or more allocations within the requesting user's applicable funds. Subsequent usage requests will also post liens while the available balance (active allocations minus liens) allows. When the usage ends, the lien is removed and the actual charge is made to the allocation(s). This procedure ensures that usage will only be permitted so long as the requestors have sufficient funds.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique lien identifier
<b>allocations</b>	<a href="#">Set&lt;LienAllocation&gt;</a>	The allocation amounts reserved with this lien.
<b>creationTime</b>	<b>Date</b>	The date this lien was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this lien is deleted or not
<b>description</b>	<b>String</b>	The lien description
<b>duration</b>	<b>Long</b>	The expected duration of the reserved usage in seconds
<b>endTime</b>	<b>Date</b>	The time the lien becomes inactive
<b>instance</b>	<b>String</b>	The lien is against the specified instance (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	The date this lien was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The time the lien becomes active
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>usageRecord</b>	<b>Long</b>	The id of the usage record associated with the lien and containing the usage properties

LienAllocation

Amounts of the allocations that the lien has holds against

Field Name	Type	Description
<b>id</b>	<b>String</b>	The child allocation id
<b>amount</b>	<b>Long</b>	The amount reserved against the allocation by this lien
<b>fund</b>	<b>Long</b>	The fund that the allocation is in
<b>lien</b>	<b>String</b>	The parent lien id

## API version 3

Organization

An organization is a virtual organization in which accounts are grouped. An account may only belong to a single organization while an organization may have multiple accounts. For example, an account may represent a project or cost-center while an organization may represent an institutional department or business division. The purpose of defining organizations is to support the ability to produce reporting for higher-order organizational entities beyond the individual account. Default organization properties include an id (name in MAM) and a description. An organization can be created, queried, modified, and deleted.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique organization identifier
<b>creationTime</b>	<b>Date</b>	The date this organization was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this organization is deleted or not
<b>description</b>	<b>String</b>	The organization description
<b>modificationTime</b>	<b>Date</b>	The date this organization was last modified
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

## API version 3

Quote

Quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	The unique quote identifier
<b>amount</b>	<b>BigDecimal</b>	The total amount of the quote
<b>chargeRates</b>	<a href="#">Set&lt;QuoteChargeRate&gt;</a>	The applied charges that make up this quote.
<b>creationTime</b>	<b>Date</b>	The date this quote was created
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this quote is deleted or not
<b>description</b>	<b>String</b>	The quote description
<b>duration</b>	<b>Long</b>	The expected duration of the quoted usage in seconds
<b>endTime</b>	<b>Date</b>	The time the quote becomes inactive
<b>instance</b>	<b>String</b>	The quote instance name. (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	The date this quote was last modified
<b>pinned</b>	<b>Boolean</b>	Boolean indicating whether the quote is pinned or not
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>startTime</b>	<b>Date</b>	The time the quote becomes active

Field Name	Type	Description
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction
<b>usageRecord</b>	<b>Long</b>	The usage record id associated with this quote

### QuoteChargeRate

Saved charge rates to be used when the quote is referenced

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>amount</b>	<b>String</b>	The charge rate amount
<b>name</b>	<b>String</b>	The child charge rate name
<b>quote</b>	<b>String</b>	The parent quote id
<b>value</b>	<b>String</b>	The child charge rate value

## API version 2

## API version 3

UsageRecord

A usage record tracks the usage of resources and services on your system, recording the charge and the details of the usage in a usage record.

Usage Record quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The replace option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The modify option may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one.

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors. By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed. If a usage record already exists for the instance being charged it will be updated with the data properties passed in with the charge request, otherwise a new usage record will be created.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	The unique usage record identifier
<b>charge</b>	<b>String</b>	No	The cumulative amount charged
<b>creationTime</b>	<b>Date</b>	No	The date this usage record was created
<b>deleted</b>	<b>Boolean</b>	No	A boolean indicating whether this usage record is deleted or not
<b>instance</b>	<b>String</b>	No	The usage record instance name (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	No	The date this usage record was last modified

Field Name	Type	POST	Description
<b>qualityOfService</b>	<b>String</b>	No	The quality of service associated with the usage
<b>quote</b>	<b>Long</b>	No	The associated quote id
<b>requestId</b>	<b>Long</b>	No	The id of the last modifying request
<b>stage</b>	<b>String</b>	No	The last affecting action (i.e. Create, Quote, Reserve, Query)
<b>transactionId</b>	<b>Long</b>	No	The id of the last modifying transaction
<b>type</b>	<b>String</b>	No	The usage record type
<b>user</b>	<b>String</b>	No	The user name associated with the usage

## API version 2

UsageRecord

A usage record tracks the usage of resources and services on your system, recording the charge and the details of the usage in a usage record.

Usage Record quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The replace option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The modify option may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one.

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors. By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed. If a usage record already exists for the instance being charged it will be updated with the data properties passed in with the charge request, otherwise a new usage record will be created.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	The unique usage record identifier
<b>charge</b>	<b>String</b>	No	The cumulative amount charged
<b>creationTime</b>	<b>Date</b>	No	The date this usage record was created
<b>deleted</b>	<b>Boolean</b>	No	A boolean indicating whether this usage record is deleted or not
<b>instance</b>	<b>String</b>	No	The usage record instance name (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	No	The date this usage record was last modified

Field Name	Type	POST	Description
<b>qualityOfService</b>	<b>String</b>	No	The quality of service associated with the usage
<b>quote</b>	<b>Long</b>	No	The associated quote id
<b>requestId</b>	<b>Long</b>	No	The id of the last modifying request
<b>stage</b>	<b>String</b>	No	The last affecting action (i.e. Create, Quote, Reserve, Query)
<b>transactionId</b>	<b>Long</b>	No	The id of the last modifying transaction
<b>type</b>	<b>String</b>	No	The usage record type
<b>user</b>	<b>String</b>	No	The user name associated with the usage

## API version 1

UsageRecord

A usage record tracks the usage of resources and services on your system, recording the charge and the details of the usage in a usage record.

Usage Record quotes can be used to determine how much it will cost to use a resource or service. Provided the cost-only option is not specified, this step will additionally verify that the submitter has sufficient funds and meets all the allocation policy requirements for the usage, and can be used at the submission of the usage request as an early filter to prevent the usage from getting blocked when it tries to obtain a lien to start later. If a guaranteed quote is requested, a quote id is returned and can be used in the subsequent charge to guarantee the rates that were used to form the original quote. A guaranteed quote has the side effect of creating a quote record and a permanent usage record. A quote id will be returned which can be used with the lien and charge to claim the quoted charge rates. A cost-only quote can be used to determine how much would be charged for usage without verifying sufficient funds or checking to see if the charge could succeed.

A usage lien can be used to place a hold on the user's fund before usage starts to ensure that the credits will be there when it completes. The replace option may be specified if you want the new lien to replace existing liens of the same instance name (associated with the same usage record). The modify option may be specified to dynamically extend any existing lien with the same instance name with the specified characteristics instead of creating a new one.

A usage charge debits the appropriate allocations based on the attributes of the usage. The charge is calculated based on factors including the resources and services used, the usage time, and other quality-based factors. By default, any liens associated with the charge will be removed. The incremental option may be specified if you want associated liens to be reduced instead of removed. If a usage record already exists for the instance being charged it will be updated with the data properties passed in with the charge request, otherwise a new usage record will be created.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	The unique usage record identifier
<b>charge</b>	<b>String</b>	No	The cumulative amount charged
<b>creationTime</b>	<b>Date</b>	No	The date this usage record was created
<b>deleted</b>	<b>Boolean</b>	No	A boolean indicating whether this usage record is deleted or not
<b>instance</b>	<b>String</b>	No	The usage record instance name (i.e. job id)
<b>modificationTime</b>	<b>Date</b>	No	The date this usage record was last modified

Field Name	Type	POST	Description
<b>qualityOfService</b>	<b>String</b>	No	The quality of service associated with the usage
<b>quote</b>	<b>Long</b>	No	The associated quote id
<b>requestId</b>	<b>Long</b>	No	The id of the last modifying request
<b>stage</b>	<b>String</b>	No	The last affecting action (i.e. Create, Quote, Reserve, Query)
<b>transactionId</b>	<b>Long</b>	No	The id of the last modifying transaction
<b>type</b>	<b>String</b>	No	The usage record type
<b>user</b>	<b>String</b>	No	The user name associated with the usage

## API version 3

User

A user is a person authorized to use a resource or service. Default user properties include the common name, phone number, email address, default account, and description for that person.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>creationTime</b>	<b>Date</b>	The date this user was created
<b>defaultAccount</b>	<b>String</b>	The default account for this user
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this user is deleted or not
<b>description</b>	<b>String</b>	The user description
<b>emailAddress</b>	<b>String</b>	The user's email address
<b>modificationTime</b>	<b>Date</b>	The date this user was last modified
<b>phoneNumber</b>	<b>String</b>	The user's phone number
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

## API version 2

User

A user is a person authorized to use a resource or service. Default user properties include the common name, phone number, email address, default account, and description for that person.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>creationTime</b>	<b>Date</b>	The date this user was created
<b>defaultAccount</b>	<b>String</b>	The default account for this user
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this user is deleted or not
<b>description</b>	<b>String</b>	The user description
<b>emailAddress</b>	<b>String</b>	The user's email address
<b>modificationTime</b>	<b>Date</b>	The date this user was last modified
<b>phoneNumber</b>	<b>String</b>	The user's phone number
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

## API version 1

User

A user is a person authorized to use a resource or service. Default user properties include the common name, phone number, email address, default account, and description for that person.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique user identifier
<b>active</b>	<b>Boolean</b>	A boolean indicating whether this user is active or not
<b>creationTime</b>	<b>Date</b>	The date this user was created
<b>defaultAccount</b>	<b>String</b>	The default account for this user
<b>deleted</b>	<b>Boolean</b>	A boolean indicating whether this user is deleted or not
<b>description</b>	<b>String</b>	The user description
<b>emailAddress</b>	<b>String</b>	The user's email address
<b>modificationTime</b>	<b>Date</b>	The date this user was last modified
<b>phoneNumber</b>	<b>String</b>	The user's phone number
<b>requestId</b>	<b>Long</b>	The id of the last modifying request
<b>transactionId</b>	<b>Long</b>	The id of the last modifying transaction

<b>Distinct query-supported</b>	No	<a href="#">Distinct on page 1526</a>

API version 3

Credential

A credential is an entity, such as a user or a group, that has access to resources. Credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	PUT	Description
<b>name</b>	<b>String</b>	No	The name of the credential.

API version 2

Credential

A credential is an entity, such as a user or a group, that has access to resources. Credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	PUT	Description
<b>name</b>	<b>String</b>	No	The name of the credential.

Type	Value	Additional information
<b>Permissions resource</b>	events	<a href="#">Permissions on page 1593</a>
<b>Hooks filename</b>	events.groovy	<a href="#">Pre and post-processing hooks on page 1434</a>
<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

API version 3

Event

Represents an event originating from any component in the system (MWM, MWS, MAM, etc). Events are related to, but not the same as, [Notifications](#). See [NotificationCondition](#) for an explanation of when to use an event vs a notification.

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique ID for this event
<b>arguments</b>	<b>List&lt;String&gt;</b>	Yes	The event's arguments
<b>associatedObjects</b>	<a href="#">Set&lt;AssociatedObject&gt;</a>	Yes	Objects relating to the event
<b>code</b>	<b>int</b>	Yes	This is a positive, 32-bit numeric value. Source code that needs to take action on events based on which event (error) occurred can switch based on this value. The top 16 bits are determined by the severity of the event and the component that emits it. The bottom 16 bits are assigned by any arbitrary mechanism convenient to a component. Each component thus has 64k unique event codes that it can assign. Once assigned, event codes are immutable; it can never be the case that error 12345 means one thing in release A, and a different thing in release B.
<b>eventDate</b>	<b>Date</b>	Yes	The date and time the event occurred, not the date and time MWS received the event. It is up to the reporting component to report this time accurately. Required during POST.
<b>eventType</b>	<b>String</b>	Yes	Signifies what type of event. Cannot contain single quotes(') or double quotes(").
<b>message</b>	<b>String</b>	Yes	A summary of what happened that caused this event
<b>origin</b>	<b>String</b>	Yes	The origin of this event. Cannot contain single quotes(') or double quotes(").
<b>severity</b>	<a href="#">EventSeverity</a>	Yes	Signifies the severity of an event.

Field Name	Type	POST	Description
<b>tenant</b>	<b>Map&lt;String, String&gt;</b>	No	The event's tenant (contains tenant id and name)

AssociatedObject

Represents and uniquely identifies an object associated with an event. (e.g node, job, reservation, trigger)

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	Yes	The object id (e.g. reservation.1, job.21, vm3). Cannot contain single quotes(') or double quotes(").
<b>type</b>	<b>String</b>	Yes	The type of object (e.g. node, job, reservation). Cannot contain single quotes(') or double quotes(").

EventSeverity

Value	Description
<b>INFO</b>	
<b>WARN</b>	
<b>ERROR</b>	
<b>FATAL</b>	

API version 2

EventVersion2

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique ID for this event
<b>details</b>	<b>Map&lt;String, Map&gt;</b>	Yes	A map where detail name maps to detail value. (e.g. "sourceHypervisor" => "blade256", "destinationHypervisor" => "blade257", "os" => "centos-5.5-stateless")
<b>errorMessage</b>	<a href="#"><u>ErrorMessageVersion2</u></a>	Yes	Details about any errors associated with the event. If this event was not associated with any errors this field will be null
<b>eventCategory</b>	<b>String</b>	Yes	Signifies what category of event.
<b>eventTime</b>	<b>Date</b>	Yes	The time the event occurred, not the time MWS received the event. It is up to the reporting component to report this time accurately. Corresponds to eventDate in API Version 3. Required during POST.
<b>eventType</b>	<b>String</b>	Yes	Signifies what type of event.
<b>facility</b>	<b>String</b>	Yes	A categorization of how this event fits in with other events.
<b>initiatedBy</b>	<a href="#"><u>UserDetailsVersion2</u></a>	Yes	Details about the user that initiated this event
<b>primaryObject</b>	<a href="#"><u>MoabObjectVersion2</u></a>	Yes	Most events will have a "primary object" associated with it. An event can have at most ONE primary object. For example, a JobStart event will have a primary job object, so the type would be "job" and the object ID would be the ID of the job. Primary objects are, however, optional, depending on the type of event. For example, a "SchedulerCommand" event does not have a primary object.

Field Name	Type	POST	Description
<b>relatedObjects</b>	<a href="#">Set&lt;MoabObjectVersion2&gt;</a>	Yes	Objects relating to the event that are not the primary object. Corresponds to associatedObjects in API Version 3.
<b>severity</b>	<b>String</b>	Yes	Signifies the severity of an event. Severity can be "FATAL", "ERROR", "WARN", "INFO"
<b>sourceComponent</b>	<b>String</b>	Yes	What Adaptive Computing component reported this event. Examples: "MWM", "MWS", "MAM", etc. Corresponds to origin in API Version 3.
<b>status</b>	<b>String</b>	Yes	The status of the reported event.

[ErrorMessageVersion2](#)

Field Name	Type	POST	Description
<b>errorCode</b>	<b>String</b>	Yes	The original error code generated or detected by the originator.
<b>message</b>	<b>String</b>	Yes	If an event has a status of "failure" or other non-successful operation, this field should provide a human-friendly error message Corresponds to Event.message in API Version 3 and above.
<b>originator</b>	<b>String</b>	Yes	The software component or entity that generated or detected the error (e.g. Moab, Torque, MWS, Viewpoint, RM, Database, etc).

[UserDetailsVersion2](#)

Field Name	Type	POST	Description
<b>proxyUser</b>	<b>String</b>	Yes	The proxy user that initiated the event.
<b>user</b>	<b>String</b>	Yes	The user that initiated the event.

[MoabObjectVersion2](#)

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	Yes	The moab object id (e.g. reservation.1, job.21, vm3)
<b>serialization</b>	<b>String</b>	Yes	A serialized representation of the object
<b>type</b>	<b>String</b>	Yes	The moab object type (e.g. node, job, reservation)

## API version 1

EventVersion2

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique ID for this event
<b>details</b>	<b>Map&lt;String, Map&gt;</b>	Yes	A map where detail name maps to detail value. (e.g. "sourceHypervisor" => "blade256", "destinationHypervisor" => "blade257", "os" => "centos-5.5-stateless")
<b>errorMessage</b>	<a href="#"><u>ErrorMessageVersion2</u></a>	Yes	Details about any errors associated with the event. If this event was not associated with any errors this field will be null
<b>eventCategory</b>	<b>String</b>	Yes	Signifies what category of event.
<b>eventTime</b>	<b>Date</b>	Yes	The time the event occurred, not the time MWS received the event. It is up to the reporting component to report this time accurately. Corresponds to eventDate in API Version 3. Required during POST.
<b>eventType</b>	<b>String</b>	Yes	Signifies what type of event.
<b>facility</b>	<b>String</b>	Yes	A categorization of how this event fits in with other events.
<b>initiatedBy</b>	<a href="#"><u>UserDetailsVersion2</u></a>	Yes	Details about the user that initiated this event
<b>primaryObject</b>	<a href="#"><u>MoabObjectVersion2</u></a>	Yes	Most events will have a "primary object" associated with it. An event can have at most ONE primary object. For example, a JobStart event will have a primary job object, so the type would be "job" and the object ID would be the ID of the job. Primary objects are, however, optional, depending on the type of event. For example, a "SchedulerCommand" event does not have a primary object.

Field Name	Type	POST	Description
<b>relatedObjects</b>	<a href="#">Set&lt;MoabObjectVersion2&gt;</a>	Yes	Objects relating to the event that are not the primary object. Corresponds to associatedObjects in API Version 3.
<b>severity</b>	<b>String</b>	Yes	Signifies the severity of an event. Severity can be "FATAL", "ERROR", "WARN", "INFO"
<b>sourceComponent</b>	<b>String</b>	Yes	What Adaptive Computing component reported this event. Examples: "MWM", "MWS", "MAM", etc. Corresponds to origin in API Version 3.
<b>status</b>	<b>String</b>	Yes	The status of the reported event.

#### [ErrorMessageVersion2](#)

Field Name	Type	POST	Description
<b>errorCode</b>	<b>String</b>	Yes	The original error code generated or detected by the originator.
<b>message</b>	<b>String</b>	Yes	If an event has a status of "failure" or other non-successful operation, this field should provide a human-friendly error message Corresponds to Event.message in API Version 3 and above.

<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

## API version 3

Image

An image is used to track the different types of operating systems and hypervisors available in a data center. If the image is a hypervisor, it can contain other images which are the available virtual machines of the hypervisor.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this image.
<b>active</b>	<b>Boolean</b>	Yes	Yes	If false, the image is flagged as inactive and should not be used. Defaults to true.

Field Name	Type	POST	PUT	Description
<b>extensions</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	<p>A map containing maps which represent settings for provisioning managers. Only one extension may be present on an image at a time currently. Valid default provisioning manager specific extensions include 'xcat'.</p> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is false:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> </ul> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is true:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> <li>• hvGroupName - The name of the xCAT hypervisor group</li> <li>• vmGroupName - The name of the xCAT VM group</li> </ul>
<b>features</b>	<b>Set&lt;String&gt;</b>	Yes	Yes	The set of features used by the provisioning manager.

Field Name	Type	POST	PUT	Description
<b>hypervisor</b>	<b>Boolean</b>	Yes	Yes	Whether or not the image is a hypervisor. Required during POST. Note that this is related to, but not the same as, <a href="#">supportsPhysicalMachine</a> . Also, when this is false, no <a href="#">virtualizedImages</a> may be specified for an image.
<b>hypervisorType</b>	<b>String</b>	Yes	Yes	The type of the hypervisor, which is indicative of the hypervisor technology used in this image. Required if this image is a hypervisor image.
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this image. Required during POST.
<b>osType</b>	<b>String</b>	Yes	Yes	The type of the operating system such as 'Linux' or 'Windows'. Required during POST.
<b>supportsPhysicalMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a physical machine, defaults to false. Either this or <a href="#">supportsVirtualMachine</a> must be set to true. Note that this is related to, but not the same as, <a href="#">hypervisor</a> . Some images may not be hypervisors but can be provisioned on a physical machine.
<b>supportsVirtualMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a virtual machine, defaults to false. Either this or <a href="#">supportsPhysicalMachine</a> must be set to true.
<b>templateName</b>	<b>String</b>	Yes	Yes	The VM template to use for this image. Only valid if the <a href="#">type</a> is set to a valid template type such as 'ImageType.LINKED_CLONE'.

Field Name	Type	POST	PUT	Description
<b>type</b>	<a href="#">ImageType</a>	Yes	Yes	The type of the image. This property may affect the valid values to use for other fields. See <a href="#">ImageType</a> for more information. (See also: <a href="#">templateName</a> .)
<b>virtualizedImages</b>	<a href="#">Set&lt;Image&gt;</a>	Yes	Yes	The set of images available on this hypervisor.

[ImageType](#)

Represents an image type, such as stateful or stateless. This is used by provisioning managers and applications to correctly provision and represent the image.

Certain types are only valid for images configured as templates using the [Image.templateName](#) field. This currently includes [ImageType.LINKED\\_CLONE](#) and [ImageType.FULL\\_CLONE](#).

Value	Description
<b>STATEFUL</b>	
<b>STATELESS</b>	
<b>STATELITE</b>	
<b>LINKED_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.
<b>FULL_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.

## API version 2

Image

An image is used to track the different types of operating systems and hypervisors available in a data center. If the image is a hypervisor, it can contain other images which are the available virtual machines of the hypervisor.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this image.
<b>active</b>	<b>Boolean</b>	Yes	Yes	If false, the image is flagged as inactive and should not be used. Defaults to true.

Field Name	Type	POST	PUT	Description
<b>extensions</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	<p>A map containing maps which represent settings for provisioning managers. Only one extension may be present on an image at a time currently. Valid default provisioning manager specific extensions include 'xcat'.</p> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is false:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> </ul> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is true:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> <li>• hvGroupName - The name of the xCAT hypervisor group</li> <li>• vmGroupName - The name of the xCAT VM group</li> </ul>
<b>features</b>	<b>Set&lt;String&gt;</b>	Yes	Yes	The set of features used by the provisioning manager.

Field Name	Type	POST	PUT	Description
<b>hypervisor</b>	<b>Boolean</b>	Yes	Yes	Whether or not the image is a hypervisor. Required during POST. Note that this is related to, but not the same as, <a href="#">supportsPhysicalMachine</a> . Also, when this is false, no <a href="#">virtualizedImages</a> may be specified for an image.
<b>hypervisorType</b>	<b>String</b>	Yes	Yes	The type of the hypervisor, which is indicative of the hypervisor technology used in this image. Required if this image is a hypervisor image.
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this image. Required during POST.
<b>osType</b>	<b>String</b>	Yes	Yes	The type of the operating system such as 'Linux' or 'Windows'. Required during POST.
<b>supportsPhysicalMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a physical machine, defaults to false. Either this or <a href="#">supportsVirtualMachine</a> must be set to true. Note that this is related to, but not the same as, <a href="#">hypervisor</a> . Some images may not be hypervisors but can be provisioned on a physical machine.
<b>supportsVirtualMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a virtual machine, defaults to false. Either this or <a href="#">supportsPhysicalMachine</a> must be set to true.
<b>templateName</b>	<b>String</b>	Yes	Yes	The VM template to use for this image. Only valid if the <a href="#">type</a> is set to a valid template type such as 'ImageType.LINKED_CLONE'.

Field Name	Type	POST	PUT	Description
<b>type</b>	<a href="#">ImageType</a>	Yes	Yes	The type of the image. This property may affect the valid values to use for other fields. See <a href="#">ImageType</a> for more information. (See also: <a href="#">templateName</a> .)
<b>virtualizedImages</b>	<a href="#">Set&lt;Image&gt;</a>	Yes	Yes	The set of images available on this hypervisor.

[ImageType](#)

Represents an image type, such as stateful or stateless. This is used by provisioning managers and applications to correctly provision and represent the image.

Certain types are only valid for images configured as templates using the [Image.templateName](#) field. This currently includes [ImageType.LINKED\\_CLONE](#) and [ImageType.FULL\\_CLONE](#).

Value	Description
<b>STATEFUL</b>	
<b>STATELESS</b>	
<b>STATELITE</b>	
<b>LINKED_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.
<b>FULL_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.

## API version 1

Image

An image is used to track the different types of operating systems and hypervisors available in a data center. If the image is a hypervisor, it can contain other images which are the available virtual machines of the hypervisor.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this image.
<b>active</b>	<b>Boolean</b>	Yes	Yes	If false, the image is flagged as inactive and should not be used. Defaults to true.

Field Name	Type	POST	PUT	Description
<b>extensions</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	<p>A map containing maps which represent settings for provisioning managers. Only one extension may be present on an image at a time currently. Valid default provisioning manager specific extensions include 'xcat'.</p> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is false:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> </ul> <p>Required properties for 'xcat' when <a href="#">hypervisor</a> is true:</p> <ul style="list-style-type: none"> <li>• os - The name of the operating system according to xCAT</li> <li>• architecture - The architecture, such as x86_64</li> <li>• profile - The xCAT profile to use for the image</li> <li>• hvGroupName - The name of the xCAT hypervisor group</li> <li>• vmGroupName - The name of the xCAT VM group</li> </ul>
<b>features</b>	<b>Set&lt;String&gt;</b>	Yes	Yes	The set of features used by the provisioning manager.

Field Name	Type	POST	PUT	Description
<b>hypervisor</b>	<b>Boolean</b>	Yes	Yes	Whether or not the image is a hypervisor. Required during POST. Note that this is related to, but not the same as, <a href="#">supportsPhysicalMachine</a> . Also, when this is false, no <a href="#">virtualizedImages</a> may be specified for an image.
<b>hypervisorType</b>	<b>String</b>	Yes	Yes	The type of the hypervisor, which is indicative of the hypervisor technology used in this image. Required if this image is a hypervisor image.
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this image. Required during POST.
<b>osType</b>	<b>String</b>	Yes	Yes	The type of the operating system such as 'Linux' or 'Windows'. Required during POST.
<b>supportsPhysicalMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a physical machine, defaults to false. Either this or <a href="#">supportsVirtualMachine</a> must be set to true. Note that this is related to, but not the same as, <a href="#">hypervisor</a> . Some images may not be hypervisors but can be provisioned on a physical machine.
<b>supportsVirtualMachine</b>	<b>Boolean</b>	Yes	Yes	Specifies whether the image can be used to provision a virtual machine, defaults to false. Either this or <a href="#">supportsPhysicalMachine</a> must be set to true.
<b>templateName</b>	<b>String</b>	Yes	Yes	The VM template to use for this image. Only valid if the <a href="#">type</a> is set to a valid template type such as 'ImageType.LINKED_CLONE'.

Field Name	Type	POST	PUT	Description
<b>type</b>	<a href="#">ImageType</a>	Yes	Yes	The type of the image. This property may affect the valid values to use for other fields. See <a href="#">ImageType</a> for more information. (See also: <a href="#">templateName</a> .)
<b>virtualizedImages</b>	<a href="#">Set&lt;Image&gt;</a>	Yes	Yes	The set of images available on this hypervisor.

### [ImageType](#)

Represents an image type, such as stateful or stateless. This is used by provisioning managers and applications to correctly provision and represent the image.

Certain types are only valid for images configured as templates using the [Image.templateName](#) field. This currently includes [ImageType.LINKED\\_CLONE](#) and [ImageType.FULL\\_CLONE](#).

Value	Description
<b>STATEFUL</b>	
<b>STATELESS</b>	
<b>STATELITE</b>	
<b>LINKED_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.
<b>FULL_CLONE</b>	Template type. When this image type is used, the <a href="#">Image.hypervisor</a> field must be set to false, <a href="#">Image.supportsVirtualMachine</a> must be true, and <a href="#">Image.supportsPhysicalMachine</a> must be false.

## API version 3

JobArray

Job arrays are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if 235[1] is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Field Name	Type	POST	Description
<b>cancellationPolicy</b>	<a href="#">CancellationPolicyInformation</a>	Yes	Represents the cancellation policy to use for the job array.
<b>indexRanges</b>	<a href="#">List&lt;JobArrayIndexRange&gt;</a>	Yes	The index ranges used to generate the sub-job indices. To use hard-coded values, see <a href="#">indexValues</a> .
<b>indexValues</b>	<b>List&lt;Long&gt;</b>	Yes	The index values to use for the sub-jobs. To use ranges, see <a href="#">indexRanges</a> .
<b>jobPrototype</b>	<a href="#">Job</a>	Yes	The definition of the job to use for each sub-job.
<b>name</b>	<b>String</b>	Yes	The name of the job array. In MWS API version 1, this is stored in the <code>name</code> field of the created jobs. In MWS API version 2, this is stored in the <code>customName</code> field of the created jobs.
<b>slotLimit</b>	<b>Long</b>	Yes	(Optional) The number of sub-jobs in the array that can run at a time.

CancellationPolicyInformation

Job arrays can be canceled based on the success or failure of the first or any sub-job. This class represents the failure policies.

Field Name	Type	POST	Description
<b>anyJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of any sub-job. May be used in combination with <a href="#">firstJob</a> .
<b>firstJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of the first sub-job (array index 1). May be used in combination with <a href="#">anyJob</a> .

CancellationPolicy

This enumeration represents job array cancellation policies, and is to be used in combination with CancellationPolicyInformation.

Value	Description
<b>SUCCESS</b>	Cancels the job array if the specified sub-job succeeds.
<b>FAILURE</b>	Cancels the job array if the specified sub-job fails.

JobArrayIndexRange

Represents information about a job index expression. This is used when creating job arrays only.

Field Name	Type	POST	Description
<b>endIndex</b>	<b>Long</b>	Yes	The end of the index range. i.e. 10 for 1-10.
<b>increment</b>	<b>Long</b>	Yes	The increment of the index range, defaults to 1 and must be greater than 0. For a range of 1-10 with an increment of 2, the list of indices will be [1, 3, 5, 7, 9].
<b>startIndex</b>	<b>Long</b>	Yes	The start of the index range. i.e. 1 for 1-10.

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.

Field Name	Type	POST	Description
<b>arrayIndex</b>	<b>Long</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>attributes</b>	<b>Set&lt;String&gt;</b>	Yes	The list of generic attributes associated with this job.
<b>blocks</b>	<a href="#">Set&lt;JobBlock&gt;</a>	No	Reasons the job is blocked from running.
<b>bypassCount</b>	<b>Integer</b>	No	The number of times the job has been backfilled.
<b>cancelCount</b>	<b>Integer</b>	No	The number of times a job has received a cancel request.
<b>commandFile</b>	<b>String</b>	Yes	The path to the file that is executed when this job runs. This is the script that will call all the work of this job.
<b>commandLineArguments</b>	<b>String</b>	Yes	The command line arguments passed to the <code>commandFile</code> .
<b>completionCode</b>	<b>Integer</b>	No	The exit code from this job.
<b>cpuTime</b>	<b>Long</b>	No	CPU usage time in seconds as reported by the resource manager.

Field Name	Type	POST	Description
<b>credentials</b>	<a href="#">JobCredentials</a>	Yes	The credentials (user and group, for example) associated with this job.
<b>customName</b>	<b>String</b>	Yes	The user-specified name of this job.
<b>dates</b>	<a href="#">JobDates</a>	Yes	Various dates associated with this job.
<b>deferCount</b>	<b>Integer</b>	No	The number of times a job has been deferred.
<b>dependencies</b>	<a href="#">Set&lt;JobDependency&gt;</a>	Yes	Dependencies that must be fulfilled before the job can start.
<b>description</b>	<b>String</b>	No	The description of the job. Can be set only in a job template.
<b>duration</b>	<b>Long</b>	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>durationActive</b>	<b>Long</b>	No	The length of time in seconds the job has been active or running.
<b>durationQueued</b>	<b>Long</b>	No	The length of time in seconds the job has been eligible to run in the queue.
<b>durationRemaining</b>	<b>Long</b>	No	An estimate of the time remaining, in seconds, before the job will complete.
<b>durationSuspended</b>	<b>Long</b>	No	The length of time in seconds the job has been suspended.

Field Name	Type	POST	Description
<b>emailNotifyAddresses</b>	<b>Set&lt;String&gt;</b>	Yes	The list of addresses to whom email is sent by the execution server.
<b>emailNotifyTypes</b>	<a href="#"><u>Set&lt;JobEmailNotifyType&gt;</u></a>	Yes	The list of email notify types attached to the job.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of environment variables for this job.
<b>epilogScript</b>	<b>String</b>	Yes	The path to the TORQUE epilog script.
<b>flags</b>	<a href="#"><u>Set&lt;JobFlag&gt;</u></a>	Yes	The flags that are set on this job.
<b>holdDate</b>	<b>Date</b>	No	The date the most recent hold was placed on the job.
<b>holdReason</b>	<a href="#"><u>JobHoldReason</u></a>	No	The reason the job is on hold.
<b>holds</b>	<a href="#"><u>Set&lt;JobHoldType&gt;</u></a>	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
<b>initialWorkingDirectory</b>	<b>String</b>	Yes	The path to the directory in which the job will be started.
<b>isActive</b>	<b>Boolean</b>	No	True if the job is active, false if the job is complete.
<b>jobGroup</b>	<b>String</b>	Yes	The job group to which this job belongs (different from credentials.group).

Field Name	Type	POST	Description
<b>masterNode</b>	<a href="#">DomainProxy</a>	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
<b>memorySecondsDedicated</b>	Double	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>memorySecondsUtilized</b>	Double	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	No	The list of messages associated with the job. The "message" field is valid during PUT.
<b>migrateCount</b>	Integer	No	The number of times the job has been migrated.
<b>minimumPreemptTime</b>	Long	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
<b>mwmName</b>	String	No	The name of the Moab Workload Manager instance that owns this job.
<b>name</b>	String	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>nodesExcluded</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The list of nodes that should not be considered for this job.

Field Name	Type	POST	Description
<b>nodesRequested</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The exact set, superset, or subset of nodes on which this job must run. (See also: <a href="#">nodesRequestedPolicy</a> .)
<b>nodesRequestedPolicy</b>	<a href="#">JobHostListMode</a>	Yes	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <a href="#">nodesRequested</a> .)
<b>partitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	The list of partitions that this job can access.
<b>partitionAccessListRequested</b>	<b>Set&lt;String&gt;</b>	Yes	The list of partitions that this job has requested.
<b>preemptCount</b>	<b>Integer</b>	No	The number of times the job has been preempted.
<b>priorities</b>	<a href="#">JobPriority</a>	Yes	The list of priorities for the job.
<b>processorSecondsDedicated</b>	<b>Double</b>	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>processorSecondsLimit</b>	<b>Double</b>	No	The limit for processorSecondsUtilized.
<b>processorSecondsUtilized</b>	<b>Double</b>	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>prologScript</b>	<b>String</b>	Yes	The path to the TORQUE prolog script.

Field Name	Type	POST	Description
<b>queueStatus</b>	<a href="#">JobQueueStatus</a>	No	The status of the job in its queue.
<b>rejectPolicies</b>	<a href="#">Set&lt;JobRejectPolicy&gt;</a>	No	The list of policies enabled when a job is rejected.
<b>requirements</b>	<a href="#">Set&lt;JobRequirement&gt;</a>	Yes	The list of items required for this job to run. Only <a href="#">JobRequirement.features</a> is valid during PUT.
<b>reservationRequested</b>	<a href="#">DomainProxy</a>	Yes	The reservation that the job requested.
<b>resourceFailPolicy</b>	<a href="#">JobResourceFailPolicyType</a>	Yes	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
<b>resourceManagerExtension</b>	String	Yes	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
<b>resourceManagers</b>	<a href="#">Set&lt;ResourceManager&gt;</a>	No	The list of resource managers associated with this job.
<b>rmStandardErrorFilePath</b>	String	No	The path to the remote file containing the standard error of the job.
<b>rmStandardOutputFilePath</b>	String	No	The path to the remote file containing the standard output of the job.

Field Name	Type	POST	Description
<b>standardErrorFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard output of the job.
<b>startCount</b>	<b>Integer</b>	No	The number of times the job has been started.
<b>states</b>	<a href="#"><u>JobStateInformation</u></a>	No	Information about the state of the job.
<b>submitHost</b>	<b>String</b>	Yes	The host from which the job was submitted.
<b>systemJobAction</b>	<b>String</b>	No	The action the system job will take.
<b>systemJobType</b>	<a href="#"><u>JobSystemJobType</u></a>	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
<b>targetedJobAction</b>	<a href="#"><u>JobActionType</u></a>	No	The action that this job is performing on another job.
<b>targetedJobName</b>	<b>String</b>	No	The name of the job on which this job is performing the targetedJobAction.
<b>templates</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	Yes	The list of all job templates to be set on this job.
<b>triggers</b>	<b>Set&lt;String&gt;</b>	No	The list of triggers associated with this job.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of variables that this job owns or sets on completion.

Field Name	Type	POST	Description
<b>virtualContainers</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	Yes	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>virtualMachines</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	No	The list of virtual machines that are allocated to this job.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	Yes	The requested Virtual Machine Usage Policy for this job.

JobBlock

Field Name	Type	POST	Description

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	Description
<b>account</b>	<b>String</b>	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
<b>group</b>	<b>String</b>	Yes	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
<b>jobClass</b>	<b>String</b>	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
<b>qos</b>	<b>String</b>	No	The quality of service assigned to this job.  The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
<b>qosRequested</b>	<b>String</b>	Yes	The quality of service requested for this job.

Field Name	Type	POST	Description
<b>user</b>	<b>String</b>	Yes	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	Description
<b>completedDate</b>	<b>Date</b>	No	
<b>createdDate</b>	<b>Date</b>	No	
<b>deadlineDate</b>	<b>Date</b>	Yes	The deadline for completion of the job.
<b>dispatchedDate</b>	<b>Date</b>	No	
<b>earliestRequestedStartDate</b>	<b>Date</b>	Yes	The job will start no sooner than this date.
<b>earliestStartDate</b>	<b>Date</b>	No	
<b>eligibleDate</b>	<b>Date</b>	No	
<b>lastCanceledDate</b>	<b>Date</b>	No	
<b>lastChargedDate</b>	<b>Date</b>	No	
<b>lastPreemptedDate</b>	<b>Date</b>	No	
<b>lastUpdatedDate</b>	<b>Date</b>	No	
<b>startDate</b>	<b>Date</b>	No	
<b>submitDate</b>	<b>Date</b>	No	
<b>terminationDate</b>	<b>Date</b>	No	

JobDependency

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object on on which the job is dependent.
<b>type</b>	<a href="#"><u>JobDependencyType</u></a>	Yes	The type of job dependency. Only set is valid for POST.
<b>value</b>	<b>String</b>	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
<b>set</b>	

JobEmailNotifyType

Value	Description
<b>JobStart</b>	
<b>JobEnd</b>	
<b>JobFail</b>	
<b>All</b>	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	

Value	Description
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.

Value	Description
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.

Value	Description
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

<b>Batch</b>	
<b>Defer</b>	
<b>All</b>	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object.

Message

Field Name	Type	POST	Description
<b>count</b>	<b>Integer</b>	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	The date this message was created.
<b>expireDate</b>	<b>Date</b>	No	The date this message expires.
<b>message</b>	<b>String</b>	No	The message itself.

JobHostListMode

Value	Description
<b>superset</b>	
<b>subset</b>	
<b>exactset</b>	

JobPriority

Field Name	Type	POST	Description
<b>run</b>	<b>Long</b>	No	
<b>start</b>	<b>Long</b>	No	
<b>system</b>	<b>Long</b>	No	

Field Name	Type	POST	Description
<b>user</b>	<b>Long</b>	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
<b>active</b>	
<b>blocked</b>	
<b>completed</b>	
<b>eligible</b>	

JobRejectPolicy

Value	Description
<b>CANCEL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>MAIL</b>	
<b>RETRY</b>	

JobRequirement

Field Name	Type	POST	Description
<b>architecture</b>	<b>String</b>	Yes	The architecture required by the job.
<b>attributes</b>	<a href="#">Map&lt;String, JobRequirementAttribute&gt;</a>	Yes	Required node attributes with version number support.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	The list of node features the job is scheduled against.
<b>featuresExcluded</b>	<b>Set&lt;String&gt;</b>	Yes	Excluded node features. That is, do not select nodes with these features. (See also: <a href="#">featuresExcludedMode</a> .)
<b>featuresExcludedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: <a href="#">featuresExcluded</a> .)
<b>featuresRequested</b>	<b>Set&lt;String&gt;</b>	Yes	Requested node features. (See also: <a href="#">featuresRequestedMode</a> .)
<b>featuresRequestedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: <a href="#">featuresRequested</a> .)
<b>image</b>	<b>String</b>	Yes	The image required by the job.
<b>index</b>	<b>Integer</b>	No	The index of the requirement, starting with 0.
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	No	Generic metrics associated with the job as reported by the resource manager.
<b>nodeAccessPolicy</b>	<a href="#">NodeAccessPolicy</a>	Yes	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.

Field Name	Type	POST	Description
<b>nodeAllocationPolicy</b>	<a href="#">NodeAllocationPolicy</a>	Yes	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
<b>nodeCount</b>	<b>Integer</b>	Yes	The number of nodes required by the job.
<b>nodeSet</b>	<b>String</b>	Yes	<p>The requested node set of the job. This must follow the format <code>SETSELECTION:SETTYPE[:SETLIST]</code></p> <ul style="list-style-type: none"> <li>• SETSELECTION - ANYOF, ONEOF, or FIRSTOF</li> <li>• SETTYPE - FEATURE or VARATTR</li> <li>• SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• ONEOF:FEATURE:fastos,hiprio,bigmem</li> <li>• FIRSTOF:VARATTR:datacenter=Provo:atacenter=SaltLake</li> </ul>
<b>nodes</b>	<a href="#">Set&lt;AllocatedNode&gt;</a>	No	Nodes that have been allocated to meet this requirement.
<b>reservation</b>	<a href="#">DomainProxy</a>	No	The allocated reservation (assigned after the job has a reservation).
<b>resourcesPerTask</b>	<a href="#">Map&lt;String, JobResource&gt;</a>	Yes	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
<b>taskCount</b>	<b>Integer</b>	Yes	The number of tasks (processors) required by this job.
<b>tasksPerNode</b>	<b>Integer</b>	Yes	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	Description
<b>comparator</b>	<b>String</b>	Yes	The comparison operator. Valid values: <ul style="list-style-type: none"> <li>• &gt;= - Greater than or equal to</li> <li>• &gt; - Greater than</li> <li>• &lt;= - Less than</li> <li>• &lt; - Less than</li> <li>• %= - Equals</li> <li>• %! - Not equals</li> <li>• Null - Defaults to %=</li> <li>• = - (Deprecated) Equivalent to %=</li> </ul>
<b>displayValue</b>	<b>String</b>	Yes	The display value for the required attribute.
<b>restriction</b>	<a href="#"><u>JobRequirementAttributeRestriction</u></a>	Yes	The restriction of this attribute. May be null, but defaults to <a href="#"><u>JobRequirementAttributeRestriction.must</u></a> .
<b>value</b>	<b>String</b>	Yes	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
<b>must</b>	

JobRequirementFeaturesMode

Value	Description
<b>OR</b>	
<b>AND</b>	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
<b>FIRSTSET</b>	

Value	Description
<b>MINGLOBAL</b>	
<b>MINLOCAL</b>	
<b>PLUGIN</b>	
<b>NONE</b>	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
<b>FIRSTAVAILABLE</b>	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
<b>LASTAVAILABLE</b>	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
<b>MINRESOURCE</b>	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
<b>CPULOAD</b>	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the <b>MINRESOURCE</b> algorithm is used.
<b>LOCAL</b>	This will call the locally created <b>contrib</b> node allocation algorithm.
<b>CONTIGUOUS</b>	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
<b>PRIORITY</b>	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
<b>FASTEST</b>	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
<b>PROCESSORLOAD</b>	Alias for CPULOAD.
<b>NODESPEED</b>	Alias for FASTEST.
<b>INREPORTEDORDER</b>	Alias for FIRSTAVAILABLE.
<b>INREVERSEREPORTEDORDER</b>	Alias for LASTAVAILABLE.
<b>CUSTOMPRIORITY</b>	Alias for PRIORITY.
<b>PROCESSORSPEEDBALANCE</b>	Alias for MAXBALANCE.
<b>MINIMUMCONFIGUREDRESOURCES</b>	Alias for MINRESOURCE.

#### AllocatedNode

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	No	
<b>taskCount</b>	<b>Integer</b>	No	

#### JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	Description
<b>dedicated</b>	<b>Integer</b>	No	The amount of this resource that has been allocated for running workload.
<b>utilized</b>	<b>Integer</b>	No	The amount of this resource that is currently reported as utilized by resource managers.

JobResourceFailPolicyType

Value	Description
<b>CANCEL</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>NOTIFY</b>	
<b>REQUEUE</b>	

ResourceManager

Field Name	Type	POST	Description
<b>isDestination</b>	<b>Boolean</b>	No	
<b>isSource</b>	<b>Boolean</b>	No	
<b>jobName</b>	<b>String</b>	No	
<b>name</b>	<b>String</b>	No	

JobStateInformation

Field Name	Type	POST	Description
<b>state</b>	<a href="#">JobState</a>	No	
<b>stateExpected</b>	<a href="#">JobState</a>	No	
<b>stateLastUpdatedDate</b>	Date	No	
<b>subState</b>	<a href="#">JobSubState</a>	No	

JobState

Value	Description
<b>Idle</b>	
<b>Starting</b>	
<b>Running</b>	
<b>Removed</b>	
<b>Completed</b>	
<b>Hold</b>	
<b>Deferred</b>	
<b>Vacated</b>	
<b>NotQueued</b>	
<b>Unknown</b>	
<b>Staging</b>	
<b>Suspended</b>	
<b>Blocked</b>	

JobSubState

Value	Description
<b>Epilogue</b>	
<b>Migrated</b>	
<b>Preempted</b>	
<b>Prologue</b>	

JobSystemJobType

Value	Description
<b>generic</b>	
<b>osprovision</b>	
<b>osprovision2</b>	
<b>poweroff</b>	
<b>poweron</b>	
<b>reset</b>	
<b>storage</b>	
<b>vmmap</b>	
<b>vmmigrate</b>	
<b>vmtracking</b>	

JobActionType

Value	Description
<b>DESTROY</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 2

JobArray

Job arrays are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if 235[1] is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Field Name	Type	POST	Description
<b>cancellationPolicy</b>	<a href="#">CancellationPolicyInformation</a>	Yes	Represents the cancellation policy to use for the job array.
<b>indexRanges</b>	<a href="#">List&lt;JobArrayIndexRange&gt;</a>	Yes	The index ranges used to generate the sub-job indices. To use hard-coded values, see <a href="#">indexValues</a> .
<b>indexValues</b>	<b>List&lt;Long&gt;</b>	Yes	The index values to use for the sub-jobs. To use ranges, see <a href="#">indexRanges</a> .
<b>jobPrototype</b>	<a href="#">Job</a>	Yes	The definition of the job to use for each sub-job.
<b>name</b>	<b>String</b>	Yes	The name of the job array. In MWS API version 1, this is stored in the <code>name</code> field of the created jobs. In MWS API version 2, this is stored in the <code>customName</code> field of the created jobs.
<b>slotLimit</b>	<b>Long</b>	Yes	(Optional) The number of sub-jobs in the array that can run at a time.

CancellationPolicyInformation

Job arrays can be canceled based on the success or failure of the first or any sub-job. This class represents the failure policies.

Field Name	Type	POST	Description
<b>anyJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of any sub-job. May be used in combination with <a href="#">firstJob</a> .
<b>firstJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of the first sub-job (array index 1). May be used in combination with <a href="#">anyJob</a> .

CancellationPolicy

This enumeration represents job array cancellation policies, and is to be used in combination with CancellationPolicyInformation.

Value	Description
<b>SUCCESS</b>	Cancels the job array if the specified sub-job succeeds.
<b>FAILURE</b>	Cancels the job array if the specified sub-job fails.

JobArrayIndexRange

Represents information about a job index expression. This is used when creating job arrays only.

Field Name	Type	POST	Description
<b>endIndex</b>	<b>Long</b>	Yes	The end of the index range. i.e. 10 for 1-10.
<b>increment</b>	<b>Long</b>	Yes	The increment of the index range, defaults to 1 and must be greater than 0. For a range of 1-10 with an increment of 2, the list of indices will be [1, 3, 5, 7, 9].
<b>startIndex</b>	<b>Long</b>	Yes	The start of the index range. i.e. 1 for 1-10.

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.

Field Name	Type	POST	Description
<b>arrayIndex</b>	<b>Long</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>attributes</b>	<b>Set&lt;String&gt;</b>	Yes	The list of generic attributes associated with this job.
<b>blocks</b>	<a href="#">Set&lt;JobBlock&gt;</a>	No	Reasons the job is blocked from running.
<b>bypassCount</b>	<b>Integer</b>	No	The number of times the job has been backfilled.
<b>cancelCount</b>	<b>Integer</b>	No	The number of times a job has received a cancel request.
<b>commandFile</b>	<b>String</b>	Yes	The path to the file that is executed when this job runs. This is the script that will call all the work of this job.
<b>commandLineArguments</b>	<b>String</b>	Yes	The command line arguments passed to the <code>commandFile</code> .
<b>completionCode</b>	<b>Integer</b>	No	The exit code from this job.
<b>cpuTime</b>	<b>Long</b>	No	CPU usage time in seconds as reported by the resource manager.

Field Name	Type	POST	Description
<b>credentials</b>	<a href="#">JobCredentials</a>	Yes	The credentials (user and group, for example) associated with this job.
<b>customName</b>	<b>String</b>	Yes	The user-specified name of this job.
<b>dates</b>	<a href="#">JobDates</a>	Yes	Various dates associated with this job.
<b>deferCount</b>	<b>Integer</b>	No	The number of times a job has been deferred.
<b>dependencies</b>	<a href="#">Set&lt;JobDependency&gt;</a>	Yes	Dependencies that must be fulfilled before the job can start.
<b>description</b>	<b>String</b>	No	The description of the job. Can be set only in a job template.
<b>duration</b>	<b>Long</b>	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>durationActive</b>	<b>Long</b>	No	The length of time in seconds the job has been active or running.
<b>durationQueued</b>	<b>Long</b>	No	The length of time in seconds the job has been eligible to run in the queue.
<b>durationRemaining</b>	<b>Long</b>	No	An estimate of the time remaining, in seconds, before the job will complete.
<b>durationSuspended</b>	<b>Long</b>	No	The length of time in seconds the job has been suspended.

Field Name	Type	POST	Description
<b>emailNotifyAddresses</b>	<b>Set&lt;String&gt;</b>	Yes	The list of addresses to whom email is sent by the execution server.
<b>emailNotifyTypes</b>	<a href="#"><u>Set&lt;JobEmailNotifyType&gt;</u></a>	Yes	The list of email notify types attached to the job.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of environment variables for this job.
<b>epilogScript</b>	<b>String</b>	Yes	The path to the TORQUE epilog script.
<b>flags</b>	<a href="#"><u>Set&lt;JobFlag&gt;</u></a>	Yes	The flags that are set on this job.
<b>holdDate</b>	<b>Date</b>	No	The date the most recent hold was placed on the job.
<b>holdReason</b>	<a href="#"><u>JobHoldReason</u></a>	No	The reason the job is on hold.
<b>holds</b>	<a href="#"><u>Set&lt;JobHoldType&gt;</u></a>	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
<b>initialWorkingDirectory</b>	<b>String</b>	Yes	The path to the directory in which the job will be started.
<b>isActive</b>	<b>Boolean</b>	No	True if the job is active, false if the job is complete.
<b>jobGroup</b>	<b>String</b>	Yes	The job group to which this job belongs (different from credentials.group).

Field Name	Type	POST	Description
<b>masterNode</b>	<a href="#">DomainProxy</a>	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
<b>memorySecondsDedicated</b>	Double	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>memorySecondsUtilized</b>	Double	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	No	The list of messages associated with the job. The "message" field is valid during PUT.
<b>migrateCount</b>	Integer	No	The number of times the job has been migrated.
<b>minimumPreemptTime</b>	Long	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
<b>mwmName</b>	String	No	The name of the Moab Workload Manager instance that owns this job.
<b>name</b>	String	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>nodesExcluded</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The list of nodes that should not be considered for this job.

Field Name	Type	POST	Description
<b>nodesRequested</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The exact set, superset, or subset of nodes on which this job must run. (See also: <a href="#">nodesRequestedPolicy</a> .)
<b>nodesRequestedPolicy</b>	<a href="#">JobHostListMode</a>	Yes	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <a href="#">nodesRequested</a> .)
<b>partitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	The list of partitions that this job can access.
<b>partitionAccessListRequested</b>	<b>Set&lt;String&gt;</b>	Yes	The list of partitions that this job has requested.
<b>preemptCount</b>	<b>Integer</b>	No	The number of times the job has been preempted.
<b>priorities</b>	<a href="#">JobPriority</a>	Yes	The list of priorities for the job.
<b>processorSecondsDedicated</b>	<b>Double</b>	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>processorSecondsLimit</b>	<b>Double</b>	No	The limit for processorSecondsUtilized.
<b>processorSecondsUtilized</b>	<b>Double</b>	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>prologScript</b>	<b>String</b>	Yes	The path to the TORQUE prolog script.

Field Name	Type	POST	Description
<b>queueStatus</b>	<a href="#">JobQueueStatus</a>	No	The status of the job in its queue.
<b>rejectPolicies</b>	<a href="#">Set&lt;JobRejectPolicy&gt;</a>	No	The list of policies enabled when a job is rejected.
<b>requirements</b>	<a href="#">Set&lt;JobRequirement&gt;</a>	Yes	The list of items required for this job to run. Only <a href="#">JobRequirement.features</a> is valid during PUT.
<b>reservationRequested</b>	<a href="#">DomainProxy</a>	Yes	The reservation that the job requested.
<b>resourceFailPolicy</b>	<a href="#">JobResourceFailPolicyType</a>	Yes	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
<b>resourceManagerExtension</b>	String	Yes	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
<b>resourceManagers</b>	<a href="#">Set&lt;ResourceManager&gt;</a>	No	The list of resource managers associated with this job.
<b>rmStandardErrorFilePath</b>	String	No	The path to the remote file containing the standard error of the job.
<b>rmStandardOutputFilePath</b>	String	No	The path to the remote file containing the standard output of the job.

Field Name	Type	POST	Description
<b>standardErrorFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard output of the job.
<b>startCount</b>	<b>Integer</b>	No	The number of times the job has been started.
<b>states</b>	<a href="#">JobStateInformation</a>	No	Information about the state of the job.
<b>submitHost</b>	<b>String</b>	Yes	The host from which the job was submitted.
<b>systemJobAction</b>	<b>String</b>	No	The action the system job will take.
<b>systemJobType</b>	<a href="#">JobSystemJobType</a>	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
<b>targetedJobAction</b>	<a href="#">JobActionType</a>	No	The action that this job is performing on another job.
<b>targetedJobName</b>	<b>String</b>	No	The name of the job on which this job is performing the targetedJobAction.
<b>templates</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The list of all job templates to be set on this job.
<b>triggers</b>	<b>Set&lt;String&gt;</b>	No	The list of triggers associated with this job.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of variables that this job owns or sets on completion.

Field Name	Type	POST	Description
<b>virtualContainers</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	Yes	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>virtualMachines</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	No	The list of virtual machines that are allocated to this job.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	Yes	The requested Virtual Machine Usage Policy for this job.

JobBlock

Field Name	Type	POST	Description
<b>category</b>	<a href="#"><u>JobBlockCategory</u></a>	No	
<b>message</b>	String	No	
<b>type</b>	<a href="#"><u>JobBlockType</u></a>	No	

JobBlockCategory

Value	Description
<b>depend</b>	
<b>jobBlock</b>	
<b>migrate</b>	

JobBlockType

<b>NoTime</b>	
<b>PartitionAccess</b>	
<b>Priority</b>	
<b>RMSubmissionFailure</b>	
<b>StartDate</b>	
<b>State</b>	
<b>SysLimits</b>	

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	Description
<b>account</b>	<b>String</b>	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
<b>group</b>	<b>String</b>	Yes	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
<b>jobClass</b>	<b>String</b>	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
<b>qos</b>	<b>String</b>	No	The quality of service assigned to this job.  The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
<b>qosRequested</b>	<b>String</b>	Yes	The quality of service requested for this job.

Field Name	Type	POST	Description
<b>user</b>	<b>String</b>	Yes	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	Description
<b>completedDate</b>	<b>Date</b>	No	
<b>createdDate</b>	<b>Date</b>	No	
<b>deadlineDate</b>	<b>Date</b>	Yes	The deadline for completion of the job.
<b>dispatchedDate</b>	<b>Date</b>	No	
<b>earliestRequestedStartDate</b>	<b>Date</b>	Yes	The job will start no sooner than this date.
<b>earliestStartDate</b>	<b>Date</b>	No	
<b>eligibleDate</b>	<b>Date</b>	No	
<b>lastCanceledDate</b>	<b>Date</b>	No	
<b>lastChargedDate</b>	<b>Date</b>	No	
<b>lastPreemptedDate</b>	<b>Date</b>	No	
<b>lastUpdatedDate</b>	<b>Date</b>	No	
<b>startDate</b>	<b>Date</b>	No	
<b>submitDate</b>	<b>Date</b>	No	
<b>terminationDate</b>	<b>Date</b>	No	

JobDependency

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object on on which the job is dependent.
<b>type</b>	<a href="#"><u>JobDependencyType</u></a>	Yes	The type of job dependency. Only set is valid for POST.
<b>value</b>	<b>String</b>	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
<b>set</b>	

JobEmailNotifyType

Value	Description
<b>JobStart</b>	
<b>JobEnd</b>	
<b>JobFail</b>	
<b>All</b>	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	

Value	Description
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.

Value	Description
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.

Value	Description
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobHoldReason

Value	Description
<b>Admin</b>	
<b>NoResources</b>	
<b>SystemLimitsExceeded</b>	
<b>BankFailure</b>	
<b>CannotDebitAccount</b>	

Value	Description
<b>InvalidAccount</b>	
<b>RMFailure</b>	
<b>RMReject</b>	
<b>PolicyViolation</b>	
<b>CredAccess</b>	
<b>CredHold</b>	
<b>PreReq</b>	
<b>Data</b>	
<b>Security</b>	
<b>MissingDependency</b>	

#### JobHoldType

Value	Description
<b>User</b>	
<b>System</b>	
<b>Batch</b>	
<b>Defer</b>	
<b>All</b>	

#### DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object.

Message

Field Name	Type	POST	Description
<b>count</b>	<b>Integer</b>	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	The date this message was created.
<b>expireDate</b>	<b>Date</b>	No	The date this message expires.
<b>message</b>	<b>String</b>	No	The message itself.

JobHostListMode

Value	Description
<b>superset</b>	
<b>subset</b>	
<b>exactset</b>	

JobPriority

Field Name	Type	POST	Description
<b>run</b>	<b>Long</b>	No	
<b>start</b>	<b>Long</b>	No	
<b>system</b>	<b>Long</b>	No	

Field Name	Type	POST	Description
<b>user</b>	<b>Long</b>	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
<b>active</b>	
<b>blocked</b>	
<b>completed</b>	
<b>eligible</b>	

JobRejectPolicy

Value	Description
<b>CANCEL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>MAIL</b>	
<b>RETRY</b>	

JobRequirement

Field Name	Type	POST	Description
<b>architecture</b>	<b>String</b>	Yes	The architecture required by the job.
<b>attributes</b>	<a href="#">Map&lt;String, JobRequirementAttribute&gt;</a>	Yes	Required node attributes with version number support.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	The list of node features the job is scheduled against.
<b>featuresExcluded</b>	<b>Set&lt;String&gt;</b>	Yes	Excluded node features. That is, do not select nodes with these features. (See also: <a href="#">featuresExcludedMode</a> .)
<b>featuresExcludedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: <a href="#">featuresExcluded</a> .)
<b>featuresRequested</b>	<b>Set&lt;String&gt;</b>	Yes	Requested node features. (See also: <a href="#">featuresRequestedMode</a> .)
<b>featuresRequestedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: <a href="#">featuresRequested</a> .)
<b>image</b>	<b>String</b>	Yes	The image required by the job.
<b>index</b>	<b>Integer</b>	No	The index of the requirement, starting with 0.
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	No	Generic metrics associated with the job as reported by the resource manager.
<b>nodeAccessPolicy</b>	<a href="#">NodeAccessPolicy</a>	Yes	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.

Field Name	Type	POST	Description
<b>nodeAllocationPolicy</b>	<a href="#">NodeAllocationPolicy</a>	Yes	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
<b>nodeCount</b>	<b>Integer</b>	Yes	The number of nodes required by the job.
<b>nodeSet</b>	<b>String</b>	Yes	<p>The requested node set of the job. This must follow the format <code>SETSELECTION:SETTYPE[:SETLIST]</code></p> <ul style="list-style-type: none"> <li>• SETSELECTION - ANYOF, ONEOF, or FIRSTOF</li> <li>• SETTYPE - FEATURE or VARATTR</li> <li>• SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• ONEOF:FEATURE:fastos,hiprio,bigmem</li> <li>• FIRSTOF:VARATTR:datacenter=Provo:atacenter=SaltLake</li> </ul>
<b>nodes</b>	<a href="#">Set&lt;AllocatedNode&gt;</a>	No	Nodes that have been allocated to meet this requirement.
<b>reservation</b>	<a href="#">DomainProxy</a>	No	The allocated reservation (assigned after the job has a reservation).
<b>resourcesPerTask</b>	<a href="#">Map&lt;String, JobResource&gt;</a>	Yes	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
<b>taskCount</b>	<b>Integer</b>	Yes	The number of tasks (processors) required by this job.
<b>tasksPerNode</b>	<b>Integer</b>	Yes	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	Description
<b>comparator</b>	<b>String</b>	Yes	The comparison operator. Valid values: <ul style="list-style-type: none"> <li>• &gt;= - Greater than or equal to</li> <li>• &gt; - Greater than</li> <li>• &lt;= - Less than</li> <li>• &lt; - Less than</li> <li>• %= - Equals</li> <li>• %! - Not equals</li> <li>• Null - Defaults to %=</li> <li>• = - (Deprecated) Equivalent to %=</li> </ul>
<b>displayValue</b>	<b>String</b>	Yes	The display value for the required attribute.
<b>restriction</b>	<a href="#"><u>JobRequirementAttributeRestriction</u></a>	Yes	The restriction of this attribute. May be null, but defaults to <a href="#"><u>JobRequirementAttributeRestriction.must</u></a> .
<b>value</b>	<b>String</b>	Yes	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
<b>must</b>	

JobRequirementFeaturesMode

Value	Description
<b>OR</b>	
<b>AND</b>	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
<b>FIRSTSET</b>	

Value	Description
<b>MINGLOBAL</b>	
<b>MINLOCAL</b>	
<b>PLUGIN</b>	
<b>NONE</b>	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
<b>FIRSTAVAILABLE</b>	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
<b>LASTAVAILABLE</b>	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
<b>MINRESOURCE</b>	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
<b>CPULOAD</b>	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the <b>MINRESOURCE</b> algorithm is used.
<b>LOCAL</b>	This will call the locally created <b>contrib</b> node allocation algorithm.
<b>CONTIGUOUS</b>	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
<b>PRIORITY</b>	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
<b>FASTEST</b>	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
<b>PROCESSORLOAD</b>	Alias for CPULOAD.
<b>NODESPEED</b>	Alias for FASTEST.
<b>INREPORTEDORDER</b>	Alias for FIRSTAVAILABLE.
<b>INREVERSEREPORTEDORDER</b>	Alias for LASTAVAILABLE.
<b>CUSTOMPRIORITY</b>	Alias for PRIORITY.
<b>PROCESSORSPEEDBALANCE</b>	Alias for MAXBALANCE.
<b>MINIMUMCONFIGUREDRESOURCES</b>	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	No	
<b>taskCount</b>	<b>Integer</b>	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	Description
<b>dedicated</b>	<b>Integer</b>	No	The amount of this resource that has been allocated for running workload.
<b>utilized</b>	<b>Integer</b>	No	The amount of this resource that is currently reported as utilized by resource managers.

JobResourceFailPolicyType

Value	Description
<b>CANCEL</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>NOTIFY</b>	
<b>REQUEUE</b>	

ResourceManager

Field Name	Type	POST	Description
<b>isDestination</b>	<b>Boolean</b>	No	
<b>isSource</b>	<b>Boolean</b>	No	
<b>jobName</b>	<b>String</b>	No	
<b>name</b>	<b>String</b>	No	

JobStateInformation

Field Name	Type	POST	Description
<b>state</b>	<a href="#">JobState</a>	No	
<b>stateExpected</b>	<a href="#">JobState</a>	No	
<b>stateLastUpdatedDate</b>	Date	No	
<b>subState</b>	<a href="#">JobSubState</a>	No	

JobState

Value	Description
<b>Idle</b>	
<b>Starting</b>	
<b>Running</b>	
<b>Removed</b>	
<b>Completed</b>	
<b>Hold</b>	
<b>Deferred</b>	
<b>Vacated</b>	
<b>NotQueued</b>	
<b>Unknown</b>	
<b>Staging</b>	
<b>Suspended</b>	
<b>Blocked</b>	

JobSubState

Value	Description
<b>Epilogue</b>	
<b>Migrated</b>	
<b>Preempted</b>	
<b>Prologue</b>	

JobSystemJobType

Value	Description
<b>generic</b>	
<b>osprovision</b>	
<b>osprovision2</b>	
<b>poweroff</b>	
<b>poweron</b>	
<b>reset</b>	
<b>storage</b>	
<b>vmmap</b>	
<b>vmmigrate</b>	
<b>vmtracking</b>	

JobActionType

Value	Description
<b>DESTROY</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 1

JobArray

Job arrays are an easy way to submit many sub-jobs that perform the same work using the same script, but operate on different sets of data. Sub-jobs are the jobs created by an array job and are identified by the array job ID and an index; for example, if 235[1] is an identifier, the number 235 is a job array ID, and 1 is the sub-job.

Field Name	Type	POST	Description
<b>cancellationPolicy</b>	<a href="#">CancellationPolicyInformation</a>	Yes	Represents the cancellation policy to use for the job array.
<b>indexRanges</b>	<a href="#">List&lt;JobArrayIndexRange&gt;</a>	Yes	The index ranges used to generate the sub-job indices. To use hard-coded values, see <a href="#">indexValues</a> .
<b>indexValues</b>	<b>List&lt;Long&gt;</b>	Yes	The index values to use for the sub-jobs. To use ranges, see <a href="#">indexRanges</a> .
<b>jobPrototype</b>	<a href="#">Job</a>	Yes	The definition of the job to use for each sub-job.
<b>name</b>	<b>String</b>	Yes	The name of the job array. In MWS API version 1, this is stored in the <code>name</code> field of the created jobs. In MWS API version 2, this is stored in the <code>customName</code> field of the created jobs.
<b>slotLimit</b>	<b>Long</b>	Yes	(Optional) The number of sub-jobs in the array that can run at a time.

CancellationPolicyInformation

Job arrays can be canceled based on the success or failure of the first or any sub-job. This class represents the failure policies.

Field Name	Type	POST	Description
<b>anyJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of any sub-job. May be used in combination with <a href="#">firstJob</a> .
<b>firstJob</b>	<a href="#">CancellationPolicy</a>	Yes	The cancellation policy based on the result of the first sub-job (array index 1). May be used in combination with <a href="#">anyJob</a> .

CancellationPolicy

This enumeration represents job array cancellation policies, and is to be used in combination with CancellationPolicyInformation.

Value	Description
<b>SUCCESS</b>	Cancels the job array if the specified sub-job succeeds.
<b>FAILURE</b>	Cancels the job array if the specified sub-job fails.

JobArrayIndexRange

Represents information about a job index expression. This is used when creating job arrays only.

Field Name	Type	POST	Description
<b>endIndex</b>	<b>Long</b>	Yes	The end of the index range. i.e. 10 for 1-10.
<b>increment</b>	<b>Long</b>	Yes	The increment of the index range, defaults to 1 and must be greater than 0. For a range of 1-10 with an increment of 2, the list of indices will be [1, 3, 5, 7, 9].
<b>startIndex</b>	<b>Long</b>	Yes	The start of the index range. i.e. 1 for 1-10.

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.

Field Name	Type	POST	Description
<b>arrayIndex</b>	<b>Long</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>attributes</b>	<b>Set&lt;String&gt;</b>	Yes	The list of generic attributes associated with this job.
<b>blocks</b>	<b><a href="#">Set&lt;JobBlock&gt;</a></b>	No	Reasons the job is blocked from running.
<b>bypassCount</b>	<b>Integer</b>	No	The number of times the job has been backfilled.
<b>cancelCount</b>	<b>Integer</b>	No	The number of times a job has received a cancel request.
<b>commandFile</b>	<b>String</b>	Yes	The path to the file that is executed when this job runs. This is the script that will call all the work of this job.
<b>commandLineArguments</b>	<b>String</b>	Yes	The command line arguments passed to the <code>commandFile</code> .
<b>completionCode</b>	<b>Integer</b>	No	The exit code from this job.
<b>cpuTime</b>	<b>Long</b>	No	CPU usage time in seconds as reported by the resource manager.

Field Name	Type	POST	Description
<b>credentials</b>	<a href="#">JobCredentials</a>	Yes	The credentials (user and group, for example) associated with this job.
<b>customName</b>	<b>String</b>	Yes	The user-specified name of this job.
<b>dates</b>	<a href="#">JobDates</a>	Yes	Various dates associated with this job.
<b>deferCount</b>	<b>Integer</b>	No	The number of times a job has been deferred.
<b>dependencies</b>	<a href="#">Set&lt;JobDependency&gt;</a>	Yes	Dependencies that must be fulfilled before the job can start.
<b>description</b>	<b>String</b>	No	The description of the job. Can be set only in a job template.
<b>duration</b>	<b>Long</b>	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>durationActive</b>	<b>Long</b>	No	The length of time in seconds the job has been active or running.
<b>durationQueued</b>	<b>Long</b>	No	The length of time in seconds the job has been eligible to run in the queue.
<b>durationRemaining</b>	<b>Long</b>	No	An estimate of the time remaining, in seconds, before the job will complete.
<b>durationSuspended</b>	<b>Long</b>	No	The length of time in seconds the job has been suspended.

Field Name	Type	POST	Description
<b>emailNotifyAddresses</b>	<b>Set&lt;String&gt;</b>	Yes	The list of addresses to whom email is sent by the execution server.
<b>emailNotifyTypes</b>	<a href="#"><u>Set&lt;JobEmailNotifyType&gt;</u></a>	Yes	The list of email notify types attached to the job.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of environment variables for this job.
<b>epilogScript</b>	<b>String</b>	Yes	The path to the TORQUE epilog script.
<b>flags</b>	<a href="#"><u>Set&lt;JobFlag&gt;</u></a>	Yes	The flags that are set on this job.
<b>holdDate</b>	<b>Date</b>	No	The date the most recent hold was placed on the job.
<b>holdReason</b>	<a href="#"><u>JobHoldReason</u></a>	No	The reason the job is on hold.
<b>holds</b>	<a href="#"><u>Set&lt;JobHoldType&gt;</u></a>	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
<b>initialWorkingDirectory</b>	<b>String</b>	Yes	The path to the directory in which the job will be started.
<b>isActive</b>	<b>Boolean</b>	No	True if the job is active, false if the job is complete.
<b>jobGroup</b>	<b>String</b>	Yes	The job group to which this job belongs (different from credentials.group).

Field Name	Type	POST	Description
<b>masterNode</b>	<a href="#">DomainProxy</a>	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
<b>memorySecondsDedicated</b>	Double	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>memorySecondsUtilized</b>	Double	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	No	The list of messages associated with the job. The "message" field is valid during PUT.
<b>migrateCount</b>	Integer	No	The number of times the job has been migrated.
<b>minimumPreemptTime</b>	Long	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
<b>mwmName</b>	String	No	The name of the Moab Workload Manager instance that owns this job.
<b>name</b>	String	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>nodesExcluded</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The list of nodes that should not be considered for this job.

Field Name	Type	POST	Description
<b>nodesRequested</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	The exact set, superset, or subset of nodes on which this job must run. (See also: <a href="#">nodesRequestedPolicy</a> .)
<b>nodesRequestedPolicy</b>	<a href="#">JobHostListMode</a>	Yes	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <a href="#">nodesRequested</a> .)
<b>partitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	The list of partitions that this job can access.
<b>partitionAccessListRequested</b>	<b>Set&lt;String&gt;</b>	Yes	The list of partitions that this job has requested.
<b>preemptCount</b>	<b>Integer</b>	No	The number of times the job has been preempted.
<b>priorities</b>	<a href="#">JobPriority</a>	Yes	The list of priorities for the job.
<b>processorSecondsDedicated</b>	<b>Double</b>	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>processorSecondsLimit</b>	<b>Double</b>	No	The limit for processorSecondsUtilized.
<b>processorSecondsUtilized</b>	<b>Double</b>	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>prologScript</b>	<b>String</b>	Yes	The path to the TORQUE prolog script.

Field Name	Type	POST	Description
<b>queueStatus</b>	<a href="#">JobQueueStatus</a>	No	The status of the job in its queue.
<b>rejectPolicies</b>	<a href="#">Set&lt;JobRejectPolicy&gt;</a>	No	The list of policies enabled when a job is rejected.
<b>requirements</b>	<a href="#">Set&lt;JobRequirement&gt;</a>	Yes	The list of items required for this job to run. Only <a href="#">JobRequirement.features</a> is valid during PUT.
<b>reservationRequested</b>	<a href="#">DomainProxy</a>	Yes	The reservation that the job requested.
<b>resourceFailPolicy</b>	<a href="#">JobResourceFailPolicyType</a>	Yes	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
<b>resourceManagerExtension</b>	String	Yes	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
<b>resourceManagers</b>	<a href="#">Set&lt;ResourceManager&gt;</a>	No	The list of resource managers associated with this job.
<b>rmStandardErrorFilePath</b>	String	No	The path to the remote file containing the standard error of the job.
<b>rmStandardOutputFilePath</b>	String	No	The path to the remote file containing the standard output of the job.

Field Name	Type	POST	Description
<b>standardErrorFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	<b>String</b>	Yes	The path to the file containing the standard output of the job.
<b>startCount</b>	<b>Integer</b>	No	The number of times the job has been started.
<b>states</b>	<a href="#"><u>JobStateInformation</u></a>	No	Information about the state of the job.
<b>submitHost</b>	<b>String</b>	Yes	The host from which the job was submitted.
<b>systemJobAction</b>	<b>String</b>	No	The action the system job will take.
<b>systemJobType</b>	<a href="#"><u>JobSystemJobType</u></a>	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
<b>targetedJobAction</b>	<a href="#"><u>JobActionType</u></a>	No	The action that this job is performing on another job.
<b>targetedJobName</b>	<b>String</b>	No	The name of the job on which this job is performing the targetedJobAction.
<b>templates</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	Yes	The list of all job templates to be set on this job.
<b>triggers</b>	<b>Set&lt;String&gt;</b>	No	The list of triggers associated with this job.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	The list of variables that this job owns or sets on completion.

Field Name	Type	POST	Description
<b>virtualContainers</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	Yes	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>virtualMachines</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	No	The list of virtual machines that are allocated to this job.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	Yes	The requested Virtual Machine Usage Policy for this job.

JobBlock

Field Name	Type	POST	Description
<b>category</b>	<a href="#"><u>JobBlockCategory</u></a>	No	
<b>message</b>	String	No	
<b>type</b>	<a href="#"><u>JobBlockType</u></a>	No	

JobBlockCategory

Value	Description
<b>depend</b>	
<b>jobBlock</b>	
<b>migrate</b>	

JobBlockType

Value	Description
<b>ActivePolicy</b>	
<b>BadUser</b>	
<b>Dependency</b>	
<b>EState</b>	
<b>FairShare</b>	
<b>Hold</b>	
<b>IdlePolicy</b>	
<b>LocalPolicy</b>	
<b>NoClass</b>	
<b>NoData</b>	
<b>NoResource</b>	
<b>NoTime</b>	
<b>PartitionAccess</b>	
<b>Priority</b>	
<b>RMSubmissionFailure</b>	
<b>StartDate</b>	
<b>State</b>	
<b>SysLimits</b>	

JobCredentials

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	Description
<b>account</b>	<b>String</b>	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
<b>group</b>	<b>String</b>	Yes	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
<b>jobClass</b>	<b>String</b>	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
<b>qos</b>	<b>String</b>	No	The quality of service assigned to this job.  The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
<b>qosRequested</b>	<b>String</b>	Yes	The quality of service requested for this job.

Field Name	Type	POST	Description
<b>user</b>	<b>String</b>	Yes	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	Description
<b>completedDate</b>	<b>Date</b>	No	
<b>createdDate</b>	<b>Date</b>	No	
<b>deadlineDate</b>	<b>Date</b>	Yes	The deadline for completion of the job.
<b>dispatchedDate</b>	<b>Date</b>	No	
<b>earliestRequestedStartDate</b>	<b>Date</b>	Yes	The job will start no sooner than this date.
<b>earliestStartDate</b>	<b>Date</b>	No	
<b>eligibleDate</b>	<b>Date</b>	No	
<b>lastCanceledDate</b>	<b>Date</b>	No	
<b>lastChargedDate</b>	<b>Date</b>	No	
<b>lastPreemptedDate</b>	<b>Date</b>	No	
<b>lastUpdatedDate</b>	<b>Date</b>	No	
<b>startDate</b>	<b>Date</b>	No	
<b>submitDate</b>	<b>Date</b>	No	
<b>terminationDate</b>	<b>Date</b>	No	

JobDependency

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object on on which the job is dependent.
<b>type</b>	<a href="#"><u>JobDependencyType</u></a>	Yes	The type of job dependency. Only set is valid for POST.
<b>value</b>	<b>String</b>	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
<b>set</b>	

JobEmailNotifyType

Value	Description
<b>JobStart</b>	
<b>JobEnd</b>	
<b>JobFail</b>	
<b>All</b>	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	

Value	Description
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.

Value	Description
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.

Value	Description
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobHoldReason

Value	Description
<b>Admin</b>	
<b>NoResources</b>	
<b>SystemLimitsExceeded</b>	
<b>BankFailure</b>	
<b>CannotDebitAccount</b>	

Value	Description
<b>InvalidAccount</b>	
<b>RMFailure</b>	
<b>RMReject</b>	
<b>PolicyViolation</b>	
<b>CredAccess</b>	
<b>CredHold</b>	
<b>PreReq</b>	
<b>Data</b>	
<b>Security</b>	
<b>MissingDependency</b>	

JobHoldType

Value	Description
<b>User</b>	
<b>System</b>	
<b>Batch</b>	
<b>Defer</b>	
<b>All</b>	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	Yes	The name of the object.

Message

Field Name	Type	POST	Description
<b>count</b>	<b>Integer</b>	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	The date this message was created.
<b>expireDate</b>	<b>Date</b>	No	The date this message expires.
<b>message</b>	<b>String</b>	No	The message itself.

JobHostListMode

Value	Description
<b>superset</b>	
<b>subset</b>	
<b>exactset</b>	

JobPriority

Field Name	Type	POST	Description
<b>run</b>	<b>Long</b>	No	
<b>start</b>	<b>Long</b>	No	
<b>system</b>	<b>Long</b>	No	

Field Name	Type	POST	Description
<b>user</b>	<b>Long</b>	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
<b>active</b>	
<b>blocked</b>	
<b>completed</b>	
<b>eligible</b>	

JobRejectPolicy

Value	Description
<b>CANCEL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>MAIL</b>	
<b>RETRY</b>	

JobRequirement

Field Name	Type	POST	Description
<b>architecture</b>	<b>String</b>	Yes	The architecture required by the job.
<b>attributes</b>	<a href="#">Map&lt;String, JobRequirementAttribute&gt;</a>	Yes	Required node attributes with version number support.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	The list of node features the job is scheduled against.
<b>featuresExcluded</b>	<b>Set&lt;String&gt;</b>	Yes	Excluded node features. That is, do not select nodes with these features. (See also: <a href="#">featuresExcludedMode</a> .)
<b>featuresExcludedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: <a href="#">featuresExcluded</a> .)
<b>featuresRequested</b>	<b>Set&lt;String&gt;</b>	Yes	Requested node features. (See also: <a href="#">featuresRequestedMode</a> .)
<b>featuresRequestedMode</b>	<a href="#">JobRequirementFeaturesMode</a>	Yes	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: <a href="#">featuresRequested</a> .)
<b>image</b>	<b>String</b>	Yes	The image required by the job.
<b>index</b>	<b>Integer</b>	No	The index of the requirement, starting with 0.
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	No	Generic metrics associated with the job as reported by the resource manager.
<b>nodeAccessPolicy</b>	<a href="#">NodeAccessPolicy</a>	Yes	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.

Field Name	Type	POST	Description
<b>nodeAllocationPolicy</b>	<a href="#">NodeAllocationPolicy</a>	Yes	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
<b>nodeCount</b>	<b>Integer</b>	Yes	The number of nodes required by the job.
<b>nodeSet</b>	<b>String</b>	Yes	<p>The requested node set of the job. This must follow the format <code>SETSELECTION:SETTYPE[:SETLIST]</code></p> <ul style="list-style-type: none"> <li>• SETSELECTION - ANYOF, ONEOF, or FIRSTOF</li> <li>• SETTYPE - FEATURE or VARATTR</li> <li>• SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• ONEOF:FEATURE:fastos,hiprio,bigmem</li> <li>• FIRSTOF:VARATTR:datacenter=Provo:atacenter=SaltLake</li> </ul>
<b>nodes</b>	<a href="#">Set&lt;AllocatedNode&gt;</a>	No	Nodes that have been allocated to meet this requirement.
<b>reservation</b>	<a href="#">DomainProxy</a>	No	The allocated reservation (assigned after the job has a reservation).
<b>resourcesPerTask</b>	<a href="#">Map&lt;String, JobResource&gt;</a>	Yes	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
<b>taskCount</b>	<b>Integer</b>	Yes	The number of tasks (processors) required by this job.
<b>tasksPerNode</b>	<b>Integer</b>	Yes	The number of tasks to map to each node.

JobRequirementAttribute

Field Name	Type	POST	Description
<b>comparator</b>	<b>String</b>	Yes	The comparison operator. Valid values: <ul style="list-style-type: none"> <li>• &gt;= - Greater than or equal to</li> <li>• &gt; - Greater than</li> <li>• &lt;= - Less than</li> <li>• &lt; - Less than</li> <li>• %= - Equals</li> <li>• %! - Not equals</li> <li>• Null - Defaults to %=</li> <li>• = - (Deprecated) Equivalent to %=</li> </ul>
<b>displayValue</b>	<b>String</b>	Yes	The display value for the required attribute.
<b>restriction</b>	<a href="#"><u>JobRequirementAttributeRestriction</u></a>	Yes	The restriction of this attribute. May be null, but defaults to <a href="#"><u>JobRequirementAttributeRestriction.must</u></a> .
<b>value</b>	<b>String</b>	Yes	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
<b>must</b>	

JobRequirementFeaturesMode

Value	Description
<b>OR</b>	
<b>AND</b>	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
<b>FIRSTSET</b>	

Value	Description
<b>MINGLOBAL</b>	
<b>MINLOCAL</b>	
<b>PLUGIN</b>	
<b>NONE</b>	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
<b>FIRSTAVAILABLE</b>	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
<b>LASTAVAILABLE</b>	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
<b>MINRESOURCE</b>	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
<b>CPULOAD</b>	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the <b>MINRESOURCE</b> algorithm is used.
<b>LOCAL</b>	This will call the locally created <b>contrib</b> node allocation algorithm.
<b>CONTIGUOUS</b>	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
<b>PRIORITY</b>	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
<b>FASTEST</b>	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
<b>PROCESSORLOAD</b>	Alias for CPULOAD.
<b>NODESPEED</b>	Alias for FASTEST.
<b>INREPORTEDORDER</b>	Alias for FIRSTAVAILABLE.
<b>INREVERSEREPORTEDORDER</b>	Alias for LASTAVAILABLE.
<b>CUSTOMPRIORITY</b>	Alias for PRIORITY.
<b>PROCESSORSPEEDBALANCE</b>	Alias for MAXBALANCE.
<b>MINIMUMCONFIGUREDRESOURCES</b>	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	Description
<b>name</b>	<b>String</b>	No	
<b>taskCount</b>	<b>Integer</b>	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	Description
<b>dedicated</b>	<b>Integer</b>	No	The amount of this resource that has been allocated for running workload.
<b>utilized</b>	<b>Integer</b>	No	The amount of this resource that is currently reported as utilized by resource managers.

JobResourceFailPolicyType

Value	Description
<b>CANCEL</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>NOTIFY</b>	
<b>REQUEUE</b>	

ResourceManager

Field Name	Type	POST	Description
<b>isDestination</b>	<b>Boolean</b>	No	
<b>isSource</b>	<b>Boolean</b>	No	
<b>jobName</b>	<b>String</b>	No

API version 3

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POS T	PU T	Description
<b>id</b>	<b>String</b>	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
<b>arrayIndex</b>	<b>Long</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>attributes</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of generic attributes associated with this job.
<b>blocks</b>	<a href="#">Set&lt;JobBlock&gt;</a>	No	No	Reasons the job is blocked from running.
<b>bypassCount</b>	<b>Integer</b>	No	No	The number of times the job has been backfilled.

Field Name	Type	POST	PUT	Description
<b>cancelCount</b>	<b>Integer</b>	No	No	The number of times a job has received a cancel request.
<b>commandFile</b>	<b>String</b>	Yes	No	The path to the file that is executed when this job runs. This is the script that will call all the work of this job.
<b>commandLineArguments</b>	<b>String</b>	Yes	No	The command line arguments passed to the commandFile.
<b>completionCode</b>	<b>Integer</b>	No	No	The exit code from this job.
<b>cpuTime</b>	<b>Long</b>	No	No	CPU usage time in seconds as reported by the resource manager.
<b>credentials</b>	<a href="#"><u>JobCredentials</u></a>	Yes	Yes	The credentials (user and group, for example) associated with this job.
<b>customName</b>	<b>String</b>	Yes	Yes	The user-specified name of this job.
<b>dates</b>	<a href="#"><u>JobDates</u></a>	Yes	Yes	Various dates associated with this job.
<b>deferCount</b>	<b>Integer</b>	No	No	The number of times a job has been deferred.
<b>dependencies</b>	<a href="#"><u>Set&lt;JobDependency&gt;</u></a>	Yes	No	Dependencies that must be fulfilled before the job can start.
<b>description</b>	<b>String</b>	No	No	The description of the job. Can be set only in a job template.

Field Name	Type	POST	PUT	Description
<b>duration</b>	<b>Long</b>	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>durationActive</b>	<b>Long</b>	No	No	The length of time in seconds the job has been active or running.
<b>durationQueued</b>	<b>Long</b>	No	No	The length of time in seconds the job has been eligible to run in the queue.
<b>durationRemaining</b>	<b>Long</b>	No	No	An estimate of the time remaining, in seconds, before the job will complete.
<b>durationSuspended</b>	<b>Long</b>	No	No	The length of time in seconds the job has been suspended.
<b>emailNotifyAddresses</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of addresses to whom email is sent by the execution server.
<b>emailNotifyTypes</b>	<a href="#"><u>Set&lt;JobEmailNotifyType&gt;</u></a>	Yes	No	The list of email notify types attached to the job.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	No	The list of environment variables for this job.
<b>epilogScript</b>	<b>String</b>	Yes	No	The path to the TORQUE epilog script.

Field Name	Type	POST	PUT	Description
<b>flags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Yes	Yes	The flags that are set on this job.
<b>holdDate</b>	<b>Date</b>	No	No	The date the most recent hold was placed on the job.
<b>holdReason</b>	<a href="#">JobHoldReason</a>	No	No	The reason the job is on hold.
<b>holds</b>	<a href="#">Set&lt;JobHoldType&gt;</a>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
<b>initialWorkingDirectory</b>	<b>String</b>	Yes	No	The path to the directory in which the job will be started.
<b>isActive</b>	<b>Boolean</b>	No	No	True if the job is active, false if the job is complete.
<b>jobGroup</b>	<b>String</b>	Yes	No	The job group to which this job belongs (different from credentials.group).
<b>masterNode</b>	<a href="#">DomainProxy</a>	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
<b>memorySecondsDedicated</b>	<b>Double</b>	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>memorySecondsUtilized</b>	<b>Double</b>	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	PUT	Description
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
<b>migrateCount</b>	<b>Integer</b>	No	No	The number of times the job has been migrated.
<b>minimumPreemptTime</b>	<b>Long</b>	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
<b>mwmName</b>	<b>String</b>	No	No	The name of the Moab Workload Manager instance that owns this job.
<b>name</b>	<b>String</b>	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>nodesExcluded</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The list of nodes that should not be considered for this job.
<b>nodesRequested</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: <a href="#">nodesRequestedPolicy</a> .)
<b>nodesRequestedPolicy</b>	<a href="#">JobHostListMode</a>	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <a href="#">nodesRequested</a> .)
<b>partitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	No	The list of partitions that this job can access.

Field Name	Type	POST	PUT	Description
<b>partitionAccessListRequested</b>	<b>Set&lt;String&gt;</b>	Yes	Yes	The list of partitions that this job has requested.
<b>preemptCount</b>	<b>Integer</b>	No	No	The number of times the job has been preempted.
<b>priorities</b>	<a href="#">JobPriority</a>	Yes	Yes	The list of priorities for the job.
<b>processorSecondsDedicated</b>	<b>Double</b>	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>processorSecondsLimit</b>	<b>Double</b>	No	No	The limit for processorSecondsUtilized.
<b>processorSecondsUtilized</b>	<b>Double</b>	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>prologScript</b>	<b>String</b>	Yes	No	The path to the TORQUE prolog script.
<b>queueStatus</b>	<a href="#">JobQueueStatus</a>	No	No	The status of the job in its queue.
<b>rejectPolicies</b>	<a href="#">Set&lt;JobRejectPolicy&gt;</a>	No	No	The list of policies enabled when a job is rejected.
<b>requirements</b>	<a href="#">Set&lt;JobRequirement&gt;</a>	Yes	Yes	The list of items required for this job to run. Only <a href="#">JobRequirement.features</a> is valid during PUT.

Field Name	Type	POST	PULL	Description
<b>reservationRequested</b>	<a href="#">DomainProxy</a>	Yes	Yes	The reservation that the job requested.
<b>resourceFailPolicy</b>	<a href="#">JobResourceFailPolicy Type</a>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
<b>resourceManagerExtension</b>	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
<b>resourceManagers</b>	<a href="#">Set&lt;ResourceManager&gt;</a>	No	No	The list of resource managers associated with this job.
<b>rmStandardErrorFilePath</b>	String	No	No	The path to the remote file containing the standard error of the job.
<b>rmStandardOutputFilePath</b>	String	No	No	The path to the remote file containing the standard output of the job.
<b>standardErrorFilePath</b>	String	Yes	No	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	String	Yes	No	The path to the file containing the standard output of the job.
<b>startCount</b>	Integer	No	No	The number of times the job has been started.

Field Name	Type	POST	PUT	Description
<b>states</b>	<a href="#">JobStateInformation</a>	No	No	Information about the state of the job.
<b>submitHost</b>	String	Yes	No	The host from which the job was submitted.
<b>systemJobAction</b>	String	No	No	The action the system job will take.
<b>systemJobType</b>	<a href="#">JobSystemJobType</a>	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
<b>targetedJobAction</b>	<a href="#">JobActionType</a>	No	No	The action that this job is performing on another job.
<b>targetedJobName</b>	String	No	No	The name of the job on which this job is performing the targetedJobAction.
<b>templates</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The list of all job templates to be set on this job.
<b>triggers</b>	Set<String>	No	No	The list of triggers associated with this job.
<b>variables</b>	Map<String, Map>	Yes	Yes	The list of variables that this job owns or sets on completion.
<b>virtualContainers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>virtualMachines</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	No	The list of virtual machines that are allocated to this job.

Field Name	Type	POST	PUT	Description
<b>vmUsagePolicy</b>	<a href="#">VMUsagePolicy</a>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobBlock

Field Name	Type	POST	PUT	Description
<b>category</b>	<a href="#">JobBlockCategory</a>	No	No	
<b>message</b>	String	No	No	
<b>type</b>	<a href="#">JobBlockType</a>	No	No	

JobBlockCategory

Value	Description
<b>depend</b>	
<b>jobBlock</b>	
<b>migrate</b>	

JobBlockType

Value	Description
<b>ActivePolicy</b>	
<b>BadUser</b>	
<b>Dependency</b>	
<b>EState</b>	

Value	Description
<b>FairShare</b>	
<b>Hold</b>

<b>LocalPolicy</b>	
<b>NoClass</b>	
<b>NoData</b>	
<b>NoResource</b>	
<b>NoTime</b>	
<b>PartitionAccess</b>	
<b>Priority</b>	
<b>RMSubmissionFailure</b>	
<b>StartDate</b>	
<b>State</b>	
<b>SysLimits</b>	

[JobCredentials](#)

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
<b>account</b>	<b>String</b>	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
<b>group</b>	<b>String</b>	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
<b>jobClass</b>	<b>String</b>	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
<b>qos</b>	<b>String</b>	No	No	The quality of service assigned to this job.  The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
<b>qosRequested</b>	<b>String</b>	Yes	Yes	The quality of service requested for this job.

Field Name	Type	POST	PUT	Description
<b>user</b>	<b>String</b>	Yes	No	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

### JobDates

Field Name	Type	POST	PUT	Description
<b>completedDate</b>	<b>Date</b>	No	No	
<b>createdDate</b>	<b>Date</b>	No	No	
<b>deadlineDate</b>	<b>Date</b>	Yes	No	The deadline for completion of the job.
<b>dispatchedDate</b>	<b>Date</b>	No	No	
<b>earliestRequestedStartDate</b>	<b>Date</b>	Yes	Yes	The job will start no sooner than this date.
<b>earliestStartDate</b>	<b>Date</b>	No	No	
<b>eligibleDate</b>	<b>Date</b>	No	No	
<b>lastCanceledDate</b>	<b>Date</b>	No	No	
<b>lastChargedDate</b>	<b>Date</b>	No	No	
<b>lastPreemptedDate</b>	<b>Date</b>	No	No	
<b>lastUpdatedDate</b>	<b>Date</b>	No	No	
<b>startDate</b>	<b>Date</b>	No	No	
<b>submitDate</b>	<b>Date</b>	No	No	

Field Name	Type	POST	PUT	Description
<b>terminationDate</b>	<b>Date</b>	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	No	The name of the object on on which the job is dependent.
<b>type</b>	<a href="#"><u>JobDependencyType</u></a>	Yes	No	The type of job dependency. Only set is valid for POST.
<b>value</b>	<b>String</b>	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
<b>set</b>	

JobEmailNotifyType

Value	Description
<b>JobStart</b>	
<b>JobEnd</b>	
<b>JobFail</b>	
<b>All</b>	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.

Value	Description
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.

Value	Description
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobHoldReason

Value	Description
<b>Admin</b>	
<b>NoResources</b>	
<b>SystemLimitsExceeded</b>	
<b>BankFailure</b>	

Value	Description
<b>CannotDebitAccount</b>	
<b>InvalidAccount</b>	
<b>RMFailure</b>	
<b>RMReject</b>	
<b>PolicyViolation</b>	
<b>CredAccess</b>	
<b>CredHold</b>	
<b>PreReq</b>	
<b>Data</b>	
<b>Security</b>	
<b>MissingDependency</b>	

JobHoldType

Value	Description
<b>User</b>	
<b>System</b>	
<b>Batch</b>	
<b>Defer</b>	
<b>All</b>	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	No	The name of the object.

Message

Field Name	Type	POST	PUT	Description
<b>count</b>	<b>Integer</b>	No	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	No	The date this message was created.
<b>expireDate</b>	<b>Date</b>	No	No	The date this message expires.
<b>message</b>	<b>String</b>	No	Yes	The message itself.

JobHostListMode

Value	Description
<b>superset</b>	
<b>subset</b>	
<b>exactset</b>	

JobPriority

Field Name	Type	POST	PUT	Description
<b>run</b>	<b>Long</b>	No	No	
<b>start</b>	<b>Long</b>	No	No	

Field Name	Type	POST	PUT	Description
<b>system</b>	<b>Long</b>	No	No	
<b>user</b>	<b>Long</b>	Yes	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
<b>active</b>	
<b>blocked</b>	
<b>completed</b>	
<b>eligible</b>	

JobRejectPolicy

Value	Description
<b>CANCEL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>MAIL</b>	
<b>RETRY</b>	

JobRequirement

Field Name	Type	P O S T	P U T	Description
<b>architecture</b>	<b>String</b>	Ye s	N o	The architecture required by the job.
<b>attributes</b>	<a href="#"><u>Map&lt;String, JobRequirementAttribute&gt;</u></a>	Ye s	N o	Required node attributes with version number support.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	Ye s	The list of node features the job is scheduled against.
<b>featuresExcluded</b>	<b>Set&lt;String&gt;</b>	Ye s	N o	Excluded node features. That is, do not select nodes with these features. (See also: <a href="#"><u>featuresExcludedMode</u></a> .)
<b>featuresExcludedMode</b>	<a href="#"><u>JobRequirementFeaturesMode</u></a>	Ye s	N o	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: <a href="#"><u>featuresExcluded</u></a> .)
<b>featuresRequested</b>	<b>Set&lt;String&gt;</b>	Ye s	N o	Requested node features. (See also: <a href="#"><u>featuresRequestedMode</u></a> .)
<b>featuresRequestedMode</b>	<a href="#"><u>JobRequirementFeaturesMode</u></a>	Ye s	N o	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: <a href="#"><u>featuresRequested</u></a> .)
<b>image</b>	<b>String</b>	Ye s	N o	The image required by the job.
<b>index</b>	<b>Integer</b>	No	N o	The index of the requirement, starting with 0.
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	No	N o	Generic metrics associated with the job as reported by the resource manager.

Field Name	Type	P O S T	P U T	Description
<b>nodeAccessPolicy</b>	<a href="#">NodeAccessPolicy</a>	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
<b>nodeAllocationPolicy</b>	<a href="#">NodeAllocationPolicy</a>	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
<b>nodeCount</b>	<b>Integer</b>	Yes	No	The number of nodes required by the job.
<b>nodeSet</b>	<b>String</b>	Yes	No	<p>The requested node set of the job. This must follow the format <code>SETSELECTION:SETTYPE[:SETLIST]</code></p> <ul style="list-style-type: none"> <li>• SETSELECTION - ANYOF, ONEOF, or FIRSTOF</li> <li>• SETTYPE - FEATURE or VARATTR</li> <li>• SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• ONEOF:FEATURE:fastos,hiprio,bigm em</li> <li>• FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake</li> </ul>
<b>nodes</b>	<a href="#">Set&lt;AllocatedNode&gt;</a>	No	No	Nodes that have been allocated to meet this requirement.

Field Name	Type	P O S T	P U T	Description
<b>reservation</b>	<a href="#"><u>DomainProxy</u></a>	No	No	The allocated reservation (assigned after the job has a reservation).
<b>resourcesPerTask</b>	<a href="#"><u>Map&lt;String, JobResource&gt;</u></a>	Yes	No	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
<b>taskCount</b>	<b>Integer</b>	Yes	No	The number of tasks (processors) required by this job.
<b>tasksPerNode</b>	<b>Integer</b>	Yes	No	The number of tasks to map to each node.

[JobRequirementAttribute](#)

Field Name	Type	POST	PUT	Description
<b>comparator</b>	<b>String</b>	Yes	No	The comparison operator. Valid values: <ul style="list-style-type: none"> <li>• &gt;= - Greater than or equal to</li> <li>• &gt; - Greater than</li> <li>• &lt;= - Less than</li> <li>• &lt; - Less than</li> <li>• %= - Equals</li> <li>• %! - Not equals</li> <li>• Null - Defaults to %=</li> <li>• = - (Deprecated) Equivalent to %=</li> </ul>
<b>displayValue</b>	<b>String</b>	Yes	No	The display value for the required attribute.
<b>restriction</b>	<a href="#">JobRequirementAttributeRestriction</a>	Yes	No	The restriction of this attribute. May be null, but defaults to <a href="#">JobRequirementAttributeRestriction.must</a> .
<b>value</b>	<b>String</b>	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
<b>must</b>	

JobRequirementFeaturesMode

Value	Description
<b>OR</b>	
<b>AND</b>	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
<b>FIRSTSET</b>	

Value	Description
<b>MINGLOBAL</b>	
<b>MINLOCAL</b>	
<b>PLUGIN</b>	
<b>NONE</b>	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
<b>FIRSTAVAILABLE</b>	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
<b>LASTAVAILABLE</b>	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
<b>MINRESOURCE</b>	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
<b>CPULOAD</b>	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the <b>MINRESOURCE</b> algorithm is used.
<b>LOCAL</b>	This will call the locally created <b>contrib</b> node allocation algorithm.
<b>CONTIGUOUS</b>	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
<b>PRIORITY</b>	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
<b>FASTEST</b>	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
<b>PROCESSORLOAD</b>	Alias for CPULOAD.
<b>NODESPEED</b>	Alias for FASTEST.
<b>INREPORTEDORDER</b>	Alias for FIRSTAVAILABLE.
<b>INREVERSEREPORTEDORDER</b>	Alias for LASTAVAILABLE.
<b>CUSTOMPRIORITY</b>	Alias for PRIORITY.
<b>PROCESSORSPEEDBALANCE</b>	Alias for MAXBALANCE.
<b>MINIMUMCONFIGUREDRESOURCES</b>	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	No	No	
<b>taskCount</b>	<b>Integer</b>	No	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	PUT	Description
<b>dedicated</b>	<b>Integer</b>	No	No	The amount of this resource that has been allocated for running workload.
<b>utilized</b>	<b>Integer</b>	No	No	The amount of this resource that is currently reported as utilized by resource managers.

JobActionType

Value	Description
<b>DESTROY</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

API version 2

Job

This class represents a job in the Moab Workload Manager. A job is a request for compute resources (CPUs, memory, storage) with which the requester can do work for a given amount of time. In an HPC environment, this might be a batch script to perform a Monte Carlo simulation. In a cloud environment, this would be a virtual machine and its associated storage. Moab will evaluate the request and assign the requested resources to the requester based on policies, current demand, and other factors in the data center. A job will also usually have some process that Moab starts automatically at the assigned start time. In an HPC environment, this can be starting a batch script on the assigned nodes. In a cloud environment, this can be starting provisioning processes to create the virtual machine and storage and install software on it.

Field Name	Type	POS T	PU T	Description
<b>id</b>	<b>String</b>	No	No	The unique identifier of this job. Note: this field is not user-assigned and is generated by the database.
<b>arrayIndex</b>	<b>Long</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>attributes</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of generic attributes associated with this job.
<b>blocks</b>	<a href="#">Set&lt;JobBlock&gt;</a>	No	No	Reasons the job is blocked from running.
<b>bypassCount</b>	<b>Integer</b>	No	No	The number of times the job has been backfilled.

Field Name	Type	POST	PUT	Description
<b>cancelCount</b>	<b>Integer</b>	No	No	The number of times a job has received a cancel request.
<b>commandFile</b>	<b>String</b>	Yes	No	The path to the file that is executed when this job runs. This is the script that will call all the work of this job.
<b>commandLineArguments</b>	<b>String</b>	Yes	No	The command line arguments passed to the commandFile.
<b>completionCode</b>	<b>Integer</b>	No	No	The exit code from this job.
<b>cpuTime</b>	<b>Long</b>	No	No	CPU usage time in seconds as reported by the resource manager.
<b>credentials</b>	<a href="#">JobCredentials</a>	Yes	Yes	The credentials (user and group, for example) associated with this job.
<b>customName</b>	<b>String</b>	Yes	Yes	The user-specified name of this job.
<b>dates</b>	<a href="#">JobDates</a>	Yes	Yes	Various dates associated with this job.
<b>deferCount</b>	<b>Integer</b>	No	No	The number of times a job has been deferred.
<b>dependencies</b>	<a href="#">Set&lt;JobDependency&gt;</a>	Yes	No	Dependencies that must be fulfilled before the job can start.
<b>description</b>	<b>String</b>	No	No	The description of the job. Can be set only in a job template.

Field Name	Type	POST	PUR	Description
<b>duration</b>	<b>Long</b>	Yes	Yes	The length of time in seconds requested for the job. Note that it is possible to set duration to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>durationActive</b>	<b>Long</b>	No	No	The length of time in seconds the job has been active or running.
<b>durationQueued</b>	<b>Long</b>	No	No	The length of time in seconds the job has been eligible to run in the queue.
<b>durationRemaining</b>	<b>Long</b>	No	No	An estimate of the time remaining, in seconds, before the job will complete.
<b>durationSuspended</b>	<b>Long</b>	No	No	The length of time in seconds the job has been suspended.
<b>emailNotifyAddresses</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of addresses to whom email is sent by the execution server.
<b>emailNotifyTypes</b>	<a href="#"><u>Set&lt;JobEmailNotifyType&gt;</u></a>	Yes	No	The list of email notify types attached to the job.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	No	Setting this field to true tells the Moab Workload Manager to set various variables, if populated, in the job's environment.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	No	The list of environment variables for this job.
<b>epilogScript</b>	<b>String</b>	Yes	No	The path to the TORQUE epilog script.

Field Name	Type	POST	PUT	Description
<b>flags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Yes	Yes	The flags that are set on this job.
<b>holdDate</b>	<b>Date</b>	No	No	The date the most recent hold was placed on the job.
<b>holdReason</b>	<a href="#">JobHoldReason</a>	No	No	The reason the job is on hold.
<b>holds</b>	<a href="#">Set&lt;JobHoldType&gt;</a>	Yes	Yes	The holds that are set on the job. The "User" hold type is valid during POST.
<b>initialWorkingDirectory</b>	<b>String</b>	Yes	No	The path to the directory in which the job will be started.
<b>isActive</b>	<b>Boolean</b>	No	No	True if the job is active, false if the job is complete.
<b>jobGroup</b>	<b>String</b>	Yes	No	The job group to which this job belongs (different from credentials.group).
<b>masterNode</b>	<a href="#">DomainProxy</a>	No	No	The first node in the list of allocated nodes for this job. For TORQUE jobs, this represents the "mother superior."
<b>memorySecondsDedicated</b>	<b>Double</b>	No	No	The memory seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>memorySecondsUtilized</b>	<b>Double</b>	No	No	The memory seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.

Field Name	Type	POST	PUT	Description
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	No	Yes	The list of messages associated with the job. The "message" field is valid during PUT.
<b>migrateCount</b>	<b>Integer</b>	No	No	The number of times the job has been migrated.
<b>minimumPreemptTime</b>	<b>Long</b>	No	No	The minimum length of time, in seconds, an active job must be running before it is eligible for preemption.
<b>mwmName</b>	<b>String</b>	No	No	The name of the Moab Workload Manager instance that owns this job.
<b>name</b>	<b>String</b>	No	No	The name of this job. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>nodesExcluded</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The list of nodes that should not be considered for this job.
<b>nodesRequested</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The exact set, superset, or subset of nodes on which this job must run. (See also: <a href="#">nodesRequestedPolicy</a> .)
<b>nodesRequestedPolicy</b>	<a href="#">JobHostListMode</a>	Yes	No	Indicates an exact set, superset, or subset of nodes on which the job must run. Only relevant if nodesRequested is provided. (See also: <a href="#">nodesRequested</a> .)
<b>partitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	No	The list of partitions that this job can access.

Field Name	Type	POST	PUT	Description
<b>partitionAccessListRequested</b>	<b>Set&lt;String&gt;</b>	Yes	Yes	The list of partitions that this job has requested.
<b>preemptCount</b>	<b>Integer</b>	No	No	The number of times the job has been preempted.
<b>priorities</b>	<a href="#">JobPriority</a>	Yes	Yes	The list of priorities for the job.
<b>processorSecondsDedicated</b>	<b>Double</b>	No	No	The processor seconds dedicated to the job as reported by its resource manager. Not all resource managers provide this information.
<b>processorSecondsLimit</b>	<b>Double</b>	No	No	The limit for processorSecondsUtilized.
<b>processorSecondsUtilized</b>	<b>Double</b>	No	No	The processor seconds utilized by the job as reported by its resource manager. Not all resource managers provide this information.
<b>prologScript</b>	<b>String</b>	Yes	No	The path to the TORQUE prolog script.
<b>queueStatus</b>	<a href="#">JobQueueStatus</a>	No	No	The status of the job in its queue.
<b>rejectPolicies</b>	<a href="#">Set&lt;JobRejectPolicy&gt;</a>	No	No	The list of policies enabled when a job is rejected.
<b>requirements</b>	<a href="#">Set&lt;JobRequirement&gt;</a>	Yes	Yes	The list of items required for this job to run. Only <a href="#">JobRequirement.features</a> is valid during PUT.

Field Name	Type	POST	PULL	Description
<b>reservationRequested</b>	<a href="#">DomainProxy</a>	Yes	Yes	The reservation that the job requested.
<b>resourceFailPolicy</b>	<a href="#">JobResourceFailPolicy Type</a>	Yes	No	The policy that dictates what should happen to the job if it is running and at least one of the resources it is using fails.
<b>resourceManagerExtension</b>	String	Yes	No	If provided during POST, this string will be added to the resource manager extension section of the job submission. Example: "bandwidth=120;queuejob=false" Note that the delimiter between resourceManagerExtension elements is the semicolon.
<b>resourceManagers</b>	<a href="#">Set&lt;ResourceManager&gt;</a>	No	No	The list of resource managers associated with this job.
<b>rmStandardErrorFilePath</b>	String	No	No	The path to the remote file containing the standard error of the job.
<b>rmStandardOutputFilePath</b>	String	No	No	The path to the remote file containing the standard output of the job.
<b>standardErrorFilePath</b>	String	Yes	No	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	String	Yes	No	The path to the file containing the standard output of the job.
<b>startCount</b>	Integer	No	No	The number of times the job has been started.

Field Name	Type	POST	PUT	Description
<b>states</b>	<a href="#">JobStateInformation</a>	No	No	Information about the state of the job.
<b>submitHost</b>	<b>String</b>	Yes	No	The host from which the job was submitted.
<b>systemJobAction</b>	<b>String</b>	No	No	The action the system job will take.
<b>systemJobType</b>	<a href="#">JobSystemJobType</a>	No	No	The type of system job. In the Moab Cloud Suite, this will usually be "vmtracking" or "generic."
<b>targetedJobAction</b>	<a href="#">JobActionType</a>	No	No	The action that this job is performing on another job.
<b>targetedJobName</b>	<b>String</b>	No	No	The name of the job on which this job is performing the targetedJobAction.
<b>templates</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	The list of all job templates to be set on this job.
<b>triggers</b>	<b>Set&lt;String&gt;</b>	No	No	The list of triggers associated with this job.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The list of variables that this job owns or sets on completion.
<b>virtualContainers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>virtualMachines</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	No	The list of virtual machines that are allocated to this job.

Field Name	Type	POST	PUT	Description
<b>vmUsagePolicy</b>	<a href="#">VMUsagePolicy</a>	Yes	No	The requested Virtual Machine Usage Policy for this job.

JobBlock

Field Name	Type	POST	PUT	Description
<b>category</b>	<a href="#">JobBlockCategory</a>	No	No	
<b>message</b>	String	No	No	
<b>type</b>	<a href="#">JobBlockType</a>	No	No	

JobBlockCategory

Value	Description
<b>depend</b>	
<b>jobBlock</b>	
<b>migrate</b>	

JobBlockType

Value	Description
<b>ActivePolicy</b>	
<b>BadUser</b>	
<b>Dependency</b>	
<b>EState</b>	

Value	Description
<b>FairShare</b>	
<b>Hold</b>	
<b>IdlePolicy</b>	
<b>LocalPolicy</b>	
<b>NoClass</b>	
<b>NoData</b>	
<b>NoResource</b>	
<b>NoTime</b>	
<b>PartitionAccess</b>	
<b>Priority</b>	
<b>RMSubmissionFailure</b>	
<b>StartDate</b>	
<b>State</b>	
<b>SysLimits</b>	

[JobCredentials](#)

Moab Workload Manager supports the concept of credentials, which provide a means of attributing policy and resource access to entities such as users and groups. These credentials allow specification of job ownership, tracking of resource usage, enforcement of policies, and many other features.

Field Name	Type	POST	PUT	Description
<b>account</b>	<b>String</b>	Yes	Yes	The account credential is also referred to as the project. This credential is generally associated with a group of users along the lines of a particular project for accounting and billing purposes.
<b>group</b>	<b>String</b>	Yes	No	The group credential represents an aggregation of users. User-to-group mappings are often specified by the operating system or resource manager and typically map to a user's UNIX group ID. However, user-to-group mappings may also be provided by a security and identity management service, or you can specify such directly within Moab.
<b>jobClass</b>	<b>String</b>	Yes	Yes	The concept of the class credential is derived from the resource manager class or queue object. Classes differ from other credentials in that they more directly impact job attributes. In standard HPC usage, a user submits a job to a class and this class imposes a number of factors on the job. The attributes of a class may be specified within the resource manager or directly within Moab.
<b>qos</b>	<b>String</b>	No	No	The quality of service assigned to this job.  The concept of a quality of service (QoS) credential is unique to Moab and is not derived from any underlying concept or peer service. In most cases, the QoS credential is used to allow a site to set up a selection of service levels for end-users to choose from on a long-term or job-by-job basis. QoS's differ from other credentials in that they are centered around special access where this access may allow use of additional services, additional resources, or improved responsiveness. Unique to this credential, organizations may also choose to apply different charge rates to the varying levels of service available within each QoS. As QoS is an internal credential, all QoS configuration occurs within Moab.
<b>qosRequested</b>	<b>String</b>	Yes	Yes	The quality of service requested for this job.

Field Name	Type	POST	PUT	Description
<b>user</b>	<b>String</b>	Yes	No	The user credential is the fundamental credential within a workload manager; each job requires an association with exactly one user. In fact, the user credential is the only required credential in Moab; all others are optional. In most cases, the job's user credential is configured within or managed by the operating system itself, although Moab may be configured to obtain this information from an independent security and identity management service.

JobDates

Field Name	Type	POST	PUT	Description
<b>completedDate</b>	<b>Date</b>	No	No	
<b>createdDate</b>	<b>Date</b>	No	No	
<b>deadlineDate</b>	<b>Date</b>	Yes	No	The deadline for completion of the job.
<b>dispatchedDate</b>	<b>Date</b>	No	No	
<b>earliestRequestedStartDate</b>	<b>Date</b>	Yes	Yes	The job will start no sooner than this date.
<b>earliestStartDate</b>	<b>Date</b>	No	No	
<b>eligibleDate</b>	<b>Date</b>	No	No	
<b>lastCanceledDate</b>	<b>Date</b>	No	No	
<b>lastChargedDate</b>	<b>Date</b>	No	No	
<b>lastPreemptedDate</b>	<b>Date</b>	No	No	
<b>lastUpdatedDate</b>	<b>Date</b>	No	No	
<b>startDate</b>	<b>Date</b>	No	No	
<b>submitDate</b>	<b>Date</b>	No	No	

Field Name	Type	POST	PUT	Description
<b>terminationDate</b>	<b>Date</b>	No	No	

JobDependency

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	No	The name of the object on on which the job is dependent.
<b>type</b>	<a href="#"><u>JobDependencyType</u></a>	Yes	No	The type of job dependency. Only set is valid for POST.
<b>value</b>	<b>String</b>	No	No	

JobDependencyType

Represents the type of a job dependency. For now, only the "set" type is supported.

Value	Description
<b>set</b>	

JobEmailNotifyType

Value	Description
<b>JobStart</b>	
<b>JobEnd</b>	
<b>JobFail</b>	
<b>All</b>	

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.

Value	Description
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.

Value	Description
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobHoldReason

Value	Description
<b>Admin</b>	
<b>NoResources</b>	
<b>SystemLimitsExceeded</b>	
<b>BankFailure</b>	

Value	Description
<b>CannotDebitAccount</b>	
<b>InvalidAccount</b>	
<b>RMFailure</b>	
<b>RMReject</b>	
<b>PolicyViolation</b>	
<b>CredAccess</b>	
<b>CredHold</b>	
<b>PreReq</b>	
<b>Data</b>	
<b>Security</b>	
<b>MissingDependency</b>	

JobHoldType

Value	Description
<b>User</b>	
<b>System</b>	
<b>Batch</b>	
<b>Defer</b>	
<b>All</b>	

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	No	The name of the object.

Message

Field Name	Type	POST	PUT	Description
<b>count</b>	<b>Integer</b>	No	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	No	The date this message was created.
<b>expireDate</b>	<b>Date</b>	No	No	The date this message expires.
<b>message</b>	<b>String</b>	No	Yes	The message itself.

JobHostListMode

Value	Description
<b>superset</b>	
<b>subset</b>	
<b>exactset</b>	

JobPriority

Field Name	Type	POST	PUT	Description
<b>run</b>	<b>Long</b>	No	No	
<b>start</b>	<b>Long</b>	No	No	

Field Name	Type	POST	PUT	Description
<b>system</b>	<b>Long</b>	No	No	
<b>user</b>	<b>Long</b>	Yes	Yes	The user-requested priority for the job. By default, the range is between -1024 and 0. To enable priority range from -1024 to +1023, set <code>ENABLEPOSUSERPRIORITY</code> in the <code>moab.cfg</code> file.

JobQueueStatus

Value	Description
<b>active</b>	
<b>blocked</b>	
<b>completed</b>	
<b>eligible</b>	

JobRejectPolicy

Value	Description
<b>CANCEL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>MAIL</b>	
<b>RETRY</b>	

JobRequirement

Field Name	Type	P O S T	P U T	Description
<b>architecture</b>	<b>String</b>	Ye s	N o	The architecture required by the job.
<b>attributes</b>	<a href="#"><u>Map&lt;String, JobRequirementAttribute&gt;</u></a>	Ye s	N o	Required node attributes with version number support.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	Ye s	The list of node features the job is scheduled against.
<b>featuresExcluded</b>	<b>Set&lt;String&gt;</b>	Ye s	N o	Excluded node features. That is, do not select nodes with these features. (See also: <a href="#"><u>featuresExcludedMode</u></a> .)
<b>featuresExcludedMode</b>	<a href="#"><u>JobRequirementFeaturesMode</u></a>	Ye s	N o	Indicates whether excluded features should be AND'ed or OR'd. The default is AND. Only relevant if featuresExcluded is provided. (See also: <a href="#"><u>featuresExcluded</u></a> .)
<b>featuresRequested</b>	<b>Set&lt;String&gt;</b>	Ye s	N o	Requested node features. (See also: <a href="#"><u>featuresRequestedMode</u></a> .)
<b>featuresRequestedMode</b>	<a href="#"><u>JobRequirementFeaturesMode</u></a>	Ye s	N o	Indicates whether requested features should be AND'ed or OR'd. The default is AND. Only relevant if featuresRequested is provided. (See also: <a href="#"><u>featuresRequested</u></a> .)
<b>image</b>	<b>String</b>	Ye s	N o	The image required by the job.
<b>index</b>	<b>Integer</b>	No	N o	The index of the requirement, starting with 0.
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	No	N o	Generic metrics associated with the job as reported by the resource manager.

Field Name	Type	P O S T	P U T	Description
<b>nodeAccessPolicy</b>	<a href="#">NodeAccessPolicy</a>	Yes	No	Specifies how node resources should be accessed. Note: If the job requirements array has more than one element that contains nodeAccessPolicy, only the first occurrence will be used.
<b>nodeAllocationPolicy</b>	<a href="#">NodeAllocationPolicy</a>	Yes	No	Specifies how node resources should be selected and allocated to the job. Note: If the job requirements array has more than one element that contains nodeAllocationPolicy, only the first occurrence will be used.
<b>nodeCount</b>	<b>Integer</b>	Yes	No	The number of nodes required by the job.
<b>nodeSet</b>	<b>String</b>	Yes	No	<p>The requested node set of the job. This must follow the format SETSELECTION:SETTYPE[:SETLIST]</p> <ul style="list-style-type: none"> <li>• SETSELECTION - ANYOF, ONEOF, or FIRSTOF</li> <li>• SETTYPE - FEATURE or VARATTR</li> <li>• SETLIST - For FEATURE, a comma-separated list of features. For VARATTR, a key=value pair.</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• ONEOF:FEATURE:fastos,hiprio,bigm em</li> <li>• FIRSTOF:VARATTR:datacenter=Provo :datacenter=SaltLake</li> </ul>
<b>nodes</b>	<a href="#">Set&lt;AllocatedNode&gt;</a>	No	No	Nodes that have been allocated to meet this requirement.

Field Name	Type	P O S T	P U T	Description
<b>reservation</b>	<a href="#">DomainProxy</a>	No	No	The allocated reservation (assigned after the job has a reservation).
<b>resourcesPerTask</b>	<a href="#">Map&lt;String, JobResource&gt;</a>	Yes	No	Contains requirements for disk, memory, processors, swap, and generic resources. For disk, memory, and swap, the unit is MB. For each resource, the "dedicated" field can be set during POST.
<b>taskCount</b>	<b>Integer</b>	Yes	No	The number of tasks (processors) required by this job.
<b>tasksPerNode</b>	<b>Integer</b>	Yes	No	The number of tasks to map to each node.

[JobRequirementAttribute](#)

Field Name	Type	POST	PUT	Description
<b>comparator</b>	<b>String</b>	Yes	No	The comparison operator. Valid values: <ul style="list-style-type: none"> <li>• &gt;= - Greater than or equal to</li> <li>• &gt; - Greater than</li> <li>• &lt;= - Less than</li> <li>• &lt; - Less than</li> <li>• %= - Equals</li> <li>• %! - Not equals</li> <li>• Null - Defaults to %=</li> <li>• = - (Deprecated) Equivalent to %=</li> </ul>
<b>displayValue</b>	<b>String</b>	Yes	No	The display value for the required attribute.
<b>restriction</b>	<a href="#">JobRequirementAttributeRestriction</a>	Yes	No	The restriction of this attribute. May be null, but defaults to <a href="#">JobRequirementAttributeRestriction.must</a> .
<b>value</b>	<b>String</b>	Yes	No	The value of the required attribute. During POST, if value is missing, blank, or null, do not provide a comparator.

JobRequirementAttributeRestriction

Represents a restriction for a job requirement attribute.

Value	Description
<b>must</b>	

JobRequirementFeaturesMode

Value	Description
<b>OR</b>	
<b>AND</b>	

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

NodeAllocationPolicy

Node Allocation enumeration.

Value	Description
<b>FIRSTSET</b>	

Value	Description
<b>MINGLOBAL</b>	
<b>MINLOCAL</b>	
<b>PLUGIN</b>	
<b>NONE</b>	No node allocation policy is specified. Moab defaults to MINRESOURCE when this is the case.
<b>FIRSTAVAILABLE</b>	Simple first come, first served algorithm where nodes are allocated in the order they are presented by the resource manager. This is a very simple, very fast algorithm.
<b>LASTAVAILABLE</b>	This algorithm selects resources so as to minimize the amount of time after the job and before the trailing reservation. This algorithm is a best fit in time algorithm which minimizes the impact of reservation based node-time fragmentation. It is useful in systems where a large number of reservations (job, standing, or administrative) are in place.
<b>MINRESOURCE</b>	This algorithm prioritizes nodes according to the configured resources on each node. Those nodes with the fewest configured resources which still meet the job's resource constraints are selected.
<b>CPULOAD</b>	Nodes are selected which have the maximum amount of available, unused cpu power, i.e. [# of CPU's] - [CPU load]. Good algorithm for timesharing node systems. This algorithm is only applied to jobs starting immediately. For the purpose of future reservations, the <b>MINRESOURCE</b> algorithm is used.
<b>LOCAL</b>	This will call the locally created <b>contrib</b> node allocation algorithm.
<b>CONTIGUOUS</b>	This algorithm will allocate nodes in contiguous (linear) blocks as required by the Compaq RMS system.
<b>MAXBALANCE</b>	This algorithm will attempt to allocate the most 'balanced' set of nodes possible to a job. In most cases, but not all, the metric for balance of the nodes is node speed. Thus, if possible, nodes with identical speeds will be allocated to the job. If identical speed nodes cannot be found, the algorithm will allocate the set of nodes with the minimum node speed 'span' or range.

Value	Description
<b>PRIORITY</b>	This algorithm allows a site to specify the priority of various static and dynamic aspects of compute nodes and allocate them with preference for higher priority nodes. It is highly flexible allowing node attribute and usage information to be combined with reservation affinity.
<b>FASTEST</b>	This algorithm will select nodes in 'fastest node first' order. Nodes will be selected by node speed if specified. If node speed is not specified, nodes will be selected by processor speed. If neither is specified, nodes will be selected in a random order.
<b>PROCESSORLOAD</b>	Alias for CPULOAD.
<b>NODESPEED</b>	Alias for FASTEST.
<b>INREPORTEDORDER</b>	Alias for FIRSTAVAILABLE.
<b>INREVERSEREPORTEDORDER</b>	Alias for LASTAVAILABLE.
<b>CUSTOMPRIORITY</b>	Alias for PRIORITY.
<b>PROCESSORSPEEDBALANCE</b>	Alias for MAXBALANCE.
<b>MINIMUMCONFIGUREDRESOURCES</b>	Alias for MINRESOURCE.

AllocatedNode

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	No	No	
<b>taskCount</b>	<b>Integer</b>	No	No	

JobResource

Represents counts of dedicated and utilized resources.

Field Name	Type	POST	PUT	Description
<b>dedicated</b>	<b>Integer</b>	No	No	The amount of this resource that has been allocated for running workload.
<b>utilized</b>	<b>Integer</b>	No	No	The amount of this resource that is currently reported as utilized by resource managers.

JobResourceFailPolicyType

Value	Description
<b>CANCEL</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>IGNORE</b>	
<b>NOTIFY</b>	
<b>REQUEUE</b>	

ResourceManager

Field Name	Type	POST	PUT	Description
<b>isDestination</b>	<b>Boolean</b>	No	No	
<b>isSource</b>	<b>Boolean</b>	No	No	
<b>jobName</b>	<b>String</b>	No	No	
<b>name</b>	<b>String</b>	No	No	

JobStateInformation

Field Name	Type	POST	PUT	Description
<b>state</b>	<a href="#">JobState</a>	No	No	
<b>stateExpected</b>	<a href="#">JobState</a>	No	No	
<b>stateLastUpdatedDate</b>	Date	No	No	
<b>subState</b>	<a href="#">JobSubState</a>	No	No	

JobState

Value	Description
<b>Idle</b>	
<b>Starting</b>	
<b>Running</b>	
<b>Removed</b>	
<b>Completed</b>	
<b>Hold</b>	
<b>Deferred</b>	
<b>Vacated</b>	
<b>NotQueued</b>	
<b>Unknown</b>	
<b>Staging</b>	
<b>Suspended</b>	
<b>Blocked</b>	

JobSubState

Value	Description
<b>Epilogue</b>	
<b>Migrated</b>	
<b>Preempted</b>	
<b>Prologue</b>	

JobSystemJobType

Value	Description
<b>generic</b>	
<b>osprovision</b>	
<b>osprovision2</b>	
<b>poweroff</b>	
<b>poweron</b>	
<b>reset</b>	
<b>storage</b>	
<b>vmmap</b>	
<b>vmmigrate</b>	
<b>vmtracking</b>	

JobActionType

Value	Description
<b>DESTROY</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 1

JobVersion1

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of the job.
<b>account</b>	<b>String</b>	Yes	Yes	The account under which this job runs for billing purposes.
<b>activeDuration</b>	<b>Long</b>	No	No	The duration in seconds the job has spent active or running.
<b>allocatedNodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The nodes that are allocated to this job.
<b>allocatedVMs</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The list of VMs that are allocated to this job.
<b>arrayIndex</b>	<b>Long</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the index of this job in the array. For example, if this job is <code>Moab.1[2]</code> , the array index would be 2.
<b>arrayMasterName</b>	<b>String</b>	No	No	If this job is a sub-job of a <a href="#">JobArray</a> , this field contains the name of the job array master. For example, if this job is <code>Moab.1[2]</code> , the array master name would be <code>Moab.1</code> .
<b>arraySubJobs</b>	<a href="#">Set&lt;JobArraySubJob&gt;</a>	No	No	If this job is the job array master, this field contains information concerning the array's sub-jobs.
<b>blockReason</b>	<a href="#">JobBlockReasonVersion1</a>	No	No	The reason the job is blocked.
<b>bypass</b>	<b>Integer</b>	No	No	The number of times the job has been backfilled.

Field Name	Type	PO ST	P U T	Description
<b>commandFile</b>	<b>String</b>	Yes	No	The path to the file that is executed when the job runs. This is the script that will call all the work of the job.
<b>commandLineArguments</b>	<b>String</b>	Yes	No	The command line arguments passed in when the job is run.
<b>completionCode</b>	<b>Integer</b>	No	No	The exit code from the job.
<b>completionDate</b>	<b>Date</b>	No	No	The date the job completed. If null, the job hasn't completed yet.
<b>dedicatedProcessorSeconds</b>	<b>Double</b>	No	No	Number of processor seconds dedicated to the job.
<b>dependencies</b>	<a href="#">Set&lt;JobDependencyVersion1&gt;</a>	Yes	No	The list of dependencies for this job. Valid during POST, but only JobDependencyTypeVersion1.SET dependencies are supported. Not defined during GET.
<b>destinationRmJobId</b>	<b>String</b>	No	No	The ID of the job as known by the destination resource manager.
<b>durationRequested</b>	<b>Long</b>	Yes	Yes	The amount of time (in seconds) requested for the job. Note that it is possible to set durationRequested to "INFINITY" if the AllowInfiniteJobs flag is set on the scheduler in the moab.cfg.
<b>earliestStartDate</b>	<b>Date</b>	No	No	Is usually the same as <a href="#">earliestStartDateRequested</a> . Reported by Moab and cannot be changed by the user.

Field Name	Type	POST	PUT	Description
<b>earliestStartDateRequested</b>	<b>Date</b>	Yes	Yes	Used in job creation or modification to set the minimum start time.
<b>effectivePartitionAccessList</b>	<b>Set&lt;String&gt;</b>	No	No	The list of partitions that this job can access.
<b>effectiveQueueDuration</b>	<b>Long</b>	No	No	The duration in seconds the job has been eligible to run in the queue.
<b>emailNotifyTypes</b>	<a href="#">Set&lt;JobEmailNotifyTypeVersion1&gt;</a>	Yes	No	The set of email notify types attached to the job.
<b>emailNotifyUsers</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of users to whom email is sent by the execution server.
<b>environmentRequested</b>	<b>Boolean</b>	Yes	No	Setting this field to true tells Moab to set various variables, if populated, to the job's environment. Not defined during GET.
<b>environmentVariables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	No	The set of environment variables for this job.
<b>expectedState</b>	<a href="#">JobStateVersion1</a>	No	No	The expected state of the job based on scheduler action.
<b>flags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Yes	Yes	The flags that are set on this job.
<b>genericAttributes</b>	<b>Set&lt;String&gt;</b>	No	No	The list of generic attributes the job has requested.
<b>group</b>	<b>String</b>	Yes	No	The group under which the job is run.

Field Name	Type	POST	PUT	Description
<b>holds</b>	<a href="#">Set&lt;JobHoldTypeVersion1&gt;</a>	Yes	Yes	The holds that are set on the job. During POST, only the USER hold type is supported.
<b>hosts</b>	Set<String>	Yes	No	The set of hosts/nodes the job is running on.
<b>initialWorkingDirectory</b>	String	Yes	No	The path to the directory in which the job will be started.
<b>latestCompletedDateRequested</b>	Date	No	No	The latest completion date requested by the job.
<b>masterHost</b>	String	No	No	The node/host that the primary task will run on.
<b>memoryRequested</b>	Integer	No	No	The amount of memory in MB requested by the job.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	No	Yes	The list of system and user messages.
<b>name</b>	String	Yes	Yes	The user-specified name of the job.
<b>os</b>	String	Yes	No	The operating system required for the job.
<b>partitionAccessList</b>	Set<String>	No	No	The list of partitions that this job has requested.
<b>qos</b>	String	No	No	The QoS under which the job is running.
<b>qosRequested</b>	String	Yes	Yes	The QoS the job requested. This may not be the QoS the job is given based on policies.

Field Name	Type	POST	PUT	Description
<b>queue</b>	<b>String</b>	Yes	Yes	The class or queue in which the job is running.
<b>queueStatus</b>	<a href="#">JobQueueStatusVersion1</a>	No	No	The status of the job in its queue.
<b>requirements</b>	<a href="#">Set&lt;JobRequirementVersion1&gt;</a>	Yes	Yes	The list of items required for this job to run. Only <a href="#">JobRequirementVersion1.requiredPartition</a> is valid during PUT.
<b>reservationRequested</b>	<b>String</b>	Yes	Yes	The reservation that the job requested.
<b>reservationStartDate</b>	<b>Date</b>	No	No	The start date of the reservation in which the job is running.
<b>rmExtension</b>	<b>String</b>	No	No	The resource manager extension String that describes information passed to the the resource manager accounting for the job.
<b>rmName</b>	<b>String</b>	No	No	The name of the resource manager that is reporting this job.
<b>rmStandardErrorFilePath</b>	<b>String</b>	No	No	The path to the remote file containing the standard error of the job.
<b>rmStandardInputFilePath</b>	<b>String</b>	No	No	The path to the file containing the standard input of the job.
<b>rmStandardOutputFilePath</b>	<b>String</b>	No	No	The path to the file containing the standard output of the job.
<b>runPriority</b>	<b>Long</b>	No	No	The priority to start running the job.

Field Name	Type	PO ST	P U T	Description
<b>sourceRmJobId</b>	<b>String</b>	No	No	The ID of the job as known by the source resource manager.
<b>standardErrorFilePath</b>	<b>String</b>	Yes	No	The path to the file containing the standard error of the job.
<b>standardOutputFilePath</b>	<b>String</b>	Yes	No	The path to the file containing the standard output of the job.
<b>startCount</b>	<b>Integer</b>	No	No	The number of times the job has been started.
<b>startDate</b>	<b>Date</b>	No	No	The date the job started.
<b>startPriority</b>	<b>Long</b>	No	No	The priority used when the job is first starting.
<b>state</b>	<a href="#">JobStateVersion1</a>	No	No	The job's state.
<b>submitDate</b>	<b>Date</b>	No	No	The time when this job was submitted to Moab.
<b>submitHost</b>	<b>String</b>	Yes	No	The host from which the job was submitted.
<b>suspendDuration</b>	<b>Long</b>	No	No	The duration for which the job has been suspended.
<b>systemPriority</b>	<b>Long</b>	No	No	Administrator-specified system priority level.
<b>templateList</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of all job templates to be set on this job. Not defined during GET.
<b>trigger</b>	<b>String</b>	No	Ye s	Add this trigger to the specified job. Not defined during GET.

Field Name	Type	POST	PUT	Description
<b>user</b>	<b>String</b>	Yes	No	The user that is running the job.
<b>userPriority</b>	<b>Long</b>	Yes	Yes	The user-specified priority for the job.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The set of variables this job "owns" or sets on completion.
<b>virtualContainers</b>	<a href="#"><u>Set&lt;VirtualContainer&gt;</u></a>	Yes	No	When submitting this job, add it to the specified existing virtual container. Valid during POST, but only one virtual container can be specified.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	Yes	No	The requested VM Usage Policy for this job.

[DomainProxyVersion1](#)

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The id of the object.

[JobArraySubJob](#)

Represents information about a job array sub-job. This is used in retrieving Job information only. See [JobArray](#) for the fields used when creating a job array. This class exists only in MWS API version 1.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The ID of this sub-job.
<b>arrayIndex</b>	<b>Long</b>	No	No	The index of this sub-job. For example, if the job ID is <code>Moab.1[4]</code> , the array index would be 4.
<b>state</b>	<a href="#"><u>JobStateVersion1</u></a>	No	No	The current state of this sub-job.

JobStateVersion1

Value	Description
<b>IDLE</b>	Eligible according to all resource manager constraints.
<b>STARTING</b>	Job launching, executing prolog.
<b>RUNNING</b>	Job is executing.
<b>REMOVED</b>	Job canceled before executing.
<b>COMPLETED</b>	Job successfully completed execution.
<b>HOLD</b>	Job is blocked by hold.
<b>DEFERRED</b>	
<b>VACATED</b>	Job canceled after partial execution.
<b>NOT_QUEUED</b>	Job not eligible for execution.
<b>UNKNOWN</b>	
<b>STAGING</b>	Staging of input/output data is currently underway.
<b>SUSPENDED</b>	
<b>BLOCKED</b>	State used only by database for job that is idle but has a block reason.

JobBlockReasonVersion1

Field Name	Type	POST	PUT	Description
<b>message</b>	<b>String</b>	No	No	The message associated with the the reason the job is blocked.
<b>type</b>	<a href="#"><u>JobBlockReasonTypeVersion1</u></a>	No	No	The reason type.

JobBlockReasonTypeVersion1

Value	Description
<b>ACTIVEPOLICY</b>	
<b>BADUSER</b>	
<b>DEPENDENCY</b>	
<b>ESTATE</b>	
<b>FAIRSHARE</b>	
<b>HOLD</b>	
<b>IDLEPOLICY</b>	
<b>LOCALPOLICY</b>	
<b>NOCLASS</b>	
<b>NODATA</b>	
<b>NONE</b>	
<b>NORESOURCE</b>	
<b>NOTIME</b>	
<b>PARTITIONACCESS</b>	
<b>PRIORITY</b>	
<b>RMSUBMISSIONFAILURE</b>	
<b>STARTDATE</b>	
<b>STATE</b>	
<b>SYSLIMITS</b>	

JobDependencyVersion1

Field Name	Type	POST	PUT	Description
<b>dependentJobsCount</b>	<b>Integer</b>	No	No	The number of dependent jobs.
<b>type</b>	<a href="#"><u>JobDependencyTypeVersion1</u></a>	No	No	The dependency type.

JobDependencyTypeVersion1

Value	Description
<b>JOBSTART</b>	Job may start at any time after specified jobs have started execution.
<b>JOBSUCCESSFULCOMPLETE</b>	Job may be start at any time after all specified jobs have successfully completed.
<b>JOBFAILEDCOMPLETE</b>	Job may start at any time after any specified jobs have completed unsuccessfully.
<b>JOBCOMPLETE</b>	Job may start at any time after all specified jobs have completed regardless of completion status.
<b>BEFORE</b>	Job may start at any time before specified jobs have started execution. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREANY</b>	Job may start at any time before all specified jobs have completed regardless of completion status. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREOK</b>	Job may start at any time before all specified jobs have successfully completed. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFORENOTOK</b>	Job may start at any time before any specified jobs have completed unsuccessfully. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>HIBERNATE</b>	Job was set to Hibernate mode.

Value	Description
<b>SYNCWITH</b>	Job will wait until it can start simultaneously with a master job
<b>SYNCCOUNT</b>	This job will wait until it can start simultaneously with synccount jobs of type syncwith that have all specified this synccount job is their master job.
<b>SET</b>	Job will wait until a variable on a Moab object is set before starting.

JobEmailNotifyTypeVersion1

Value	Description
<b>END</b>	An email will be sent out when the job successfully ends.
<b>FAIL</b>	An email will be sent out when the job fails.
<b>START</b>	An email will be sent out when the job starts.

JobStateVersion1

Value	Description
<b>IDLE</b>	Eligible according to all resource manager constraints.
<b>STARTING</b>	Job launching, executing prolog.
<b>RUNNING</b>	Job is executing.
<b>REMOVED</b>	Job canceled before executing.
<b>COMPLETED</b>	Job successfully completed execution.
<b>HOLD</b>	Job is blocked by hold.
<b>DEFERRED</b>	
<b>VACATED</b>	Job canceled after partial execution.

Value	Description
<b>NOT_QUEUED</b>	Job not eligible for execution.
<b>UNKNOWN</b>	
<b>STAGING</b>	Staging of input/output data is currently underway.
<b>SUSPENDED</b>	
<b>BLOCKED</b>	State used only by database for job that is idle but has a block reason.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.

Value	Description
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.

Value	Description
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.

Value	Description
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobHoldTypeVersion1

Value	Description
<b>NONE</b>	The job does not have a hold.
<b>USER</b>	The user has manually specified a hold on a job.
<b>SYSTEM</b>	Moab has put a hold on the job.
<b>BATCH</b>	The batch queue has placed a hold on the job.
<b>DEFER</b>	The job has been deferred.
<b>ALL</b>	The job has all holds applied to it.

MessageVersion1

Field Name	Type	POST	PUT	Description
<b>author</b>	<b>String</b>	No	No	The author of the message.
<b>creationTime</b>	<b>Date</b>	No	No	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	No	No	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	No	No	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	No	Yes	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	No	No	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	No	No	An optional priority that can be attached to the comment.

JobQueueStatusVersion1

Value	Description
<b>ACTIVE</b>	A job is actively running in a queue.
<b>BLOCKED</b>	A job has been blocked because of policy violation or resource requirements cannot be met.
<b>COMPLETED</b>	A job has completed running.
<b>ELIGIBLE</b>	A job is eligible to run, but has not started yet.
<b>NONE</b>	A job's state type is unknown.

JobRequirementVersion1

Field Name	Type	POST	PUT	Description
<b>allocatedNodes</b>	<a href="#"><u>Set&lt;DomainProxyVersion1&gt;</u></a>	No	No	The set of nodes to which the requirement is allocated.
<b>allocatedPartition</b>	<b>String</b>	No	No	The partition allocated to the requirement.
<b>genericResources</b>	<b>Map&lt;String, Integer&gt;</b>	Yes	No	The set of generic resources for this job. Each generic resource has a name and an associated amount.

Field Name	Type	POST	PUT	Description
<b>nodeAccessPolicy</b>	<a href="#"><u>NodeAccessPolicy</u></a>	Yes	No	The node access policy the requirement asks for.
<b>preferredNodeFeatures</b>	<b>Set&lt;String&gt;</b>	No	No	The list of preferred node features.
<b>requiredArchitecture</b>	<b>String</b>	Yes	No	The required architecture.
<b>requiredClass</b>	<b>String</b>	No	No	The required class/queue.
<b>requiredDiskPerTask</b>	<b>Integer</b>	Yes	No	Required disk per task, in MB.
<b>requiredMemoryPerTask</b>	<b>Integer</b>	Yes	No	Required memory per task, in MB.
<b>requiredNetwork</b>	<b>String</b>	No	No	The required network.
<b>requiredNodeCountMinimum</b>	<b>Integer</b>	No	No	The minimum number of nodes called for by the requirement.
<b>requiredNodeDisk</b>	<b>Integer</b>	No	No	The required disk space in MB across all nodes.

Field Name	Type	POST	PUT	Description
<b>requiredNodeFeatures</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of required node features.
<b>requiredNodeMemory</b>	<b>Integer</b>	No	No	The required memory in MB across all nodes.
<b>requiredNodeProcessors</b>	<b>Integer</b>	No	No	The required processors needed on a per node basis.
<b>requiredNodeSwap</b>	<b>Integer</b>	No	No	The required swap in MB across all nodes.
<b>requiredPartition</b>	<b>String</b>	Yes	Yes	A colon-separated list that specifies the partition (or partitions) in which the job must run.
<b>requiredProcessorCountMinimum</b>	<b>Integer</b>	Yes	No	The minimum task count for this requirement.
<b>requiredProcessorsPerTask</b>	<b>Integer</b>	Yes	No	Required processors per task.
<b>requiredSwapPerTask</b>	<b>Integer</b>	Yes	No	Required swap per task, in MB.

Field Name	Type	POST	PUT	Description
<b>tasksPerNode</b>	<b>Integer</b>	Yes	No	The number of tasks to map to each node.

### NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

### VirtualContainer

A virtual container is a logical grouping of objects with a shared variable space and applied policies. Containers can hold virtual machines, physical machines, jobs, reservations, and/or nodes and req node sets. Containers can also be nested inside other containers.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this virtual container.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	No	No	The set of access control rules associated with this virtual container.
<b>createDate</b>	<b>Date</b>	No	No	The date/time that the virtual container was created.
<b>creator</b>	<b>String</b>	No	No	The creator of the virtual container.
<b>description</b>	<b>String</b>	Yes	Yes	A user-defined string that acts as a label.
<b>flags</b>	<a href="#">Set&lt;VirtualContainerFlag&gt;</a>	No	Yes	The flags on this virtual container.
<b>jobs</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	Yes	The set of jobs in this virtual container.
<b>nodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	Yes	The set of nodes in this virtual container.
<b>owner</b>	<a href="#">EmbeddedCredential</a>	Yes	Yes	The owner of the virtual container.
<b>reservations</b>	<a href="#">Set&lt;Reservation&gt;</a>	No	Yes	The set of reservations in this virtual container.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	No	Yes	Variables associated with the virtual container.
<b>virtualContainers</b>	<a href="#">Set&lt;VirtualContainer&gt;</a>	No	Yes	The set of virtual containers in this virtual container.
<b>virtualMachines</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	Yes	The set of virtual machines in this virtual container.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
<b>affinity</b>	<u><a href="#">AclAffinity</a></u>	No	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <u><a href="#">AclAffinity.POSITIVE</a></u> .
<b>comparator</b>	<u><a href="#">ComparisonOperator</a></u>	No	Yes	The type of comparison to make against the ACL object.  Defaults to <u><a href="#">ComparisonOperator.EQUAL</a></u> .
<b>type</b>	<u><a href="#">AclType</a></u>	No	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

AcType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported

Value	Description
<b>QUEUE</b>	Not supported
<b>RACK</b>	Not supported
<b>SCHED</b>	Not supported
<b>SYSTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

[VirtualContainerFlag](#)

This enumeration specifies the flag types of a virtual container.

Value	Description
<b>DESTROYOBJECTS</b>	Destroy reservations, jobs, and virtual machines in virtual container when the virtual container is destroyed.
<b>DESTROYWHENEMPTY</b>	Destroy virtual container when it contains no objects.
<b>DELETING</b>	Virtual container has started removal process -- might be waiting on workflows, etc. to finish.
<b>HASSTARTED</b>	Virtual container has jobs that have started -- workflows only.
<b>HOLDJOBS</b>	Virtual container will place a hold on jobs that are submitted to it while this flag is set.
<b>WORKFLOW</b>	Virtual container for a workflow -- maximum of one workflow virtual container per workflow.

[EmbeddedCredential](#)

<b>ACCOUNT</b>	
<b>CLASS</b>	
<b>QOS</b>	
<b>NOT_SPECIFIED</b>	

[Reservation](#)

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Yes	No	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Yes	No	Accountable Group.

Field Name	Type	POST	PUT	Description
<b>accountingQOS</b>	<b>String</b>	Yes	No	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Yes	No	Accountable User.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	Yes	No	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	No	No	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	No	No	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	No	No	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Yes	No	Reservation's comments or description.
<b>creationDate</b>	<b>Date</b>	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	Yes	No	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.

Field Name	Type	POST	PUT	Description
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	No	No	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	Yes	No	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	No	No	Global reservation ID.
<b>hostListExpression</b>	<b>String</b>	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	No	No	State whether or not this reservation is currently active.

Field Name	Type	POST	PUT	Description
<b>isTracked</b>	<b>Boolean</b>	No	No	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	No	No	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#"><u>Set&lt;MessageVersion1&gt;</u></a>	No	No	Messages for the reservation.
<b>owner</b>	<a href="#"><u>EmbeddedCredential</u></a>	Yes	No	The owner of the reservation
<b>partitionId</b>	<b>String</b>	Yes	No	The ID of the partition this reservation is for.
<b>profile</b>	<b>String</b>	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#"><u>ReservationRequirement</u></a>	Yes	No	The reservation's requirements.
<b>reservationGroup</b>	<b>String</b>	Yes	No	The reservation group to which the reservation belongs.

Field Name	Type	POST	PUT	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	<b>Date</b>	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#"><u>ReservationStatistics</u></a>	No	No	The reservation's statistical information.
<b>subType</b>	<b>String</b>	Yes	No	The reservation sub-type.
<b>taskCount</b>	<b>Integer</b>	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	Yes	No	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	No	No	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	No	No	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The set of variables for this reservation.

ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOverlap</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.
<b>NOVMMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.

Value	Description
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRED</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.

Value	Description
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
<b>TRIGHASFIRED</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

### ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
<b>architecture</b>	<b>String</b>	Yes	No	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	No	No	Required feature mode.
<b>memory</b>	<b>Integer</b>	Yes	No	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	No	No	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	No	No	The list of node IDs required for this reservation.
<b>os</b>	<b>String</b>	Yes	No	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Yes	No	Required task count.

### ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
<b>caps</b>	<b>Double</b>	No	No	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	No	No	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	No	No	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	No	No	The total idle processor-seconds over the life of the reservation.

### Trigger

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#">TriggerActionType</a>	No	No	
<b>blockTime</b>	<b>Date</b>	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	No	No	
<b>eventType</b>	<a href="#">TriggerEventType</a>	No	No	
<b>expireTime</b>	<b>Date</b>	No	No	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	<b>Date</b>	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	No	No	
<b>interval</b>	<b>Boolean</b>	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false

Field Name	Type	POST	PUT	Description
<b>maxRetry</b>	<b>Integer</b>	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	No	No	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	No	No	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#">TriggerPeriod</a>	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	No	No	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	POST	PUT	Description
<b>sets</b>	<b>String</b>	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.

Value	Description
MAIL	
THRESHOLD	
INTERNAL	
EXEC	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
CANCEL	
CHECKPOINT	
CREATE	
END	
EPOCH	
FAIL	
HOLD	
MIGRATE	
MODIFY	
PREEMPT	
STANDING	
START	
THRESHOLD	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.

Value	Description
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	<p>By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.

Value	Description
<b>PREFPM</b>	Prefers a physical machine.
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 3

JobTemplate

This class represents a job template in the Moab Workload Manager. Job templates are used for two primary purposes: (1) to provide a means of generically matching and categorizing jobs, and (2) to provide a means of setting arbitrary default or forced attributes for certain jobs.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this job template.
<b>account</b>	<b>String</b>	The account under which this job will run for billing purposes.
<b>args</b>	<b>String</b>	Command-line arguments that get passed to commandFile.
<b>commandFile</b>	<b>String</b>	The path to the file that is executed when the job runs. This is the script that will actually call all the work of the job. Can be null.
<b>description</b>	<b>String</b>	The description of the job.
<b>durationRequested</b>	<b>Long</b>	The amount of time (in seconds) requested for the job.
<b>genericSystemJob</b>	<b>Boolean</b>	True if this template will instantiate a generic system job.
<b>inheritResources</b>	<b>Boolean</b>	True if jobs instantiated from this template inherit resources.
<b>jobDependencies</b>	<a href="#">Set&lt;JobTemplateDependency&gt;</a>	The list of dependencies for this job template.
<b>jobFlags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Job flags for this template.
<b>jobTemplateFlags</b>	<a href="#">Set&lt;JobTemplateFlag&gt;</a>	Job template flags for this template.
<b>jobTemplateRequirements</b>	<a href="#">Set&lt;JobTemplateRequirement&gt;</a>	The requirements for this job template.

Field Name	Type	Description
<b>priority</b>	<b>Long</b>	Relative job priority.
<b>qos</b>	<b>String</b>	The Quality of Service for the job.
<b>queue</b>	<b>String</b>	The class or queue in which the job will run.
<b>select</b>	<b>Boolean</b>	True if job template can be directly requested by job at submission.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	The trigger that is typically assigned to generic system jobs.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	The virtual machine usage policy.

[JobTemplateDependency](#)

Field Name	Type	Description
<b>name</b>	<b>String</b>	The name of the template on which this template depends.
<b>type</b>	<a href="#"><u>JobDependencyTypeVersion1</u></a>	The type of the dependency.

[JobDependencyTypeVersion1](#)

Value	Description
<b>JOBSTART</b>	Job may start at any time after specified jobs have started execution.
<b>JOBSUCCESSFULCOMPLETE</b>	Job may be start at any time after all specified jobs have successfully completed.
<b>JOBFAILEDCOMPLETE</b>	Job may start at any time after any specified jobs have completed unsuccessfully.

Value	Description
<b>JOBCOMPLETE</b>	Job may start at any time after all specified jobs have completed regardless of completion status.
<b>BEFORE</b>	Job may start at any time before specified jobs have started execution. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREANY</b>	Job may start at any time before all specified jobs have completed regardless of completion status. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREOK</b>	Job may start at any time before all specified jobs have successfully completed. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFORENOTOK</b>	Job may start at any time before any specified jobs have completed unsuccessfully. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>HIBERNATE</b>	Job was set to Hibernate mode.
<b>SYNCWITH</b>	Job will wait until it can start simultaneously with a master job
<b>SYNCCOUNT</b>	This job will wait until it can start simultaneously with synccount jobs of type syncwith that have all specified this synccount job is their master job.
<b>SET</b>	Job will wait until a variable on a Moab object is set before starting.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.

Value	Description
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.

Value	Description
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).

Value	Description
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobTemplateFlag

This enumeration specifies the flag types of a job template.

Value	Description
<b>GLOBALRSVACCESS</b>	
<b>HIDDEN</b>	
<b>HWJOB</b>	
<b>PRIVATE</b>	
<b>SYNCJOBID</b>	
<b>TEMPLATEISDYNAMIC</b>	True if the template is dynamic (not specified via moab.cfg).
<b>SELECT</b>	True if a job can select this template.

JobTemplateRequirement

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	The architecture requirement.
<b>diskRequirement</b>	<b>Integer</b>	The amount of disk space required (in MB).
<b>genericResources</b>	<b>Map&lt;String, Integer&gt;</b>	Consumable generic attributes associated with individual nodes or the special pseudo-node global, which provides shared cluster (floating) consumable resources.
<b>nodeAccessPolicy</b>	<a href="#"><u>NodeAccessPolicy</u></a>	The node access policy. Specifies how node resources will be shared by a job.
<b>operatingSystem</b>	<b>String</b>	The operating system requirement.
<b>requiredDiskPerTask</b>	<b>Integer</b>	Disk space (in MB).
<b>requiredFeatures</b>	<b>Set&lt;String&gt;</b>	The features required by this template.
<b>requiredMemoryPerTask</b>	<b>Integer</b>	Memory (in MB).
<b>requiredProcessorsPerTask</b>	<b>Integer</b>	Number of processors.
<b>requiredSwapPerTask</b>	<b>Integer</b>	Swap space (in MB).
<b>taskCount</b>	<b>Integer</b>	The number of tasks required.

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.

Value	Description
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

### TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.

Value	Description
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 2

JobTemplate

This class represents a job template in the Moab Workload Manager. Job templates are used for two primary purposes: (1) to provide a means of generically matching and categorizing jobs, and (2) to provide a means of setting arbitrary default or forced attributes for certain jobs.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this job template.
<b>account</b>	<b>String</b>	The account under which this job will run for billing purposes.
<b>args</b>	<b>String</b>	Command-line arguments that get passed to commandFile.
<b>commandFile</b>	<b>String</b>	The path to the file that is executed when the job runs. This is the script that will actually call all the work of the job. Can be null.
<b>description</b>	<b>String</b>	The description of the job.
<b>durationRequested</b>	<b>Long</b>	The amount of time (in seconds) requested for the job.
<b>genericSystemJob</b>	<b>Boolean</b>	True if this template will instantiate a generic system job.
<b>inheritResources</b>	<b>Boolean</b>	True if jobs instantiated from this template inherit resources.
<b>jobDependencies</b>	<a href="#">Set&lt;JobTemplateDependency&gt;</a>	The list of dependencies for this job template.
<b>jobFlags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Job flags for this template.
<b>jobTemplateFlags</b>	<a href="#">Set&lt;JobTemplateFlag&gt;</a>	Job template flags for this template.
<b>jobTemplateRequirements</b>	<a href="#">Set&lt;JobTemplateRequirement&gt;</a>	The requirements for this job template.

Field Name	Type	Description
<b>priority</b>	<b>Long</b>	Relative job priority.
<b>qos</b>	<b>String</b>	The Quality of Service for the job.
<b>queue</b>	<b>String</b>	The class or queue in which the job will run.
<b>select</b>	<b>Boolean</b>	True if job template can be directly requested by job at submission.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	The trigger that is typically assigned to generic system jobs.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	The virtual machine usage policy.

[JobTemplateDependency](#)

Field Name	Type	Description
<b>name</b>	<b>String</b>	The name of the template on which this template depends.
<b>type</b>	<a href="#"><u>JobDependencyTypeVersion1</u></a>	The type of the dependency.

[JobDependencyTypeVersion1](#)

Value	Description
<b>JOBSTART</b>	Job may start at any time after specified jobs have started execution.
<b>JOBSUCCESSFULCOMPLETE</b>	Job may be start at any time after all specified jobs have successfully completed.
<b>JOBFAILEDCOMPLETE</b>	Job may start at any time after any specified jobs have completed unsuccessfully.

Value	Description
<b>JOBCOMPLETE</b>	Job may start at any time after all specified jobs have completed regardless of completion status.
<b>BEFORE</b>	Job may start at any time before specified jobs have started execution. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREANY</b>	Job may start at any time before all specified jobs have completed regardless of completion status. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREOK</b>	Job may start at any time before all specified jobs have successfully completed. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFORENOTOK</b>	Job may start at any time before any specified jobs have completed unsuccessfully. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>HIBERNATE</b>	Job was set to Hibernate mode.
<b>SYNCWITH</b>	Job will wait until it can start simultaneously with a master job
<b>SYNCCOUNT</b>	This job will wait until it can start simultaneously with synccount jobs of type syncwith that have all specified this synccount job is their master job.
<b>SET</b>	Job will wait until a variable on a Moab object is set before starting.

JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.

Value	Description
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.

Value	Description
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).

Value	Description
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

JobTemplateFlag

This enumeration specifies the flag types of a job template.

Value	Description
<b>GLOBALRSVACCESS</b>	
<b>HIDDEN</b>	
<b>HWJOB</b>	
<b>PRIVATE</b>	
<b>SYNCJOBID</b>	
<b>TEMPLATEISDYNAMIC</b>	True if the template is dynamic (not specified via moab.cfg).
<b>SELECT</b>	True if a job can select this template.

JobTemplateRequirement

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	The architecture requirement.
<b>diskRequirement</b>	<b>Integer</b>	The amount of disk space required (in MB).
<b>genericResources</b>	<b>Map&lt;String, Integer&gt;</b>	Consumable generic attributes associated with individual nodes or the special pseudo-node global, which provides shared cluster (floating) consumable resources.
<b>nodeAccessPolicy</b>	<a href="#"><u>NodeAccessPolicy</u></a>	The node access policy. Specifies how node resources will be shared by a job.
<b>operatingSystem</b>	<b>String</b>	The operating system requirement.
<b>requiredDiskPerTask</b>	<b>Integer</b>	Disk space (in MB).
<b>requiredFeatures</b>	<b>Set&lt;String&gt;</b>	The features required by this template.
<b>requiredMemoryPerTask</b>	<b>Integer</b>	Memory (in MB).
<b>requiredProcessorsPerTask</b>	<b>Integer</b>	Number of processors.
<b>requiredSwapPerTask</b>	<b>Integer</b>	Swap space (in MB).
<b>taskCount</b>	<b>Integer</b>	The number of tasks required.

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.

Value	Description
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

### TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.

Value	Description
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 1

JobTemplate

This class represents a job template in the Moab Workload Manager. Job templates are used for two primary purposes: (1) to provide a means of generically matching and categorizing jobs, and (2) to provide a means of setting arbitrary default or forced attributes for certain jobs.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique identifier for this job template.
<b>account</b>	<b>String</b>	The account under which this job will run for billing purposes.
<b>args</b>	<b>String</b>	Command-line arguments that get passed to commandFile.
<b>commandFile</b>	<b>String</b>	The path to the file that is executed when the job runs. This is the script that will actually call all the work of the job. Can be null.
<b>description</b>	<b>String</b>	The description of the job.
<b>durationRequested</b>	<b>Long</b>	The amount of time (in seconds) requested for the job.
<b>genericSystemJob</b>	<b>Boolean</b>	True if this template will instantiate a generic system job.
<b>inheritResources</b>	<b>Boolean</b>	True if jobs instantiated from this template inherit resources.
<b>jobDependencies</b>	<a href="#">Set&lt;JobTemplateDependency&gt;</a>	The list of dependencies for this job template.
<b>jobFlags</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Job flags for this template.
<b>jobTemplateFlags</b>	<a href="#">Set&lt;JobTemplateFlag&gt;</a>	Job template flags for this template.
<b>jobTemplateRequirements</b>	<a href="#">Set&lt;JobTemplateRequirement&gt;</a>	The requirements for this job template.

Field Name	Type	Description
<b>priority</b>	<b>Long</b>	Relative job priority.
<b>qos</b>	<b>String</b>	The Quality of Service for the job.
<b>queue</b>	<b>String</b>	The class or queue in which the job will run.
<b>select</b>	<b>Boolean</b>	True if job template can be directly requested by job at submission.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	The trigger that is typically assigned to generic system jobs.
<b>vmUsagePolicy</b>	<a href="#"><u>VMUsagePolicy</u></a>	The virtual machine usage policy.

#### [JobTemplateDependency](#)

Field Name	Type	Description
<b>name</b>	<b>String</b>	The name of the template on which this template depends.
<b>type</b>	<a href="#"><u>JobDependencyTypeVersion1</u></a>	The type of the dependency.

#### [JobDependencyTypeVersion1](#)

Value	Description
<b>JOBSTART</b>	Job may start at any time after specified jobs have started execution.
<b>JOBSUCCESSFULCOMPLETE</b>	Job may be start at any time after all specified jobs have successfully completed.
<b>JOBFAILEDCOMPLETE</b>	Job may start at any time after any specified jobs have completed unsuccessfully.

Value	Description
<b>JOBCOMPLETE</b>	Job may start at any time after all specified jobs have completed regardless of completion status.
<b>BEFORE</b>	Job may start at any time before specified jobs have started execution. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREANY</b>	Job may start at any time before all specified jobs have completed regardless of completion status. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFOREOK</b>	Job may start at any time before all specified jobs have successfully completed. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>BEFORENOTOK</b>	Job may start at any time before any specified jobs have completed unsuccessfully. NOTE: Only reported to Moab and then reported back. Moab currently cannot internally handle this type of dependency.
<b>HIBERNATE</b>	Job was set to Hibernate mode.
<b>SYNCWITH</b>	Job will wait until it can start simultaneously with a master job
<b>SYNCCOUNT</b>	This job will wait until it can start simultaneously with synccount jobs of type syncwith that have all specified this synccount job is their master job.
<b>SET</b>	Job will wait until a variable on a Moab object is set before starting.

### JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.

Value	Description
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.

Value	Description
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).

Value	Description
<b>DESTROYTEMPLATESUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

#### JobTemplateFlag

This enumeration specifies the flag types of a job template.

Value	Description
<b>GLOBALRSVACCESS</b>	
<b>HIDDEN</b>	
<b>HWJOB</b>	
<b>PRIVATE</b>	
<b>SYNCJOBID</b>	
<b>TEMPLATEISDYNAMIC</b>	True if the template is dynamic (not specified via moab.cfg).
<b>SELECT</b>	True if a job can select this template.

JobTemplateRequirement

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	The architecture requirement.
<b>diskRequirement</b>	<b>Integer</b>	The amount of disk space required (in MB).
<b>genericResources</b>	<b>Map&lt;String, Integer&gt;</b>	Consumable generic attributes associated with individual nodes or the special pseudo-node global, which provides shared cluster (floating) consumable resources.
<b>nodeAccessPolicy</b>	<a href="#"><u>NodeAccessPolicy</u></a>	The node access policy. Specifies how node resources will be shared by a job.
<b>operatingSystem</b>	<b>String</b>	The operating system requirement.
<b>requiredDiskPerTask</b>	<b>Integer</b>	Disk space (in MB).
<b>requiredFeatures</b>	<b>Set&lt;String&gt;</b>	The features required by this template.
<b>requiredMemoryPerTask</b>	<b>Integer</b>	Memory (in MB).
<b>requiredProcessorsPerTask</b>	<b>Integer</b>	Number of processors.
<b>requiredSwapPerTask</b>	<b>Integer</b>	Swap space (in MB).
<b>taskCount</b>	<b>Integer</b>	The number of tasks required.

NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.

Value	Description
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

VMUsagePolicy

This enumeration describes the virtual machine requirements of a job

Value	Description
<b>REQUIREPM</b>	Requires a physical machine.
<b>PREFPM</b>	Prefers a physical machine.

Value	Description
<b>CREATEVM</b>	Creates a virtual machine.
<b>CREATEPERSISTENTVM</b>	Creates a virtual machine that doesn't go away after the job is done.
<b>REQUIREVM</b>	Requires a virtual machine.
<b>PREFVM</b>	Prefers a virtual machine.

## API version 3

Node

This class represents a node in the Moab Workload Manager. Moab recognizes a node as a collection of resources with a particular set of associated attributes. This definition is similar to the traditional notion of a node found in a Linux cluster or supercomputer wherein a node is defined as one or more CPUs, associated memory, and possibly other compute resources such as local disk, swap, network adapters, and software licenses. Additionally, this node is described by various attributes such as an architecture type or operating system. Nodes range in size from small uniprocessor PCs to large symmetric multiprocessing (SMP) systems where a single node may consist of hundreds of CPUs and massive amounts of memory.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier of this node. Note: this field is not user-assigned and is generated by the database.
<b>architecture</b>	<b>String</b>	No	This node's processor architecture.
<b>attributes</b>	<b>Map&lt;String, Map&gt;</b>	No	Attributes is a map of attribute names to tuples (maps) that describe the scheduling attributes of a node. Each tuple should contain the following entries: <ul style="list-style-type: none"> <li>• <b>value</b> - the attribute value</li> <li>• <b>displayValue</b> - the attribute display value</li> </ul>
<b>classes</b>	<b>Set&lt;String&gt;</b>	No	The classes that this node can be scheduled for.
<b>featuresCustom</b>	<b>Set&lt;String&gt;</b>	Yes	The features this node advertises which are customizable at run-time. This can be used to define node sets. (See also: <a href="#">featuresReported</a> .)

Field Name	Type	P UT	Description
<b>featuresReported</b>	<b>Set&lt;String&gt;</b>	No	The features this node advertises which are reported by resource managers or are present in the Moab Workload Manager configuration. This can be used to define node sets. (See also: <a href="#">featuresCustom</a> .)
<b>index</b>	<b>Integer</b>	No	The index for this node as reported by the resource manager.
<b>ipAddress</b>	<b>String</b>	No	This node's IPv4 address.
<b>isHypervisor</b>	<b>Boolean</b>	No	True if the node is a hypervisor, false otherwise. This is based on the <a href="#">NodeOperatingSystemInformation.hypervisorType</a> field. If hypervisorType is present, the node is a hypervisor. If it is null, then it is not a hypervisor.
<b>jobs</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Jobs associated with this node.
<b>lastUpdatedDate</b>	<b>Date</b>	No	The timestamp of the last moment when this node was updated. There is no guarantee that all user modifications to a node would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this node.
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	Yes	The list of messages attached to this node. They can be attached by admins, the resource manager layer, or triggers.

Field Name	Type	PUT	Description
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this node. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> <li>• <b>speed</b> - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis.</li> <li>• <b>cpuLoad</b> - This is the CPU load on this node. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. For example, Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.</li> </ul>
<b>migrationDisabled</b>	<b>Boolean</b>	No	True if VM migration is disabled on this node.
<b>name</b>	<b>String</b>	No	The name of this node. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>operatingSystem</b>	<a href="#">NodeOperatingSystemInformation</a>	Yes	Describes the current or expected operating system image information for this node. The <code>operatingSystem.image</code> field can be changed using PUT.
<b>partition</b>	<b>String</b>	Yes	The partition this node belongs to.
<b>processorSpeed</b>	<b>Integer</b>	No	The speed, in MHz, or the processors on this node.

Field Name	Type	P U T	Description
<b>profilingEnabled</b>	<b>Boolean</b>	No	Indicates whether historical data gathering and reporting is enabled for this node. This is also controlled by the same setting on the default node (i.e. all nodes). If set to false (default), node statistics are not gathered.
<b>rack</b>	<b>Integer</b>	No	The rack where this node is located in the datacenter/cluster.
<b>reservations</b>	<a href="#"><u>Set&lt;DomainProxy&gt;</u></a>	No	Reservations associated with this node.
<b>resourceManagerMessages</b>	<b>Map&lt;String, Map&gt;</b>	No	The resource manager messages for this node. Each key is the name of a resource manager, and the value is the message that the resource manager has posted onto the node.
<b>resourceManagers</b>	<a href="#"><u>Set&lt;NodeResourceManager&gt;</u></a>	No	The resource managers that are reporting or have previously reported this node. Each object also contains information on the resource manager reports.
<b>resources</b>	<a href="#"><u>Map&lt;String, Resource&gt;</u></a>	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.
<b>slot</b>	<b>Integer</b>	No	The slot in the rack where this node is located.

Field Name	Type	PUT	Description
<b>states</b>	<a href="#">NodeStateInformation</a>	Yes	This node's state. The states.powerState and states.state fields can be changed using PUT.
<b>triggers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Triggers associated with this node.
<b>type</b>	<a href="#">NodeType</a>	No	The type of this node is governed by the types of resources it offers.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this node.
<b>virtualContainers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	The set of virtual containers that directly (not recursively) contain this node.
<b>virtualMachines</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Virtual machines associated with this node.

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
<b>name</b>	<b>String</b>	No	The name of the object.

Message

Field Name	Type	PUT	Description
<b>count</b>	<b>Integer</b>	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	The date this message was created.

Field Name	Type	PUT	Description
<b>expireDate</b>	<b>Date</b>	No	The date this message expires.
<b>message</b>	<b>String</b>	Yes	The message itself.

### NodeOperatingSystemInformation

Describes the current or expected operating system image information for a node.

Field Name	Type	PUT	Description
<b>hypervisorType</b>	<b>String</b>	No	The hypervisor technology that this node uses. May be null if the node is not a hypervisor.
<b>image</b>	<b>String</b>	Yes	The name of the operating system currently running on this node. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>imageExpected</b>	<b>String</b>	No	The name of the image that was requested to run on this node (i.e. with <code>mnodectl -m os=myOs</code> ). In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>imageLastUpdatedDate</b>	<b>Date</b>	No	The last time the image of this node was modified.
<b>imagesAvailable</b>	<b>Set&lt;String&gt;</b>	No	The list of image names that can be applied to this node. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>virtualMachineImages</b>	<b>Set&lt;String&gt;</b>	No	The list of virtual machine image names the node is capable of supporting. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)

### NodeResourceManager

Field Name	Type	PUT	Description
<b>isMaster</b>	<b>Boolean</b>	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
<b>name</b>	<b>String</b>	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code> ).
<b>stateReported</b>	<a href="#">NodeState</a>	No	The state reported by this resource manager. See the State section for more details.

### [NodeState](#)

This enumeration tracks the state of a node.

Value	Description
<b>NONE</b>	The node is set to none by the resource manager.
<b>DOWN</b>	The node is not available for workload.
<b>IDLE</b>	The node is available for workload but is not running anything.
<b>BUSY</b>	The node is running workload and cannot accept more.
<b>RUNNING</b>	The node is running workload and can accept more.
<b>DRAINED</b>	The node has been sent the drain request and has no workload on it.
<b>DRAINING</b>	The node has been sent the drain request, but still has workload on it.
<b>FLUSH</b>	The node is being reprovisioned.
<b>RESERVED</b>	The node is being reserved. This is an internal Moab state.
<b>UNKNOWN</b>	The state of the node is unknown.

Resource

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
<b>available</b>	<b>Integer</b>	No	The amount of this resource that is currently available for allocation to workload.
<b>configured</b>	<b>Integer</b>	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, <code>configured = overcommitFactor * real</code> .
<b>dedicated</b>	<b>Integer</b>	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
<b>real</b>	<b>Integer</b>	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
<b>utilized</b>	<b>Integer</b>	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
<b>powerState</b>	<a href="#">NodePower</a>	Yes	The state of the node's power system, as reported by the RM layer. Modifying the <code>powerState</code> is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
<b>powerStateExpected</b>	<a href="#">NodePower</a>	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the <code>powerState</code> attribute to <a href="#">NodePower.OFF</a> ), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.

Field Name	Type	PUT	Description
<b>state</b>	<a href="#">NodeState</a>	Yes	The scheduling state of the Node, as reported by the resource management layer.
<b>stateExpected</b>	<a href="#">NodeState</a>	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
<b>stateLastUpdatedDate</b>	<b>Date</b>	No	A timestamp recording when the state of the Node was last modified.
<b>subState</b>	<b>String</b>	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
<b>subStateLast</b>	<b>String</b>	No	The previous sub-state of the Node as reported by the resource management layer.
<b>subStateLastUpdatedDate</b>	<b>Date</b>	No	A timestamp recording when the sub-state was last modified.

### [NodePower](#)

Represents the various options for a Node's power state.

Value	Description
<b>NONE</b>	
<b>ON</b>	
<b>OFF</b>	

### [NodeType](#)

Represents the type of node as reported by a resource manager.

Value	Description
<b>Compute</b>	
<b>License</b>	
<b>Network</b>	
<b>Storage</b>	

## API version 2

Node

This class represents a node in the Moab Workload Manager. Moab recognizes a node as a collection of resources with a particular set of associated attributes. This definition is similar to the traditional notion of a node found in a Linux cluster or supercomputer wherein a node is defined as one or more CPUs, associated memory, and possibly other compute resources such as local disk, swap, network adapters, and software licenses. Additionally, this node is described by various attributes such as an architecture type or operating system. Nodes range in size from small uniprocessor PCs to large symmetric multiprocessing (SMP) systems where a single node may consist of hundreds of CPUs and massive amounts of memory.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier of this node. Note: this field is not user-assigned and is generated by the database.
<b>architecture</b>	<b>String</b>	No	This node's processor architecture.
<b>attributes</b>	<b>Map&lt;String, Map&gt;</b>	No	Attributes is a map of attribute names to tuples (maps) that describe the scheduling attributes of a node. Each tuple should contain the following entries: <ul style="list-style-type: none"> <li>• <b>value</b> - the attribute value</li> <li>• <b>displayValue</b> - the attribute display value</li> </ul>
<b>classes</b>	<b>Set&lt;String&gt;</b>	No	The classes that this node can be scheduled for.
<b>featuresCustom</b>	<b>Set&lt;String&gt;</b>	Yes	The features this node advertises which are customizable at run-time. This can be used to define node sets. (See also: <a href="#">featuresReported</a> .)

Field Name	Type	P UT	Description
<b>featuresReported</b>	<b>Set&lt;String&gt;</b>	No	The features this node advertises which are reported by resource managers or are present in the Moab Workload Manager configuration. This can be used to define node sets. (See also: <a href="#">featuresCustom</a> .)
<b>index</b>	<b>Integer</b>	No	The index for this node as reported by the resource manager.
<b>ipAddress</b>	<b>String</b>	No	This node's IPv4 address.
<b>isHypervisor</b>	<b>Boolean</b>	No	True if the node is a hypervisor, false otherwise. This is based on the <a href="#">NodeOperatingSystemInformation.hypervisorType</a> field. If hypervisorType is present, the node is a hypervisor. If it is null, then it is not a hypervisor.
<b>jobs</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Jobs associated with this node.
<b>lastUpdatedDate</b>	<b>Date</b>	No	The timestamp of the last moment when this node was updated. There is no guarantee that all user modifications to a node would be picked up. This will also be changed every RMPOLLINTERVAL even if a resource manager does not report information on this node.
<b>messages</b>	<a href="#">Set&lt;Message&gt;</a>	Yes	The list of messages attached to this node. They can be attached by admins, the resource manager layer, or triggers.

Field Name	Type	PUT	Description
<b>metrics</b>	<b>Map&lt;String, Double&gt;</b>	Yes	<p>Metrics are the measurable, quantitative, and changing aspects of this node. They are used to define workload placement, attach triggers, etc. There are some built-in metrics:</p> <ul style="list-style-type: none"> <li>• <b>speed</b> - A number from 0.0 to 1.0 describing the relative speed of the system for computational tasks. This is a composite metric, and is defined on a per-site basis.</li> <li>• <b>cpuLoad</b> - This is the CPU load on this node. This value is defined at the resource manager layer, but is generally defined on a per-operating system basis. For example, Unix-based OS's use some aspect of the Unix load average, as reported by the resource manager layer, while Windows-based OS's use CPU utilization.</li> </ul>
<b>migrationDisabled</b>	<b>Boolean</b>	No	True if VM migration is disabled on this node.
<b>name</b>	<b>String</b>	No	The name of this node. This name is unique <i>per instance</i> of Moab Workload Manager (i.e. not globally).
<b>operatingSystem</b>	<a href="#">NodeOperatingSystemInformation</a>	Yes	Describes the current or expected operating system image information for this node. The operatingSystem.image field can be changed using PUT.
<b>partition</b>	<b>String</b>	Yes	The partition this node belongs to.
<b>processorSpeed</b>	<b>Integer</b>	No	The speed, in MHz, or the processors on this node.

Field Name	Type	P U T	Description
<b>profilingEnabled</b>	<b>Boolean</b>	No	Indicates whether historical data gathering and reporting is enabled for this node. This is also controlled by the same setting on the default node (i.e. all nodes). If set to false (default), node statistics are not gathered.
<b>rack</b>	<b>Integer</b>	No	The rack where this node is located in the datacenter/cluster.
<b>reservations</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Reservations associated with this node.
<b>resourceManagerMessages</b>	<b>Map&lt;String, Map&gt;</b>	No	The resource manager messages for this node. Each key is the name of a resource manager, and the value is the message that the resource manager has posted onto the node.
<b>resourceManagers</b>	<a href="#">Set&lt;NodeResourceManager&gt;</a>	No	The resource managers that are reporting or have previously reported this node. Each object also contains information on the resource manager reports.
<b>resources</b>	<a href="#">Map&lt;String, Resource&gt;</a>	No	Contains references of a string representing a resource name to a resource object detailing the amount of the resource that is available, configured, etc. Each key is the name of the resource, which equates to the generic resource identifier or one of "processors", "memory", "disk", or "swap". This name may be used as an id in the resource types web service.
<b>slot</b>	<b>Integer</b>	No	The slot in the rack where this node is located.

Field Name	Type	PUT	Description
<b>states</b>	<a href="#">NodeStateInformation</a>	Yes	This node's state. The states.powerState and states.state fields can be changed using PUT.
<b>triggers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Triggers associated with this node.
<b>type</b>	<a href="#">NodeType</a>	No	The type of this node is governed by the types of resources it offers.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Variables is a map of key-value pairs, synonymous, but not directly related to, environment variables. They provide the mechanism to store arbitrary metadata which is useful to external systems in memory on this node.
<b>virtualContainers</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	The set of virtual containers that directly (not recursively) contain this node.
<b>virtualMachines</b>	<a href="#">Set&lt;DomainProxy&gt;</a>	No	Virtual machines associated with this node.

DomainProxy

A reference to an object contained within an object. For example, a Virtual Machine object contains a reference to the Node on which it is running. That reference is represented by this class.

Field Name	Type	PUT	Description
<b>name</b>	<b>String</b>	No	The name of the object.

Message

Field Name	Type	PUT	Description
<b>count</b>	<b>Integer</b>	No	The number of times this message has occurred.
<b>createdDate</b>	<b>Date</b>	No	The date this message was created.

Field Name	Type	PUT	Description
<b>expireDate</b>	<b>Date</b>	No	The date this message expires.
<b>message</b>	<b>String</b>	Yes	The message itself.

NodeOperatingSystemInformation

Describes the current or expected operating system image information for a node.

Field Name	Type	PUT	Description
<b>hypervisorType</b>	<b>String</b>	No	The hypervisor technology that this node uses. May be null if the node is not a hypervisor.
<b>image</b>	<b>String</b>	Yes	The name of the operating system currently running on this node. In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>imageExpected</b>	<b>String</b>	No	The name of the image that was requested to run on this node (i.e. with <code>mnodectl -m os=myOs</code> ). In cloud mode, this corresponds to the ID or name of an image in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>imageLastUpdatedDate</b>	<b>Date</b>	No	The last time the image of this node was modified.
<b>imagesAvailable</b>	<b>Set&lt;String&gt;</b>	No	The list of image names that can be applied to this node. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)
<b>virtualMachineImages</b>	<b>Set&lt;String&gt;</b>	No	The list of virtual machine image names the node is capable of supporting. In cloud mode, this corresponds to IDs or names of images in the image management API in MWS. (See also: <a href="#">Image.id</a> , <a href="#">Image.name</a> .)

NodeResourceManager

Field Name	Type	PUT	Description
<b>isMaster</b>	<b>Boolean</b>	No	Indicates whether this resource manager is the "master" of this Node. If true, it means that this resource manager has the final say on all properties reported about this Node. Note that the first resource manager to report a node is the master resource manager.
<b>name</b>	<b>String</b>	No	The name of the resource manager, according to Moab. This name appears in both the RMCFG parameter, and when diagnosing resource managers (e.g. <code>mdiag -R</code> ).
<b>stateReported</b>	<a href="#">NodeState</a>	No	The state reported by this resource manager. See the State section for more details.

### NodeState

This enumeration tracks the state of a node.

Value	Description
<b>NONE</b>	The node is set to none by the resource manager.
<b>DOWN</b>	The node is not available for workload.
<b>IDLE</b>	The node is available for workload but is not running anything.
<b>BUSY</b>	The node is running workload and cannot accept more.
<b>RUNNING</b>	The node is running workload and can accept more.
<b>DRAINED</b>	The node has been sent the drain request and has no workload on it.
<b>DRAINING</b>	The node has been sent the drain request, but still has workload on it.
<b>FLUSH</b>	The node is being reprovisioned.
<b>RESERVED</b>	The node is being reserved. This is an internal Moab state.
<b>UNKNOWN</b>	The state of the node is unknown.

Resource

Represents counts of resources available, configured, etc.

Field Name	Type	PUT	Description
<b>available</b>	<b>Integer</b>	No	The amount of this resource that is currently available for allocation to workload.
<b>configured</b>	<b>Integer</b>	No	The amount of this resource that is considered possible to schedule. Overcommit specifically applies to this, in other words, <code>configured = overcommitFactor * real</code> .
<b>dedicated</b>	<b>Integer</b>	No	The amount of this resource that has been allocated for running workload. When used in a job submission, this number is the amount of the resource required by the job.
<b>real</b>	<b>Integer</b>	No	The amount of this resource that physically exists on the node. Overcommit specifically doesn't apply to this. Note that overcommit currently only applies to "processors" and "memory", and so, for most cases, real and configured will always be the same.
<b>utilized</b>	<b>Integer</b>	No	The amount of this resource that is currently reported as utilized by resource managers.

NodeStateInformation

Field Name	Type	PUT	Description
<b>powerState</b>	<a href="#">NodePower</a>	Yes	The state of the node's power system, as reported by the RM layer. Modifying the powerState is possible, and, if Moab is configured properly, a request will be made to modify the power state accordingly.
<b>powerStateExpected</b>	<a href="#">NodePower</a>	No	The expected state of the node's power system. If a user has requested that a node be powered off (e.g. by modifying the <a href="#">powerState</a> attribute to <a href="#">NodePower.OFF</a> ), the requested state will be shown in this field until the state change is completed. If there is no pending power change request, this will be null.

Field Name	Type	PUT	Description
<b>state</b>	<a href="#">NodeState</a>	Yes	The scheduling state of the Node, as reported by the resource management layer.
<b>stateExpected</b>	<a href="#">NodeState</a>	No	The scheduling state of the Node, as expected by Moab. For example, Moab may think that a Node is "Busy" because it has allocated all configured resources, but a resource manager may report the state as "Running" based on actual utilization of the resources.
<b>stateLastUpdatedDate</b>	<b>Date</b>	No	A timestamp recording when the state of the Node was last modified.
<b>subState</b>	<b>String</b>	No	A text description of the state of the Node, with the intention of giving more details. Resource Managers may use this field to further describe the state being reported. Resource Managers should provide documented meaning to the possible sub-states that they can report.
<b>subStateLast</b>	<b>String</b>	No	The previous sub-state of the Node as reported by the resource management layer.
<b>subStateLastUpdatedDate</b>	<b>Date</b>	No	A timestamp recording when the sub-state was last modified.

### [NodePower](#)

Represents the various options for a Node's power state.

Value	Description
<b>NONE</b>	
<b>ON</b>	
<b>OFF</b>	

### [NodeType](#)

Represents the type of node as reported by a resource manager.

Value	Description
<b>Compute</b>	
<b>License</b>	
<b>Network</b>	
<b>Storage</b>	

## API version 1

NodeVersion1

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique ID of the node.
<b>accessPolicy</b>	<a href="#">NodeAccessPolicy</a>	No	The node's access policy.
<b>aliases</b>	<b>Set&lt;String&gt;</b>	No	Holds DNS aliases associated with the node
<b>architecture</b>	<b>String</b>	No	The node's processor architecture.
<b>availableClasses</b>	<b>Set&lt;String&gt;</b>	No	The classes that are available to the node.
<b>availableDisk</b>	<b>Integer</b>	No	The node's available disk space in MB.
<b>availableEndDate</b>	<b>Date</b>	No	The time when the node will stop being available.
<b>availableGenericResources</b>	<b>Map&lt;String, Integer&gt;</b>	No	The node's available generic resources. Stored as name and associated amount.
<b>availableMemory</b>	<b>Integer</b>	No	The node's available memory in MB.
<b>availableProcessors</b>	<b>Integer</b>	No	The node's available processors.
<b>availableStartDate</b>	<b>Date</b>	No	The time when the node will become available.
<b>availableSwap</b>	<b>Integer</b>	No	The node's available swap space in MB.

Field Name	Type	PUT	Description
<b>blockReason</b>	<b>String</b>	No	The reason why jobs are blocked from running on the node.
<b>comments</b>	<b>String</b>	No	User-specified comments regarding the node.
<b>configuredClasses</b>	<b>Set&lt;String&gt;</b>	No	The classes reported by the resource manager for the node.
<b>cpuLoad</b>	<b>Double</b>	No	The current load of the node as a percentage.
<b>dynamic</b>	<b>Boolean</b>	No	If true, the node is associated with a dynamic resource manager.
<b>externalLoad</b>	<b>Double</b>	No	The load on the node not attributed to any batch queues.
<b>features</b>	<b>Set&lt;String&gt;</b>	No	The collection of any opaque node features used to describe and categorize the node.
<b>flags</b>	<a href="#"><u>Set&lt;NodeFlag&gt;</u></a>	No	The flags that are set on this node. Valid only during GET.
<b>genericEvents</b>	<a href="#"><u>Set&lt;GenericEvent&gt;</u></a>	Yes	The list of generic events reported on this node.
<b>genericMetrics</b>	<b>Map&lt;String, Double&gt;</b>	Yes	The values for the generic metrics for this node.
<b>genericResources</b>	<b>Map&lt;String, Integer&gt;</b>	No	The generic resources attached to this node. With each generic resource there is a name and an associated amount.

Field Name	Type	PUT	Description
<b>hypervisorType</b>	<b>String</b>	No	The hypervisor type. Null if this is not a hypervisor.
<b>iOLoad</b>	<b>Double</b>	No	The load reported by the node on its I/O.
<b>index</b>	<b>Integer</b>	No	The index for this node as reported by the resource manager.
<b>jobs</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	The list of jobs on the node.
<b>lastStateUpdateDate</b>	<b>Date</b>	No	The date of the last resource manager update of the node's state.
<b>lastUpdateDate</b>	<b>Date</b>	No	The date of the last resource manager update
<b>maxIOIn</b>	<b>Double</b>	No	The maximum input as a percentage allowed for the node's I/O.
<b>maxIOLoad</b>	<b>Double</b>	No	The maximum total load as a percentage allowed for the node's I/O.
<b>maxIOOut</b>	<b>Double</b>	No	The maximum output as a percentage allowed for the node's I/O.
<b>maxJob</b>	<b>Integer</b>	No	The maximum number of jobs allowed to run on the node.
<b>maxJobPerUser</b>	<b>Integer</b>	No	The maximum number of jobs for a single user allowed to run on the node.

Field Name	Type	PUT	Description
<b>maxLoad</b>	<b>Double</b>	No	The maximum total load as a percentage allowed on the node.
<b>maxPEPerJob</b>	<b>Double</b>	No	The maximum processor equivalence per job allowed on the node.
<b>maxPageIn</b>	<b>Double</b>	No	The maximum total page in allowed on the node.
<b>maxPageOut</b>	<b>Double</b>	No	The maximum total page out allowed on the node.
<b>maxProc</b>	<b>Integer</b>	No	The maximum number of processors available on the node.
<b>maxProcPerClass</b>	<b>Integer</b>	No	The maximum number of processors per class available on the node.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	Yes	The list of system and user messages on the node.
<b>network</b>	<b>String</b>	No	The name of the node's network.
<b>networkAddress</b>	<b>String</b>	No	The network (usually IP) address of this node.
<b>networkLoad</b>	<b>Double</b>	No	The load of the node's network as a percentage.
<b>nextOS</b>	<b>String</b>	No	If populated, the next operating system that is currently being provisioned.
<b>operations</b>	<a href="#">Set&lt;NodeOperation&gt;</a>	No	The list of operations that can be performed on this node.

Field Name	Type	PUT	Description
<b>os</b>	<b>String</b>	Yes	The operating system of the node.
<b>osList</b>	<b>Set&lt;String&gt;</b>	No	The list of potential operating systems for the node.
<b>overcommit</b>	<a href="#"><u>OverCommitFactor</u></a>	No	This is the coefficient that determines how much resources may be overutilized on this hypervisor. Will normally be null for non-hypervisor nodes.
<b>partition</b>	<b>String</b>	Yes	The partition this node belongs to.
<b>power</b>	<a href="#"><u>NodePower</u></a>	Yes	The node's power state according to the resource managers reporting this node.
<b>powerPolicy</b>	<a href="#"><u>PowerPolicy</u></a>	No	The power policy for this node. The default is static where the power is controlled manually.
<b>powerSelected</b>	<a href="#"><u>NodePower</u></a>	No	The node's power state that Moab is currently scheduling. This could be different from the actual node power itself.
<b>priority</b>	<b>Double</b>	No	The priority associated with the node.
<b>priorityFunction</b>	<b>String</b>	No	The function used to calculate this node's priority.
<b>procSpeed</b>	<b>Integer</b>	No	The node's processor speed in MHz.

Field Name	Type	PUT	Description
<b>profilingEnabled</b>	<b>Boolean</b>	No	Indicates whether statistical profiling is enabled for this node. If set to false, node statistics will not be gathered. Defaults to false.
<b>rack</b>	<b>Integer</b>	No	The node's rack location.
<b>reservationCount</b>	<b>Integer</b>	No	The number of reservations on the node.
<b>reservations</b>	<b>Set&lt;String&gt;</b>	No	The list of reservations' names currently on this node.
<b>rmAccessList</b>	<b>String</b>	No	A comma-separated list of resource managers that have access to this node.
<b>size</b>	<b>Integer</b>	No	The number of slots or size units consumed by the node.
<b>slot</b>	<b>Integer</b>	No	The node's slot location.
<b>speed</b>	<b>Double</b>	No	The relative speed of the node. The speed must be between .1 and 100.0. The default value for speed is 1.0.
<b>speedWeight</b>	<b>Double</b>	No	The weight of the speed metric in the node's priority function
<b>state</b>	<a href="#"><u>NodeState</u></a>	Yes	The node's current state.
<b>substate</b>	<b>String</b>	No	The substate that will give more information about the status of the VM.
<b>taskCount</b>	<b>Integer</b>	No	The number of tasks currently running on the node.

Field Name	Type	PUT	Description
<b>totalActiveTime</b>	<b>Long</b>	No	The epoch time in seconds that the node was tracked as being busy with jobs.
<b>totalAvailableTime</b>	<b>Long</b>	No	The epoch time in seconds that the node is available.
<b>totalDisk</b>	<b>Integer</b>	No	The node's total disk space in MB.
<b>totalMemory</b>	<b>Integer</b>	No	The node's total memory in MB.
<b>totalProcessors</b>	<b>Integer</b>	No	The node's total processors.
<b>totalStatsTime</b>	<b>Long</b>	No	The epoch time in seconds that stats have been tracked for the node.
<b>totalSwap</b>	<b>Integer</b>	No	The node's total swap space in MB.
<b>totalUpTime</b>	<b>Long</b>	No	The epoch time in seconds that the node was tracked as being up.
<b>type</b>	<b>String</b>	No	The type of the node. This is used for allocation management purposes.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Variables associated with the node.
<b>virtualMachines</b>	<a href="#">Set&lt;VirtualMachineVersion1&gt;</a>	No	The list of virtual machines on the node.
<b>vmOsList</b>	<b>Set&lt;String&gt;</b>	No	The list of potential operating systems that can be used when creating a virtual machine on the node

### NodeAccessPolicy

This enumeration describes how node resources will be shared by various tasks.

Value	Description
<b>NONE</b>	
<b>SHARED</b>	Tasks from any combination of jobs may utilize available resources.
<b>SHAREDONLY</b>	Only jobs requesting shared node access may utilize available resources.
<b>SINGLEJOB</b>	Tasks from a single job may utilize available resources.
<b>SINGLETASK</b>	A single task from a single job may run on the node.
<b>SINGLEUSER</b>	Tasks from any jobs owned by the same user may utilize available resources.
<b>UNIQUEUSER</b>	Any number of tasks from a single job may allocate resources from a node but only if the user has no other jobs running on that node.
<b>SINGLEGROUP</b>	Any number of tasks from the same group may utilize node.
<b>SINGLEACCOUNT</b>	Any number of tasks from the same account may utilize node.

### NodeFlag

Represents the various flags for nodes.

Value	Description
<b>NONE</b>	
<b>GLOBAL_VARS</b>	Node has variables available for triggers.
<b>NO_VM_MIGRATIONS</b>	Node is excluded from all virtual machine migration decisions.

### GenericEvent

A `GenericEvent` is an event that is reported by a [NodeResourceManager](#) on a [Node](#) or [VirtualMachine](#). Usually, there is some corresponding action defined in the `moab.cfg` file.

GenericEvents are defined by a "name" characteristic, which indicates the type of thing happened on the resource associated with it. For example, a "highcputemp" GenericEvent might be reported by a NodeResourceManager when it detects that the CPU temperature has risen about 50 degrees C.

Note that GenericEvents vary by configuration: one installation of Moab may report GenericEvents of "highcputemp" while another would report "cputemphigh". Although the *meaning* is the same, the *type* or *name* is different.

Field Name	Type	PUT	Description
<b>date</b>	<b>Date</b>	No	The timestamp of when this GenericEvent was <i>reported</i> to Moab
<b>message</b>	<b>String</b>	Yes	The message that goes with this GenericEvent
<b>name</b>	<b>String</b>	Yes	The name of the GenericEvent. In other words, the type.
<b>severity</b>	<b>Integer</b>	No	The severity level of the event (1-4, 1 is low severity, 0 is unset)

DomainProxyVersion1

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The id of the object.

MessageVersion1

Field Name	Type	PUT	Description
<b>author</b>	<b>String</b>	No	The author of the message.
<b>creationTime</b>	<b>Date</b>	No	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	No	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	No	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	Yes	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	No	The number of times this message has been displayed.

Field Name	Type	PUT	Description
<b>priority</b>	<b>Double</b>	No	An optional priority that can be attached to the comment.

### NodeOperation

This class represents an operation that can be taken on a given node.

Value	Description
<b>CREATE_VM</b>	
<b>MIGRATE_VM</b>	
<b>MODIFY_OS</b>	
<b>OFFLINE</b>	
<b>ONLINE</b>	
<b>POWER_ON</b>	
<b>POWER_OFF</b>	
<b>REBOOT</b>	

### OverCommitFactor

This class represents the multipliers to use for over committing the basic grouping of resource types that Moab generally uses when scheduling and taking policy actions in a system. These resource types are the following:

- Disk
- Memory
- Processors
- Swap

These over commit factors are used in multiplying the reported resources from an RM for servers. In addition, these factors are used in establishing when VMs are migrated away from a hypervisor.

Field Name	Type	PUT	Description
<b>overcommitMap</b>	<b>Map&lt;String, Double&gt;</b>	No	

NodePower

Represents the various options for a Node's power state.

Value	Description
<b>NONE</b>	
<b>ON</b>	
<b>OFF</b>	

PowerPolicy

This enumeration represents the power policy to take when deciding about resource power.

Value	Description
<b>NONE</b>	
<b>ONDEMAND</b>	Moab will attempt to power the server off if there is no workload running on it.
<b>STATIC</b>	The power is handled manually.
<b>GREEN</b>	

NodeState

This enumeration tracks the state of a node.

Value	Description
<b>NONE</b>	The node is set to none by the resource manager.

Value	Description
<b>DOWN</b>	The node is not available for workload.
<b>IDLE</b>	The node is available for workload but is not running anything.
<b>BUSY</b>	The node is running workload and cannot accept more.
<b>RUNNING</b>	The node is running workload and can accept more.
<b>DRAINED</b>	The node has been sent the drain request and has no workload on it.
<b>DRAINING</b>	The node has been sent the drain request, but still has workload on it.
<b>FLUSH</b>	The node is being reprovisioned.
<b>RESERVED</b>	The node is being reserved. This is an internal Moab state.
<b>UNKNOWN</b>	The state of the node is unknown.

#### VirtualMachineVersion1

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique ID of the VM.
<b>aliases</b>	<b>Set&lt;String&gt;</b>	No	The list of aliases that refer to this VM.
<b>availableDisk</b>	<b>Integer</b>	No	The amount of disk space available on this VM.
<b>availableMemory</b>	<b>Integer</b>	No	The amount of memory available on this VM.
<b>availableProcessors</b>	<b>Integer</b>	No	The number of processors available on this VM.
<b>cpuLoad</b>	<b>Double</b>	No	The CPU load for this VM.

Field Name	Type	PUT	Description
<b>description</b>	<b>String</b>	No	A description of this VM.
<b>effectiveTimeToLive</b>	<b>Long</b>	No	Time (in seconds) that this VM has to run (0 means not set).
<b>flags</b>	<a href="#"><u>Set&lt;VMFlag&gt;</u></a>	Yes	The flags associated with this VM.
<b>genericEvents</b>	<a href="#"><u>Set&lt;GenericEvent&gt;</u></a>	Yes	The list of generic events reported on this VM.
<b>genericMetrics</b>	<b>Map&lt;String, Double&gt;</b>	Yes	The values for the generic metrics for this VM.
<b>lastMigrationDate</b>	<b>Date</b>	No	The date when this VM was last migrated.
<b>lastSubstate</b>	<b>String</b>	No	Last reported substate (substate is not always reported).
<b>lastSubstateModificationDate</b>	<b>Date</b>	No	Date/time that lastSubstate was modified.
<b>lastUpdateDate</b>	<b>Date</b>	No	The date of when this VM was last updated.
<b>migrationCount</b>	<b>Integer</b>	No	The number of times this VM has been migrated.
<b>networkAddress</b>	<b>String</b>	No	The network address of this VM.
<b>node</b>	<a href="#"><u>DomainProxyVersion1</u></a>	Yes	The physical node on which this VM is running.
<b>os</b>	<b>String</b>	Yes	The current operating system of the VM.
<b>osList</b>	<b>Set&lt;String&gt;</b>	No	The list of operating systems that the VM can run.

Field Name	Type	PUT	Description
<b>powerSelectState</b>	<a href="#">NodePower</a>	No	The selected power state of this VM.
<b>powerState</b>	<a href="#">NodePower</a>	Yes	The power state of this VM.
<b>rack</b>	<b>Integer</b>	No	The rack of the VM inside a given node.
<b>requestedTimeToLive</b>	<b>Long</b>	No	User-specified time (in seconds) that this VM has to run (0 means not set).
<b>slot</b>	<b>Integer</b>	No	The slot of the VM inside a given node.
<b>sovereign</b>	<b>Boolean</b>	No	
<b>startDate</b>	<b>Date</b>	No	Date/time that this VM was started (ready and usable)
<b>state</b>	<a href="#">NodeState</a>	Yes	The state of the VM.
<b>storage</b>	<b>String</b>	No	
<b>substate</b>	<b>String</b>	No	The substate that will give more information about the status of the VM.
<b>template</b>	<b>String</b>	No	
<b>totalDisk</b>	<b>Integer</b>	No	The amount of disk space configured in MB.
<b>totalMemory</b>	<b>Integer</b>	No	The amount of memory configured in MB.
<b>totalProcessors</b>	<b>Integer</b>	No	The number of virtual processors in the VM.
<b>trackingJob</b>	<a href="#">DomainProxyVersion1</a>	No	The tracking job for this VM.

Field Name	Type	PUT	Description
<b>triggers</b>	<a href="#">Set&lt;Trigger&gt;</a>	Yes	The list of triggers on this VM.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Variables associated with this VM.

VMFlag

This enumeration specifies the VM flag types of a virtual machine.

Value	Description
<b>CAN_MIGRATE</b>	VM may be directly migrated without direction from parent workload.
<b>CANNOT_MIGRATE</b>	This value is used to remove the CAN_MIGRATE flag.
<b>CONSUMER</b>	VM should be treated as resource consumer regardless of Moab-tracked workload.
<b>CREATION_COMPLETED</b>	VM creation completed.
<b>DELETED</b>	VM deleted.
<b>DESTROY_PENDING</b>	VM destroy requested.
<b>DESTROYED</b>	VM reported destroyed by Resource Manager (VM will be removed when resource manager no longer reports VM).
<b>INITIALIZING</b>	VM is initializing.
<b>ONETIMEUSE</b>	VM is was created for a job with vmusagepolicy=createvm.
<b>SHARED</b>	Multiple jobs can use VM resources simultaneously.
<b>UTILIZATION_REPORTED</b>	

Trigger

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	No	
<b>blockTime</b>	<b>Date</b>	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	No	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	No	
<b>expireTime</b>	<b>Date</b>	No	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	<b>Date</b>	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	No	
<b>interval</b>	<b>Boolean</b>	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	No	Specifies whether this trigger can fire multiple times. Defaults to false.

Field Name	Type	PUT	Description
<b>name</b>	<b>String</b>	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	No	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	No	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#">TriggerPeriod</a>	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	No	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.

Field Name	Type	PUT	Description
<b>timeout</b>	<b>Date</b>	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	

Value	Description
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id

Value	Description
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	<p>By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
MINUTE	
HOUR	
DAY	
WEEK	
MONTH

## API version 3

### NotificationCondition

A notification condition is related to an [Event](#), but differs in three distinct areas:

- Notification conditions are a persistent condition of the system or a component rather than a single occurrence.
  - They are ongoing rather than reoccurring, which is why they are generated from [NotificationConditions](#).
  - They may be observed many times, but the condition is always the same.
  - A good test for this is if something "is" wrong rather than something "went" wrong.
- Notification conditions can be acted on to result in a resolved state, mean the administrator or user can and must take actions to "fix" the condition or problem.
- Notification conditions contain state information based on administrator or user input, meaning that they contain information about the condition (similar to events), but also contain the "status" of the administrator's view of the notification, whether it is currently open, dismissed, or ignored.

In general, questions may be asked to ascertain whether an Event or a Notification Condition is the right fit for an occurrence. These questions, along with some sample situations, are provided below.

- Is the occurrence the root cause of a potentially ongoing condition?
  - A VM migration failed because the VM's state was unknown. The root cause was that the state was unknown, not that the VM migration failed. Therefore, VM migration failed would be an event, while the unknown state would be a notification condition.
  - A VM service provision fails because there are no hypervisors that satisfy the requirements. This would be an event. Note that there may be a notification related to this failure, such as a service template requires a feature that does not exist on *any* hypervisors in the system, but this would be distinctly detected and managed from the provision failure event.

- A request to MWS failed because the connection between MWM and MongoDB was misconfigured. The failed request may be represented as an event, but a notification condition should exist that the connection between MWM and MongoDB was down.
- Can an administrator or user affect the outcome of the occurrence?
    - The outcome of a VM migration failing is in the past and cannot be changed by the administrator. However, the outcome of a *future* VM migration may be changed when the administrator resolves the root problem (i.e. VM state is unknown).

A notification condition is an observed condition for which [Notifications](#) are created. These conditions are created or updated on every PUT request based on the [NotificationCondition.escalationLevel](#), [NotificationCondition.origin](#), [NotificationCondition.message](#), [NotificationCondition.objectType](#), and [NotificationCondition.objectId](#) fields. When notifications are requested, these observed conditions are used to create the notifications for the requesting user.

While notification conditions may not be deleted, they "expire" after a specified amount of time and are no longer considered as active conditions for which notifications are created.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The identifier of the condition.
<b>createdDate</b>	<b>Date</b>	No	The date that the condition first started appearing.
<b>details</b>	<b>Map&lt;String, Map&gt;</b>	No	Arbitrary storage of details for this notification. This could include "pluginType", "pluginId", etc.
<b>escalationLevel</b>	<a href="#">EscalationLevel</a>	No	The escalation level of the condition. This indicates who should care about the condition or who can respond to it. This may NOT be <a href="#">EscalationLevel.INTERNAL</a> .
<b>expirationDate</b>	<b>Date</b>	No	The date at which the condition is considered "expired" and notifications are no longer created for it. This is typically set using the <a href="#">expirationDuration</a> field.

Field Name	Type	PUT	Description
<b>expirationDuration</b>	<b>Long</b>	No	The duration in seconds that may pass before a notification will not be created for a user. Effectively this can disable notifications from being created if they are too old. When this field is set, it will set the <a href="#">expirationDate</a> field automatically each time the condition is updated or on creation. This field must be set to 1 or greater or else set to null.
<b>message</b>	<b>String</b>	No	A message detailing the notification and why it exists, with possible action items.
<b>objectId</b>	<b>String</b>	No	The identifier of the object which this notification affects, such as "node1" or "vm1".
<b>objectType</b>	<b>String</b>	No	The object type that this notification affects, such as "Node", "VM", "System", etc.
<b>observedDate</b>	<b>Date</b>	No	The latest date that the condition was observed. If this field is not set in an update request, it will automatically be set to the current date.
<b>origin</b>	<b>String</b>	No	The origin of the notification.
<b>tenant</b>	<b>Map&lt;String, Map&gt;</b>	No	The tenant that this notification came from. (contains tenant id and name)

EscalationLevel

Value	Description
<b>USER</b>	
<b>POWER_USER</b>	
<b>ADMIN</b>	
<b>INTERNAL</b>

## API version 3

Notification

Notifications, while related to [Events](#), are used for different purposes. See [NotificationCondition](#) for more information on when notifications should be used as opposed to events.

Notifications are a per-user representation of all notification conditions present in the system at any one time. When an administrator or user requests this resource, notifications are automatically created from the notification conditions that they have access to (determined by the [Notification.tenant](#) or the [NotificationCondition.escalationLevel](#) fields).

Notifications are expected to contain messages and details that may be understood by a user or admin depending on the escalation level, and contain fields that control whether the user or admin will be notified of future updates to their corresponding condition.

Notifications cannot be deleted, but they can be marked as ignored (see [Notification.ignoredDate](#) or dismissed (see [Notification.dismissedDate](#)).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The identifier of the notification.
<b>conditionId</b>	<b>String</b>	No	The identifier of the <a href="#">NotificationCondition</a> from which this notification was created.
<b>createdDate</b>	<b>Date</b>	No	The date that the notification condition first appeared.
<b>details</b>	<b>Map&lt;String, Map&gt;</b>	No	Arbitrary storage of details for this notification. This could include "pluginType", "pluginId", etc.
<b>dismissedDate</b>	<b>Date</b>	No	The date that the notification was dismissed by a user or admin, meaning that they acknowledged the notification and wanted to know of future updates to this notification. This field is cleared every time the attached notification condition is updated/observed again. (See also: <a href="#">conditionId</a> .)
<b>ignoredDate</b>	<b>Date</b>	No	The date that the notification was ignored by a user or admin, meaning that they acknowledged the notification now and in the future and did not wish to know of any updates. This field is never cleared, even if the attached notification condition is updated/observed again.
<b>message</b>	<b>String</b>	No	A message detailing the notification and why it exists, with possible action items.

Field Name	Type	PUT	Description
<b>objectId</b>	<b>String</b>	No	The identifier of the object which this notification affects, such as "node1" or "vm1".
<b>objectType</b>	<b>String</b>	No	The object type that this notification affects, such as "Node", "VM", "System", etc.
<b>observedDate</b>	<b>Date</b>	No	The latest date that the notification condition was observed. If this field, <a href="#">ignoredDate</a> , and <a href="#">dismissedDate</a> are not set during an update (i.e. a user/admin is not ignoring or dismissing the notification), this field will automatically be set to the current date.
<b>origin</b>	<b>String</b>	No	The origin of the notification.
<b>user</b>	<b>String</b>	No	The user that this notification was created for.

<b>Distinct query-supported</b>	No	<a href="#">Distinct on page 1526</a>

## API version 3

PluginInstance

This class represents a configured plugin created from a plugin type.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	Yes	No	Unique identifier for the plugin. Must contain at least one letter and must also start with a letter. Reserved IDs are "all" and "moab". If these are used an error will be returned.
<b>autoStart</b>	<b>Boolean</b>	Yes	Yes	Whether the plugin should start automatically when created.
<b>config</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The configuration of the plugin. Plugin types may define constraints on the configuration, therefore it is recommended to view the plugin type's documentation for more information on required and optional fields. Regardless, the plugin configuration supports arbitrary keys and values.
<b>dateCreated</b>	<b>Date</b>	No	No	The date that this plugin was created.
<b>lastPollDate</b>	<b>Date</b>	No	No	The date of the last polling event that occurred. This may be null if the plugin is in the STOPPED state or has not yet been polled.
<b>lastUpdated</b>	<b>Date</b>	No	No	The date that this plugin was last updated.
<b>nextPollDate</b>	<b>Date</b>	No	No	The date of the next polling event that is scheduled to occur. This may be null if the plugin is in the STOPPED state.
<b>pluginType</b>	<b>String</b>	Yes	No	The plugin name as in Native or Example for the plugin called ExamplePlugin.
<b>pollInterval</b>	<b>Integer</b>	Yes	Yes	The polling interval to use for the plugin in seconds. This is ignored if the plugin type does not support polling.

Field Name	Type	POST	PUT	Description
<b>precedence</b>	<b>Long</b>	Yes	Yes	<p>The precedence of this plugin, with the lowest value being the highest precedence. Minimum of 1. This is used when doing data consolidation when reporting current state data. Lower numbers results in a higher precedence (i.e. 1 is higher precedence than 10).</p> <p>If not specified during creation, this will be automatically set to 1 for the first plugin created, then 1 greater for each subsequently created plugin (i.e. 1 for plugin1, 2 for plugin2, etc). It is always set to 1 greater than the plugin with the greatest precedence number (i.e. 11 if two plugins exist with precedence 1 and 10).</p>
<b>state</b>	<a href="#"><u>PluginState</u></a>	No	No	The current state of the plugin. Defaults to <a href="#"><u>PluginState.STOPPED</u></a> .

[PluginState](#)

Represents the current state of a plugin.

Value	Description
<b>STOPPED</b>	The plugin is created and ready for use, but is not currently receiving any events
<b>STARTED</b>	The plugin is currently receiving events and is working correctly.
<b>PAUSED</b>	<p>The plugin is currently not receiving any events but is also not stopped.</p> <p>This should be used when polling or other events should stop only temporarily without firing the stop events.</p>
<b>ERRORED</b>	<p>MWS has detected an error with the plugin and has automatically stopped it. Errors could be due to the following reasons:</p> <ol style="list-style-type: none"> <li>1. An invalid configuration was detected when running the <a href="#"><u>AbstractPlugin.configure</u></a> method.</li> <li>2. An unexpected exception was thrown during an event, such as during polling.</li> </ol>

## API version 2

PluginInstance

This class represents a configured plugin created from a plugin type.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	Yes	No	Unique identifier for the plugin. Must contain at least one letter and must also start with a letter. Reserved IDs are "all" and "moab". If these are used an error will be returned.
<b>autoStart</b>	<b>Boolean</b>	Yes	Yes	Whether the plugin should start automatically when created.
<b>config</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The configuration of the plugin. Plugin types may define constraints on the configuration, therefore it is recommended to view the plugin type's documentation for more information on required and optional fields. Regardless, the plugin configuration supports arbitrary keys and values.
<b>dateCreated</b>	<b>Date</b>	No	No	The date that this plugin was created.
<b>lastPollDate</b>	<b>Date</b>	No	No	The date of the last polling event that occurred. This may be null if the plugin is in the STOPPED state or has not yet been polled.
<b>lastUpdated</b>	<b>Date</b>	No	No	The date that this plugin was last updated.
<b>nextPollDate</b>	<b>Date</b>	No	No	The date of the next polling event that is scheduled to occur. This may be null if the plugin is in the STOPPED state.
<b>pluginType</b>	<b>String</b>	Yes	No	The plugin name as in Native or Example for the plugin called ExamplePlugin.
<b>pollInterval</b>	<b>Integer</b>	Yes	Yes	The polling interval to use for the plugin in seconds. This is ignored if the plugin type does not support polling.

Field Name	Type	POST	PUT	Description
<b>precedence</b>	<b>Long</b>	Yes	Yes	<p>The precedence of this plugin, with the lowest value being the highest precedence. Minimum of 1. This is used when doing data consolidation when reporting current state data. Lower numbers results in a higher precedence (i.e. 1 is higher precedence than 10).</p> <p>If not specified during creation, this will be automatically set to 1 for the first plugin created, then 1 greater for each subsequently created plugin (i.e. 1 for plugin1, 2 for plugin2, etc). It is always set to 1 greater than the plugin with the greatest precedence number (i.e. 11 if two plugins exist with precedence 1 and 10).</p>
<b>state</b>	<a href="#"><u>PluginState</u></a>	No	No	The current state of the plugin. Defaults to <a href="#"><u>PluginState.STOPPED</u></a> .

[PluginState](#)

Represents the current state of a plugin.

Value	Description
<b>STOPPED</b>	The plugin is created and ready for use, but is not currently receiving any events
<b>STARTED</b>	The plugin is currently receiving events and is working correctly.
<b>PAUSED</b>	<p>The plugin is currently not receiving any events but is also not stopped.</p> <p>This should be used when polling or other events should stop only temporarily without firing the stop events.</p>
<b>ERRORED</b>	<p>MWS has detected an error with the plugin and has automatically stopped it. Errors could be due to the following reasons:</p> <ol style="list-style-type: none"> <li>1. An invalid configuration was detected when running the <a href="#"><u>AbstractPlugin.configure</u></a> method.</li> <li>2. An unexpected exception was thrown during an event, such as during polling.</li> </ol>

## API version 1

## API version 3

PluginType

Represents a MWS plugin type. All fields in this class are generated from plugin project and type metadata and cannot be modified directly. Consequentially, all fields are only valid for list/show/GET operations.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier of the plugin type. This is based on the class name of the plugin. Ex:  <b>Plugin Class Name -&gt; ID</b> NativePlugin -> Native MSMPlugin -> MSM MyExamplePlugin -> MyExample
<b>author</b>	<b>String</b>	No	The main author (company or person) of the plugin type.
<b>commonsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of the plugin framework (plugins-commons dependency) is required for the plugin type. In the format 'COMMONS_VERSION > *', meaning that any version greater or equal to COMMONS_VERSION is valid.
<b>description</b>	<b>String</b>	No	The full description of the plugin type.
<b>documentationLink</b>	<b>String</b>	No	A full URL to the complete documentation for the plugin type.
<b>email</b>	<b>String</b>	No	The email of the author.
<b>eventComponent</b>	<b>Integer</b>	No	The event component ID of the plugin type. This should be unique for each plugin type and should be 1 or greater.
<b>initialPlugins</b>	<b>Map&lt;String, Map&gt;</b>	No	Represents the plugins that are initially configured when the plugin type is loaded. Each key represents the plugin ID.
<b>issueManagementLink</b>	<b>String</b>	No	A full URL to the issue management system or project for the plugin type.

Field Name	Type	PUT	Description
<b>license</b>	<b>String</b>	No	The license of this plugin type, typically APACHE.
<b>mwsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of MWS is required for the plugin type. In the format 'MWS_VERSION > *', meaning that any version greater or equal to MWS_VERSION is valid.
<b>pollMethod</b>	<b>boolean</b>	No	Indicates whether the plugin type has a defined 'poll' method (event handler) or not.
<b>realizedEventComponent</b>	<b>Integer</b>	No	The fully realized event component ID of the plugin type, including the MWS bits. This should take the form of 0x201. If the <a href="#">eventComponent</a> is not set, this will be 0x2FF, meaning the component ID is an unknown plugin type.
<b>scmLink</b>	<b>String</b>	No	A full URL to the Source Control Management (SCM) system or project for the plugin type.
<b>title</b>	<b>String</b>	No	A short name describing the plugin type.
<b>website</b>	<b>String</b>	No	The website of the author.

## API version 2

PluginType

Represents a MWS plugin type. All fields in this class are generated from plugin project and type metadata and cannot be modified directly. Consequentially, all fields are only valid for list/show/GET operations.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier of the plugin type. This is based on the class name of the plugin. Ex:  <b>Plugin Class Name -&gt; ID</b> NativePlugin -> Native MSMPlugin -> MSM MyExamplePlugin -> MyExample
<b>author</b>	<b>String</b>	No	The main author (company or person) of the plugin type.
<b>commonsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of the plugin framework (plugins-commons dependency) is required for the plugin type. In the format 'COMMONS_VERSION > *', meaning that any version greater or equal to COMMONS_VERSION is valid.
<b>description</b>	<b>String</b>	No	The full description of the plugin type.
<b>documentationLink</b>	<b>String</b>	No	A full URL to the complete documentation for the plugin type.
<b>email</b>	<b>String</b>	No	The email of the author.
<b>eventComponent</b>	<b>Integer</b>	No	The event component ID of the plugin type. This should be unique for each plugin type and should be 1 or greater.
<b>initialPlugins</b>	<b>Map&lt;String, Map&gt;</b>	No	Represents the plugins that are initially configured when the plugin type is loaded. Each key represents the plugin ID.
<b>issueManagementLink</b>	<b>String</b>	No	A full URL to the issue management system or project for the plugin type.

Field Name	Type	PUT	Description
<b>license</b>	<b>String</b>	No	The license of this plugin type, typically APACHE.
<b>mwsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of MWS is required for the plugin type. In the format 'MWS_VERSION > *', meaning that any version greater or equal to MWS_VERSION is valid.
<b>pollMethod</b>	<b>boolean</b>	No	Indicates whether the plugin type has a defined 'poll' method (event handler) or not.
<b>realizedEventComponent</b>	<b>Integer</b>	No	The fully realized event component ID of the plugin type, including the MWS bits. This should take the form of 0x201. If the <a href="#">eventComponent</a> is not set, this will be 0x2FF, meaning the component ID is an unknown plugin type.
<b>scmLink</b>	<b>String</b>	No	A full URL to the Source Control Management (SCM) system or project for the plugin type.
<b>title</b>	<b>String</b>	No	A short name describing the plugin type.
<b>website</b>	<b>String</b>	No	The website of the author.

## API version 1

PluginType

Represents a MWS plugin type. All fields in this class are generated from plugin project and type metadata and cannot be modified directly. Consequentially, all fields are only valid for list/show/GET operations.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier of the plugin type. This is based on the class name of the plugin. Ex:  <b>Plugin Class Name -&gt; ID</b> NativePlugin -> Native MSMPlugin -> MSM MyExamplePlugin -> MyExample
<b>author</b>	<b>String</b>	No	The main author (company or person) of the plugin type.
<b>commonsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of the plugin framework (plugins-commons dependency) is required for the plugin type. In the format 'COMMONS_VERSION > *', meaning that any version greater or equal to COMMONS_VERSION is valid.
<b>description</b>	<b>String</b>	No	The full description of the plugin type.
<b>documentationLink</b>	<b>String</b>	No	A full URL to the complete documentation for the plugin type.
<b>email</b>	<b>String</b>	No	The email of the author.
<b>eventComponent</b>	<b>Integer</b>	No	The event component ID of the plugin type. This should be unique for each plugin type and should be 1 or greater.
<b>initialPlugins</b>	<b>Map&lt;String, Map&gt;</b>	No	Represents the plugins that are initially configured when the plugin type is loaded. Each key represents the plugin ID.
<b>issueManagementLink</b>	<b>String</b>	No	A full URL to the issue management system or project for the plugin type.

Field Name	Type	PUT	Description
<b>license</b>	<b>String</b>	No	The license of this plugin type, typically APACHE.
<b>mwsVersion</b>	<b>String</b>	No	A string representing the restriction on which version of MWS is required for the plugin type. In the format 'MWS_VERSION > *', meaning that any version greater or equal to MWS_VERSION is valid.
<b>pollMethod</b>	<b>boolean</b>	No	Indicates whether the plugin type has a defined 'poll' method (event handler) or not.
<b>realizedEventComponent</b>	<b>Integer</b>	No	The fully realized event component ID of the plugin type, including the MWS bits. This should take the form of 0x201. If the <a href="#">eventComponent</a> is not set, this will be 0x2FF, meaning the component ID is an unknown plugin type.
<b>scmLink</b>	<b>String</b>	No	A full URL to the Source Control Management (SCM) system or project for the plugin type.
<b>title</b>	<b>String</b>	No	A short name describing the plugin type.
<b>website</b>	<b>String</b>	No	The website of the author.

## API version 3

Policy

A Moab Workload Manager policy which can affect scheduling decisions such as resource allocation. A policy contains state, identifying information, a priority, and metadata about the policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

AutoVMMigrationPolicy

The Moab policy used to enabled and configure policy-based VM migration. Using information about data center applications and server load, Moab can aim to keep VMs in the data center optimally distributed across all hypervisors.

This class inherits fields from Policy.

Field Name	Type	P U T	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>genericMetricThresholds</b>	<b>Map&lt;String, Double&gt;</b>	Yes	A map of generic metric pairings where each value must be greater than or equal to 0 such as:  METRIC1 => 5.6 METRIC2 => 0.0 METRIC3 => 102.4
<b>memoryUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the utilization threshold for memory. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>migrationAlgorithmType</b>	<u><a href="#">AutoVMMigrationPolicyType</a></u>	Yes	Configures the VM migration algorithm utilized when the policy is active. Defaults to <u><a href="#">NONE</a></u> . When <u><a href="#">ENABLED</a></u> , this must <b>not</b> be set to NONE.

Field Name	Type	P U T	Description
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>processorUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the load utilization threshold for processors. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

#### [AutoVMMigrationPolicyType](#)

Represents the algorithm used to migrate VMs when the [AutoVMMigrationPolicy](#) is used.

Value	Description
<b>NONE</b>	Used when the Auto VM Migration policy is currently disabled in Moab and before any settings are saved the first time.  For example, if the policy is disabled on the first read of Moab policies, the <a href="#">AutoVMMigrationPolicy.migrationAlgorithmType</a> will be set to NONE. If the policy is enabled and the type is set to OVERCOMMIT, followed by a disabling of the policy, it will then be represented as having a state of DISABLED with a migrationAlgorithmType of OVERCOMMIT.
<b>OVERCOMMIT</b>	Use the "overcommit" algorithm for migration. The goal of this algorithm is to equalize loads across hypervisors as migrations are queued due to overcommit conditions. This places VMs to be migrated on the least-loaded hypervisor available.
<b>CONSOLIDATION</b>	Use the "consolidation" algorithm for migration. The goal of this algorithm is to load hypervisors as close to thresholds as possible, without exceeding them. This policy places VMs to be migrated on the most loaded hypervisor possible, within these constraints. A second loop of this policy will select lightly-loaded hypervisors to be evacuated completely.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

HVAllocationOvercommitPolicy

The Hypervisor Allocation Overcommit policy controls how many virtual machines can be placed on a hypervisor. By enabling this policy, you are allowing Moab to allocate more resources to a set of virtual machines than a hypervisor may actually have. This is possible due to virtualization. In other words, this policy allows you to set the high-water mark for virtual machine allocation for hypervisors. At least one of these limits must be greater than 1.0, or the policy will not be able to set to a state of [PolicyState.ENABLED](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>memoryAllocationLimit</b>	<b>Double</b>	Yes	Setting this to 1 effectively disables the allocation overcommit based on memory. If this and <a href="#">processorAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a> .
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>processorAllocationLimit</b>	<b>Double</b>	Yes	<p>The Allocation Limit defines the upper bound or maximum amount of VCPUs that can be created on any given hypervisor (HV). For example, if you have a hypervisor with 12 processors or cores (Moab sees them as 12 processors), and have an Allocation Limit of 2.0 for procs, then Moab will not allow, under any condition, more than 24 VCPU's to be allocated on this hypervisor. Remember: a VM can have one or more VCPU's. So, in this example, the HV could only support 8 VM's if they all had 3 VPCU's each. It could support 4 VM's if they had 6 VPCU's each, and so forth</p> <p>From <a href="http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html">http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html</a></p> <p>Setting this to 1 effectively disables the allocation overcommit based on processors. If this and <a href="#">memoryAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a>.</p>
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

NodeAllocationPolicy

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Moab contains a number of allocation algorithms that address this in the NodeAllocationPolicy.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>customPriorityFunction</b>	<b>String</b>	Yes	Defines the priority function when the <a href="#">CustomPriority</a> algorithm is used.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>nodeAllocationAlgorithm</b>	<a href="#">NodeAllocationAlgorithm</a>	Yes	Configures the node allocation algorithm utilized when the policy is active. Defaults to <b>NONE</b> . When <a href="#">ENABLED</a> , this must <b>not</b> be set to NONE.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[NodeAllocationAlgorithm](#)

Represents the algorithm used to allocate Nodes when the [NodeAllocationPolicy](#) is used.

Value	Description
<b>NONE</b>	
<b>InReportedOrder</b>	
<b>InReverseReportedOrder</b>	
<b>CustomPriority</b>	
<b>ProcessorLoad</b>	
<b>MinimumConfiguredResources</b>	
<b>Contiguous</b>	
<b>ProcessorSpeedBalance</b>	
<b>NodeSpeed</b>	

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

MigrationExclusionListPolicy

Specify which virtual machines and hypervisors to exclude from automatic migration operations.

This class inherits fields from Policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>hvExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of hypervisor IDs on the exclusion list.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<u><a href="#">PolicyState</a></u>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <u><a href="#">PolicyState.DISABLED</a></u> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.

Field Name	Type	PUT	Description
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.
<b>vmExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of VM IDs on the exclusion list.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

FairsharePolicy

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect. <http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php>

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.

Field Name	Type	PUT	Description
<b>decayFactor</b>	<b>Double</b>	Yes	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing aged usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage.
<b>depth</b>	<b>Integer</b>	Yes	Number of fairshare windows factored into current fairshare utilization. Note: The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab).
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>intervalSeconds</b>	<b>Long</b>	Yes	Specifies the length of each fairshare window in seconds.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#"><u>PolicyState</u></a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#"><u>PolicyState.DISABLED</u></a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

Field Name	Type	PUT	Description
<b>usageMetric</b>	<a href="#">FairshareUsageMetric</a>	Yes	As Moab runs, it records how available resources are used. Each iteration it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the usage metric allowing various aspects of resource consumption information to be measured. The usage metric allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

FairshareUsageMetric

Specifies the unit of tracking [FairsharePolicy](#) usage.

<http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php#fspolicy>

Value	Description
<b>NONE</b>	
<b>DEDICATED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds dedicated to each job relative to other processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)
<b>DEDICATED_PROCESSOR_SECONDS_AVAILABLE</b>	Usage tracked by processor seconds dedicated to each job relative to all available processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)

Value	Description
<b>DEDICATED_PROCESSOR_EQUIVALENT_SECONDS_DELIVERED</b>	Usage tracked by processor-equivalent seconds dedicated to each job relative to other processor-equivalent seconds dedicated to other jobs on the system. (Useful in dedicated and shared nodes environments).
<b>UTILIZED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds used by each job relative to other processor seconds used by other jobs on the system. (Useful in shared node/SMP environments.)

## API version 2

Policy

A Moab Workload Manager policy which can affect scheduling decisions such as resource allocation. A policy contains state, identifying information, a priority, and metadata about the policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

AutoVMMigrationPolicy

The Moab policy used to enabled and configure policy-based VM migration. Using information about data center applications and server load, Moab can aim to keep VMs in the data center optimally distributed across all hypervisors.

This class inherits fields from Policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>genericMetricThresholds</b>	<b>Map&lt;String, Double&gt;</b>	Yes	A map of generic metric pairings where each value must be greater than or equal to 0 such as:  METRIC1 => 5.6 METRIC2 => 0.0 METRIC3 => 102.4
<b>memoryUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the utilization threshold for memory. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>migrationAlgorithmType</b>	<u><a href="#">AutoVMMigrationPolicyType</a></u>	Yes	Configures the VM migration algorithm utilized when the policy is active. Defaults to <u><a href="#">NONE</a></u> . When <u><a href="#">ENABLED</a></u> , this must <b>not</b> be set to NONE.

Field Name	Type	P U T	Description
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>processorUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the load utilization threshold for processors. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

#### [AutoVMMigrationPolicyType](#)

Represents the algorithm used to migrate VMs when the [AutoVMMigrationPolicy](#) is used.

Value	Description
<b>NONE</b>	Used when the Auto VM Migration policy is currently disabled in Moab and before any settings are saved the first time.  For example, if the policy is disabled on the first read of Moab policies, the <a href="#">AutoVMMigrationPolicy.migrationAlgorithmType</a> will be set to NONE. If the policy is enabled and the type is set to OVERCOMMIT, followed by a disabling of the policy, it will then be represented as having a state of DISABLED with a migrationAlgorithmType of OVERCOMMIT.
<b>OVERCOMMIT</b>	Use the "overcommit" algorithm for migration. The goal of this algorithm is to equalize loads across hypervisors as migrations are queued due to overcommit conditions. This places VMs to be migrated on the least-loaded hypervisor available.
<b>CONSOLIDATION</b>	Use the "consolidation" algorithm for migration. The goal of this algorithm is to load hypervisors as close to thresholds as possible, without exceeding them. This policy places VMs to be migrated on the most loaded hypervisor possible, within these constraints. A second loop of this policy will select lightly-loaded hypervisors to be evacuated completely.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

HVAllocationOvercommitPolicy

The Hypervisor Allocation Overcommit policy controls how many virtual machines can be placed on a hypervisor. By enabling this policy, you are allowing Moab to allocate more resources to a set of virtual machines than a hypervisor may actually have. This is possible due to virtualization. In other words, this policy allows you to set the high-water mark for virtual machine allocation for hypervisors. At least one of these limits must be greater than 1.0, or the policy will not be able to set to a state of [PolicyState.ENABLED](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>memoryAllocationLimit</b>	<b>Double</b>	Yes	Setting this to 1 effectively disables the allocation overcommit based on memory. If this and <a href="#">processorAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a> .
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>processorAllocationLimit</b>	<b>Double</b>	Yes	The Allocation Limit defines the upper bound or maximum amount of VCPUs that can be created on any given hypervisor (HV). For example, if you have a hypervisor with 12 processors or cores (Moab sees them as 12 processors), and have an Allocation Limit of 2.0 for procs, then Moab will not allow, under any condition, more than 24 VCPU's to be allocated on this hypervisor. Remember: a VM can have one or more VCPU's. So, in this example, the HV could only support 8 VM's if they all had 3 VPCU's each. It could support 4 VM's if they had 6 VPCU's each, and so forth  From <a href="http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html">http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html</a> Setting this to 1 effectively disables the allocation overcommit based on processors. If this and <a href="#">memoryAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a> .
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

NodeAllocationPolicy

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Moab contains a number of allocation algorithms that address this in the NodeAllocationPolicy.

This class inherits fields from Policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>customPriorityFunction</b>	<b>String</b>	Yes	Defines the priority function when the <u>CustomPriority</u> algorithm is used.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>nodeAllocationAlgorithm</b>	<u><a href="#">NodeAllocationAlgorithm</a></u>	Yes	Configures the node allocation algorithm utilized when the policy is active. Defaults to <b>NONE</b> . When <u><a href="#">ENABLED</a></u> , this must <b>not</b> be set to <b>NONE</b> .
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

[NodeAllocationAlgorithm](#)

Represents the algorithm used to allocate Nodes when the [NodeAllocationPolicy](#) is used.

Value	Description
<b>NONE</b>	
<b>InReportedOrder</b>	
<b>InReverseReportedOrder</b>	
<b>CustomPriority</b>	
<b>ProcessorLoad</b>	
<b>MinimumConfiguredResources</b>	
<b>Contiguous</b>	
<b>ProcessorSpeedBalance</b>	
<b>NodeSpeed</b>	

[PolicyState](#)

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

### MigrationExclusionListPolicy

Specify which virtual machines and hypervisors to exclude from automatic migration operations.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>hvExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of hypervisor IDs on the exclusion list.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.

Field Name	Type	PUT	Description
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.
<b>vmExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of VM IDs on the exclusion list.

### PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

### FairsharePolicy

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect. <http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php>

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.

Field Name	Type	PUT	Description
<b>decayFactor</b>	<b>Double</b>	Yes	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing aged usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage.
<b>depth</b>	<b>Integer</b>	Yes	Number of fairshare windows factored into current fairshare utilization. Note: The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab).
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>intervalSeconds</b>	<b>Long</b>	Yes	Specifies the length of each fairshare window in seconds.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#"><u>PolicyState</u></a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#"><u>PolicyState.DISABLED</u></a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

Field Name	Type	PUT	Description
<b>usageMetric</b>	<a href="#">FairshareUsageMetric</a>	Yes	As Moab runs, it records how available resources are used. Each iteration it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the usage metric allowing various aspects of resource consumption information to be measured. The usage metric allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

FairshareUsageMetric

Specifies the unit of tracking [FairsharePolicy](#) usage.

<http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php#fspolicy>

Value	Description
<b>NONE</b>	
<b>DEDICATED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds dedicated to each job relative to other processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)
<b>DEDICATED_PROCESSOR_SECONDS_AVAILABLE</b>	Usage tracked by processor seconds dedicated to each job relative to all available processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)

Value	Description
<b>DEDICATED_PROCESSOR_EQUIVALENT_SECONDS_DELIVERED</b>	Usage tracked by processor-equivalent seconds dedicated to each job relative to other processor-equivalent seconds dedicated to other jobs on the system. (Useful in dedicated and shared nodes environments).
<b>UTILIZED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds used by each job relative to other processor seconds used by other jobs on the system. (Useful in shared node/SMP environments.)

## API version 1

Policy

A Moab Workload Manager policy which can affect scheduling decisions such as resource allocation. A policy contains state, identifying information, a priority, and metadata about the policy.

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

AutoVMMigrationPolicy

The Moab policy used to enabled and configure policy-based VM migration. Using information about data center applications and server load, Moab can aim to keep VMs in the data center optimally distributed across all hypervisors.

This class inherits fields from Policy.

Field Name	Type	P U T	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>genericMetricThresholds</b>	<b>Map&lt;String, Double&gt;</b>	Yes	A map of generic metric pairings where each value must be greater than or equal to 0 such as:  METRIC1 => 5.6 METRIC2 => 0.0 METRIC3 => 102.4
<b>memoryUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the utilization threshold for memory. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>migrationAlgorithmType</b>	<u><a href="#">AutoVMMigrationPolicyType</a></u>	Yes	Configures the VM migration algorithm utilized when the policy is active. Defaults to <u><a href="#">NONE</a></u> . When <u><a href="#">ENABLED</a></u> , this must <b>not</b> be set to NONE.

Field Name	Type	P U T	Description
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>processorUtilizationThreshold</b>	<b>Double</b>	Yes	Defines the load utilization threshold for processors. This must be greater than 0 and less than or equal to 1. A value of 1 effectively disables the threshold.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

#### [AutoVMMigrationPolicyType](#)

Represents the algorithm used to migrate VMs when the [AutoVMMigrationPolicy](#) is used.

Value	Description
<b>NONE</b>	Used when the Auto VM Migration policy is currently disabled in Moab and before any settings are saved the first time.  For example, if the policy is disabled on the first read of Moab policies, the <a href="#">AutoVMMigrationPolicy.migrationAlgorithmType</a> will be set to NONE. If the policy is enabled and the type is set to OVERCOMMIT, followed by a disabling of the policy, it will then be represented as having a state of DISABLED with a migrationAlgorithmType of OVERCOMMIT.
<b>OVERCOMMIT</b>	Use the "overcommit" algorithm for migration. The goal of this algorithm is to equalize loads across hypervisors as migrations are queued due to overcommit conditions. This places VMs to be migrated on the least-loaded hypervisor available.
<b>CONSOLIDATION</b>	Use the "consolidation" algorithm for migration. The goal of this algorithm is to load hypervisors as close to thresholds as possible, without exceeding them. This policy places VMs to be migrated on the most loaded hypervisor possible, within these constraints. A second loop of this policy will select lightly-loaded hypervisors to be evacuated completely.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

HVAllocationOvercommitPolicy

The Hypervisor Allocation Overcommit policy controls how many virtual machines can be placed on a hypervisor. By enabling this policy, you are allowing Moab to allocate more resources to a set of virtual machines than a hypervisor may actually have. This is possible due to virtualization. In other words, this policy allows you to set the high-water mark for virtual machine allocation for hypervisors. At least one of these limits must be greater than 1.0, or the policy will not be able to set to a state of [PolicyState.ENABLED](#).

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>memoryAllocationLimit</b>	<b>Double</b>	Yes	Setting this to 1 effectively disables the allocation overcommit based on memory. If this and <a href="#">processorAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a> .
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>processorAllocationLimit</b>	<b>Double</b>	Yes	<p>The Allocation Limit defines the upper bound or maximum amount of VCPUs that can be created on any given hypervisor (HV). For example, if you have a hypervisor with 12 processors or cores (Moab sees them as 12 processors), and have an Allocation Limit of 2.0 for procs, then Moab will not allow, under any condition, more than 24 VCPU's to be allocated on this hypervisor. Remember: a VM can have one or more VCPU's. So, in this example, the HV could only support 8 VM's if they all had 3 VPCU's each. It could support 4 VM's if they had 6 VPCU's each, and so forth</p> <p>From <a href="http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html">http://www.adaptivecomputing.com/resources/docs/mwm/7-1-1/Content/topics/vm/allocation_limits_and_utilization_threshold.html</a></p> <p>Setting this to 1 effectively disables the allocation overcommit based on processors. If this and <a href="#">memoryAllocationLimit</a> are both set to 1.0 (the default), the policy state cannot be set to <a href="#">PolicyState.ENABLED</a>.</p>
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

NodeAllocationPolicy

Node allocation is the process of selecting the best resources to allocate to a job from a list of available resources. Moab contains a number of allocation algorithms that address this in the NodeAllocationPolicy.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>customPriorityFunction</b>	<b>String</b>	Yes	Defines the priority function when the <a href="#">CustomPriority</a> algorithm is used.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>nodeAllocationAlgorithm</b>	<a href="#">NodeAllocationAlgorithm</a>	Yes	Configures the node allocation algorithm utilized when the policy is active. Defaults to <b>NONE</b> . When <a href="#">ENABLED</a> , this must <b>not</b> be set to NONE.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.

Field Name	Type	PUT	Description
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	Set<String>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	Set<String>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

NodeAllocationAlgorithm

Represents the algorithm used to allocate Nodes when the [NodeAllocationPolicy](#) is used.

Value	Description
<b>NONE</b>	
<b>InReportedOrder</b>	
<b>InReverseReportedOrder</b>	
<b>CustomPriority</b>	
<b>ProcessorLoad</b>	
<b>MinimumConfiguredResources</b>	
<b>Contiguous</b>	
<b>ProcessorSpeedBalance</b>	
<b>NodeSpeed</b>	

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

### MigrationExclusionListPolicy

Specify which virtual machines and hypervisors to exclude from automatic migration operations.

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>hvExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of hypervisor IDs on the exclusion list.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#">PolicyState</a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#">PolicyState.DISABLED</a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.

Field Name	Type	PUT	Description
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.
<b>vmExclusionList</b>	<b>List&lt;String&gt;</b>	Yes	The list of VM IDs on the exclusion list.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

FairsharePolicy

Fairshare allows historical resource utilization information to be incorporated into job feasibility and priority decisions. This feature allows site administrators to set system utilization targets for users, groups, accounts, classes, and QoS levels. Administrators can also specify the time frame over which resource utilization is evaluated in determining whether the goal is being reached. Parameters allow sites to specify the utilization metric, how historical information is aggregated, and the effect of fairshare state on scheduling behavior. You can specify fairshare targets for any credentials (such as user, group, and class) that administrators want such information to affect. <http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php>

This class inherits fields from [Policy](#).

Field Name	Type	PUT	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the policy. Must contain only lowercase letters and dashes, such as 'auto-vm-migration'.
<b>conflicted</b>	<b>Boolean</b>	No	Signifies whether any other policies are currently activated that potentially conflict with this policy. If true, it signifies a <b>potential</b> conflict.

Field Name	Type	PUT	Description
<b>decayFactor</b>	<b>Double</b>	Yes	Specifies decay rate applied to past fairshare interval when computing effective fairshare usage. Values may be in the range of 0.01 to 1.0. A smaller value causes more rapid decay causing aged usage to contribute less to the overall effective fairshare usage. A value of 1.0 indicates that no decay will occur and all fairshare intervals will be weighted equally when determining effective fairshare usage.
<b>depth</b>	<b>Integer</b>	Yes	Number of fairshare windows factored into current fairshare utilization. Note: The number of available fairshare windows is bounded by the MAX_FSDEPTH value (32 in Moab).
<b>description</b>	<b>String</b>	No	The user friendly description of the policy.
<b>intervalSeconds</b>	<b>Long</b>	Yes	Specifies the length of each fairshare window in seconds.
<b>name</b>	<b>String</b>	No	The user friendly name of the policy.
<b>potentialConflicts</b>	<b>Set&lt;String&gt;</b>	No	A set of policy IDs that may potentially conflict with this policy.
<b>priority</b>	<b>Integer</b>	No	Indicates the absolute priority of the policy with respect to others. It is possible that more than one policy has the same priority. The higher the number, the greater the priority. Minimum is 0.
<b>state</b>	<a href="#"><u>PolicyState</u></a>	Yes	Defines the current state of the policy: enabled or disabled. Defaults to <a href="#"><u>PolicyState.DISABLED</u></a> .
<b>tags</b>	<b>Set&lt;String&gt;</b>	No	A set of strings that can be used to aid in filtering or querying policies.
<b>types</b>	<b>Set&lt;String&gt;</b>	No	A set of categories or types that the policy is included in. This may be used to filter or query on groups of policies.

Field Name	Type	PUT	Description
<b>usageMetric</b>	<a href="#">FairshareUsageMetric</a>	Yes	As Moab runs, it records how available resources are used. Each iteration it updates fairshare resource utilization statistics. Resource utilization is tracked in accordance with the usage metric allowing various aspects of resource consumption information to be measured. The usage metric allows selection of both the types of resources to be tracked as well as the method of tracking. It provides the option of tracking usage by dedicated or consumed resources, where dedicated usage tracks what the scheduler assigns to the job and consumed usage tracks what the job actually uses.

PolicyState

Represents the state of a policy. A policy may only be enabled or disabled.

Value	Description
<b>ENABLED</b>	The policy is enabled or active.
<b>DISABLED</b>	The policy is disabled or inactive.

FairshareUsageMetric

Specifies the unit of tracking [FairsharePolicy](#) usage.

<http://docs.adaptivecomputing.com/mwm/archive/6-0-4/6.3fairshare.php#fspolicy>

Value	Description
<b>NONE</b>	
<b>DEDICATED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds dedicated to each job relative to other processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)
<b>DEDICATED_PROCESSOR_SECONDS_AVAILABLE</b>	Usage tracked by processor seconds dedicated to each job relative to all available processor seconds dedicated to other jobs on the system. (Useful in dedicated node environments.)

Value	Description
<b>DEDICATED_PROCESSOR_EQUIVALENT_SECONDS_DELIVERED</b>	Usage tracked by processor-equivalent seconds dedicated to each job relative to other processor-equivalent seconds dedicated to other jobs on the system. (Useful in dedicated and shared nodes environments).
<b>UTILIZED_PROCESSOR_SECONDS_DELIVERED</b>	Usage tracked by processor seconds used by each job relative to other processor seconds used by other jobs on the system. (Useful in shared node/SMP environments.)

## Fields: Principals

 See the associated [Principals on page 1627](#) resource section for more information on how to use this resource and supported operations.

Additional references

Type	Value	Additional information
<b>Permissions resource</b>	principals	<a href="#">Permissions on page 1593</a>
<b>Hooks filename</b>	principals.groovy	<a href="#">Pre and post-processing hooks on page 1434</a>
<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

API version 3

Principal

A principal maps to a set of ldap users and/or ldap groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this principal.
<b>attachedRoles</b>	<a href="#">Set&lt;Role&gt;</a>	Yes	Yes	The MWS roles this principal is authorized to use.
<b>description</b>	<b>String</b>	Yes	Yes	The principal description.
<b>groups</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"}
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this principal. Required during POST.
<b>users</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The users associated with this principal. Each user has a name and type. The only valid type of user is LDAP. Example user: {"name": "jhammon", "type": "LDAP"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>description</b>	<b>String</b>	Yes	Yes	The role description.

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this role. Required during POST.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	Yes	Yes	The set of permissions enforced based on the proxy-user.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>action</b>	<b>String</b>	No	No	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	No	No	A description of this permission.
<b>fieldPath</b>	<b>String</b>	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	No	No	A human readable label for this permission.
<b>resource</b>	<b>String</b>	No	No	The resource the permission applies to.
<b>resourceFilter</b>	<b>Map&lt;String, Map&gt;</b>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	Whether this permission applies to the principal's tenant-associated resources or globally

Field Name	Type	POST	PUT	Description
<b>type</b>	<b>String</b>	No	No	The type of the permission. Only 'api' type permissions are enforced.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 2

Principal

A principal maps to a set of ldap users and/or ldap groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this principal.
<b>attachedRoles</b>	<a href="#">Set&lt;Role&gt;</a>	Yes	Yes	The MWS roles this principal is authorized to use.
<b>description</b>	<b>String</b>	Yes	Yes	The principal description.
<b>groups</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"}
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this principal. Required during POST.
<b>users</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The users associated with this principal. Each user has a name and type. The only valid type of user is LDAP. Example user: {"name": "jhammon", "type": "LDAP"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>description</b>	<b>String</b>	Yes	Yes	The role description.

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this role. Required during POST.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	Yes	Yes	The set of permissions enforced based on the proxy-user.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>action</b>	<b>String</b>	No	No	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	No	No	A description of this permission.
<b>fieldPath</b>	<b>String</b>	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	No	No	A human readable label for this permission.
<b>resource</b>	<b>String</b>	No	No	The resource the permission applies to.
<b>resourceFilter</b>	<b>Map&lt;String, Map&gt;</b>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	Whether this permission applies to the principal's tenant-associated resources or globally

Field Name	Type	POST	PUT	Description
<b>type</b>	<b>String</b>	No	No	The type of the permission. Only 'api' type permissions are enforced.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 1

Principal

A principal maps to a set of ldap users and/or ldap groups. MWS roles are attached to the principals to authorize the group to use the specific MWS roles.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this principal.
<b>attachedRoles</b>	<a href="#">Set&lt;Role&gt;</a>	Yes	Yes	The MWS roles this principal is authorized to use.
<b>description</b>	<b>String</b>	Yes	Yes	The principal description.
<b>groups</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The groups associated with this principal. Each group has a name and a type. The valid types of groups are LDAPOU, LDAPGROUP, and SSO. Example group: {"name": "CN=Engineering,CN=Users,DC=corp,DC=cloud,DC=dev", "type": "LDAPGROUP"}
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this principal. Required during POST.
<b>users</b>	<b>List&lt;Map&gt;</b>	Yes	Yes	The users associated with this principal. Each user has a name and type. The only valid type of user is LDAP. Example user: {"name": "jhammon", "type": "LDAP"}

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>description</b>	<b>String</b>	Yes	Yes	The role description.

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this role. Required during POST.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	Yes	Yes	The set of permissions enforced based on the proxy-user.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>action</b>	<b>String</b>	No	No	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	No	No	A description of this permission.
<b>fieldPath</b>	<b>String</b>	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	No	No	A human readable label for this permission.
<b>resource</b>	<b>String</b>	No	No	The resource the permission applies to.
<b>resourceFilter</b>	<b>Map&lt;String, Map&gt;</b>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	Whether this permission applies to the principal's tenant-associated resources or globally

Field Name	Type	POST	PUT	Description
<b>type</b>	<b>String</b>	No	No	The type of the permission. Only 'api' type permissions are enforced.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

### API version 3

#### Datapoint

A metric that measures system state over a specified period of time. For example, a datapoint may contain data on CPU utilization by specific users. A datapoint is generated by the consolidation of zero or more [Samples](#). It could be said that a datapoint represents a smoothing of samples.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>data</b>	<b>Map&lt;String, Map&gt;</b>	The actual consolidated sample data. This property may be 'null' if the <a href="#">Report.minimumSampleSize</a> was not met when consolidating the datapoint.
<b>endDate</b>	<b>Date</b>	The ending date that the datapoint covers.
<b>firstSampleDate</b>	<b>Date</b>	The date of the first sample consolidated in this datapoint. (See also: <a href="#">Sample.timestamp</a> .)
<b>lastSampleDate</b>	<b>Date</b>	The date of the last sample consolidated in this datapoint. (See also: <a href="#">Sample.timestamp</a> .)
<b>startDate</b>	<b>Date</b>	The beginning date that the datapoint covers.

## API version 2

Datapoint

A metric that measures system state over a specified period of time. For example, a datapoint may contain data on CPU utilization by specific users. A datapoint is generated by the consolidation of zero or more [Samples](#). It could be said that a datapoint represents a smoothing of samples.

Field Name	Type	Description
<b>id</b>	<b>Long</b>	
<b>data</b>	<b>Map&lt;String, Map&gt;</b>	The actual consolidated sample data. This property may be 'null' if the <a href="#">Report.minimumSampleSize</a> was not met when consolidating the datapoint.
<b>endDate</b>	<b>Date</b>	The ending date that the datapoint covers.
<b>firstSampleDate</b>	<b>Date</b>	The date of the first sample consolidated in this datapoint. (See also: <a href="#">Sample.timestamp</a> .)
<b>lastSampleDate</b>	<b>Date</b>	The date of the last sample consolidated in this datapoint. (See also: <a href="#">Sample.timestamp</a> .)
<b>startDate</b>	<b>Date</b>	The beginning date that the datapoint covers.

<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

API version 3

Report

A set of time-based values that share similar context. For example, a report may contain data on CPU or power utilization for all nodes in a cluster.

A report is composed of metadata and a collection of [Datapoints](#). [Samples](#) are also associated with reports, but these are consolidated using the [Report.consolidationFunction](#) to create [Datapoints](#).

If the datapoint documents are being truncated in any way or there are warnings about documents being too large, it may be necessary to increase the [Report.reportDocumentSize](#).

Field Name	Type	POST	Description
<b>id</b>	<b>String</b>	No	The unique identifier for the report. This is automatically assigned and will be ignored if specified duration creation.
<b>consolidationFunction</b>	<b>String</b>	Yes	The consolidation function is the process used to convert a set of samples into a datapoint. Currently the only supported function is "average", which is used if none is specified.
<b>datapointDuration</b>	<b>Long</b>	Yes	Required. How long the datapoints are, in seconds.
<b>datapoints</b>	<a href="#">List&lt;Datapoint&gt;</a>	Yes	This is the set of datapoints that have been consolidated for the report or are desired to be included in the report during creation time. In the latter case, these represent historical data created outside of the reporting framework. Only present when getting a single report.
<b>description</b>	<b>String</b>	Yes	A description of the report.
<b>keepSamples</b>	<b>Boolean</b>	Yes	Controls if samples are retained after consolidation. Defaults to false, which means that after consolidation, samples are discarded.
<b>minimumSampleSize</b>	<b>Integer</b>	Yes	If number of samples is below this number, the datapoint data field is "null". Defaults to 1.
<b>name</b>	<b>String</b>	Yes	Required. A unique name identifying the report. Valid characters are all alphanumeric characters, dashes (-), periods (.), and underscores (_).

Field Name	Type	POST	Description
<b>reportDocumentSize</b>	<b>Long</b>	Yes	<p>The maximum size in bytes of each datapoint document stored for this report. This option is provided to maximize the amount of disk space used for a single report. The default value for this option is 100*1024, or 100 KB. The maximum value of this option is 16*1024*1024 (16777216) or 16 MB, which represents the maximum document size in MongoDB. See also <a href="http://www.mongodb.org/display/DOCS/Documents">http://www.mongodb.org/display/DOCS/Documents</a>.</p> <p>Keep in mind that when creating a new report, MongoDB will initialize all needed space for all possible datapoint documents up front. This can easily fill a disk unless this parameter is modified.</p>
<b>reportSize</b>	<b>Long</b>	Yes	<p>Required. The size of the report in datapoints. After this number of datapoints is reached, the old datapoints will be discarded.</p> <p><b>WARNING:</b> On report creation, a Mongo collection will be initialized that is the maximum size of a single entry (currently 16 MB) multiplied by the report size. Be careful in setting a large report size as this will quickly allocate the entire disk if many reports with large report sizes are created.</p>

### Datapoint

A metric that measures system state over a specified period of time. For example, a datapoint may contain data on CPU utilization by specific users. A datapoint is generated by the consolidation of zero or more [Samples](#). It could be said that a datapoint represents a smoothing of samples.

## API version 3

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Yes	No	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Yes	No	Accountable Group.
<b>accountingQOS</b>	<b>String</b>	Yes	No	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Yes	No	Accountable User.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	Yes	No	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	No	No	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	No	No	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	No	No	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Yes	No	Reservation's comments or description.

Field Name	Type	POST	PUT	Description
<b>creationDate</b>	<b>Date</b>	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	Yes	No	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	No	No	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	Yes	No	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	No	No	Global reservation ID.

Field Name	Type	POST	PUT	Description
<b>hostListExpression</b>	<b>String</b>	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	No	No	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	No	No	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	No	No	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	No	No	Messages for the reservation.

Field Name	Type	POST	PUT	Description
<b>owner</b>	<a href="#">EmbeddedCredential</a>	Yes	No	The owner of the reservation
<b>partitionId</b>	String	Yes	No	The ID of the partition this reservation is for.
<b>profile</b>	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	Yes	No	The reservation's requirements.
<b>reservationGroup</b>	String	Yes	No	The reservation group to which the reservation belongs.
<b>resources</b>	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#">ReservationStatistics</a>	No	No	The reservation's statistical information.
<b>subType</b>	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
<b>taskCount</b>	<b>Integer</b>	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#">Trigger</a>	Yes	No	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	No	No	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	No	No	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The set of variables for this reservation.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
<b>affinity</b>	<a href="#">AclAffinity</a>	No	Yes	<p>Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.</p> <p>Defaults to <a href="#">AclAffinity.POSITIVE</a>.</p>
<b>comparator</b>	<a href="#">ComparisonOperator</a>	No	Yes	<p>The type of comparison to make against the ACL object.</p> <p>Defaults to <a href="#">ComparisonOperator.EQUAL</a>.</p>
<b>type</b>	<a href="#">AclType</a>	No	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.

Value	Description
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported

Value	Description
<b>RACK</b>	Not supported
<b>SCHED</b>	Not supported
<b>SYTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The id of the object.

ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOVERLAP</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.

Value	Description
<b>NOVMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRE</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.

Value	Description
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

Value	Description
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
<b>TRIGHASFIRED</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

#### MessageVersion1

Field Name	Type	POST	PUT	Description
<b>author</b>	<b>String</b>	No	No	The author of the message.
<b>creationTime</b>	<b>Date</b>	No	No	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	No	No	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	No	No	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	No	Yes	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	No	No	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	No	No	An optional priority that can be attached to the comment.

#### EmbeddedCredential

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	No	No	
<b>type</b>	<a href="#">CredentialType</a>	No	No	

CredentialType

Value	Description
<b>USER</b>	
<b>GROUP</b>	
<b>ACCOUNT</b>	
<b>CLASS</b>	
<b>QOS</b>	
<b>NOT_SPECIFIED</b>	

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
<b>architecture</b>	<b>String</b>	Yes	No	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	No	No	Required feature mode.
<b>memory</b>	<b>Integer</b>	Yes	No	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	No	No	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	No	No	The list of node IDs required for this reservation.

Field Name	Type	POST	PUT	Description
<b>os</b>	<b>String</b>	Yes	No	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Yes	No	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
<b>caps</b>	<b>Double</b>	No	No	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	No	No	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	No	No	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	No	No	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).

Field Name	Type	POST	PUT	Description
<b>actionType</b>	<a href="#">TriggerActionType</a>	No	No	
<b>blockTime</b>	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	String	No	No	
<b>eventType</b>	<a href="#">TriggerEventType</a>	No	No	
<b>expireTime</b>	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	No	No	
<b>interval</b>	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	String	No	No	The ID of the object which this is attached to.

Field Name	Type	POST	PUT	Description
<b>objectType</b>	<b>String</b>	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	No	No	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	No	No	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.

Field Name	Type	POST	PUT	Description
<b>threshold</b>	<b>String</b>	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.

Value	Description
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.

Value	Description
<b>SOFT_KILL</b>	<p>By default, a <code>SIGKILL</code> (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a <code>SIGTERM</code> (kill -15) signal to kill the script. The <code>SIGTERM</code> signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the <code>SIGKILL</code> signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the <code>SIGTERM</code> signal, and never the <code>SIGKILL</code> signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

## API version 2

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Yes	No	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Yes	No	Accountable Group.
<b>accountingQOS</b>	<b>String</b>	Yes	No	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Yes	No	Accountable User.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	Yes	No	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	No	No	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	No	No	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	No	No	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Yes	No	Reservation's comments or description.

Field Name	Type	POST	PUT	Description
<b>creationDate</b>	<b>Date</b>	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	Yes	No	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	No	No	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	Yes	No	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	No	No	Global reservation ID.

Field Name	Type	POST	PUT	Description
<b>hostListExpression</b>	<b>String</b>	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	No	No	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	No	No	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	No	No	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	No	No	Messages for the reservation.

Field Name	Type	POST	PUT	Description
<b>owner</b>	<a href="#">EmbeddedCredential</a>	Yes	No	The owner of the reservation
<b>partitionId</b>	String	Yes	No	The ID of the partition this reservation is for.
<b>profile</b>	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	Yes	No	The reservation's requirements.
<b>reservationGroup</b>	String	Yes	No	The reservation group to which the reservation belongs.
<b>resources</b>	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#">ReservationStatistics</a>	No	No	The reservation's statistical information.
<b>subType</b>	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
<b>taskCount</b>	<b>Integer</b>	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#">Trigger</a>	Yes	No	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	No	No	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	No	No	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The set of variables for this reservation.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
<b>affinity</b>	<a href="#">AclAffinity</a>	No	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#">AclAffinity.POSITIVE</a> .
<b>comparator</b>	<a href="#">ComparisonOperator</a>	No	Yes	The type of comparison to make against the ACL object.  Defaults to <a href="#">ComparisonOperator.EQUAL</a> .
<b>type</b>	<a href="#">AclType</a>	No	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.

Value	Description
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported

Value	Description
<b>RACK</b>	Not supported
<b>SCHED</b>	Not supported
<b>SYTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The id of the object.

ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOVERLAP</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.

Value	Description
<b>NOVMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRE</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.

Value	Description
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

Value	Description
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
<b>TRIGHASFIRED</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

#### MessageVersion1

Field Name	Type	POST	PUT	Description
<b>author</b>	<b>String</b>	No	No	The author of the message.
<b>creationTime</b>	<b>Date</b>	No	No	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	No	No	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	No	No	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	No	Yes	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	No	No	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	No	No	An optional priority that can be attached to the comment.

#### EmbeddedCredential

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	No	No	
<b>type</b>	<a href="#">CredentialType</a>	No	No	

CredentialType

Value	Description
<b>USER</b>	
<b>GROUP</b>	
<b>ACCOUNT</b>	
<b>CLASS</b>	
<b>QOS</b>	
<b>NOT_SPECIFIED</b>	

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
<b>architecture</b>	<b>String</b>	Yes	No	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	No	No	Required feature mode.
<b>memory</b>	<b>Integer</b>	Yes	No	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	No	No	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	No	No	The list of node IDs required for this reservation.

Field Name	Type	POST	PUT	Description
<b>os</b>	<b>String</b>	Yes	No	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Yes	No	Required task count.

### ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
<b>caps</b>	<b>Double</b>	No	No	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	No	No	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	No	No	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	No	No	The total idle processor-seconds over the life of the reservation.

### Trigger

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).

Field Name	Type	POST	PUT	Description
<b>actionType</b>	<a href="#">TriggerActionType</a>	No	No	
<b>blockTime</b>	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	String	No	No	
<b>eventType</b>	<a href="#">TriggerEventType</a>	No	No	
<b>expireTime</b>	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	No	No	
<b>interval</b>	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	String	No	No	The ID of the object which this is attached to.

Field Name	Type	POST	PUT	Description
<b>objectType</b>	<b>String</b>	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	No	No	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	No	No	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.

Field Name	Type	POST	PUT	Description
<b>threshold</b>	<b>String</b>	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.

Value	Description
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.

Value	Description
<b>SOFT_KILL</b>	<p>By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

## API version 1

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Yes	No	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Yes	No	Accountable Group.
<b>accountingQOS</b>	<b>String</b>	Yes	No	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Yes	No	Accountable User.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	Yes	No	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	No	No	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#">Set&lt;DomainProxyVersion1&gt;</a>	No	No	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	No	No	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	No	No	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Yes	No	Reservation's comments or description.

Field Name	Type	POST	PUT	Description
<b>creationDate</b>	<b>Date</b>	No	No	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	Yes	No	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	Yes	No	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	No	No	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	Yes	No	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	No	No	Global reservation ID.

Field Name	Type	POST	PUT	Description
<b>hostListExpression</b>	<b>String</b>	Yes	No	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	Yes	No	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	No	No	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	No	No	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	Yes	No	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	No	No	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	No	No	Messages for the reservation.

Field Name	Type	POST	PUT	Description
<b>owner</b>	<a href="#">EmbeddedCredential</a>	Yes	No	The owner of the reservation
<b>partitionId</b>	String	Yes	No	The ID of the partition this reservation is for.
<b>profile</b>	String	Yes	No	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	Yes	No	The reservation's requirements.
<b>reservationGroup</b>	String	Yes	No	The reservation group to which the reservation belongs.
<b>resources</b>	Map<String, Integer>	Yes	No	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	Date	Yes	No	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#">ReservationStatistics</a>	No	No	The reservation's statistical information.
<b>subType</b>	String	Yes	No	The reservation sub-type.

Field Name	Type	POST	PUT	Description
<b>taskCount</b>	<b>Integer</b>	No	No	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#">Trigger</a>	Yes	No	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	No	No	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	No	No	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	Yes	Yes	The set of variables for this reservation.

[AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	POST	PUT	Description
<b>affinity</b>	<a href="#">AclAffinity</a>	No	Yes	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#">AclAffinity.POSITIVE</a> .
<b>comparator</b>	<a href="#">ComparisonOperator</a>	No	Yes	The type of comparison to make against the ACL object.  Defaults to <a href="#">ComparisonOperator.EQUAL</a> .
<b>type</b>	<a href="#">AclType</a>	No	Yes	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	No	Yes	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.

Value	Description
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcIType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported

Value	Description
<b>RACK</b>	Not supported
<b>SCHED</b>	Not supported
<b>SYTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

DomainProxyVersion1

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The id of the object.

ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOVERLAP</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.

Value	Description
<b>NOVMMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER==ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRE</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.

Value	Description
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.

Value	Description
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.
<b>TRIGHASFIRED</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

#### MessageVersion1

Field Name	Type	POST	PUT	Description
<b>author</b>	<b>String</b>	No	No	The author of the message.
<b>creationTime</b>	<b>Date</b>	No	No	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	No	No	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	No	No	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	No	Yes	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	No	No	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	No	No	An optional priority that can be attached to the comment.

#### EmbeddedCredential

Field Name	Type	POST	PUT	Description
<b>name</b>	<b>String</b>	No	No	
<b>type</b>	<a href="#">CredentialType</a>	No	No	

CredentialType

Value	Description
<b>USER</b>	
<b>GROUP</b>	
<b>ACCOUNT</b>	
<b>CLASS</b>	
<b>QOS</b>	
<b>NOT_SPECIFIED</b>	

ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	POST	PUT	Description
<b>architecture</b>	<b>String</b>	Yes	No	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	Yes	No	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	No	No	Required feature mode.
<b>memory</b>	<b>Integer</b>	Yes	No	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	No	No	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	No	No	The list of node IDs required for this reservation.

Field Name	Type	POST	PUT	Description
<b>os</b>	<b>String</b>	Yes	No	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Yes	No	Required task count.

### ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	POST	PUT	Description
<b>caps</b>	<b>Double</b>	No	No	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	No	No	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	No	No	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	No	No	The total idle processor-seconds over the life of the reservation.

### Trigger

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	No	No	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).

Field Name	Type	POST	PUT	Description
<b>actionType</b>	<a href="#">TriggerActionType</a>	No	No	
<b>blockTime</b>	Date	No	No	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	String	No	No	
<b>eventType</b>	<a href="#">TriggerEventType</a>	No	No	
<b>expireTime</b>	Date	No	No	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	Date	No	No	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	No	No	
<b>interval</b>	Boolean	No	No	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	Integer	No	No	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	Boolean	No	No	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	String	No	No	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	String	No	No	The ID of the object which this is attached to.

Field Name	Type	POST	PUT	Description
<b>objectType</b>	<b>String</b>	No	No	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	No	No	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	No	No	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	No	No	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	No	No	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	No	No	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.

Field Name	Type	POST	PUT	Description
<b>threshold</b>	<b>String</b>	No	No	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	No	No	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	No	No	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.

Value	Description
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.

Value	Description
<b>SOFT_KILL</b>	<p>By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).</p> <p>NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.</p>

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>

<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

API version 3

Role

A role defines a set of permissions that are based on the proxy-user. If no proxy user is specified then access to objects in MWS are limited to its application permissions. For example if the application has permission to update all resources in MWS and no proxy-user is specified in the request then the request can access all resources in MWS.

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>description</b>	<b>String</b>	Yes	Yes	The role description.
<b>name</b>	<b>String</b>	Yes	Yes	The unique human-readable name of this role. Required during POST.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	Yes	Yes	The set of permissions enforced based on the proxy-user.
<b>scope</b>	<a href="#">PrivilegeScope</a>	No	No	

Permission

Represents a permission

Field Name	Type	POST	PUT	Description
<b>id</b>	<b>String</b>	No	No	The unique ID of this role.
<b>action</b>	<b>String</b>	No	No	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	No	No	A description of this permission.
<b>fieldPath</b>	<b>String</b>	No	No	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	No	No	A human readable label for this permission.

Field Name	Type	POST	PUT	Description
<b>resource</b>	<b>String</b>	No	No	The resource the permission applies to.
<b>resourceFilter</b>	<b>Map&lt;String, Map&gt;</b>	No	No	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
<b>scope</b>	<a href="#"><u>PrivilegeScope</u></a>	No	No	Whether this permission applies to the principal's tenant-associated resources or globally
<b>type</b>	<b>String</b>	No	No	The type of the permission. Only 'api' type permissions are enforced.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

[PrivilegeScope](#)

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.

Value	Description
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

API version 2

## API version 3

Sample

A single snapshot of system state. It can contain all the same information as [Datapoint.data](#) in the sample's [data](#) field.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	
<b>agent</b>	<b>String</b>	No	A unique identifier for the agent that recorded this sample.
<b>data</b>	<b>Map&lt;String, Map&gt;</b>	No	Arbitrary data that was recorded for this sample. Defaults to an empty object if none is supplied.
<b>timestamp</b>	<b>Date</b>	No	The date and time at which this sample was recorded. Defaults to the current date if none is supplied.

## API version 2

Sample

A single snapshot of system state. It can contain all the same information as [Datapoint.data](#) in the sample's [data](#) field.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	
<b>agent</b>	<b>String</b>	No	A unique identifier for the agent that recorded this sample.
<b>data</b>	<b>Map&lt;String, Map&gt;</b>	No	Arbitrary data that was recorded for this sample. Defaults to an empty object if none is supplied.
<b>timestamp</b>	<b>Date</b>	No	The date and time at which this sample was recorded. Defaults to the current date if none is supplied.

## API version 1

Sample

A single snapshot of system state. It can contain all the same information as [Datapoint.data](#) in the sample's [data](#) field.

Field Name	Type	POST	Description
<b>id</b>	<b>Long</b>	No	
<b>agent</b>	<b>String</b>	No	A unique identifier for the agent that recorded this sample.
<b>data</b>	<b>Map&lt;String, Map&gt;</b>	No	Arbitrary data that was recorded for this sample. Defaults to an empty object if none is supplied.
<b>timestamp</b>	<b>Date</b>	No	The date and time at which this sample was recorded. Defaults to the current date if none is supplied.

## Fields: Standing Reservations

**i** See the associated [Standing reservations on page 1661](#) resource section for more information on how to use this resource and supported operations.

Additional references

Type	Value	Additional information
<b>Permissions resource</b>	standing-reservations	<a href="#">Permissions on page 1593</a>
<b>Hooks filename</b>	standing-reservations.groovy	<a href="#">Pre and post-processing hooks on page 1434</a>
<b>Distinct query-supported</b>	No	<a href="#">Distinct on page 1526</a>

## API version 3

StandingReservation

This class represents a standing reservation.

A standing reservation is any reservation that is not a one-time reservation. This includes reservations that recur every day or every week, or infinite reservations.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the standing reservation.
<b>access</b>	<a href="#">ReservationAccess</a>	If set to <a href="#">ReservationAccess.SHARED</a> , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
<b>accounts</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	The set of access control rules associated with this standing reservation.
<b>chargeAccount</b>	<b>String</b>	Specifies the account to which Moab will charge all idle cycles within the reservation (via the allocation manager).
<b>chargeUser</b>	<b>String</b>	Specifies the user to which Moab will charge all idle cycles within the reservation (via the allocation manager). Must be used in conjunction with <a href="#">chargeAccount</a>
<b>classes</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
<b>clusters</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
<b>comment</b>	<b>String</b>	Specifies a descriptive message associated with the standing reservation and all child reservations

Field Name	Type	Description
<b>days</b>	<b>Set&lt;String&gt;</b>	Specifies which days of the week the standing reservation is active. Valid values are Mon, Tue, Wed, Thu, Fri, Sat, Sun, or [ALL].
<b>depth</b>	<b>Integer</b>	Specifies the depth of standing reservations to be created, starting at depth 0 (one per <a href="#">period</a> ).
<b>disabled</b>	<b>Boolean</b>	Specifies if the standing reservation should no longer spawn child reservations.
<b>endOffset</b>	<b>Long</b>	The ending offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. See examples at <a href="#">startOffset</a> .
<b>flags</b>	<a href="#">Set&lt;ReservationFlag&gt;</a>	Specifies special reservation attributes.
<b>groups</b>	<b>Set&lt;String&gt;</b>	Specifies the groups allowed access to this standing reservation.
<b>hosts</b>	<b>Set&lt;String&gt;</b>	Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the class:X format, Moab only selects hosts that support the specified class. If TASKCOUNT is also specified, only TASKCOUNT tasks are reserved. Otherwise, all matching hosts are reserved.
<b>jobAttributes</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Specifies job attributes that grant a job access to the reservation. Values can be specified with a != assignment to only allow jobs NOT requesting a certain feature inside the reservation.
<b>maxJob</b>	<b>Integer</b>	Specifies the maximum number of jobs that can run in the reservation.
<b>maxTime</b>	<b>Integer</b>	Specifies the maximum time for jobs allowable. Can be used with affinity to attract jobs with same maxTime.
<b>messages</b>	<b>Set&lt;String&gt;</b>	Messages associated with the reservation.

Field Name	Type	Description
<b>nodeFeatures</b>	<b>Set&lt;String&gt;</b>	Specifies the required node features for nodes that are part of the standing reservation.
<b>os</b>	<b>String</b>	Specifies the operating system that should be in place during the reservation. Moab provisions this OS at reservation start and restores the original OS at reservation completion.
<b>owner</b>	<a href="#"><u>EmbeddedCredential</u></a>	Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it. Setting a user as the owner of a reservation gives that user privileges to query and release the reservation. For sandbox reservations, sandboxes are applied to a specific peer only if owner is set to CLUSTER:<PEERNAME>
<b>partition</b>	<b>String</b>	Specifies the partition in which to create the standing reservation. Defaults to ALL.
<b>period</b>	<a href="#"><u>TimeWindow</u></a>	Period of the Standing reservation. Defaults to <a href="#"><u>TimeWindow.DAY</u></a> .
<b>procLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor limit for jobs requesting access to this standing reservation.
<b>psLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
<b>qoses</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the listed QoS names can access the reserved resources.
<b>reservationAccessList</b>	<a href="#"><u>Set&lt;Reservation&gt;</u></a>	A list of reservations to which the specified reservation has access.
<b>reservationGroup</b>	<b>String</b>	The group of the reservation.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.) Supported resources currently include the following:</p> <ul style="list-style-type: none"> <li>• PROCS (number of processors)</li> <li>• MEM (real memory in MB)</li> <li>• DISK (local disk in MB)</li> <li>• SWAP (virtual memory in MB)</li> </ul>
<b>rollbackOffset</b>	<b>Integer</b>	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See QoS Credential in the Moab Workload Manager documentation for more information on quality of service and service level agreements.</p>
<b>startOffset</b>	<b>Long</b>	<p>The starting offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. If period is DAY, the offset is from midnight (00:00) of the current day. If period is WEEK, the offset is from midnight Sunday of the current week.</p> <p>Example 1: For a standing reservation that begins at 9:00 and ends at 17:00 every day, period is DAY, startOffset is 32400 (9*60*60), and endOffset is 61200 (17*60*60).</p> <p>Example 2: For a standing reservation that begins at 9:00 Monday and ends at 17:00 Friday every week, period is WEEK, startOffset is 118800 ((24+9)*60*60), and endOffset is 493200 (((5*24)+17)*60*60).</p>

Field Name	Type	Description
<b>taskCount</b>	<b>Integer</b>	Specifies how many tasks should be reserved for the reservation Default is 0 (unlimited tasks).
<b>tasksPerNode</b>	<b>Integer</b>	Specifies the minimum number of tasks per node that must be available on eligible nodes. Default is 0 (no TPN constraint)
<b>timeLimit</b>	<b>Integer</b>	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access. Default is null (-1 in moab)
<b>triggers</b>	<a href="#">Set&lt;Trigger&gt;</a>	Triggers associated with the reservation.
<b>type</b>	<b>String</b>	The type of the reservation.
<b>users</b>	<b>Set&lt;String&gt;</b>	Specifies which users have access to the resources reserved by this reservation.

### ReservationAccess

The access type of a standing reservation. If set to SHARED, allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.

Value	Description
<b>DEDICATED</b>	
<b>SHARED</b>	

### AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	Description
<b>affinity</b>	<a href="#"><u>AclAffinity</u></a>	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#"><u>AclAffinity.POSITIVE</u></a> .
<b>comparator</b>	<a href="#"><u>ComparisonOperator</u></a>	The type of comparison to make against the ACL object.  Defaults to <a href="#"><u>ComparisonOperator.EQUAL</u></a> .
<b>type</b>	<a href="#"><u>AclType</u></a>	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.

Value	Description
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User

Value	Description
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported
<b>RACK</b>	Not supported

Value	Description
<b>SCHED</b>	Not supported
<b>SYSTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

### ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOverlap</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.
<b>NOVMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).

Value	Description
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER>=ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRED</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.

Value	Description
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.

Value	Description
<b>TRIGHASFIRE</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

### JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.

Value	Description
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.

Value	Description
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESSUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

[EmbeddedCredential](#)

Field Name	Type	Description
<b>name</b>	<b>String</b>	
<b>type</b>	<a href="#"><u>CredentialType</u></a>

<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

Value	Description
<b>YEAR</b>	
<b>INFINITY</b>	

IntLimit

Field Name	Type	Description
<b>qualifier</b>	<b>String</b>	One of: <ul style="list-style-type: none"> <li>• &lt;</li> <li>• &lt;=</li> <li>• ==</li> <li>• &gt;=</li> <li>• &gt;</li> </ul>
<b>value</b>	<b>Integer</b>	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Accountable Group.

Field Name	Type	Description
<b>accountingQOS</b>	<b>String</b>	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Accountable User.
<b>aclRules</b>	<a href="#"><u>Set&lt;AclRule&gt;</u></a>	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#"><u>Set&lt;DomainProxyVersion1&gt;</u></a>	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Reservation's comments or description.
<b>creationDate</b>	<b>Date</b>	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	Global reservation ID.

Field Name	Type	Description
<b>hostListExpression</b>	<b>String</b>	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	Messages for the reservation.
<b>owner</b>	<a href="#">EmbeddedCredential</a>	The owner of the reservation
<b>partitionId</b>	<b>String</b>	The ID of the partition this reservation is for.
<b>profile</b>	<b>String</b>	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	The reservation's requirements.
<b>reservationGroup</b>	<b>String</b>	The reservation group to which the reservation belongs.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	<b>Date</b>	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#"><u>ReservationStatistics</u></a>	The reservation's statistical information.
<b>subType</b>	<b>String</b>	The reservation sub-type.
<b>taskCount</b>	<b>Integer</b>	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	The set of variables for this reservation.

[DomainProxyVersion1](#)

Field Name	Type	Description
<b>id</b>	<b>String</b>	The id of the object.

[MessageVersion1](#)

Field Name	Type	Description
<b>author</b>	<b>String</b>	The author of the message.
<b>creationTime</b>	<b>Date</b>	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	An optional priority that can be attached to the comment.

#### ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	Required feature mode.
<b>memory</b>	<b>Integer</b>	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	The list of node IDs required for this reservation.
<b>os</b>	<b>String</b>	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	Description
<b>caps</b>	<b>Double</b>	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#">TriggerActionType</a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#">TriggerEventType</a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

### TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

### TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers

Field Name	Type	Description
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#">TriggerActionType</a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#">TriggerEventType</a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.

Field Name	Type	Description
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

## API version 2

StandingReservation

This class represents a standing reservation.

A standing reservation is any reservation that is not a one-time reservation. This includes reservations that recur every day or every week, or infinite reservations.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the standing reservation.
<b>access</b>	<a href="#">ReservationAccess</a>	If set to <a href="#">ReservationAccess.SHARED</a> , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
<b>accounts</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	The set of access control rules associated with this standing reservation.
<b>chargeAccount</b>	<b>String</b>	Specifies the account to which Moab will charge all idle cycles within the reservation (via the allocation manager).
<b>chargeUser</b>	<b>String</b>	Specifies the user to which Moab will charge all idle cycles within the reservation (via the allocation manager). Must be used in conjunction with <a href="#">chargeAccount</a>
<b>classes</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
<b>clusters</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
<b>comment</b>	<b>String</b>	Specifies a descriptive message associated with the standing reservation and all child reservations

Field Name	Type	Description
<b>days</b>	<b>Set&lt;String&gt;</b>	Specifies which days of the week the standing reservation is active. Valid values are Mon, Tue, Wed, Thu, Fri, Sat, Sun, or [ALL].
<b>depth</b>	<b>Integer</b>	Specifies the depth of standing reservations to be created, starting at depth 0 (one per <a href="#">period</a> ).
<b>disabled</b>	<b>Boolean</b>	Specifies if the standing reservation should no longer spawn child reservations.
<b>endOffset</b>	<b>Long</b>	The ending offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. See examples at <a href="#">startOffset</a> .
<b>flags</b>	<a href="#">Set&lt;ReservationFlag&gt;</a>	Specifies special reservation attributes.
<b>groups</b>	<b>Set&lt;String&gt;</b>	Specifies the groups allowed access to this standing reservation.
<b>hosts</b>	<b>Set&lt;String&gt;</b>	Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the class:X format, Moab only selects hosts that support the specified class. If TASKCOUNT is also specified, only TASKCOUNT tasks are reserved. Otherwise, all matching hosts are reserved.
<b>jobAttributes</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Specifies job attributes that grant a job access to the reservation. Values can be specified with a != assignment to only allow jobs NOT requesting a certain feature inside the reservation.
<b>maxJob</b>	<b>Integer</b>	Specifies the maximum number of jobs that can run in the reservation.
<b>maxTime</b>	<b>Integer</b>	Specifies the maximum time for jobs allowable. Can be used with affinity to attract jobs with same maxTime.
<b>messages</b>	<b>Set&lt;String&gt;</b>	Messages associated with the reservation.

Field Name	Type	Description
<b>nodeFeatures</b>	<b>Set&lt;String&gt;</b>	Specifies the required node features for nodes that are part of the standing reservation.
<b>os</b>	<b>String</b>	Specifies the operating system that should be in place during the reservation. Moab provisions this OS at reservation start and restores the original OS at reservation completion.
<b>owner</b>	<a href="#"><u>EmbeddedCredential</u></a>	Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it. Setting a user as the owner of a reservation gives that user privileges to query and release the reservation. For sandbox reservations, sandboxes are applied to a specific peer only if owner is set to CLUSTER:<PEERNAME>
<b>partition</b>	<b>String</b>	Specifies the partition in which to create the standing reservation. Defaults to ALL.
<b>period</b>	<a href="#"><u>TimeWindow</u></a>	Period of the Standing reservation. Defaults to <a href="#"><u>TimeWindow.DAY</u></a> .
<b>procLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor limit for jobs requesting access to this standing reservation.
<b>psLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
<b>qoses</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the listed QoS names can access the reserved resources.
<b>reservationAccessList</b>	<a href="#"><u>Set&lt;Reservation&gt;</u></a>	A list of reservations to which the specified reservation has access.
<b>reservationGroup</b>	<b>String</b>	The group of the reservation.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.) Supported resources currently include the following:</p> <ul style="list-style-type: none"> <li>• PROCS (number of processors)</li> <li>• MEM (real memory in MB)</li> <li>• DISK (local disk in MB)</li> <li>• SWAP (virtual memory in MB)</li> </ul>
<b>rollbackOffset</b>	<b>Integer</b>	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See QoS Credential in the Moab Workload Manager documentation for more information on quality of service and service level agreements.</p>
<b>startOffset</b>	<b>Long</b>	<p>The starting offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. If period is DAY, the offset is from midnight (00:00) of the current day. If period is WEEK, the offset is from midnight Sunday of the current week.</p> <p>Example 1: For a standing reservation that begins at 9:00 and ends at 17:00 every day, period is DAY, startOffset is 32400 (9*60*60), and endOffset is 61200 (17*60*60).</p> <p>Example 2: For a standing reservation that begins at 9:00 Monday and ends at 17:00 Friday every week, period is WEEK, startOffset is 118800 ((24+9)*60*60), and endOffset is 493200 (((5*24)+17)*60*60).</p>

Field Name	Type	Description
<b>taskCount</b>	<b>Integer</b>	Specifies how many tasks should be reserved for the reservation Default is 0 (unlimited tasks).
<b>tasksPerNode</b>	<b>Integer</b>	Specifies the minimum number of tasks per node that must be available on eligible nodes. Default is 0 (no TPN constraint)
<b>timeLimit</b>	<b>Integer</b>	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access. Default is null (-1 in moab)
<b>triggers</b>	<a href="#">Set&lt;Trigger&gt;</a>	Triggers associated with the reservation.
<b>type</b>	<b>String</b>	The type of the reservation.
<b>users</b>	<b>Set&lt;String&gt;</b>	Specifies which users have access to the resources reserved by this reservation.

### ReservationAccess

The access type of a standing reservation. If set to SHARED, allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.

Value	Description
<b>DEDICATED</b>	
<b>SHARED</b>	

### AclRule

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	Description
<b>affinity</b>	<a href="#"><u>AclAffinity</u></a>	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#"><u>AclAffinity.POSITIVE</u></a> .
<b>comparator</b>	<a href="#"><u>ComparisonOperator</u></a>	The type of comparison to make against the ACL object.  Defaults to <a href="#"><u>ComparisonOperator.EQUAL</u></a> .
<b>type</b>	<a href="#"><u>AclType</u></a>	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.

Value	Description
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User

Value	Description
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JPRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported
<b>RACK</b>	Not supported

Value	Description
<b>SCHED</b>	Not supported
<b>SYSTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

### ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOverlap</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.
<b>NOVMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).

Value	Description
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER>=ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRED</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.

Value	Description
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.

Value	Description
<b>TRIGHASFIRE</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

### JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.

Value	Description
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.

Value	Description
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESSUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

[EmbeddedCredential](#)

Field Name	Type	Description
<b>name</b>	<b>String</b>	
<b>type</b>	<a href="#"><u>CredentialType</u></a>	

[CredentialType](#)

Value	Description
<b>USER</b>	
<b>GROUP</b>	
<b>ACCOUNT</b>	
<b>CLASS</b>	
<b>QOS</b>	
<b>NOT_SPECIFIED</b>	

[TimeWindow](#)

This enumeration represents some common time windows. It can be used when for many purposes, but was created specifically for statistics.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

Value	Description
<b>YEAR</b>	
<b>INFINITY</b>	

IntLimit

Field Name	Type	Description
<b>qualifier</b>	<b>String</b>	One of: <ul style="list-style-type: none"> <li>• &lt;</li> <li>• &lt;=</li> <li>• ==</li> <li>• &gt;=</li> <li>• &gt;</li> </ul>
<b>value</b>	<b>Integer</b>	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Accountable Group.

Field Name	Type	Description
<b>accountingQOS</b>	<b>String</b>	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Accountable User.
<b>aclRules</b>	<a href="#"><u>Set&lt;AclRule&gt;</u></a>	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#"><u>Set&lt;DomainProxyVersion1&gt;</u></a>	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Reservation's comments or description.
<b>creationDate</b>	<b>Date</b>	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	Global reservation ID.

Field Name	Type	Description
<b>hostListExpression</b>	<b>String</b>	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	Messages for the reservation.
<b>owner</b>	<a href="#">EmbeddedCredential</a>	The owner of the reservation
<b>partitionId</b>	<b>String</b>	The ID of the partition this reservation is for.
<b>profile</b>	<b>String</b>	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	The reservation's requirements.
<b>reservationGroup</b>	<b>String</b>	The reservation group to which the reservation belongs.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	<b>Date</b>	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#"><u>ReservationStatistics</u></a>	The reservation's statistical information.
<b>subType</b>	<b>String</b>	The reservation sub-type.
<b>taskCount</b>	<b>Integer</b>	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	The set of variables for this reservation.

[DomainProxyVersion1](#)

Field Name	Type	Description
<b>id</b>	<b>String</b>	The id of the object.

[MessageVersion1](#)

Field Name	Type	Description
<b>author</b>	<b>String</b>	The author of the message.
<b>creationTime</b>	<b>Date</b>	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	An optional priority that can be attached to the comment.

#### ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	Required feature mode.
<b>memory</b>	<b>Integer</b>	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	The list of node IDs required for this reservation.
<b>os</b>	<b>String</b>	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	Description
<b>caps</b>	<b>Double</b>	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#">TriggerActionType</a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#">TriggerEventType</a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

### TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers

Field Name	Type	Description
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.

Field Name	Type	Description
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

## API version 1

StandingReservation

This class represents a standing reservation.

A standing reservation is any reservation that is not a one-time reservation. This includes reservations that recur every day or every week, or infinite reservations.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the standing reservation.
<b>access</b>	<a href="#">ReservationAccess</a>	If set to <a href="#">ReservationAccess.SHARED</a> , allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.
<b>accounts</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated accounts may use the resources contained within this reservation.
<b>aclRules</b>	<a href="#">Set&lt;AclRule&gt;</a>	The set of access control rules associated with this standing reservation.
<b>chargeAccount</b>	<b>String</b>	Specifies the account to which Moab will charge all idle cycles within the reservation (via the allocation manager).
<b>chargeUser</b>	<b>String</b>	Specifies the user to which Moab will charge all idle cycles within the reservation (via the allocation manager). Must be used in conjunction with <a href="#">chargeAccount</a>
<b>classes</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the associated classes/queues may use the resources contained within this reservation.
<b>clusters</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs originating within the listed clusters may use the resources contained within this reservation.
<b>comment</b>	<b>String</b>	Specifies a descriptive message associated with the standing reservation and all child reservations

Field Name	Type	Description
<b>days</b>	<b>Set&lt;String&gt;</b>	Specifies which days of the week the standing reservation is active. Valid values are Mon, Tue, Wed, Thu, Fri, Sat, Sun, or [ALL].
<b>depth</b>	<b>Integer</b>	Specifies the depth of standing reservations to be created, starting at depth 0 (one per <a href="#">period</a> ).
<b>disabled</b>	<b>Boolean</b>	Specifies if the standing reservation should no longer spawn child reservations.
<b>endOffset</b>	<b>Long</b>	The ending offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. See examples at <a href="#">startOffset</a> .
<b>flags</b>	<a href="#">Set&lt;ReservationFlag&gt;</a>	Specifies special reservation attributes.
<b>groups</b>	<b>Set&lt;String&gt;</b>	Specifies the groups allowed access to this standing reservation.
<b>hosts</b>	<b>Set&lt;String&gt;</b>	Specifies the set of hosts that the scheduler can search for resources to satisfy the reservation. If specified using the class:X format, Moab only selects hosts that support the specified class. If TASKCOUNT is also specified, only TASKCOUNT tasks are reserved. Otherwise, all matching hosts are reserved.
<b>jobAttributes</b>	<a href="#">Set&lt;JobFlag&gt;</a>	Specifies job attributes that grant a job access to the reservation. Values can be specified with a != assignment to only allow jobs NOT requesting a certain feature inside the reservation.
<b>maxJob</b>	<b>Integer</b>	Specifies the maximum number of jobs that can run in the reservation.
<b>maxTime</b>	<b>Integer</b>	Specifies the maximum time for jobs allowable. Can be used with affinity to attract jobs with same maxTime.
<b>messages</b>	<b>Set&lt;String&gt;</b>	Messages associated with the reservation.

Field Name	Type	Description
<b>nodeFeatures</b>	<b>Set&lt;String&gt;</b>	Specifies the required node features for nodes that are part of the standing reservation.
<b>os</b>	<b>String</b>	Specifies the operating system that should be in place during the reservation. Moab provisions this OS at reservation start and restores the original OS at reservation completion.
<b>owner</b>	<a href="#"><u>EmbeddedCredential</u></a>	Specifies the owner of the reservation. Setting ownership for a reservation grants the user management privileges, including the power to release it. Setting a user as the owner of a reservation gives that user privileges to query and release the reservation. For sandbox reservations, sandboxes are applied to a specific peer only if owner is set to CLUSTER:<PEERNAME>
<b>partition</b>	<b>String</b>	Specifies the partition in which to create the standing reservation. Defaults to ALL.
<b>period</b>	<a href="#"><u>TimeWindow</u></a>	Period of the Standing reservation. Defaults to <a href="#"><u>TimeWindow.DAY</u></a> .
<b>procLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor limit for jobs requesting access to this standing reservation.
<b>psLimit</b>	<a href="#"><u>IntLimit</u></a>	Specifies the processor-second limit for jobs requesting access to this standing reservation.
<b>qoses</b>	<b>Set&lt;String&gt;</b>	Specifies that jobs with the listed QoS names can access the reserved resources.
<b>reservationAccessList</b>	<a href="#"><u>Set&lt;Reservation&gt;</u></a>	A list of reservations to which the specified reservation has access.
<b>reservationGroup</b>	<b>String</b>	The group of the reservation.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	<p>Specifies what resources constitute a single standing reservation task. (Each task must be able to obtain all of its resources as an atomic unit on a single node.) Supported resources currently include the following:</p> <ul style="list-style-type: none"> <li>• PROCS (number of processors)</li> <li>• MEM (real memory in MB)</li> <li>• DISK (local disk in MB)</li> <li>• SWAP (virtual memory in MB)</li> </ul>
<b>rollbackOffset</b>	<b>Integer</b>	<p>Specifies the minimum time in the future at which the reservation may start. This offset is rolling meaning the start time of the reservation will continuously roll back into the future to maintain this offset. Rollback offsets are a good way of providing guaranteed resource access to users under the conditions that they must commit their resources in the future or lose dedicated access. See QoS Credential in the Moab Workload Manager documentation for more information on quality of service and service level agreements.</p>
<b>startOffset</b>	<b>Long</b>	<p>The starting offset, in seconds, from the beginning of the current <a href="#">period</a> (DAY or WEEK), for this standing reservation. If period is DAY, the offset is from midnight (00:00) of the current day. If period is WEEK, the offset is from midnight Sunday of the current week.</p> <p>Example 1: For a standing reservation that begins at 9:00 and ends at 17:00 every day, period is DAY, startOffset is 32400 (9*60*60), and endOffset is 61200 (17*60*60).</p> <p>Example 2: For a standing reservation that begins at 9:00 Monday and ends at 17:00 Friday every week, period is WEEK, startOffset is 118800 ((24+9)*60*60), and endOffset is 493200 (((5*24)+17)*60*60).</p>

Field Name	Type	Description
<b>taskCount</b>	<b>Integer</b>	Specifies how many tasks should be reserved for the reservation Default is 0 (unlimited tasks).
<b>tasksPerNode</b>	<b>Integer</b>	Specifies the minimum number of tasks per node that must be available on eligible nodes. Default is 0 (no TPN constraint)
<b>timeLimit</b>	<b>Integer</b>	Specifies the maximum allowed overlap between the standing reservation and a job requesting resource access. Default is null (-1 in moab)
<b>triggers</b>	<a href="#">Set&lt;Trigger&gt;</a>	Triggers associated with the reservation.
<b>type</b>	<b>String</b>	The type of the reservation.
<b>users</b>	<b>Set&lt;String&gt;</b>	Specifies which users have access to the resources reserved by this reservation.

### [ReservationAccess](#)

The access type of a standing reservation. If set to SHARED, allows a standing reservation to use resources already allocated to other non-job reservations. Otherwise, these other reservations block resource access.

Value	Description
<b>DEDICATED</b>	
<b>SHARED</b>	

### [AclRule](#)

This class represents a rule that can be in Moab's access control list (ACL) mechanism.

The basic AclRule information is the object's name and type. The type directly maps to an [AclType](#) value. The default mechanism Moab uses to check the ACL for a particular item is if the user or object coming in has ANY of the values in the ACL, then the user or object is given access. If no values match the user or object in question, the user or object is rejected access.

Field Name	Type	Description
<b>affinity</b>	<a href="#"><u>AclAffinity</u></a>	Reservation ACLs allow or deny access to reserved resources but they may also be configured to affect a job's affinity for a particular reservation. By default, jobs gravitate toward reservations through a mechanism known as positive affinity. This mechanism allows jobs to run on the most constrained resources leaving other, unreserved resources free for use by other jobs that may not be able to access the reserved resources. Normally this is a desired behavior. However, sometimes, it is desirable to reserve resources for use only as a last resort-using the reserved resources only when there are no other resources available. This last resort behavior is known as negative affinity.  Defaults to <a href="#"><u>AclAffinity.POSITIVE</u></a> .
<b>comparator</b>	<a href="#"><u>ComparisonOperator</u></a>	The type of comparison to make against the ACL object.  Defaults to <a href="#"><u>ComparisonOperator.EQUAL</u></a> .
<b>type</b>	<a href="#"><u>AclType</u></a>	The type of the object that is being granted (or denied) access.
<b>value</b>	<b>String</b>	The name of the object that is being granted (or denied) access.

[AclAffinity](#)

This enumeration describes the values available for describing how a rule is used in establishing access to an object in Moab. Currently, these ACL affinities are used only for granting access to reservations.

Value	Description
<b>NEGATIVE</b>	Access to the object is repelled using this rule until access is the last choice.
<b>NEUTRAL</b>	Access to the object is not affected by affinity.
<b>POSITIVE</b>	Access to the object is looked at as the first choice.
<b>PREEMPTIBLE</b>	Access to the object given the rule gives preemptible status to the accessor. Supported only during GET.

Value	Description
<b>REQUIRED</b>	The rule in question must be satisfied in order to gain access to the object. Supported only during GET.
<b>UNAVAILABLE</b>	The rule does not have its affinity available. Supported only during GET.

### ComparisonOperator

This enumeration is used when Moab needs to compare items. One such use is in Access Control Lists (ACLs).

Value	Description
<b>GREATER_THAN</b>	Valid values: ">", "gt"
<b>GREATER_THAN_OR_EQUAL</b>	Valid values: ">=", "ge"
<b>LESS_THAN</b>	Valid values: "<", "lt"
<b>LESS_THAN_OR_EQUAL</b>	Valid values: "<=", "le"
<b>EQUAL</b>	Valid values: "==", "eq", "="
<b>NOT_EQUAL</b>	Valid values: "!=", "ne", "<>"
<b>LEXIGRAPHIC_SUBSTRING</b>	Valid value: "%<"
<b>LEXIGRAPHIC_NOT_EQUAL</b>	Valid value: "%!"
<b>LEXIGRAPHIC_EQUAL</b>	Valid value: "%="

### AcType

This enumeration describes the values available for the type of an ACL Rule.

Value	Description
<b>USER</b>	User

Value	Description
<b>GROUP</b>	Group
<b>ACCOUNT</b>	Account or Project
<b>CLASS</b>	Class or Queue
<b>QOS</b>	Quality of Service
<b>CLUSTER</b>	Cluster
<b>JOB_ID</b>	Job ID
<b>RESERVATION_ID</b>	Reservation ID
<b>JOB_TEMPLATE</b>	Job Template
<b>JOB_ATTRIBUTE</b>	Job Attribute
<b>DURATION</b>	Duration in Seconds
<b>PROCESSOR_SECONDS</b>	Processor Seconds
<b>JRIORITY</b>	Not supported
<b>MEMORY</b>	Not supported
<b>NODE</b>	Not supported
<b>PAR</b>	Not supported
<b>PROC</b>	Not supported
<b>QTIME</b>	Not supported
<b>QUEUE</b>	Not supported
<b>RACK</b>	Not supported

Value	Description
<b>SCHED</b>	Not supported
<b>SYSTEM</b>	Not supported
<b>TASK</b>	Not supported
<b>VC</b>	Not supported
<b>XFACTOR</b>	Not supported

### ReservationFlag

The flag types of a reservation.

Value	Description
<b>ALLOWJOBOverlap</b>	Allows jobs to overlap this Reservation, but not start during it (unless they have ACL access).
<b>APPLYPROFRESOURCES</b>	Only apply resource allocation info from profile.
<b>DEADLINE</b>	Reservation should be scheduled against a deadline.
<b>IGNIDLEJOBS</b>	Ignore idle job reservations.
<b>IGNJOBRSV</b>	Ignore job reservations, but not user or other reservations.
<b>CHARGE</b>	Charge the idle cycles in the accounting manager.
<b>NOVMIGRATIONS</b>	Override the VM Migration Policy and don't migrate VMs that overlap this reservation.
<b>OWNERPREEMPTIGNOREMINTIME</b>	Owner ignores preemptmintime for this reservation.
<b>PROVISION</b>	Reservation should be capable of provisioning.
<b>NOACLOVERLAP</b>	Reservation will not look at ACLs to overlap job (when using exclusive).

Value	Description
<b>ADVRES</b>	If set, the reservation is created in advance of needing it.
<b>ADVRESJOBDESTROY</b>	Cancel any jobs associated with the reservation when it is released.
<b>ALLOWGRID</b>	The reservation is set up for use in a grid environment.
<b>ALLOWPRSV</b>	Personal reservations can be created within the space of this standing reservation (and ONLY this standing reservation). By default, when a standing reservation is given the flag ALLOWPRSV, it is given the ACL rule USER>=ALL+ allowing all jobs and all users access.
<b>BYNAME</b>	Reservation only allows access to jobs that meet reservation ACLs and explicitly request the resources of this reservation using the job ADVRES flag.
<b>DEDICATEDNODE</b>	If set, only one active reservation is allowed on a node.
<b>DEDICATEDRESOURCE</b>	The reservation is only placed on resources that are not reserved by any other reservation, including jobs and other reservations.
<b>EXCLUDEJOBS</b>	Makes a reservation job exclusive, where only one job can run in the reservation.
<b>ENDTRIGHASFIRED</b>	A trigger has finished firing.
<b>ENFORCENODESET</b>	Enforce node sets when creating reservation.
<b>EXCLUDEALLBUTSB</b>	Reservation only shares resources with sandboxes.
<b>EXCLUDEMYGROUP</b>	Exclude reservations within the same group.
<b>IGNRSV</b>	Forces the reservation onto nodes regardless of whether there are other reservations currently residing on the nodes.
<b>IGNSTATE</b>	Request ignores existing resource reservations, allowing the reservation to be forced onto available resources even if this conflicts with other reservations.

Value	Description
<b>ISACTIVE</b>	If set, the reservation is currently active.
<b>ISCLOSED</b>	If set, the reservation is closed.
<b>ISGLOBAL</b>	If set the reservation applies to all resources.
<b>OWNERPREEMPT</b>	The owner of the reservation is given preemptor status for resources contained in the reservation.
<b>PARENTLOCK</b>	The reservation can only be destroyed by destroying its parent.
<b>PREEMPTEE</b>	The reservation is preemptible.
<b>PLACEHOLDER</b>	The reservation is a placeholder for resources.
<b>PRSV</b>	The reservation is a non-administrator, non-standing reservation, user-created reservation.
<b>REQFULL</b>	The reservation will fail if all resources requested cannot be allocated.
<b>SCHEDULEVCRSV</b>	The reservation was created as part of a schedule VC command. This pertains to reservations creating while scheduling MWS Services, and these are filtered from the MWS output of reservations.
<b>SINGLEUSE</b>	The reservation is automatically removed after completion of the first job to use the reserved resources.
<b>SPACEFLEX</b>	The reservation is allowed to adjust resources allocated over time in an attempt to optimize resource utilization.
<b>STANDINGRSV</b>	If set, the reservation was created by a standing reservation instance.
<b>STATIC</b>	Makes a reservation ineligible to modified or canceled by an administrator.
<b>SYSTEMJOB</b>	The reservation was created by a system job.
<b>TIMEFLEX</b>	The reservation is allowed to adjust the reserved time frame in an attempt to optimize resource utilization.

Value	Description
<b>TRIGHASFIRE</b>	The reservation has one or more triggers that have fired on it.
<b>WASACTIVE</b>	The reservation was previously active.
<b>EVACVMS</b>	Evacuate virtual machines on the node when the reservation starts.

### JobFlag

This enumeration specifies the flag types of a job.

Value	Description
<b>NONE</b>	
<b>BACKFILL</b>	The job is using backfill to run.
<b>COALLOC</b>	The job can use resources from multiple resource managers and partitions.
<b>ADVRES</b>	The job requires the use of a reservation.
<b>NOQUEUE</b>	The job will attempt to execute immediately or fail.
<b>ARRAYJOB</b>	The job is part of a job array.
<b>ARRAYJOBPARLOCK</b>	This array job will only run in one partition.
<b>ARRAYJOBPARSPAN</b>	This array job will span partitions (default).
<b>ARRAYMASTER</b>	This job is the master of a job array.
<b>BESTEFFORT</b>	The job will succeed if even partial resources are available.
<b>RESTARTABLE</b>	The job is restartable.
<b>SUSPENDABLE</b>	The job is suspendable.
<b>HASPREEMPTED</b>	This job preempted other jobs to start.

Value	Description
<b>PREEMPTEE</b>	The job is a preemptee and therefore can be preempted by other jobs.
<b>PREEMPTOR</b>	The job is a preemptor and therefore can preempt other jobs.
<b>RSVMAP</b>	The job is based on a reservation.
<b>SPVIOLATION</b>	The job was started with a soft policy violation.
<b>IGNNODEPOLICIES</b>	The job will ignore node policies.
<b>IGNPOLICIES</b>	The job will ignore idle, active, class, partition, and system policies.
<b>IGNNODESTATE</b>	The job will ignore node state in order to run.
<b>IGNIDLEJOBRSV</b>	The job can ignore idle job reservations. The job granted access to all idle job reservations.
<b>INTERACTIVE</b>	The job needs to interactive input from the user to run.
<b>FSVIOLATION</b>	The job was started with a fairshare violation.
<b>GLOBALQUEUE</b>	The job is directly submitted without doing any authentication.
<b>NORESOURCES</b>	The job is a system job that does not need any resources.
<b>NORMSTART</b>	The job will not query a resource manager to run.
<b>CLUSTERLOCKED</b>	The job is locked into the current cluster and cannot be migrated elsewhere. This is for grid mode.
<b>FRAGMENT</b>	The job can be run across multiple nodes in individual chunks.
<b>SYSTEMJOB</b>	The job is a system job which simply runs on the same node that Moab is running on. This is usually used for running scripts and other executables in workflows.
<b>ADMINSETIGNPOLICIES</b>	The <a href="#">IGNPOLICIES</a> flag was set by an administrator.

Value	Description
<b>EXTENDSTARTWALLTIME</b>	The job duration (walltime) was extended at job start.
<b>SHAREDMEM</b>	The job will share its memory across nodes.
<b>BLOCKEDBYGRES</b>	The job's generic resource requirement caused the job to start later.
<b>GRESONLY</b>	The job is requesting only generic resources, no compute resources.
<b>TEMPLATESAPPLIED</b>	The job has had all applicable templates applied to it.
<b>META</b>	META job, just a container around resources.
<b>WIDERSVSEARCHALGO</b>	This job prefers the wide search algorithm.
<b>VMTRACKING</b>	The job is a VMTracking job for an externally-created VM (via job template).
<b>DESTROYTEMPLATESSUBMITTED</b>	A destroy job has already been created from the template for this job.
<b>PROCSPECIFIED</b>	The job requested processors on the command line.
<b>CANCELONFIRSTFAILURE</b>	Cancel job array on first array job failure.
<b>CANCELONFIRSTSUCCESS</b>	Cancel job array on first array job success.
<b>CANCELONANYFAILURE</b>	Cancel job array on any array job failure.
<b>CANCELONANYSUCCESS</b>	Cancel job array on any array job success.
<b>CANCELONEXITCODE</b>	Cancel job array on a specific exit code.
<b>NOVMMIGRATE</b>	Do not migrate the virtual machine that this job sets up.
<b>PURGEONSUCCESSONLY</b>	Only purge the job if it completed successfully

<b>INFINITY</b>	

IntLimit

Field Name	Type	Description
<b>qualifier</b>	<b>String</b>	One of: <ul style="list-style-type: none"> <li>• &lt;</li> <li>• &lt;=</li> <li>• ==</li> <li>• &gt;=</li> <li>• &gt;</li> </ul>
<b>value</b>	<b>Integer</b>	

Reservation

A reservation is the mechanism by which Moab guarantees the availability of a set of resources at a particular time. Each reservation consists of three major components: (1) a set of resources, (2) a time frame, and (3) an access control list. It is a scheduler role to ensure that the access control list is not violated during the reservation's lifetime (that is, its time frame) on the resources listed. For example, a reservation may specify that node002 is reserved for user Tom on Friday. The scheduler is thus constrained to make certain that only Tom's jobs can use node002 at any time on Friday.

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the reservation.
<b>accountingAccount</b>	<b>String</b>	Accountable Account.
<b>accountingGroup</b>	<b>String</b>	Accountable Group.

Field Name	Type	Description
<b>accountingQOS</b>	<b>String</b>	Accountable QOS.
<b>accountingUser</b>	<b>String</b>	Accountable User.
<b>aclRules</b>	<a href="#"><u>Set&lt;AclRule&gt;</u></a>	The set of access control rules associated with this reservation.
<b>allocatedNodeCount</b>	<b>Integer</b>	The number of allocated nodes for this reservation.
<b>allocatedNodes</b>	<a href="#"><u>Set&lt;DomainProxyVersion1&gt;</u></a>	The nodes allocated to the reservation.
<b>allocatedProcessorCount</b>	<b>Integer</b>	The number of allocated processors.
<b>allocatedTaskCount</b>	<b>Integer</b>	The number of allocated tasks.
<b>comments</b>	<b>String</b>	Reservation's comments or description.
<b>creationDate</b>	<b>Date</b>	Creation date. Automatically set by Moab when a user creates the reservation.
<b>duration</b>	<b>Long</b>	The duration of the reservation (in seconds).
<b>endDate</b>	<b>Date</b>	The end date of the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation ends.
<b>excludeJobs</b>	<b>Set&lt;String&gt;</b>	The list of jobs to exclude. Client must also set the IGNJOBRSV reservation flag. Otherwise, results are undefined. Used only during reservation creation.
<b>expireDate</b>	<b>Date</b>	The date/time when the reservation expires and vacates.
<b>flags</b>	<a href="#"><u>Set&lt;ReservationFlag&gt;</u></a>	The flags associated with the reservation.
<b>globalId</b>	<b>String</b>	Global reservation ID.

Field Name	Type	Description
<b>hostListExpression</b>	<b>String</b>	The list of nodes a user can select to reserve. This may or may not be the nodes that are currently allocated to this reservation. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>idPrefix</b>	<b>String</b>	The user-specified prefix for this reservation. If provided, Moab combines the idPrefix with an integer, and the combination is the unique identifier for this reservation.
<b>isActive</b>	<b>Boolean</b>	State whether or not this reservation is currently active.
<b>isTracked</b>	<b>Boolean</b>	States whether reservation resource usage is tracked.
<b>label</b>	<b>String</b>	When a label is assigned to a reservation, the reservation can then be referenced by that label as well as by the reservation name.
<b>maxTasks</b>	<b>Integer</b>	The maximum number of tasks for this reservation.
<b>messages</b>	<a href="#">Set&lt;MessageVersion1&gt;</a>	Messages for the reservation.
<b>owner</b>	<a href="#">EmbeddedCredential</a>	The owner of the reservation
<b>partitionId</b>	<b>String</b>	The ID of the partition this reservation is for.
<b>profile</b>	<b>String</b>	The profile that this reservation is using. A profile is a specification of attributes that all reservations share. Used only during reservation creation.
<b>requirements</b>	<a href="#">ReservationRequirement</a>	The reservation's requirements.
<b>reservationGroup</b>	<b>String</b>	The reservation group to which the reservation belongs.

Field Name	Type	Description
<b>resources</b>	<b>Map&lt;String, Integer&gt;</b>	The reservation's resources. This field is a map, where the key is PROCS, MEM DISK, SWAP, or one or more user-defined keys.
<b>startDate</b>	<b>Date</b>	The start time for the reservation. This is especially useful for one-time reservations, which have an exact time for when a reservation starts.
<b>statistics</b>	<a href="#"><u>ReservationStatistics</u></a>	The reservation's statistical information.
<b>subType</b>	<b>String</b>	The reservation sub-type.
<b>taskCount</b>	<b>Integer</b>	The number of tasks that must be allocated to satisfy the reservation request. Note: Either hostListExpression or taskCount must be set to create a reservation.
<b>trigger</b>	<a href="#"><u>Trigger</u></a>	Trigger for reservation. Used only during reservation creation.
<b>triggerIds</b>	<b>Set&lt;String&gt;</b>	The IDs of the triggers attached to this reservation.
<b>uniqueIndex</b>	<b>String</b>	The globally-unique reservation index.
<b>variables</b>	<b>Map&lt;String, Map&gt;</b>	The set of variables for this reservation.

[DomainProxyVersion1](#)

Field Name	Type	Description
<b>id</b>	<b>String</b>	The id of the object.

[MessageVersion1](#)

Field Name	Type	Description
<b>author</b>	<b>String</b>	The author of the message.
<b>creationTime</b>	<b>Date</b>	The time the message was created in epoch time.
<b>expireTime</b>	<b>Date</b>	The time the message will be deleted in epoch time.
<b>index</b>	<b>Integer</b>	The index of the message relative to other messages in Moab's memory.
<b>message</b>	<b>String</b>	The comment information itself.
<b>messageCount</b>	<b>Integer</b>	The number of times this message has been displayed.
<b>priority</b>	<b>Double</b>	An optional priority that can be attached to the comment.

#### ReservationRequirement

Represents all the types of requirements a user can request while creating a reservation.

Field Name	Type	Description
<b>architecture</b>	<b>String</b>	Required architecture.
<b>featureList</b>	<b>Set&lt;String&gt;</b>	The list of features required for this reservation.
<b>featureMode</b>	<b>String</b>	Required feature mode.
<b>memory</b>	<b>Integer</b>	Required node memory, in MB.
<b>nodeCount</b>	<b>Integer</b>	Required number of nodes.
<b>nodeIds</b>	<b>Set&lt;String&gt;</b>	The list of node IDs required for this reservation.
<b>os</b>	<b>String</b>	Required Operating System.
<b>taskCount</b>	<b>Integer</b>	Required task count.

ReservationStatistics

Represents some basic statistical information that is kept about the usage of reservations. All metrics that are kept track relate to processor-seconds usage.

Field Name	Type	Description
<b>caps</b>	<b>Double</b>	The current active processor-seconds in the last reported iteration.
<b>cips</b>	<b>Double</b>	The current idle processor-seconds in the last reported iteration.
<b>taps</b>	<b>Double</b>	The total active processor-seconds over the life of the reservation.
<b>tips</b>	<b>Double</b>	The total idle processor-seconds over the life of the reservation.

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#">TriggerActionType</a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#">TriggerEventType</a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.

Field Name	Type	Description
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#">Set&lt;TriggerFlag&gt;</a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#">TriggerEventType.EPOCH</a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#">TriggerPeriod</a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.

Field Name	Type	Description
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

### TriggerActionType

This enumeration specifies the action type of a trigger.

Value	Description
<b>CANCEL</b>	Only apply to reservation triggers
<b>CHANGE_PARAM</b>	
<b>JOB_PREEMPT</b>	This indicates that the trigger should preempt all jobs currently allocating resources assigned to the trigger's parent object. Only apply to reservation triggers.
<b>MAIL</b>	
<b>THRESHOLD</b>	
<b>INTERNAL</b>	

Value	Description
<b>EXEC</b>	

TriggerEventType

This enumeration specifies the event type of a trigger.

Value	Description
<b>CANCEL</b>	
<b>CHECKPOINT</b>	
<b>CREATE</b>	
<b>END</b>	
<b>EPOCH</b>	
<b>FAIL</b>	
<b>HOLD</b>	
<b>MIGRATE</b>	
<b>MODIFY</b>	
<b>PREEMPT</b>	
<b>STANDING</b>	
<b>START</b>	
<b>THRESHOLD</b>	

TriggerFlag

This enumeration specifies a flag belonging to a trigger.

Value	Description
<b>ATTACH_ERROR</b>	If the trigger outputs anything to stderr, Moab will attach this as a message to the trigger object.
<b>CLEANUP</b>	If the trigger is still running when the parent object completes or is canceled, the trigger will be killed.
<b>CHECKPOINT</b>	Moab should always checkpoint this trigger. See Checkpointing a Trigger in the Moab Workload Manager documentation for more information.
<b>GLOBAL_VARS</b>	The trigger will look in the name space of all nodes with the globalvars flag in addition to its own name space. A specific node to search can be specified using the following format: globalvars+node_id
<b>INTERVAL</b>	Trigger is periodic.
<b>MULTIFIRE</b>	Trigger can fire multiple times.
<b>OBJECT_XML_STDIN</b>	Trigger passes its parent's object XML information into the trigger's stdin. This only works for exec triggers with reservation type parents.
<b>USER</b>	The trigger will execute under the user ID of the object's owner. If the parent object is sched, the user to run under may be explicitly specified using the format user+<username>, for example flags=user+john:
<b>GLOBAL_TRIGGER</b>	The trigger will be (or was) inserted into the global trigger list.
<b>ASYNCHRONOUS</b>	An asynchronous trigger.
<b>LEAVE_FILES</b>	Do not remove stderr and stdout files.
<b>PROBE</b>	The trigger's stdout will be monitored.
<b>PROBE_ALL</b>	The trigger's stdout will be monitored.
<b>GENERIC_SYSTEM_JOB</b>	The trigger belongs to a generic system job (for checkpointing).

Value	Description
<b>REMOVE_STD_FILES</b>	The trigger will delete stdout/stderr files after it has been reset.
<b>RESET_ON_MODIFY</b>	The trigger resets if the object it is attached to is modified, even if multifire is not set.
<b>SOFT_KILL</b>	By default, a SIGKILL (kill -9) signal is sent to the kill the script when a trigger times out. This flag will instead send a SIGTERM (kill -15) signal to kill the script. The SIGTERM signal will allow the script to trap the signal so that the script can clean up any residual information on the system (instead of just dying, as with the SIGKILL signal).  NOTE: A timed-out trigger will only receive one kill signal. This means that if you specify this flag, a timed-out trigger will only receive the SIGTERM signal, and never the SIGKILL signal.

TriggerPeriod

This enumeration specifies the period of a trigger.

Value	Description
<b>MINUTE</b>	
<b>HOUR</b>	
<b>DAY</b>	
<b>WEEK</b>	
<b>MONTH</b>	

Trigger

Field Name	Type	Description
<b>id</b>	<b>String</b>	Trigger id - internal ID used by moab to track triggers

Field Name	Type	Description
<b>action</b>	<b>String</b>	For exec atype triggers, signifies executable and arguments. For jobpreempt atype triggers, signifies PREEMPTPOLICY to apply to jobs that are running on allocated resources. For changeparam atype triggers, specifies the parameter to change and its new value (using the same syntax and behavior as the changeparam command).
<b>actionType</b>	<a href="#"><u>TriggerActionType</u></a>	
<b>blockTime</b>	<b>Date</b>	Time (in seconds) Moab will suspend normal operation to wait for trigger execution to finish. Use caution as Moab will completely stop normal operation until BlockTime expires.
<b>description</b>	<b>String</b>	
<b>eventType</b>	<a href="#"><u>TriggerEventType</u></a>	
<b>expireTime</b>	<b>Date</b>	Time at which trigger should be terminated if it has not already been activated.
<b>failOffset</b>	<b>Date</b>	Specifies the time (in seconds) that the threshold condition must exist before the trigger fires.
<b>flags</b>	<a href="#"><u>Set&lt;TriggerFlag&gt;</u></a>	
<b>interval</b>	<b>Boolean</b>	When used in conjunction with MultiFire and RearmTime trigger will fire at regular intervals. Can be used with <a href="#"><u>TriggerEventType.EPOCH</u></a> to create a Standing Trigger. Defaults to false
<b>maxRetry</b>	<b>Integer</b>	Specifies the number of times Action will be attempted before the trigger is designated a failure.
<b>multiFire</b>	<b>Boolean</b>	Specifies whether this trigger can fire multiple times. Defaults to false.
<b>name</b>	<b>String</b>	Trigger name - can be auto assigned by moab or requested. Alphanumeric up to 16 characters in length
<b>objectId</b>	<b>String</b>	The ID of the object which this is attached to.

Field Name	Type	Description
<b>objectType</b>	<b>String</b>	The type of object which this is attached to. Possible values: <ul style="list-style-type: none"> <li>• vm - Virtual Machine</li> </ul>
<b>offset</b>	<b>Date</b>	Relative time offset from event when trigger can fire.
<b>period</b>	<a href="#"><u>TriggerPeriod</u></a>	Can be used in conjunction with Offset to have a trigger fire at the beginning of the specified period. Can be used with EType epoch to create a standing trigger.
<b>rearmTime</b>	<b>Date</b>	Time between MultiFire triggers; rearm time is enforced from the trigger event time.
<b>requires</b>	<b>String</b>	Variables this trigger requires to be set or not set before it will fire. Preceding the string with an exclamation mark (!) indicates this variable must NOT be set. Used in conjunction with Sets to create trigger dependencies.
<b>sets</b>	<b>String</b>	Variable values this trigger sets upon success or failure. Preceding the string with an exclamation mark (!) indicates this variable is set upon trigger failure. Preceding the string with a caret (^) indicates this variable is to be exported to the parent object when the current object is destroyed through a completion event. Used in conjunction with Requires to create trigger dependencies.
<b>threshold</b>	<b>String</b>	Reservation usage threshold - When reservation usage drops below Threshold, trigger will fire. Threshold usage support is only enabled for reservations and applies to percent processor utilization. gmetric thresholds are supported with job, node, credential, and reservation triggers. See Threshold Triggers in the Moab Workload Manager documentation for more information.
<b>timeout</b>	<b>Date</b>	Time allotted to this trigger before it is marked as unsuccessful and its process (if any) killed.
<b>unsets</b>	<b>String</b>	Variable this trigger destroys upon success or failure.

<b>Distinct query-supported</b>	Yes	<a href="#">Distinct on page 1526</a>

## API version 3

UserPermission

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the cached user permission.
<b>name</b>	<b>String</b>	The unique name of the user.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	The list of permissions.

Permission

Represents a permission

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of this role.
<b>action</b>	<b>String</b>	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	A description of this permission.
<b>fieldPath</b>	<b>String</b>	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	A human readable label for this permission.
<b>resource</b>	<b>String</b>	The resource the permission applies to.
<b>resourceFilter</b>	<b>Map&lt;String, Map&gt;</b>	A map used to limit which resource instances this permission applies to. If this is null then the permission will apply to all instances of the resource. For api permissions the filter uses mongo query syntax.
<b>scope</b>	<a href="#">PrivilegeScope</a>	Whether this permission applies to the principal's tenant-associated resources or globally
<b>type</b>	<b>String</b>	The type of the permission. Only 'api' type permissions are enforced.

### PrivilegeScope

Some permissions and roles ignore tenants and apply globally. Others apply only to the resources associated with the principal's tenants.

Value	Description
<b>GLOBAL</b>	Describes a role or permission that applies globally, irrespective of the principal's tenants. This scope can be applied to any role or permission.
<b>TENANT</b>	Describes a role or permission that applies only to the resources associated with the principal's tenants. This scope can be applied to any role, but only to those permissions associated with tenanted resources (e.g. nodes, services, etc.).
<b>NONE</b>	Scope doesn't apply to some permissions. As of right now, all non-domain permissions (e.g. those created by Viewpoint) don't need a scope. NONE should therefore be assigned to all non-domain permissions.

## API version 2

UserPermission

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of the cached user permission.
<b>name</b>	<b>String</b>	The unique name of the user.
<b>permissions</b>	<a href="#">List&lt;Permission&gt;</a>	The list of permissions.

Permission

Represents a permission

Field Name	Type	Description
<b>id</b>	<b>String</b>	The unique ID of this role.
<b>action</b>	<b>String</b>	The action that can be performed on the resource.
<b>description</b>	<b>String</b>	A description of this permission.
<b>fieldPath</b>	<b>String</b>	Field level ACL control, if null or '*', all fields are accessible, otherwise requests must match dot delimited path. Currently only checked when doing writable actions. Example - attributes.*: create update
<b>label</b>	<b>String</b>	A human readable label for this permission.

# Moab Cluster Manager

## MCM overview

Moab Cluster Manager (MCM) is a Java-based graphical interface for managing the Moab Workload Manager. It allows users to submit jobs, schedule reservations, view job statistics, etc. in an easy, user-friendly way. This guide contains the following sections to help you set up and use MCM.

- [Getting Started on page 2435](#) explains how to get started using the MCM by installing it, connecting it to a Moab Workload Manager, and describing its main window (see
- [Workload on page 2442](#) deals with the submitting and viewing of jobs, reservations, and triggers. These functions are used to get work done by the system.
- [Resources on page 2471](#) explains how the Resources category gives administrators the ability to view, modify, and set policies and attributes while effectively diagnosing various system resources.
- [Credentials on page 2486](#) explains how the Credentials allow an administrator to view all credentials in the system and their various roles. New credential profiles can be added as well as modified.
- [Policies on page 2508](#) offers information about how the Policies section is intended to give control over Moab's various policies.

- [Reporting on page 2524](#) explains how MCM offers a wide assortment of customizable statistics whether they be customized charts, graphs, matrix statistics, quick charts, or reports.
- [Diagnostics on page 2538](#) explains how Diagnostics are intended to give an administrator quick and easy system information for diagnosing potential problems.
- [Miscellaneous on page 2538](#) contains varied MCM information that does not fit in other categories.

## Getting Started

### Getting Started Overview

Moab Cluster Manager (MCM) is a Java-based graphical interface for managing the Moab Workload Manager. It allows administrators to schedule reservations, view job statistics, manage policies, etc., in an easy, user-friendly way.

This chapter explains how to get started using the Moab Cluster Manager by installing it, connecting it to a Moab Workload Manager, and describing its main window.

## Installation

### Unix-Based installation

You will need to have Java SE 6 or higher installed on your system to run MCM. Java SE 6 comes with a Java Runtime Environment (JRE) version 1.6. You must obtain a JRE from Oracle. MCM will not run correctly on JREs from other vendors, such as GCJ or OpenJDK. The Linux build of MCM comes bundled with a JRE. However, if you are using the generic Unix version of MCM, you will need to download a JRE separately.

To see which version of Java you are running, you can type `java` at a command prompt.

```
$ java -version
java version "1.6.0_31"
Java(TM) SE Runtime Environment (build 1.6.0_31-b04)
Java HotSpot(TM) 64-Bit Server VM (build 20.6-b01, mixed mode)
```

These install instructions assume a basic familiarity with Unix/Linux file systems, and commands such as `ls`, `tar`, `mv`, etc.

The installation steps are as follows:

1. Download the latest version of the tar file from the Adaptive Computing web site:
  - a. The `mcm-x-[build number].linux.tar.gz` builds come with a bundled JRE.
  - b. The `mcm-x-[build number].tar.gz` builds do NOT include a JRE.
2. Move the tar file to your home directory, or another directory you have access to (i.e. `/home/username/`). Unpack the tar file (`tar -xzvf xxxx.tar.gz`).

3. Change directories to the newly unpacked MCM directory.
4. Start MCM by running the MCM script as shown below:

```
$ mv mcm-8.0.0.x-xxxx.tar.gz /home/bob
$ cd /home/bob
$ tar zxvf mcm-8.0.0.x-xxxx.tar.gz
$ cd mcm-8.0.0.x-xxxx/
$ ./mcm &
```

The MCM script will check for the existence of a compatible JRE and then run MCM. After accepting the license you will see the Connection Wizard. To see how to configure MCM to connect to Moab Workload Manager, see the Connection Wizard section.

## Windows installation

1. Download the installation executable from the Adaptive Computing web site. The `mcm-8.0.0.x-[build number].exe` build contains a Windows installer that will set up MCM on your system. This build comes bundled with a compatible Java Runtime Environment (JRE).
2. Double-click the installation file. The MCM installer will guide you through the installation process.

**i** The default target folder is either `C:\Program Files\Moab Cluster Manager` or `C:\Program Files (x86)\Moab Cluster Manager` depending on what version of Windows you are running.

3. The installer will create Start Menu and Desktop icons that can be used to run MCM.
4. Double-click the Moab Cluster Manager icon on the Desktop to run MCM. After accepting the license you will see the Connection Wizard. To see how to configure MCM to connect to Moab Workload Manager, see the [Connection Wizard](#) section.

**i** If you're running Windows 7, MCM by default will NOT have permissions to create log files. This is because MCM will not have permission to write to subfolders of `C:\Program Files` or `C:\Program Files (x86)` unless it is run as an administrator. This may not be a concern. However, if you need to see log files, you can change the log file path to a folder where the user running MCM has permission to write to. To do this, edit the `C:\Program Files (x86)\Moab Cluster Manager\conf\log4j.properties` file and change the **log4j.appender.ROLL.File** property. For example, to cause logs to be written to `C:\Users\Bob\AppData\Local`, where Bob is the user running MCM, modify the property as shown below:

```
log4j.appender.Roll.File=${user.home}/AppData/Local/mcm.log
```

## Connection wizard

The Connection Wizard provides three connection options for the Moab Cluster Manager: **Remote Connection**, **Local Connection**, and **Online Demonstration**.

Connection	Description
<b>Remote Connection</b>	Connects to a remote Moab Workload Manager server over SSH.
<b>Local Connection</b>	Connects to a locally hosted Moab Workload Manager server.
<b>Online Demonstration</b>	Automatically logs in to an online demonstration cluster for a preview of the product.

## Remote Connection

The Remote Connection feature allows you to securely connect to a remote Moab Workload Manager server. Here is a description of each of the connection options:

### Host Name & Port

#### **Host Name (or IP Address)**

The Host Name (or IP address) of the server that is running Moab Workload Manager. If you do not know the host name or IP address of the server, please consult your system administrator.

#### **Port**

The port on which SSH is running on the remote server (the default is 22). If you do not know which port to use, please consult your system administrator.

### Authentication Options

#### **Password Authentication**

This option tells Moab Cluster Manager to authenticate by prompting the user for a password. Consult with your system administrator for information regarding your user name, password and the type of authentication used.

#### **Keyboard Interactive Authentication**

This option tells Moab Cluster Manager to interactively prompt for authentication information.

#### **SSH Key Authentication**

This option tells Moab Cluster Manager to connect to the remote computer using only the user name and a private key file. Consult your system administrator for information regarding your user name, private key and the type of authentication used.

 Keys should only be generated with `ssh-keygen`.

### Ask for SSH Key Passphrase

Some private keys require a passphrase to be entered before it will allow a user to authenticate. In this case this box should be checked, otherwise an empty passphrase will be used for authentication.

### Connection Settings

#### User Name

This is the name used to login to the remote computer. Because MCM is an administrator tool, the user must be configured as an [ADMINCFG\[1\]](#) in `moab.cfg`. Consult your system administrator for information regarding your user name or password.

#### Path to Moab Workload Manager Client Commands (i.e. showq)

The directory containing the Moab Client Commands, such as `showq`, `mschedctl`, `mdiag`, etc. This is not the location of the Workload Manager, but instead the location of the commands that control the Workload Manager. This location is usually `/opt/moab/bin`.

#### Private Key Path

If SSH key Authentication is being used, this field is for the path of the private key file.

### Load, save or delete stored sessions

#### Auto Connect On Next Session

This option sets the Moab Cluster Manager to automatically connect to the specified saved session the next time it is run.

#### Saved Sessions

This field is where a user is able to save his/her remote connection settings so that they don't need to be entered each time.

#### Load Button

This button will load the selected saved session in the list to the left.

#### Save Button

This button will save a session according to the name typed in the **Saved Sessions** field.

#### Delete Button

This button will delete the saved session that is selected in the list to the left.

#### Connect Button

This button will open a connection to a remote Moab Workload Manager. It will attempt to authenticate the user based on the given settings, and then open the Moab Cluster Manager.

#### Quit Button

Clicking this button will close the Moab Cluster Manager Connection Wizard.

## Local Connection

This option connects to a Moab Workload Manager running on the local machine. The only option for this mode is the Path for the Moab Workload Manager Client Commands.

### Path to Moab Workload Manager Client Commands (i.e. showq)

The directory containing the Moab Client Commands, such as `showq`, `mschedctl`, `mdiag`, etc. This is not the location of the Moab Workload Manager, but instead the location of the commands that interact with the Moab Workload Manager. This location is usually `/opt/moab/bin`.

### Connect Button

This button will open a connection to a local Moab Workload Manager and then open the Moab Cluster Manager.

### Quit Button

Clicking this button will close the Moab Cluster Manager Connection Wizard.

## Online Demonstration

The Online Demonstration is a free, online demonstration cluster for users to preview. This connection option will automatically log in to the demonstration cluster.

### Connect Button

This button will connect Moab Cluster Manager to the Adaptive Computing demonstration Moab Workload Manager.

### Quit Button

Clicking this button will close the Moab Cluster Manager Connection Wizard.

## View summary

The Moab Cluster Manager main window provides an overview of the current state of the cluster. There are four parts of this main window: the Main Menu Bar, the Navigation pane, the Summary screen, and the System Utilization Bar.

## Main Menu Bar

The Main Menu Bar is located across the top of the Moab Cluster Manager window. Through this menu (Main, Configure, Create, etc.), all Moab Cluster Manager features can be accessed. The services unique to this menu are:

- Console window
- Save System Snapshot window
- Moab Cluster Manager Preferences window

- Plugin Manager window
- About window

## Navigation Pane

The Navigation pane is a directory of all the services that the Moab Cluster Manager can provide to users and administrators. The availability of some services depends on the user's privileges, as determined by the **ADMINCFG** level defined in the `moab.cfg` file. The chapters of this User Guide mimic the layout found in the Navigation pane.

## Summary Screen

The largest area in the Moab Cluster Manager main window is the Summary screen. This screen is intended to give general information about the system that Cluster Manager is currently connected to.

### Scheduler Information

This panel displays the following information about the scheduler:

#### **Name**

The name of the scheduler. Has no impact on operation.

#### **Host**

This refers to the host computer where the Resource Manager is running.

#### **Port**

The specific port that the scheduler is operating on.

#### **Mode**

The operating mode of the scheduler. Mode options are shown in this table:

Mode	Description
<b>NORMAL (default)</b>	Normal operation, controls the Resource Manager as configured
<b>MONITOR</b>	MONITOR mode behaves identical to NORMAL mode except the ability to start, cancel, or modify jobs is disabled. This allows safe diagnosis of the scheduling state and behavior using the various diagnostic client commands.
<b>INTERACTIVE</b>	Like NORMAL mode, except Moab sends the desired change request to the screen and asks for permission to complete it.

#### **Status**

Indicates whether the scheduler is running, down, or paused.

### Node Summary

This panel displays a high-level view of the state of the nodes found within the cluster. Click on any label to obtain a detailed list of nodes in the given category. Category descriptions:

#### **Busy Nodes**

Busy nodes include all nodes which are actively executing batch jobs. A node will be listed as busy even if it is only partially loaded with jobs.

#### **Idle Nodes**

Idle nodes include all nodes which are available but are currently not running any jobs.

#### **Down Nodes**

Down nodes include all nodes which have reported major software, hardware, or batch failures or have been marked 'down' or 'offline' by an administrator.

#### **Total Nodes**

The total nodes category includes all nodes in the cluster and is a sum of the busy, idle, and down nodes listed above.

### Job Summary

This panel displays a high-level view of the state of the jobs found within the cluster. Click on any label to obtain a detailed list of jobs in the given category. Category Descriptions:

#### **Running Jobs**

Running jobs include all jobs which are actively executing or performing post-execution clean-up. This includes jobs in the states starting, running, or exiting.

#### **Eligible Jobs**

Eligible jobs include all jobs which are in state idle and are not blocked by holds, usage limits, or other policies. Eligible jobs typically will run as soon as resources become available and may already have a reservation in place.

#### **Blocked Jobs**

Blocked jobs include all jobs which cannot run due to reasons other than resource availability. Jobs may be blocked by job holds, resource manager level policies, scheduler job usage policies, job deadline constraints, or other factors. Clicking on the label will bring up the detailed blocked job list which will include additional information in the blocked reason column.

#### **Total Jobs**

The total jobs category includes all jobs in the cluster and is a sum of the running, eligible, and blocked jobs listed above.

### User Information

This panel displays the user information of whoever started the Moab Cluster Manager.

#### **User**

The name of the user running Moab Cluster Manager.

**Group**

The name of the user's group.

**Account**

Any accounts the user may belong to.

**Class**

Classes the user has access to.

**QoS**

Any QoS accounts the user may belong to.

[User Job Summary](#)

Displays information concerning jobs run by the current user.

**Running Jobs**

Jobs run by the current user.

**Eligible Jobs**

Users jobs that are waiting in the queue.

**Blocked Jobs**

Users jobs that have been blocked, either by policy or user.

**Total Jobs**

Total jobs from the user.

## System Utilization Bar

The System Utilization bar appears at the bottom of the screen. It displays historical system utilization as it pertains to utilized processors as captured by Moab profiling intervals. Also note that processors utilized are only measured once a job is finished.

# Workload

## Workload Overview

The workload category of features deals with the submitting and viewing of jobs, reservations, and triggers. These functions are used to get work done by the system.

# Jobs

## Create Job

A cluster runs programs. A job tells a cluster when, where, and how to run the programs. The **Submit Job** window, often referred to as a job submission window, is how a user creates a job.

You can choose between a basic options view, which displays the options described in the [Basic](#) table below, and an advanced options view, which displays the options described in all the tables below. To switch views, click **View** in the main menu bar and check or uncheck the **Show Advanced Options** checkbox.

### Job Creation

#### [Basic](#)

##### Template

If there are job templates that are selectable, the user can do so here. Any attributes associated with the job templates will be mapped onto the submitted job.

##### Script File

This field allows an administrator to search for a script to run.

##### Nodes

This allows an administrator to select where the job will run from the following options:

Option	Description
<b>Number of Nodes</b>	A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node. If this field is set to 0, Workload Manager assigns the job to 1 node unless the <b>Node List</b> field is populated.
<b>Node List</b>	A node is a computer consisting of 1 or more processors. This field allows the user to define which nodes a job requires to execute. If a node list is not specified the nodes needed for the job are gathered from the nodes field.
<b>VM List</b>	The specific virtual machines the job will use.

#### [Job Information](#)

##### Job Name

A user can attach a custom name to a job to assist him/her in identifying the job. The name is provided only for the user's convenience and does not affect any policies or settings.

**User Job Priority**

The higher a job's priority, the sooner it will start. By changing this field, a user can reduce the job's priority and change the order in which the job starts. This field is usually utilized to execute a user's jobs in a specific order. This field only supports negative numbers with the exception of 0. A 0 User Job Priority will not delay the job from starting. However, the higher a negative number, the lower a job's priority. For example, a job with a User Job Priority of -100 will allow more jobs to start before it starts, thus postponing the job from starting.

Resources**Processors per Node**

All jobs require at least 1 processor. If this field is not used, the processors are calculated using the available processors on a node. If a processor and a node are not requested, Workload Manager assigns 1 node to the job.

**Memory per Node**

Some jobs require a specific amount of memory. This field allows a job to request the memory it needs for each node. It should be noted that this field is not the total memory across the entire cluster but only the memory on each node needed by the job. Workload Manager will start this job only on the nodes that have sufficient memory. If this field is not used, Workload Manager will start the job on any available node.

**Swap per Node**

Some jobs require a specific amount of swap. This field allows a job to request the swap it needs for each node. It should be noted that this field is not the total swap across the entire cluster, but the swap on each node needed by the job. Workload Manager will start this job only on the nodes that have sufficient swap. If this field is not used, Workload Manager will start the job on any available node.

**Operating System**

If an operating system is selected, Moab will try to run the job on any nodes with the specified operating system.

**Architecture**

If an architecture is selected, Moab will try to run the job on any nodes with the specified architecture.

**Required Node Features**

Some jobs require a specific feature on a node. A feature is a custom tag attached to a specific list of nodes. Consult your system administrator for specific information regarding each tag.

**Partition**

Clusters are often divided into different sections. These sections are commonly called partitions. Users can only request one specific partition for their job. Consult your system administrator to learn which partition is the best suited for your job.

**Reservation**

If a reservation is specified, the job will execute only on the nodes of the selected reservation.

## Generic Resources

### **Type**

The name of the preconfigured generic resource that you want to request for this job.

### **Quantity**

The number of this type of generic resource that you want to request for this job.

## Data Management

### **Execution Directory**

Some jobs need to be executed in a specific location on each node. This field allows a user the ability to define that location. By default, the job is executed in the user's home directory. Consult your system administrator for information regarding your home directory.

### **Output File**

This field gives the user the ability to customize the location of where the standard output stream will be written. The standard output stream of the job will be placed in a directory relative to the execution directory, as shown in the following example:

```
> test12/stdout.txt
```

### **Error File**

This field gives the user the ability to customize the location of where the standard error stream will be written. The standard error stream of the job will be placed in a directory relative to the execution directory, as shown in the following example:

```
> test12/stderr.txt  
> test12/stderr.txt
```

## Credential Information

### **User**

This field defines the name of the user under whom the job will execute. Only users with Admin1 rights can change this field. See [User Access](#) for more information.

### **Group**

This field defines the name of the group under which the job will execute. Only the groups available to the user are displayed.

### **Account**

This field defines the name of the account under which the job will execute. Only the accounts available to the user are displayed.

### **Class**

This field defines the name of the class under which this job will execute. Only the classes available to the user are displayed.

**Quality of Service (QoS)**

This field defines the name of the quality of service (QoS) under which this job will execute. Only the QoSs available to the user are displayed.

Job Dependencies

**Job Dependencies**

This field allows an administrator to specify which other jobs this job is dependent on. The dependency types are as follows:

Dependency Type	Description
<b>After</b>	The job starts any time after specified jobs start executing.
<b>Afterok</b>	The job may start any time after all specified jobs have completed successfully.
<b>Afternotok</b>	The job may start any time after all specified jobs have completed unsuccessfully.
<b>Afterany</b>	The job may start at any time after all specified jobs have completed regardless of status.

Flags/Options

**Preemptible**

A job that is preemptible can be suspended or re-queued by higher priority jobs.

**Restartable**

If a job experiences a failure during execution, the user must resubmit the job to Workload Manager. However, a job that is restartable is automatically restarted by Workload Manager in the event of a failure.

**Preemptor**

The job may preempt other jobs which have the *PREEMPTEE* flag.

**Hold**

A hold can only be placed upon jobs that have not yet executed. A hold stops or halts a job from running until the user or an administrator releases the hold.

Time Frame

**Start Time**

Some jobs require a specific amount of time before they are allowed to start. This field allows the user the ability to define the earliest time that the job can begin. By default, a job may start as soon as resources become available.

### Estimated Start Time Calculator

This button displays Moab's text-based output that determines when a job can start.

### Estimated Start Time Table

This button displays a table of the estimated start times for jobs of different processor sizes.

### [Email Notification](#)

#### On Job Completion

When a job finishes execution an email notification will be sent to the user stating this.

#### On Job Execution

When a job begins execution an email notification will be sent to the user stating this.

#### On Job Failure

When a job cannot start or crashes during execution an email notification will be sent to the user stating this.

 User email addresses may be specified in the [Create/Manage Users](#) page.

## Modify a Job

### Summary

A cluster runs programs. A job tells a cluster when, where, and how to run the programs. The Modify Job window allows a user to modify an existing job. The fields that can be modified are user job priority, system priority, and duration. If multiple jobs are selected, then QoS can also be modified.

### [Overview](#)

#### ID

This field displays the unique ID given to the job by Workload Manager.

#### Name

Users can attach a custom name to the job to allow them to easily identify their jobs. The name does not change any Workload Manager settings or prioritizations. If a name has been attached, it will appear in this field.

#### State

This field displays the execution status of the job. For example, running, stopped, executing, idle, blocked, etc.

### [Credentials](#)

#### User

This field displays the user ID under which the job executes.

**Group**

This field displays the group ID under which the job executes.

**Account**

This field displays the account ID used by the job.

**Class**

This field displays the class/queue ID used by the job.

**Quality of Service (QoS)**

This field displays the quality of service (QoS) ID used by the job.

[Resources](#)**Allocated Node List**

A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node. The node list is a list of the nodes that the job is using.

**Allocated Partition**

A partition is a logical construct that divides available resources. Any single resource (compute node) may only belong to a single partition. This field displays the name of the partition to which the job is assigned.

**Processor per Task**

A task is a group of resources that must all be on the same node. One resource in that group is a processor. This field displays the number of processors in each task that the user's job requires.

**Required Minimum Nodes**

A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node. Some jobs are large and require a larger number of nodes to run. This field displays the minimum number of nodes the job requires to run.

**Required Minimum Tasks**

A task is a group of resources that must all be on the same node. This field displays the minimum number of tasks, or groups of resources, the user's job requires on each node.

**Tasks per Node**

A task is a group of resources that must all be on the same node. This field displays the number of tasks, or groups of resources, that the job requires on each node.

[Job Attributes](#)**PAL (Partition Access List)**

This field displays the partitions available for this user. Clusters can be divided into different sections commonly called partitions. Consult your system administrator to learn which partition is the best suited for your job.

### **Start Count**

This field displays the number of times the job has started. Multiple job starts could indicate job failure or rejection.

### **Start Priority**

This field displays the start priority for the job. With some exceptions, the higher a job's priority over other jobs, the sooner it will begin to execute.

### **User Job Priority**

With a few exceptions, a job with a high priority will begin sooner depending on how much greater its priority is to that of other jobs. A user has the ability to reduce the job's priority and, in effect, delay the job's start time by changing this field. This option is usually utilized by users who desire their jobs to execute in a specific order. This field only supports negative numbers with the exception of 0. A 0 user job priority will not delay the job from starting. However, a job's priority will decrease as the priority number decreases. For example, a user job delay priority of -100 will allow more jobs to start before it than a job with a user job priority of -10. It should be noted that the user job priority literally lowers the start priority of a job.

### **System Priority**

With some exceptions, the higher a job's priority over other jobs, the sooner it will begin to execute. This field allows an administrator the ability to start jobs immediately. This field adds 1,000,000,000 and the administrator priority to the start priority of the job.

## Time Frame

### **Start Time**

This field displays the date and time that the job started or is scheduled to start.

### **Duration**

This field displays the job's estimated execution time. If a job requires more time than the specified duration, duration violation policies come into effect. Consult your system administrator for more information regarding these policies. If no duration is specified, a default walltime is applied. Consult your system administrator for more information regarding your cluster's default walltime.

### **Completed Duration**

This field displays the amount of time the job has been running, or the time that has passed between the **Start Time** and now.

### **Queue Time**

This field displays the amount of time the job has been waiting to start.

## Generic Resources

### **Type**

The name of the preconfigured generic resource that you want to request for this job.

### **Quantity**

The number of this type of generic resource that you want to request for this job.

## List Jobs/Job Templates

You can change the set of columns MCM displays in the Jobs table by clicking **View > Change Column Group** in the main menu bar and selecting one of the following options.

Option	Columns Displayed
<b>Summary</b>	Job ID, Job Name, State, User, Start Time, Used Wallclock, Wall Clock, Allotted Nodes, Required Nodes
<b>Credentials</b>	Job ID, Queue Status, State, User, Group, Class, Account, QoS
<b>Time</b>	Job ID, State, Start Time, Used Wallclock, Completion Time, Submission Time, System Start Time, Wall Clock, Earliest Start Time, Latest Completion Time
<b>Node Information</b>	Job ID, State, Allocated Node List, Master Node, Node List
<b>IDs</b>	Job ID, State, Global Job ID, System ID
<b>Required Resources</b>	Job ID, State, Allocated Node List, Partition, Allocated Nodes, Required Procs, Req. Node Memory
<b>Utilized Resources</b>	Job ID, State, Mem. Seconds Utilized, Proc Seconds Dedicated, ProcSeconds Utilized
<b>Reservation</b>	Job ID, State, Reservation
<b>Script</b>	Job ID, State, Script File, Arguments, Initial Working Directory, Variables
<b>Priority</b>	Job ID, State, Run Priority, System Priority, User Job Priority, Start Priority
<b>Diagnostic</b>	Job ID, State, Suspend Duration, Execution Eligibility Time, Hold, Block Reason, Expected State, Bypass
<b>Comments</b>	Job ID, State, Messages

## List Job Fields

When you click **View > Visible Columns...** in the main menu bar, you can manually add or remove individual columns in your **Jobs** table. The following table describes each column:

Field	Field Information
<b>Account</b>	This field displays the account ID used by the job.
<b>Allocated Node List</b>	A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node. The allocated node list is a list of the nodes that the job is using.
<b>Allocated Nodes</b>	This field displays the number of nodes allocated to the job.
<b>Arguments</b>	Some programs provide users with options. This field allows the user the ability to view those options. A user should consult the program documentation to learn about the available options.
<b>Block Reason</b>	This field displays diagnostic messages related to the job.
<b>Bypass</b>	This field displays the number of times another job of a lower priority started before this job.
<b>Class</b>	This field displays the class id used by the job.
<b>Completion Time</b>	This field displays the date and time the job finished execution.
<b>Earliest Start Time</b>	This field displays the user-specified date and time the job is available to start. Workload Manager will not start the job until after this specified date and time.
<b>Execution Eligibility Time</b>	This field displays the time the job was eligible for execution. The format is <code>hours:minutes:seconds</code> .
<b>Expected State</b>	This field displays the estimated execution status of the job. For example, running, stopped, executing, idle, blocked, etc.
<b>Flags</b>	Cluster Manager schedules jobs differently according to their flags. Possible flags are hold, interactive, restartable, and preemptible. Refer to the <a href="#">create job documentation</a> for definitions of the flags.
<b>Generic Attributes</b>	This field displays a custom attribute attached to the job.
<b>Global Job ID</b>	The global job ID is used when multiple resource managers are being used.

Field	Field Information
<b>Group</b>	This field displays the group id under which the job executes.
<b>Hold</b>	This field displays whether the job has a hold. A hold can only be placed on jobs that have not started. A hold stops or halts a job from running until the user or an administrator releases the hold.
<b>Initial Working Directory</b>	Some jobs must execute in a specific location on each node. This field allows a user the ability to define that location. By default, the job is executed in the user's home directory. Consult your system administrator for information regarding your home directory.
<b>Is Template Selectable?</b>	This field displays whether the job was created from a selectable template.
<b>Is Template?</b>	This field displays whether the job was created from a template.
<b>Job ID</b>	This field displays the job's unique ID given by Workload Manager.
<b>Job Name</b>	A user can attach a custom name to the job to allow him/her to easily identify their job. The name does not change any Workload Manager settings or prioritizations. If a name has been attached it will appear in this field.
<b>Latest Completion Time</b>	This field displays the date and time the job must finish execution.
<b>Master Node</b>	In a cluster, one specific node is in charge of communication with all the other nodes on the cluster. This node is often referred to as the master node or the head node. This field will display the name of the master node.
<b>Mem. Seconds Utilized</b>	Memory seconds utilized is defined as the total amount of memory used by the job times the number of seconds the memory was used. The value is calculated as a sum total of all the memory on the cluster and not on a per node basis.
<b>Messages</b>	This field allows the user to add a comment to the job.
<b>Node Features</b>	This field displays whether the job prefers a node with a specified feature.
<b>Node List</b>	This field displays the list of nodes that the job requires to execute.

Field	Field Information
<b>Partition</b>	Clusters are often divided into different sections. These sections are commonly called partitions. Users can only request one specific partition for the job. Consult your system administrator to learn which partition is the best suited for your job.
<b>Proc Seconds Dedicated</b>	Processor seconds dedicated is the total number of processors reserved by Workload Manager for the job times the amount of time, in seconds, that the processors were reserved. The value is calculated as a sum total of all the processors on the cluster and not on a per node basis.
<b>Proc Seconds Utilized</b>	Processor seconds utilized is the total number of processors used by the job times the number of seconds the processors were reserved. The value is calculated as a sum total of all the processors on the cluster and not on a per node basis.
<b>QoS (Quality of Service)</b>	This field will display the quality of service (QoS) id used by the job.
<b>QoS (Quality of Service) Required</b>	This field displays the required QoS for this job.
<b>Queue Status</b>	This field displays the job's status in the job queue. It indicates whether the job is currently Active, Eligible, Blocked, etc.
<b>Req. Access</b>	This field displays the required access for the job.
<b>Req. Allocated Node List</b>	A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node. The allocated node list is a list of the nodes that the job is using.
<b>Req. Allocated Partition</b>	Clusters are often divided into different sections. These sections are called partitions. Users can only request one specific partition for each job. Consult your system administrator to learn which partition is the best suited for your job.
<b>Req. Architecture</b>	Some jobs require a specific node architecture. This field allows a user to view the architecture required by this job.
<b>Req. Class</b>	This field displays the required class for this job.
<b>Req. Disk per Task</b>	A task is a group of resources that must all be on the same node. One resource in that group is disk space. This field displays the amount of disk in each task that the job requires.

Field	Field Information
<b>Req. Memory Per Task</b>	A task is a group of resources that must all be on the same node. One resource in that group is memory. This field displays the amount of memory in each task that the job requires.
<b>Req. Min Nodes</b>	A node is a computer consisting of 1 or more processors. This field displays the minimum number of nodes required for the job to execute.
<b>Req. Network</b>	This field displays the network required by this job.
<b>Req. Node Disk</b>	This field displays the required amount of disk space the job needs on each node. This field is not the total disk across the entire cluster but only the disk space on each node.
<b>Req. Node Memory</b>	This field displays the requested amount of memory it needs for each node. This field is not the total memory across the entire cluster but only the memory on each node.
<b>Req. Node Proc</b>	This field displays the processors required by this job.
<b>Req. Node Swap</b>	This field displays the required swap space the job needs for each node. It should be noted that this field is not the total swap across the entire cluster but only the swap on each node.
<b>Req. OS</b>	This field allows a user to view the operating system required by this job.
<b>Req. Partition</b>	Clusters are often divided into different sections. These sections are called partitions. Users can only request one specific partition for each job. Consult your system administrator to learn which partition is the best suited for your job.
<b>Req. Proc Per Task</b>	A task is a group of resources that must all be on the same node. One resource in that group is a processor. This field displays the number of processors in each task that the job requires.
<b>Req. Set</b>	This field displays the groupings of nodes this job requires.
<b>Required Swap Per Task</b>	A task is a group of resources that must all be on the same node. One resource in that group is swap space. This field displays the amount of swap in each task that the job requires.
<b>Req. Tasks Per Nodes</b>	A task is a group of resources that must all be on the same node. This field displays the number of tasks that the job requires on each node.

Field	Field Information
<b>Required Memory</b>	This field allows a job to request the memory it needs for each node. This field is not the total memory across the entire cluster but only the memory on each node needed by the job. Workload Manager will start this job only on the nodes that have sufficient memory.
<b>Required Nodes</b>	A node is a computer consisting of 1 or more processors. A job requires at least 1 processor to execute and therefore must use at least 1 node.
<b>Required Procs</b>	This field displays the number of processors used by this job.
<b>Reservation</b>	A user can specify a reservation for this job. If a reservation is specified the job will execute only on that reservation's nodes.
<b>Run Priority</b>	This field is used by jobs that are preemptible to decide which job should be preempted. With a few exceptions, the higher a job's priority, the more likely it will be preempted.
<b>SLA (Service-Level Agreement) Violation</b>	This field indicates the job service-level agreement violation, if any exist.
<b>Script File</b>	This field displays which script file the job executes.
<b>Start Count</b>	This field displays the number of times the job has attempted to start executing.
<b>Start Priority</b>	This field displays the start priority of the job. With a few exceptions, a job with a high priority will begin sooner depending on how much greater its priority is to other jobs.
<b>Start Time</b>	This field displays the date and time the job started.
<b>State</b>	This field displays the execution status of the job. For example, running, stopped, executing, idle, blocked, etc.
<b>Submission Time</b>	This field displays the time the job was first created. The format is hours:minutes:seconds. If the exact date is desired moving the mouse over the value will display the exact date of the submission time.
<b>Suspend Duration</b>	This field displays the time the job was in a suspended state. The format is hours:minutes:seconds.
<b>System ID</b>	The system job ID is used when multiple resource managers are being used.

Field	Field Information
<b>System Priority</b>	With a few exceptions, a job with a high priority will begin sooner depending on how much greater its priority is to other jobs. This field allows an administrator the ability to start jobs immediately. This field adds 1,000,000,000 and the administrator priority to the job's priority.
<b>System Start Time</b>	This field displays the time when the job started.
<b>Used Wallclock</b>	This field displays the actual execution time of the job. The format is hours:minutes:seconds. The white space indicates the remaining time left before the job reaches its requested Wallclock time. The colored section indicates the amount of Wallclock that has been used. A red bar indicates that the job has violated its Wallclock limit. Refer to the Wallclock field for the job Wallclock.
<b>User</b>	This field will display the user id under which the job is executing.
<b>User Job Priority</b>	With a few exceptions, a job with a high priority will begin sooner depending on how much greater its priority is to other jobs. A user has the ability to reduce the job's priority and, in effect, delay its start time by changing this field. This option is usually utilized by users who desire their jobs to execute in a specific order. This field only supports negative numbers with the exception of 0. A 0 user job priority will not delay the job from starting. However, a job's priority will decrease as the priority number decreases. For example, a user job delay priority of -100 will allow more jobs to start before it starts than a user job priority of -10.
<b>Variables</b>	This field displays the variable(s) that are set on the job.
<b>Wallclock</b>	This field displays the estimated amount of time that the job will execute. If a job requires more time than the specified duration, duration violation policies come into effect. Consult your system administrator for more information regarding these policies. If no duration is specified, a default walltime is applied. Consult your system administrator for more information regarding your cluster's default wall time.

## Job Timeline

The Job Timeline window displays each executing job in a diagram. On the left side of the Now line is the amount of a job that has completed. The right side is the remaining execution time.

## Job Outlines

Job outlines are settings saved from the create/submit job window. This window, accessed through the Submit Job page by clicking **Actions > Open Job Outline** or **Actions > Save Job Outline** in the main menu bar, allows job outlines to be saved or opened either locally on the machine that Moab Cluster Manager is running on, or remotely on the machine that Moab Workload Manager is running on.

## Outline Information

This section displays information of the currently loaded job outline.

### Outline Name

This field allows a user to change the saved file name of the outline.

### Job Name

This field displays the custom name for the job outline.

### Script Name

This field displays the script that is used in the outline.

## Outline Window

- Local Job Outlines — Outlines found on the machine running Moab Cluster Manager.
- Outline Directories — Directories where outlines can be found.

### Outline Operations

#### Open

This button retrieves the selected outline information and places it in the outline information fields.

#### Save

This button saves the selected outline.

## Job Workflows

A job workflow is a visual representation of the dependency relationships between jobs. The workflow shows which jobs depend on others. Since a job can depend on any number of jobs and vice versa, the workflow can show the whole dependency relationship for any given job.

To view a job workflow, select a job from the input options at the bottom of the page. The system then determines all jobs that depend or are dependent on this target job. The results are displayed graphically in a timeline window of the main page. Jobs are placed on the graph according to their start and end times.

On the graph, time spans from left (earliest time) to right (latest time). The time window is dependent on the workflow, as the earliest time shown is the earliest job's start time and the end time is its latest job's end time. If the current time is included in the time window, a vertical bar on the graph displays the current time. Keep in mind however that some workflows are entirely in the future and others are only in the past, in which case no vertical bar will be shown.

A dependency is represented as an arrow on the graph. Jobs that are dependent on others will have an arrow pointing to it representing the expected flow of the jobs, or in other words the order in which the jobs will run. There are various dependency types and therefore various job states that must be represented. Double clicking on any job will bring up more details about the job in the modify job window.

# Reservations

## Create Reservation

### Summary

A reservation sets apart resources during a particular time frame for a particular owner. Reservations usually reserve resources such as nodes or processors on the cluster. The Create Reservation window allows you to define what resources a reservation requires, as well as the time frame for the reservation.

In addition to being able to create a basic reservation, this window also allows you to create a recurring reservation. A recurring reservation, also referred to as a standing reservation or a reservation generator/creator, provides the user with the option of having reservations automatically created according to a desired time frame. For example, if a user wants to create a reservation every Tuesday and Thursday starting at 11 am and ending at 4 pm, a recurring reservation would fulfill this need. It should be noted that a recurring reservation could potentially not be able to create a reservation if the resources are already dedicated to another reservation or job. To reduce the possibility of this occurring, the day/week depth field can be increased so Workload Manager will create the reservations further in advance.

### *Panels Containing Required Parameters*

#### Reservation Information

This panel allows the user to specify the reservation name and owner.

#### **Reservation Name**

This field allows a user to create a name for the reservation. Workload Manager appends a numerical value to the end of the reservation name which allows users the ability to enter duplicate reservation names without affecting a previous reservation.

#### **Owner**

An owner is a user, group, account, class, or quality of service. A reservation can reserve only the resources that the owner can access. This field allows a user to select the owner of the reservation.

#### Access Control List

This panel allows the user to specify what credentials have permission to access the reservation. At least one credential is required to be in the Access Control List for a reservation, otherwise it would not be very useful. The user may select from 5 different types of credentials - users, groups, accounts, classes, and quality-of-services. Any of the credentials in the Access Control List have permission to use the reservation.

#### **Add**

Pops up a window that allows the user to select credentials of a specific type to add to the Access Control List

**Clear**

Removes all credentials from the Access Control List

Resources

Allows the user to specify what resources will be.

**Host List/Host Expression**

Users often require specific nodes for their applications. A list of nodes required by the user is called a host list. If a host list is not specified, the task count must be specified.

**Task Count**

A task is a group of resources that must all be on the same node. This field defines how many groups of resources will be required to create this reservation. If the task count is not specified the host list must be specified.

**Define Tasks**

A task is a group of resources that must all be on the same node. This button displays a window allowing a user to define what those resources will be in a task.

Field	Description
<b>Memory Per Task</b>	This field provides the user with the option of requesting the amount of memory, in megabytes, a job needs on a node.
<b>Swap Per Task</b>	This field provides the user with the option of requesting the amount of swap, in megabytes, a job needs on a node.
<b>Disk Per Task</b>	This field provides the user with the option of requesting the amount of disk space, in megabytes, a job needs on a node.
<b>Procs Per Task</b>	This field provides the user with the option of requesting the number of processors a job needs on a node.

Reservation Time Frame Tabs:

**Once**

Basic reservation will be created for the desired start and end time.

Field	Description
<b>Start Time</b>	This field allows the user to select the day and time when the reservation begins.
<b>End Time</b>	This field allows the user to select the day and time when the reservation ends.

**Daily**

A recurring reservation is initialized to automatically create a reservation on the desired days at the desired start and end time. The recurring reservation continually generates new reservations. The **day depth** is used to decide when a reservation is created. For example, if a reservation starts 4 days from now and the **day depth** is set to 2 days the reservation will not be created for 2 more days.

Field	Description
<b>Days</b>	This field allows the user to select the days of the week a reservation is created.
<b>Start Time</b>	This field allows the user to select the time of day the reservation begins.
<b>End Time</b>	This field allows the user to select the time of day the reservation ends.
<b>Day Depth</b>	This field allows the user to specify how many days in advance Workload Manager should create recurring reservations.

**Weekly**

A recurring reservation will be initialized to automatically create a reservation for the week starting from the desired start day and ending on the desired end day of the week. The recurring reservation continually generates new reservations. The **week depth** is used to decide when a reservation is created. For example, if a reservation starts 4 weeks from now and the **week depth** is set to 2 weeks the reservation will not be created for 2 more weeks.

Field	Description
<b>Start Day</b>	This field allows the user to select the day and time in the week the reservation begins.
<b>End Day</b>	This field allows the user to select the day and time in the week the reservation ends.
<b>Week Depth</b>	This field allows the user to specify how many weeks in advance Workload Manager should create recurring reservations.

**Infinite Reservation**

A reservation will be created that will continue indefinitely. No start or end time is required.

## Advanced Options

### [Event Triggers](#)

#### Create Trigger 1-6

These fields allow the user the ability to attach triggers to a reservation.

#### Grid Sandboxing

Field	Description
<b>Allow grid sandboxing</b>	By default, this allows only the resources in the recurring reservation to be visible to grid peers.
<b>Cluster List</b>	List of clusters that have access to the grid sandbox.

#### Misc. Options

Field	Description
<b>Partition</b>	Clusters can be divided into different sections. These sections are called partitions. Users can only request one specific partition for each reservation. Consult with your system administrator to learn which partition is best suited for your reservation.
<b>Node Features</b>	Some jobs require a specific feature on a node. A node feature is a custom tag attached to a specific list of nodes. Consult your system administrator for specific information regarding each tag.

## Modify Reservation

### Summary

A reservation is a time frame on the cluster reserved for a particular need. Reservations usually reserve resources such as nodes or processors on the cluster. The Modify Reservation window allows you to view and modify existing reservations.

### [Basic Information](#)

#### Name

This field allows a user to create a name for the reservation. Workload Manager appends a numerical value to the end of the reservation name allowing users the ability to enter duplicate reservation names without affecting any other reservation.

### **Owner**

An owner is a user, group, account, class, or quality of service. A reservation can reserve only the resources that the owner has access to. This field displays the owner of the reservation. If the reservation is a job reservation, this field will be blank.

### **Type**

This field displays whether a reservation is a user or job reservation.

### **Sub Type**

This is the type of reservation. Some examples of the available types are grid, standing reservation, user, maintenance, etc.

### **ACL**

This field displays who is allowed to access resources on the reservation.

### **Statistics**

This field displays the percentage of processors seconds reserved by the reservation that were used by a job or multiple jobs.

## Accounting Credentials

### **User**

This field displays the user ID used by the reservation. If this field is empty no user can directly access this reservation.

### **Group**

This field displays the group ID used by the reservation. If this field is empty no group can directly access this reservation.

### **Account**

This field displays the account ID used by the reservation. If this field is empty no account can directly access this reservation.

### **Class**

This field displays the class ID used by the reservation. If this field is empty no class can directly access this reservation.

### **Quality of Service (QoS)**

This field displays the quality of service (QoS) ID used by the reservation. If this field is empty no quality of service can directly access this reservation.

## Cluster Information

### **Flags**

Cluster Manager schedules reservations differently according to their flags. This field displays the reservation flags.

**Node Expression**

This field displays a list of nodes required by the job to execute. The list of nodes is a regular expression. A node is a computer consisting of 1 or more processors.

**Partition**

This field displays the partition on which the reservation will be configured.

**Required Node Count**

This field displays the number of nodes required by the reservation. A node is a computer consisting of 1 or more processors.

**Required Node List**

This field displays a list of nodes required by the reservation. A node is a computer consisting of 1 or more processors.

**Required Task Count**

This field displays the number of processors required by the reservation.

**Resources**

This field displays what type of resource is reserved by the reservation.

Time Frame**Start Time**

Some jobs require a specific amount of time before they are allowed to start. This field allows the user to define the earliest time the job can start. By default, a job may start as soon as resources become available.

**End Time**

This field displays the time at which the reservation will finish.

**Duration**

The duration is the job's estimated execution time. If a job requires more time than the specified duration, duration violation policies come into effect. Consult your system administrator for more information regarding these policies. If no duration is specified, a default walltime is applied. Consult your system administrator for more information regarding your cluster's default walltime.

Node List**Nodes**

Each button displayed represents a node that the reservation has reserved. When the button is selected, the Modify Node window will appear containing information about the node.

## List Reservations

### Summary

A reservation is a time frame on the cluster reserved for a particular needed. Reservations usually reserve resources such as nodes or processors on the cluster. Reservations are created either by a user or by a job. A reservation created by a user is called a user reservation while a reservation created by a job is called a job reservation. All executing jobs have reservations.

### List Reservation Fields

Field	Description
<b>ACL</b>	This field displays who is allowed to access resources on the reservation.
<b>Account</b>	This field displays which accounts can access this reservation. If this field is blank, no accounts have been given access to the reservation.
<b>Accounts in ACL</b>	This field displays which accounts can access resources on the reservation.
<b>Allocated Nodes</b>	A node is a computer consisting of 1 or more processors. The allocated node list is a list of the nodes that the reservation is using.
<b>Architecture</b>	This field displays the hardware architecture of the reservation. The exact hardware information displayed will depend upon the information the resource manager supplies to Workload Manager.
<b>Class</b>	This field displays which classes can access this reservation. If this field is blank, no classes have been given access to the reservation.
<b>Classes in ACL</b>	This field displays which classes are allowed to access resources on the reservation.
<b>Duration</b>	The duration is the job's estimated execution time. The format used is <code>days:hours:minutes:seconds</code> .
<b>End Time</b>	If the reservation will end in less than 12 hours, the value is displayed in the format of <code>hours:minutes:seconds</code> , where a negative value indicates that the reservation ended that many <code>hours:minutes:seconds</code> ago. A positive value indicates that the reservation will end in that many <code>hours:minutes:seconds</code> . Resting the mouse over the value displays the exact date that the reservation ended or will end. An end time that is years in the future often indicates that the reservation was created without any end time specified and Workload Manager inserted a default end time.

Field	Description
<b>Flags</b>	Cluster Manager schedules reservations differently according to their flags. This field displays the reservation flags.
<b>Global ID</b>	This field only displays information when multiple resource managers are present.
<b>Group</b>	This field displays which groups can access the reservation. If this field is blank, no groups have been given access to the reservation.
<b>Groups in ACL</b>	This field displays which groups can access resources on the reservation.
<b>Max Tasks</b>	This field displays the maximum number of processors a reservation can use.
<b>Memory</b>	This field displays how much memory the reservation requires per task.
<b>Messages</b>	This field allows users the option of adding a message or comment to a reservation.
<b>Name</b>	This field allows users to create a name for the reservation. Workload Manager appends a numerical value to the end of the Reservation ID allowing users the ability to enter duplicate Reservation IDs without affecting any other reservation.
<b>Node Expression</b>	A node is a computer consisting of 1 or more processors. This field displays a list of nodes required by the job to execute. The list of nodes is a regular expression.
<b>Node Set Policy</b>	This field displays the policy that the reservation will use to select the nodes.
<b>OS</b>	This field displays the operating systems the job requires.
<b>Owner</b>	This field displays the owner of the reservation. A reservation can reserve only the resources that the owner has access to. An <i>owner</i> is a user, group, account, class, or quality of service.
<b>Partition</b>	Clusters can be divided into different sections. These sections are called partitions. Users can only request one specific partition for each reservation. Consult your system administrator to learn which partition is the best suited for your reservation.
<b>QoS</b>	This field displays which quality of service (QoS) will be able to access this reservation. If this field is blank, no qualities of service (QoS) have been given access to the reservation.
<b>QoS in ACL</b>	This field displays which qualities of service can access resources on the reservation.

Field	Description
<b>Req. Feature List</b>	A feature is a custom attribute attached to a node. This field displays the node features required for a node to be used for the reservation.
<b>Req. Feature Policy</b>	This field displays the policy that the reservation will use to select the features.
<b>Req. Node Count</b>	A node is a computer consisting of 1 or more processors. This field displays the number of nodes required by the reservation.
<b>Req. Node List</b>	A node is a computer consisting of 1 or more processors. This field displays a list of nodes required by the reservation.
<b>Req. Task Count</b>	This field displays the number of processors required by the reservation.
<b>Resources</b>	This field displays what type of resource is reserved by the reservation.
<b>Spec Name</b>	This field displays information for multiple resource managers.
<b>Start Time</b>	If the reservation will start in less than 12 hours, the value is displayed in the format of hours:minutes:seconds, where a negative value indicates that the reservation will start in that many hours:minutes:seconds. A positive value indicates that the reservation started that many hours:minutes:seconds ago. Resting the mouse over the value will display the exact date that the reservation started or will start. The colored bar shows the percentage of the reservation that has completed. The white space indicates the remaining reservation time.
<b>Statistics</b>	This field displays statistical information relating to the reservation.
<b>Sub Type</b>	This displays the type of reservation. Some examples of the available types are grid, standing reservation, user, maintenance, etc.
<b>Task Count</b>	A task is a group of resources that must all be on the same node. This field displays how many groups of resources will be required to create this reservation.
<b>Timeline</b>	This displays the reservation time lines. The green bar indicates the used amount of the reservation while the blue bar indicates the remaining amount of the reservation. The display options on the left side allow a user change how much of the time line is displayed.
<b>Trigger</b>	This field displays information about any trigger that is attached to the reservation.
<b>Type</b>	This field displays whether a reservation is a user or job reservation.

Field	Description
<b>User</b>	This field displays which users can access this reservation. If this field is blank, no users have been given access to the reservation.
<b>Users in ACL</b>	This field displays which users can access resources on the reservation.

*List Jobs/Job Templates*

You can change the set of columns MCM displays in the Reservations table by clicking **View > Change Column Group** in the main menu bar and selecting one of the following options.

Column Group	Categories Displayed
<b>Summary</b>	Name, Type, ACL, Start Time, End Time, Duration
<b>Credentials</b>	Name, Users in ACL, Groups in ACL, Accounts in ACL, Classes in ACL, QoS in ACL
<b>Time</b>	Name, Type, Start Time, End Time, Duration
<b>Resources</b>	Name, Type, Partition, Resources
<b>Required Resources</b>	Name, Type, Req. Feature List, Req. Feature Policy, Req. Node Count, Req. Node List, Req. Task Count
<b>Flags</b>	Name, Type, Flags
<b>Nodes</b>	Name, Type, Allocated Nodes, Node Expression, Node Set Policy
<b>Statistics</b>	Name, Type, Statistics
<b>Comments</b>	Name, Type, Messages
<b>Tasks</b>	Name, Type, Max Tasks, Req. Task Count, Task Count
<b>Identification</b>	Name, Type, Global ID, Owner
<b>Trigger</b>	Name, Type, Trigger

## List Recurring Reservations

### Summary

A recurring reservation, also referred to as a standing reservation or a reservation generator, creates reservations according to user-defined settings. To choose which fields you would like to view in the chart, click **View > Visible Columns** in the main menu bar. To add fields, create a check mark by clicking in the box to the left of the field you would like to view. To remove fields, click on the checked box.

### List Recurring Reservations

Field	Description
<b>Account</b>	This field displays which accounts can access the created reservation.
<b>Class</b>	This field displays which classes can access the created reservation.
<b>Days</b>	This field displays which days of the week the reservations will start. This field will only display information if the period is set to daily.
<b>Disabled</b>	This field displays whether a particular reservation generator setting has been disabled.
<b>Group</b>	This field displays which groups can access the created reservation.
<b>Host List</b>	The host list is a list of the nodes that the reservation is using. A node is a computer consisting of 1 or more processors.
<b>Name</b>	This field displays the reservation's name.
<b>Owner</b>	A reservation generator can reserve only the resources that the owner can access. This field displays the owner of the reservation generator. An <i>owner</i> is a user, group, account, class, or quality of service.
<b>Period</b>	This field displays the interval in which the reservations will be created. The display options are daily, weekly or infinitely.
<b>QoS</b>	This field displays which quality of service can access the created reservation.
<b>User</b>	This field displays which users can access the created reservation.

## Reservation Timeline

### Summary

The Reservation Timeline window displays each reservation. On the left side of the Now line is the amount of the reservation that has been used. The right side is the remaining amount of the reservation.

## Reservation Calendar

### Summary

The reservation calendar displays reservations color coded by Account. If a reservation does not have an Account, it is shown in gray. The height of a reservation indicates the number of processors it needs. Thus, tall reservations require more processors. Detailed information about the reservation can be seen upon mouseover. To modify a reservation, simply click on it and a reservation modification window will appear.

## Triggers

### List Triggers

#### Summary

Workload Manager can launch events or triggers based on certain events. For example, an administrator may want an email sent when the reservation usage falls below a certain percentage, or a user may want to launch an evaluation script 5 minutes before his or her job is scheduled for completion.

#### List Triggers

You can change the set of columns MCM displays in the Triggers table by clicking **View > Change Column Group** and selecting one of the following options.

Column Group	Columns Displayed
<b>Summary</b>	Trigger ID, Trigger State, Resource ID, Resource Type, Resource Event, Trigger Action, Offset, Threshold
<b>Executable</b>	Script, Flags
<b>Diagnostic</b>	Start Time, Messages, Output File, Error File

When you click **View > Visible Columns...**, you can manually add or remove individual columns in your **Triggers** table. The following table describes each column:

Field	Description
<b>Description</b>	This field displays the description of the trigger if one was written.
<b>Error File</b>	This field displays the location of the file containing all the trigger error messages.
<b>Est. Start Time</b>	This field displays the date and time the trigger will execute if it is possible to calculate it. For example, reservation end times and job completion times can be calculated. Node or scheduler failures cannot be calculated ahead of time.
<b>Flags</b>	This field displays which flags have been set for this trigger.
<b>Messages</b>	This field displays the status information indicating possible failures or unexpected conditions.
<b>Offset</b>	This field displays the number of seconds after a resource event occurs that the trigger will execute. If this value is negative, the trigger will execute that many seconds before the resource event occurs.
<b>Output File</b>	This field displays the location of the file containing all the trigger output messages.
<b>Resource Event</b>	This field displays the event that must occur for the trigger to execute. The possible events are when the resource is created, when the resource starts, when the resource ends, or when a failure occurs in the resource.
<b>Resource ID</b>	This field displays the ID of the job, reservation, or node to which the trigger is attached.
<b>Resource Type</b>	This field displays whether the trigger is attached to a job, reservation, node, or the scheduler.
<b>Script</b>	This field displays the script, application, program, or executable that will be executed when the trigger is starts.
<b>Start Time</b>	This field displays the date and time the trigger started. This field is only populated after the trigger has been executed.
<b>Threshold</b>	This field displays the reservation usage threshold for this trigger. If the reservation falls below the displayed usage, the trigger will execute.
<b>Trigger Action</b>	This field displays the type of trigger action that will occur when the trigger is executed. The possible trigger types are cancel the resource the trigger is attached to; email the administrator; or execute a script, application, program, or executable.

Field	Description
<b>Trigger ID</b>	This field displays the unique ID assigned to the trigger by Workload Manager.
<b>Trigger State</b>	This field displays the execution status of the trigger. If the state is Idle, the trigger is waiting to execute. If the state is Active, the trigger is executing. Once the trigger has executed, the state displayed will be Successful or Failure, depending on the outcome of the trigger action.

## Resources

### Resources Overview

The resources category gives administrators the ability to view, modify, and set policies and attributes while effectively diagnosing various system resources.

## Visual cluster

### Summary

The visual cluster is an easy and concise way of viewing your entire cluster and the status of each node. The table and explanation below explain how to interpret the visual cluster:

Table 4-2: Visual Cluster Example

	Slot 1	Slot 2	Slot 3
<b>Rack 1</b>	Node A		Node D
<b>Rack 2</b>		Node B	
<b>Rack 3</b>			Node C

A rack is a physical frame that holds a node. The slot is the location of the node inside the rack. The racks make up the first column of the table. The slot locations increase from left to right. For example, Node A is located on Rack 1 in Slot 1. Node D is also located on Rack 1 but instead of Slot 1 it's located in Slot 3. In the visual cluster Node A through Node D are displayed as icons. The different icons can represent node state, node attributes, reservations, jobs, and/or nodes. The subpanel sections below describe these states in more detail. Further information can be gathered about nodes by hovering the mouse over any nodes.

It should be noted that the visual cluster is for display purposes only and the location of the node does not play any part in how Workload Manager schedules.

## Node Attribute Selector

The node attribute selector gives the user the power to see various attributes of the nodes displayed in the Visual Cluster. This allows the user to compare and contrast attributes of interest. Node attributes include standard categories such as architecture, OS, hardware metrics (memory, disk, swap, etc.), as well as any metric read in through Moab as a generic metric (a node's GMETRIC). The default display for node attributes is the corresponding color of the outer rim of each node cell. This can be changed in the section titled "Node Display Preferences".

The Clear Attribute button clears any current selection and node attribute.

Once a node attribute is selected, Moab Cluster Manager determines the number of nodes and processors that describe each attribute and displays a corresponding key value that matches the Visual Cluster by color. Each attribute's display can be individually controlled via the check box next to each node attribute name and color.

If the node attribute is a numerical value - for example, a generic metric - then Moab Cluster Manager will attempt to place the values into a reasonable range as to effectively categorize the values.

## Nodes

### Modify Nodes

#### Node Information

##### **Node ID**

This field assigns the node profile to a desired node.

##### **Node State**

This field displays the operating status of the node. For example, unknown, draining, busy, running, down, idle, etc.

#### Node Usage Limits

##### **Max Jobs**

This field allows the user to specify the maximum number of simultaneous jobs allowed to run on this node.

##### **Jobs per User**

This field allows the user to specify the maximum number of simultaneous jobs per end user allowed to run on the node.

### **Max Load**

This field allows the user to specify the maximum percentage of load allowed to run on this node. Load is the number of jobs divided by the number of processors.

### General Attributes

#### **Priority**

This field allows a user to specify the fixed node priority relative to other nodes. The default node priority is 0.

#### **Speed**

This field allows a user to specify the speed as a relative value. A base node generally has a speed of 1.0, but may be changed based on memory, networking interface, etc. It does not have to be proportional to processor speeds.

#### **Processor Speed**

This field allows a user to specify the processor(s) speed on this node. This provides Workload Manager the information needed to schedule nodes with similar processor speeds.

#### **Load**

This field allows the user to specify the maximum percentage of load allowed to run on this node. Load is the number of jobs divided by the number of processors.

#### **Partition**

Clusters can be divided into different sections. These sections are called partitions. This field displays the partition to which the node is assigned.

#### **Rack**

This field allows a user to specify the rack number where the node is located.

#### **Slot**

This field allows a user to specify the slot number where the node is located.

#### **Features**

This field allows a user to specify features assigned to this node.

### Statistics

#### **Active Time**

This field displays the total time the node has actively been executing jobs.

#### **Up Time**

This field displays the total time the node has been available to execute jobs.

#### **Total Time**

This field displays the total time the node has been on the cluster.

## Node Software

### **OS**

The operating system the node uses.

### **OS List**

The list of possible operating systems the node may use.

## Node Attributes

### **Architecture**

This field displays the hardware architecture of the node. The exact hardware information displayed depends on the information the resource manager supplies to Workload Manager.

### **Available Classes**

This field displays classes that can use the node.

### **Node Priority Function**

If Moab is set up to use the **NODEALLOCATIONPOLICY** of *PRIORITY*, you will also see the Node Priority Function Editor panel. This editor allows you to modify the function that is used to assign the node its priority. This function corresponds to the **PRIORITYF** attribute in Moab's configuration.

A valid priority function consists of any number of function expressions. A function expression is a coefficient multiplied by an attribute. For example, one function expression could be 5 \* Available Memory. All the function expressions are summed up to get an effective priority value. This summation is then used to calculate the node's effective priority.

For more information about node allocation policies or the *PRIORITY* policy, see the [Moab documentation](#).

## Over Commit

### **Disk**

Allows overcommitting of the disk space of the node.

### **Memory**

Allows overcommitting of the memory of the node.

### **Processors**

Allows overcommitting of processors of the node.

### **Swap**

Allows overcommitting of the swap space of the node.

## Node Hardware

### **Free Disk Space**

This field displays the available disk space, measured in megabytes (MB), on the node.

**Free Memory**

This field displays the available memory, measured in megabytes (MB), on the node.

**Free Processors**

This field displays the number of available processors on the node.

[Job List](#)

Job List displays all the jobs scheduled on the node.

[Reservation List](#)

Reservation List displays all the reservations on the node.

**List Nodes**

You can change the set of columns MCM displays in the Nodes table by clicking **View > Change Column Group** in the main menu bar and selecting one of the following options.

Default Categories	Columns Displayed
<b>Available Resources</b>	Node ID, State, Available Disk, Available Memory, Available Proc, Available Swap
<b>Comments</b>	Node ID, State, Comments
<b>Configured Resources</b>	Node ID, State, Total Disk, Total Memory, Total Procs, Total Swap
<b>Description</b>	Node ID, State, Features, Rack, Slot, Network, Node Type, O.S., Proc Speed, Size, Speed
<b>Diagnostics</b>	Node ID, State, Load, Messages, Reservation Count, Block Reason, Power
<b>Generic Metrics</b>	Node ID, all configured GMetrics
<b>Maximum Jobs &amp; Procs</b>	Node ID, State, Max. Job, Max. Job Per User, Max. Proc, Max. Proc Per Class
<b>Summary</b>	Node ID, State, Class, Features, Job List, Messages, O.S. List, Total Procs
<b>Usage Limits</b>	Node ID, State, Max I/O In, Max I/O Out, Max. Job, Max. Job Per User, Max. Load, Max. PE Per Job, Max. Proc, Max. Proc Per Class

## List Node Fields

Field	Description
<b>Active Time</b>	This field displays the total time the node has spent doing work.
<b>Architecture</b>	This field displays the hardware architecture of the node. The exact hardware information displayed will depend upon the information the resource manager supplies to Workload Manager.
<b>Available Class</b>	This field displays the classes that can access the node.
<b>Available Consumable Resources</b>	This field displays the restricted resources and the current number available for the node. Some clusters have restrictions placed upon certain nodes. Usually these restrictions are in the form of software licenses. Sometimes a software license can restrict the number of jobs that can simultaneously be using the software on a node. Consumable resources allow a system administrator to define the number of licenses or other restricted resources available on a particular node.
<b>Available Disk</b>	This field displays the available disk space, measured in megabytes (MB), on the node.
<b>Available Memory</b>	This field displays the available memory, measured in megabytes (MB), on the node.
<b>Available Proc</b>	This field displays the number of available processors on the node.
<b>Available Swap</b>	This field displays the available swap, measured in megabytes (MB), on the node.
<b>Block Reason</b>	This field displays any error messages related to the node.
<b>Charge Rate</b>	This field displays the charging rate to the usage of particular resources.
<b>Class</b>	This field displays the classes that can access the node.
<b>Comments</b>	This field allows a user to attach a comment to the node.

Field	Description
<b>Consumable Resources</b>	This field displays the restricted resources and the current number configured for the node. Some clusters have restrictions placed upon certain nodes. Usually these restrictions are in the form of software licenses. Sometimes a software license can restrict the number of jobs that can simultaneously be using the software on a node. Consumable resources allow a system administrator to define the number of licenses or other restricted resources available on a particular node.
<b>Features</b>	A feature is a custom attribute often describing a unique hardware or software configuration associated with the node. This field displays the features associated with the node.
<b>Job List</b>	A node can execute one or more jobs simultaneously. This field displays a list of jobs currently executing on the node.
<b>Load</b>	The load is the number of processors on the node divided by the number of jobs on the node. This field displays what the current node load is.
<b>Max I.O. In</b>	This field displays the maximum disk input in bytes that can occur before the node state is changed to busy.
<b>Max I.O. Load</b>	This field displays the maximum disk input and output in bytes that can occur before the node state is changed to busy.
<b>Max I.O. Out</b>	This field displays the maximum disk output in bytes that can occur before the node state is changed to busy.
<b>Max. Job</b>	This field displays the maximum number of jobs allowed on the node at one time.
<b>Max. Job Per User</b>	This field displays the maximum number of jobs for a single user allowed on the node at one time.
<b>Max. Load</b>	The <i>load</i> is defined as the number of processors on the node divided by the number of jobs on the node. This field displays the maximum load for the node.
<b>Max. PE (Processor Equivalent) Per Job</b>	This field displays the maximum number of processor equivalents* per job allowed on this node at one time.
<b>Max. Proc</b>	This field displays the maximum number of utilized processors allowed on this node at one time.

Field	Description
<b>Max. Proc Per Class</b>	This field displays the maximum number of utilized processors per class allowed on this node at one time.
<b>Messages</b>	This field displays information messages provided by Workload Manager relating to the node.
<b>Network</b>	This field displays the network hardware on the node.
<b>Node ID</b>	All nodes require a unique ID. This field displays that ID.
<b>Node Type</b>	A <i>node type</i> is a custom tag attached to a node. It is usually used in conjunction with an allocation manager such as QBank to assign different charge rates according to the specific node type. This field displays the node type attached to the node.
<b>O.S.</b>	A node is configured with a specific operating system. This field displays the node's configured operating system.
<b>O.S. List</b>	A node is configured with a specific operating system. This field displays the node's configured operating system, as well as other operating systems that are compatible with the configured operating system.
<b>Partition</b>	Clusters can be divided into different sections. These sections are called partitions. This field displays the partition to which the node is assigned.
<b>Power</b>	This field displays whether the node is powered on or off.
<b>Priority</b>	This field displays the priority of the node. The default priority is 0.
<b>Priority Function</b>	This field displays which priority function will be used to calculate a node's priority.
<b>Proc Speed</b>	This field displays the processor speed as gathered from the resource manager.
<b>Rack</b>	This field displays the rack number where the node is logically located.
<b>Reservation Count</b>	This field displays the number of reservations on the node.
<b>Reservations</b>	This field displays reservations currently set on it.
<b>Size</b>	This field displays a description of the size of the node such as 1u or 2u.

Field	Description
<b>Slot</b>	This field displays the slot number where the node is logically located.
<b>Speed</b>	This field displays the speed of the node. A base node has a typical speed of 1.0. A node that is 50% faster has a speed of 1.5.
<b>State</b>	This field displays the operating status of the node. For example, unknown, draining, busy, running, down, idle, etc.
<b>Substate</b>	This field displays a description of the node's state generated by the resource manager.
<b>Total Disk</b>	This field displays the total disk space, measured in megabytes (MB), on the node.
<b>Total Memory</b>	This field displays the total memory, measured in megabytes (MB), on the node.
<b>Total Procs</b>	This field displays the total number of processors on the node.
<b>Total Swap</b>	This field displays the total swap space, measured in megabytes (MB), on the node.
<b>Total Time</b>	This field displays the total time the node has been on the cluster.
<b>Up Time</b>	This field displays the total time the node has been available to execute jobs

## Node calendar

### Summary

The node calendar displays the jobs and reservations on a calendar. Current and future reservations and jobs are shown as well as historical jobs and reservation. The top bar or x-axis is the displayed time frame. The left bar or y-axis is the nodes on the cluster. The colored boxes/cells in the table are identified in the display key.

The node calendar supports 4 time frames. Days in Month, Days in Week, Hours in Day, Minutes In Hour. The top left tabs allow the user to choose the desired time frame. When the **Display Selected Time Frame** button is selected, the currently selected time frame will be displayed.

### Display key

The Display Key panel allows the user to show or hide resources on the node calendar.

The Current Time displayed in green allows a user to see what the current time on the cluster is according to Moab's time reporting.

Jobs displayed in light blue shows all jobs according to the job reservations created for that job.

Reservations displayed in dark blue shows all reservations that fit within the specified time frame.

## Resize calendar

The resize calendar panel, when enabled, reduces the size of each box/cell in the table to allow the user to see more nodes at once. The node names are not visible when the table is compacted.

# Partitions

## Modify a Partition Profile

Clusters can be divided into different sections. These sections are commonly called partitions. A partition is a semi-permanent division of the cluster and is most often used when certain nodes contain unique hardware. It should be recognized that jobs are not allowed to run in more than one partition. If jobs need the ability to span multiple partitions an infinite reservation should be used instead of a partition.

The ability to modify partitions is not currently available in Cluster Manager.

## List Partitions

You can change the set of columns MCM displays in the Partitions table by clicking **View > Change Column Group** in the main menu bar and selecting one of the following options.

Default Categories	Columns Displayed
<b>Disk</b>	ID, Total Disk, Reserved Disk, Utilized Disk
<b>Memory</b>	ID, Total Memory, Reserved Memory, Utilized Memory
<b>Nodes</b>	ID, Total Nodes, Reserved Nodes, Utilized Nodes
<b>Processors</b>	ID, Total Processors, Reserved Processors, Utilized Processors
<b>Summary</b>	ID, Resource Manager
<b>Swap</b>	ID, Total Swap, Reserved Swap, Utilized Swap

## List Partition Fields

When you click **View > Visible Columns...** in the main menu bar, you can manually add or remove individual columns in your **Partitions** table. The following table describes each column:

Field	Description
<b>ID</b>	This field displays the partition ID, or the name of the partition.
<b>Reserved Disk</b>	This field displays the amount of disk space reserved by this partition. The disk space is measured in megabytes (MB).
<b>Reserved Memory</b>	This field displays the amount of memory reserved in this partition. The memory is measured in megabytes (MB).
<b>Reserved Nodes</b>	This field displays the number of nodes reserved in this partition.
<b>Reserved Processors</b>	This field displays the number of procs reserved in this partition.
<b>Reserved Swap</b>	This field displays the amount of swap space reserved by this partition. The swap space is measured in megabytes (MB).
<b>Resource Manager</b>	This field displays the resource manager ID of which this partition is a member.
<b>Total Disk</b>	This field displays the total disk space available in the partition. The disk space is measured in megabytes (MB).
<b>Total Memory</b>	This field displays the total memory available in this partition. The memory is measured in megabytes (MB).
<b>Total Nodes</b>	This field displays the total number of nodes available in this partition.
<b>Total Processors</b>	This field displays the total number of processors available in this partition.
<b>Total Swap</b>	This field displays the total swap space available in the partition. The swap space is measured in megabytes (MB).
<b>Utilized Disk</b>	This field displays the amount of disk space currently being used by this partition. The disk space is measured in megabytes (MB).

Field	Description
<b>Utilized Memory</b>	This field displays the amount of memory currently being used by this partition. The memory is measured in megabytes (MB).
<b>Utilized Nodes</b>	This field displays the number of nodes currently being used in this partition.
<b>Utilized Processor</b>	This field displays the number of processors currently being used in this partition.
<b>Utilized Swap</b>	This field displays the amount of swap space currently being used by this partition. The swap space is measured in megabytes (MB).

## Scheduler settings

This window provides a control center for the basic operations of Workload Manager.

### Control panel

Button	Description
<b>Pause/Resume</b>	The Pause button stops Workload Manager from scheduling any new jobs but will not turn Workload Manager off. The resume button, which replaces the pause button when Workload Manager is paused, will allow Workload Manager to begin scheduling jobs again.
<b>Restart</b>	The Restart button shuts down Moab and restarts it using the original execution environment and command line arguments.
<b>Shut Down</b>	The Shut Down button turns Workload Manager off. Please note that Workload Manager cannot be restarted from Cluster Manager.
<b>Stop Iterations</b>	The Stop Iterations button causes Workload Manager to stop scheduling once it reaches the iteration defined in the field. The iteration is defined as the cycle that Workload Manager is currently on. When Workload Manager starts its cycle is 0. Workload Manager increases the cycle by one approximately every 30 seconds.

### [System settings](#)

This window provides an administrator the option of changing numerous Workload Manager settings.

**Name**

This field allows an administrator to name the cluster. The name is only available for administrator convenience and is not used by Workload Manager.

**Host**

This field allows an administrator to define the host name that the Workload Manager subcomponents or clients use to connect to Workload Manager.

**Port**

This field allows an administrator to define the port that the Workload Manager subcomponents or clients use to connect to Workload Manager.

**Home Directory**

This field allows an administrator to define the directory where Workload Manager's configuration, statistics, and log files are located.

**Feedback Program**

This field allows an administrator to define a program that will be run at the completion of each job. Usually the program is used to contact the user through email informing him/her that the job completed execution.

**Notify Program**

This field allows an administrator to define a program that will be run when messages or alerts occur in Workload Manager.

**RM Poll Interval**

This field is the time in between which Workload Manager will communicate with the resource manager.

**Node Purge Time**

This field allows an administrator to define the amount of time Workload Manager will keep track of a node which is no longer reported by the resource manager. This value should be increased when using a resource manager that often loses information about a node due to internal failures.

**Job Purge Time**

This field allows an administrator to define the amount of time Workload Manager will keep track of a job which is no longer reported by the resource manager. This value should be increased when using a resource manager that often loses information about a job due to internal failures.

**[Log Settings](#)**

Logging is defined as recording error, diagnostic, and informational messages to a file. This window allows an administrator to configure the logging that occurs in Workload Manager.

### **Log Level**

This field allows an administrator the option of specifying the amount of data recorded in the log files. A value of 1 means almost no data is recorded while a value of 9 means all the data is recorded. Each value increment means that approximately double the amount of data is logged to the log files. The default log level is 3.

**Log Facilities**

This field determines what is recorded in the log file.

Setting	Description
<b>fALL</b>	This option records all the events that occur.
<b>fBANK</b>	This option records messages that involve QBank.
<b>fCKPT</b>	This option records messages that involve the checkpoint file.
<b>fCONFIG</b>	This option records messages that involve the configuration file.
<b>fCore</b>	This option records Workload Manager core messages.
<b>fFS</b>	This option records messages that involve fairshare.
<b>fLL</b>	This option records messages that come from LoadLeveler Resource Manager.
<b>fPBS</b>	This option records messages that come from the Torque/OpenPBS Resource Manager.
<b>fRM</b>	This option records resource manager messages.
<b>fSched</b>	This option records messages that involve the scheduler.
<b>fSIM</b>	This option records messages that occur during the simulation operating mode.
<b>fSock</b>	This option records messages that involve the socket communication.
<b>fSTAT</b>	This option records messages that involve statistics.
<b>fSTRUCT</b>	This option records messages that involve Workload Manager's structure.
<b>fUI</b>	This option records messages that involve the user interface.
<b>fWIKI</b>	This option records messages that involve WIKI.
<b>fSDR</b>	This option records messages that involve system data repository.

**Log Directory**

This field allows an administrator to specify the directory in which log files will be maintained.

**Log File**

This field allows an administrator to specify the name of the Workload Manager log file.

**Log File Max Size**

This field allows an administrator the option of specifying the maximum allowed size (in bytes) of the log file before it will be rolled.

**Log File Roll Depth**

When a log file reaches its maximum size, it is *rolled* or renamed to another filename and a new log file is created using the original file name. This field allows an administrator the option of defining the number of renamed files Workload Manager should maintain.

Statistics

Credential statistics are disabled by default although cluster-wide statistics are always enabled.

**Enable Credentials Statistics**

This section allows an administrator to enable or disable user, group, account, class, or quality of service statistics. Because statistics increase Workload Manager's memory usage, an administrator can decrease the memory footprint of Workload Manager by disabling credential statistics.

**Enable Node Statistics**

This section gives you the option of enabling node statistics for all nodes.

**Number of intervals in each day**

Workload Manager combines statistics into intervals. The Daily Statistical Count allows an administrator the option of increasing or decreasing the number of intervals in each day. A higher amount of intervals creates more precise statistics, but Workload Manager uses more memory when intervals are higher.

## Credentials

### Credentials Overview

The credentials section allows an administrator to view all credentials in the system and their various roles. New credential profiles can be added as well as modified.

### All credentials

This window displays all of the information regarding users, groups, accounts, classes, and qualities of service (QoS) commonly called credentials.

You can change the set of columns MCM displays in the **Credentials** table by clicking **View > Change Column Group** in the main menu bar and selecting one of the following options.

Default Categories	Columns Displayed
<b>Comments &amp; Email</b>	Credential, ID, Comments, E-mail Address
<b>Credits</b>	Credential, ID, Credits, Used Credits
<b>Default Credentials</b>	Credential, ID, User Default, Group Default, Class Default, Account Default, Default QoS
<b>Default Resources</b>	Credential, ID, Partition Default
<b>Fairshare</b>	Credential, ID, Fairshare Type, Fairshare Target
<b>Hard Max Limits</b>	Credential, ID, Max Job, Max Proc, Max Nodes, Max Proc Sec
<b>Membership</b>	Credential, ID, User, Group, Class, Account, QoS
<b>Partition &amp; Reservation</b>	Credential, ID, Partition, Reservation
<b>Priority</b>	Credential, ID, Priority
<b>Utilized Resources</b>	Credential, ID, Utilized Job, Utilized Proc, Utilized Nodes, Utilized Proc Sec
<b>Soft Max Limits</b>	Credential, ID, Soft Max Job, Soft Max Proc, Soft Max Nodes, Soft Max Proc Sec
<b>Statistics</b>	Credential, ID, Enable Statistics

## List Credential Fields

When you click **View > Visible Columns...** in the main menu bar, you can manually add or remove individual columns in your **Credentials** table. The following table describes each column:

Field	Description
<b>Access Resources QT Threshold</b>	This field displays the number of minutes that an idle job must wait before it can access any reservations owned by the Quality of Service.
<b>Access Resources XF Threshold</b>	This field displays the expansion factor value that an idle job must be greater than or equal to in order to access any reservations owned by the Quality of Service.

Field	Description
<b>Account</b>	This field displays the accounts that this particular credential ID can access.
<b>Account Default</b>	This field displays the account that will be used by this credential ID's job if no account is specified.
<b>Class</b>	This field displays the classes that this particular credential ID can access.
<b>Class Default</b>	This field displays the class that will be used by this credential ID's job if no class is specified.
<b>Comments</b>	This field allows a user to enter any comments relating to the Credential.
<b>Create Reservation QT Threshold</b>	This field displays the number of minutes that an idle job must wait before a job reservation will be created for it. A job reservation will guarantee it specific resources, as well as a specific start time.
<b>Create Reservation XF Threshold</b>	This field displays the expansion factor value that an idle job must be greater than or equal to before a job reservation will be created for it. A job reservation guarantees it specific resources, as well as a specific start time.
<b>Credential</b>	This field displays whether the credential is a user, group, account, class, or quality of service (QoS).
<b>Credits</b>	This field displays the total credits available to the credential ID.
<b>Dedicated Resource Cost</b>	What Workload Manager charges for each resource unit dedicated - whether used or not - to a job.
<b>Default QoS</b>	The default quality of service (QoS) is the quality of service (QoS) that will be used by this credential ID's job if no quality of service (QoS) is specified
<b>E-Mail Address</b>	This field allows a user to enter the e-mail address for the Credential.
<b>Enable Statistics</b>	Statistics are tracked for each credential ID. This field allows the user the option of enabling/disabling statistics for each credential ID.

Field	Description
<b>Fairshare Target</b>	Refer to the fairshare section for information regarding fairshare target.
<b>Fairshare Type</b>	Refer to the fairshare section for information regarding fairshare type.
<b>Group</b>	The operating system is usually responsible for the creation of groups. This field displays the groups that this particular credential ID can access.
<b>Group Default</b>	This field displays the group that will be used by this credential ID's job if no group is specified.
<b>ID</b>	All credentials must have an identification unique to its credential type. This field displays the credential identification.
<b>Max Job</b>	The default maximum job is the maximum job value that will be used by this credential ID's job if no maximum job is specified.
<b>Max Nodes</b>	This field displays the maximum nodes value that will be used by this credential ID's job if no maximum nodes value is specified.
<b>Max Proc</b>	This field displays the maximum processors value that will be used by this credential ID's job if no maximum processor is specified.
<b>Max Proc Sec</b>	This field displays the maximum processor seconds value that will be used by this credential ID's job if no maximum processor seconds value is specified.
<b>Partition</b>	Clusters can be divided into different sections. These sections are commonly called <i>partitions</i> . This field displays the partitions this credential ID can access.
<b>Partition Default</b>	This field displays the partition that will be used by this credential ID's job if no partition is specified.
<b>Preemption QT Threshold</b>	This field displays the number of minutes that an idle job must wait before it will be given preemptor access.
<b>Preemption XF Threshold</b>	This field displays the expansion factor value that an idle job must be greater than or equal to before it will be given preemptor access.

Field	Description
<b>Priority</b>	This field displays the priority of the credential.
<b>QoS</b>	This field displays the quality of services (QoS) that this particular credential ID can access.
<b>QoS Flags</b>	This field displays the quality of service (QoS) settings for this credential ID.
<b>Queue Time Weight</b>	This field displays the quality of service weight factor. If an idle job is submitted to this quality of service, the number of minutes that it has been in the queue is multiplied by this value. This increases the job's start priority.
<b>Reservation</b>	The required reservation that any job submitted has to use.
<b>Soft Max Job</b>	The soft maximum job limit restricts the number of jobs allowed to execute for this credential ID. If, however, additional resources are available after all the soft maximum job limits are met, then the hard maximum job limits are used.
<b>Soft Max Nodes</b>	The soft maximum node limit restricts the number of nodes used by any job for this credential ID. If, however, additional resources are available after all the soft maximum node limits are met, then the hard maximum node limits are used.
<b>Soft Max Proc</b>	The soft maximum processor limit restricts the number of processors used by any job for this credential ID. If, however, additional resources are available after all the soft maximum processor limits are met, then the hard maximum processor limits are used.
<b>Soft Max Proc Sec</b>	The soft maximum processor seconds limit restricts the number of processor seconds used by any job for this credential ID. If, however, additional resources are available after all the soft maximum processor seconds limits are met, then the hard maximum processor seconds limits are used.
<b>Used Credits</b>	This field displays the credits used by this credential ID.
<b>User</b>	This field displays the users that this particular credential ID can access.
<b>User Default</b>	This field displays the user that will be used by this credential ID's job if no user is specified.
<b>Utilized Job</b>	This field displays the number of jobs currently executing for this credential ID.
<b>Utilized Nodes</b>	This field displays the number of nodes currently being used by this credential ID's jobs.

Field	Description
<b>Utilized Proc</b>	This field displays the number of processors currently being used by this credential ID's jobs.
<b>Utilized Proc Sec</b>	This field displays the total number of processors used by executing jobs for this particular credential ID times the number of seconds each processor has been used.
<b>Utilized Resource Cost</b>	This field displays what Workload Manager charges for each resource unit consumed/utilized by a job.
<b>XFactor Weight</b>	This field displays the quality of service weight factor. If an idle job is submitted to this quality of service, its expansion factor is multiplied by this value. This increases the job's start priority.

## Visual credentials

This window allows a user to view which credentials can access which credentials. The arrows symbolize that the credential can access the other credential. There are three distinct sections displayed in the window. The first section displays all the credentials that can access the second section. The second section contains only the selected credential. The arrows from the second section to the third section show what the selected credential can access. The first and third sections may not be displayed if they do not contain credentials that are accessible to the credential in the second section.

### Display All Credentials

This field allows a user to display all of the credentials of a specific credential type.

### Display Listed Credentials

This field allows a user to display only the listed credentials.

### Display who can access the selected credential

This field allows a user to specify whether the credentials that access the selected credentials should be displayed.

### Display what the selected credential can access

This field allows a user to specify whether the credentials that the selected credential can access should be displayed.

## Create/Modify a user profile

Users are created by the operating system while user profiles are created by Workload Manager. When a user submits a job, that user becomes visible to Workload Manager and at that moment a credential profile is automatically created for the user.

To create a new user, you must click **Actions > Create User...** in the main menu bar. The following tables describe the fields in the pop-up box. To modify a user, you must double-click the user profile in the Users table (located in the Credentials folder of the Navigation pane).

To control user rights, see the [User access on page 2523](#) page.

## Credential Access

### **User Name**

This field allows an administrator to define the name of the user. Usually this is the user's login name.

### **Group Access List**

The group access is defined by the operating system and cannot be defined by Workload Manager.

### **Account Access List**

This field allows an administrator to define which accounts this user can access.

### **Default Account**

This field allows an administrator to define which accounts will be automatically used if the user doesn't specify an account.

### **QoS (Quality of Service) Access List**

This field allows an administrator to define which qualities of service (QoS) this user can access.

### **Default QoS (Quality of Service)**

This field allows an administrator to define which quality of service (QoS) will automatically be used if the user doesn't specify a quality of service (QoS).

## Resource Access

### **Partitions**

This field allows an administrator to define which partitions this user can access.

### **Default Partition**

This field allows an administrator to define which partitions this user can access by default.

### **Reservation**

This field allows an administrator to define which reservation this user can access.

## Job Usage Limits

### **Idle Max Jobs**

This field allows an administrator the option of setting the user's maximum number of simultaneously idle jobs.

**Max Jobs**

This field allows an administrator to set the user's maximum number of simultaneously executing jobs.

**Max Procs**

This field allows an administrator to set the user's maximum number of simultaneously utilized processors.

**Max Proc Seconds**

This field allows an administrator to set the user's maximum number of simultaneously utilized processor seconds. Processor seconds is the number of processors utilized times the number of seconds they are utilized.

**Max Nodes**

This field allows an administrator to set the user's maximum number of simultaneously utilized nodes. A node is a computer consisting of 1 or more processors.

**Max Wallclock**

This field allows an administrator to set the user's maximum wallclock time available when submitting a job.

**Min Wallclock**

This field allows an administrator to set the user's minimum wallclock time when submitting a job.

**Default Wallclock**

This field allows an administrator to set the user's default wallclock time set when submitting a job with no specified wallclock.

Fairshare & Priority

**Fairshare Policies**

Fairshare is a method of enforcing cluster sharing between credentials. A *credential* is a user, group, account, class/queue, or quality of service (QoS). Fairshare tracks each credential's usage for a desired amount of time and decreases a job's start priority if the fairshare policy is violated. By decreasing a job's start priority, a user specifies that the job will wait longer in the queue before it starts allowing other jobs to execute first.

Policy	Description
<b>Fairshare Floor Policy</b>	If the user's cluster usage is below the fairshare target, then the user's start priority for the job will increase. The user's cluster usage is measured as the total percentage amount of the cluster used by the user.
<b>Fairshare Target Policy</b>	If the user's cluster usage is above or below the fairshare target, then the user's start priority for the job will increase or decrease accordingly. The user's cluster usage is measured as the total percentage amount of the cluster used by the user.
<b>Fairshare Ceiling Policy</b>	If the user's cluster usage is above the fairshare target, then the user's start priority for the job decreases. The user's cluster usage is the total percentage of the cluster used by the user.

**Target**

This field allows an administrator to define the fairshare target for this user. Refer to the fairshare policy for an understanding of how fairshare target will be used.

**User Priority**

This field allows an administrator to define a user's job priority. A user's job priority will increase or decrease the start priority of this user's jobs. Workload Manager, with some exceptions, will start the jobs with the highest start priority first.

Comments

**Comments**

This field allows an administrator to enter comments regarding the user.

Email Address

**Email Address**

This field allows an administrator to add a user's email address to Workload Manager. The email address is only for contact information and is not used by Workload Manager or the resource manager.

Usage Statistics

This is only visible if a profile is being modified.

**System Utilization**

Shows what percent of the entire system has recently been dedicated to this credential. Each value in this line graph represents the number of dedicated processor seconds used by this credential during the profiling duration divided by the number of dedicated processor seconds in the entire system for the profiling duration. The number of dedicated processor seconds for the entire system for a profiling duration is equal to the size of the profiling duration in seconds multiplied by the number of processors.

## Create/Modify a group profile

Groups are created by the operating system while group profiles are created by Workload Manager. When a user submits a job, that user's group becomes visible to Workload Manager and at that moment, a credential profile is automatically created for the group.

To create a new group, you must click **Actions > Create Group...** in the main menu bar. The following tables describe the fields in the pop-up box. To modify a group, you must double-click the group profile in the Groups table (located in the Credentials folder of the Navigation pane).

Credential Access**Group Name**

This field allows an administrator to define the identification name of the group. Usually this is the login name for the group.

**User Access List**

This field allows an administrator to define which users can access this group.

**Account Access List**

This field allows an administrator to define which accounts this group can access.

**Default Account**

This field allows an administrator to define which account is the default of this group.

**QoS (Quality of Service) Access List**

This field allows an administrator to define which qualities of service (QoS) this group can access.

**Default QoS (Quality of Service)**

This field allows an administrator to define which quality of service (QoS) will automatically be used if the group doesn't specify a quality of service (QoS).

Resource Access**Partitions**

This field allows an administrator to define which partitions this group can access.

**Default Partition**

This field allows an administrator to define which partitions this group can access by default.

### **Reservation**

This field allows an administrator to define which reservation this group can access.

### Job Usage Limits

#### **Idle Max Jobs**

This field allows an administrator the option of setting the group's maximum number of simultaneously idle jobs.

#### **Max Jobs**

This field allows an administrator to set the group's maximum number of simultaneously executing jobs.

#### **Max Procs**

This field allows an administrator to set the group's maximum number of simultaneously utilized processors.

#### **Max Proc Seconds**

This field allows an administrator to set the group's maximum number of simultaneously utilized processor seconds. Processor seconds is the number of processors utilized times the number of seconds they are utilized.

#### **Max Nodes**

This field allows an administrator to set the group's maximum number of simultaneously utilized nodes. A node is a computer consisting of 1 or more processors.

#### **Max Wallclock**

This field allows an administrator to set the group's maximum wallclock time available when submitting a job.

#### **Min Wallclock**

This field allows an administrator to set the group's minimum wallclock time when submitting a job.

#### **Default Wallclock**

This field allows an administrator to set the group's default wallclock time set when submitting a job with no specified wallclock.

Fairshare & Priority

**Fairshare Policy**

Fairshare is a method of enforcing cluster sharing between credentials. A credential is a user, group, account, class, or quality of service (QoS). Fairshare tracks each credential's usage for a desired amount of time and decreases a job's start priority if the fairshare policy is violated. By decreasing a job's start priority, the job will wait longer in the queue before it starts, allowing other jobs to execute first.

Policy	Description
<b>Fairshare Floor Policy</b>	If the group's cluster usage is below the fairshare target then the group's start priority for the job increases. The group's cluster usage is measured as the total percentage amount of the cluster used by the group.
<b>Fairshare Target Policy</b>	If the group's cluster usage is above or below the fairshare target then the group's start priority for the job increases or decreases accordingly. The group's cluster usage is measured as the total percentage of the cluster used by the group.
<b>Fairshare Ceiling Policy</b>	If the group's cluster usage is above the fairshare target then the group's start priority for the job decreases. The group's cluster usage is the total percentage of the cluster used by the group.

**Target**

This field allows an administrator to define the fairshare target for this group. Refer to the Fairshare Policy for an understanding of how fairshare target will be used.

**Group Priority**

This field allows an administrator to define a group's job priority. A group's job priority will either increase or decrease the start priority of this group's jobs. Workload Manager, with some exceptions, will start the jobs with the highest start priority first.

Comments

**Comments**

This field allows an administrator to enter any comments regarding the group.

Usage Statistics

This is only visible if a profile is being modified.

### System Utilization

Shows what percent of the entire system has recently been dedicated to this credential. Each value in this line graph represents the number of dedicated processor seconds used by this credential during the profiling duration divided by the number of dedicated processor seconds in the entire system for the profiling duration. The number of dedicated processor seconds for the entire system for a profiling duration is equal to the size of the profiling duration in seconds multiplied by the number of processors.

## Create/Modify an account profile

Account creation occurs in Workload Manager.

To create a new account, you must click **Actions > Create Account...** in the main menu bar. The following tables describe the fields in the pop-up box. To modify an account, you must double-click the account profile in the Accounts table (located in the Credentials folder of the Navigation pane).

### Credential Access

#### Account Name

This field allows an administrator to define the name of the account. This is usually the login name for the account.

#### User Access List

This field allows an administrator to define which users can access this account.

#### Group Access List

This field allows an administrator to define which groups can access this account.

#### QoS (Quality of Service) Access List

This field allows an administrator to define which qualities of service (QoS) this account can access.

#### Default QoS (Quality of Service)

This field allows an administrator to define which quality of service (QoS) will automatically be used if the account doesn't specify a quality of service (QoS).

### Resource Access

#### Partition

This field allows an administrator to define which partitions this account can access.

#### Default Partition

This field allows an administrator to define which partitions this account can access by default.

#### Reservation

This field allows an administrator to define which reservation this account can access.

## Job Usage Limits

### **Idle Max Jobs**

This field allows an administrator the option of setting the account's maximum number of simultaneously idle jobs.

### **Max Jobs**

This field allows an administrator to set the account's maximum number of simultaneously executing jobs.

### **Max Procs**

This field allows an administrator to set the account's maximum number of simultaneously utilized processors.

### **Max Proc Seconds**

This field allows an administrator to set the account's maximum number of simultaneously utilized processor seconds. Processor seconds is defined as the number of processors utilized times the number of seconds they are utilized.

### **Max Nodes**

This field allows an administrator to set the account's maximum number of simultaneously utilized nodes. A node is a computer consisting of 1 or more processors.

### **Max Wallclock**

This field allows an administrator the option of setting the account's maximum wallclock time available when submitting a job.

### **Min Wallclock**

This field allows an administrator the option of setting the account's minimum wallclock time when submitting a job.

### **Default Wallclock**

This field allows an administrator the option of setting the account's default wallclock time set when submitting a job with no specified wallclock.

## Fairshare & Priority

### Fairshare Policies

Fairshare is a method of enforcing cluster sharing between credentials. A credential is a user, group, account, class, or quality of service (QoS). Fairshare tracks each credential's usage for a desired amount of time and decreases a job's start priority if the fairshare policy is violated. By decreasing a job's start priority, the job will wait longer in the queue before it starts, allowing other jobs to execute first.

Policy	Description
<b>Fairshare Floor Policy</b>	If the account's cluster usage is below the fairshare target, then the account's start priority for the job will increase. The account's cluster usage is the total percentage of the cluster used by the account.
<b>Fairshare Target Policy</b>	If the account's cluster usage is above or below the fairshare target, then the account's start priority for the job increases or decreases accordingly. The account's cluster usage is measured as the total percentage amount of the cluster used by the account.
<b>Fairshare Ceiling Policy</b>	If the account's cluster usage is above the fairshare target, then the account's start priority for the job increases or decreases. The account's cluster usage is the total percentage of the cluster used by the account.

### Target

This field allows an administrator to define the fairshare target for this account. Refer to the Fairshare Policy for an understanding of how fairshare target will be used.

### Account Priority

This field allows an administrator to define an account's job priority. An account's job priority increases or decreases the start priority of this account's jobs. Workload Manager, with some exceptions, starts the jobs with the highest start priority first.

### Comments

#### Comments

This field allows an administrator to enter comments regarding the account.

### Usage Statistics

This is only visible if a profile is being modified.

### System Utilization

Shows what percent of the entire system has recently been dedicated to this credential. Each value in this line graph represents the number of dedicated processor seconds used by this credential during the profiling duration divided by the number of dedicated processor seconds in the entire system during the profiling duration. The number of dedicated processor seconds for the entire system for a profiling duration is equal to the size of the profiling duration in seconds multiplied by the number of processors.

## Create/Modify a class profile

Classes are created by the resource manager while class profiles are created by Workload Manager.

To create a new class, you must click **Actions > Create Class...** in the main menu bar. The following tables describe the fields in the pop-up box. To modify a class, you must double-click the class profile in the Class table (located in the Credentials folder of the Navigation pane).

### Credential Access

#### **Class Name**

This field allows an administrator to define the name of the class. Usually this is the login name for the class.

#### **User Access List**

This field allows an administrator to define which users can access this class.

#### **Group Access List**

This field allows an administrator to define which groups can access this class.

#### **Account Access List**

This field allows an administrator to define which accounts this class can access.

#### **Default Account**

This field allows an administrator to define which accounts will automatically be used if the class doesn't specify an account.

#### **QoS (Quality of Service) Access List**

This field allows an administrator to define which qualities of service (QoS) this class can access.

#### **Default QoS (Quality of Service)**

This field allows an administrator to define which quality of service (QoS) will automatically be used if the class doesn't specify a quality of service (QoS).

### Resource Access

#### **Partitions**

This field allows an administrator to define which partitions this class can access.

**Default Partition**

This field allows an administrator to define which partitions this class can access by default.

**Reservation**

This field allows an administrator to define which reservation this class can access.

Job Usage Limits**Idle Max Jobs**

This field allows an administrator to set the class's maximum number of simultaneously idle jobs.

**Max Jobs**

This field allows an administrator to set the class's maximum number of simultaneously executing jobs.

**Max Procs**

This field allows an administrator to set the class's maximum number of simultaneously utilized processors.

**Max Proc Seconds**

This field allows an administrator to set the class's maximum number of simultaneously utilized processor seconds. Processor seconds is the number of processors utilized times the number of seconds they are utilized.

**Max Nodes**

This field allows an administrator to set the class's maximum number of simultaneously utilized nodes. A node is a computer consisting of 1 or more processors.

**Max Wallclock**

This field allows an administrator to set the class's maximum wallclock time available when submitting a job.

**Min Wallclock**

This field allows an administrator to set the class's minimum wallclock time when submitting a job.

**Default Wallclock**

This field allows an administrator to set the class's default wallclock time set when submitting a job with no specified wallclock.

## Fairshare & Priority

### **Fairshare Policies**

Fairshare is a method of enforcing cluster sharing between credentials. A *credential* is a user, group, account, class, or quality of service (QoS). Fairshare tracks each credential's usage for a desired amount of time and decreases a job's start priority if the fairshare policy is violated. By decreasing a job's start priority, the job will wait longer in the queue before it starts, allowing other jobs to execute first.

Policy	Description
<b>Fairshare Floor Policy</b>	If the class's cluster usage is below the fairshare target, then the class's start priority for the job increases. The class's cluster usage is the total percentage of the cluster used by the class.
<b>Fairshare Target Policy</b>	If the class's cluster usage is above or below the fairshare target, then the class's start priority for the job increases or decreases accordingly. The class's cluster usage is the total percentage of the cluster used by the class.
<b>Fairshare Ceiling Policy</b>	If the class's cluster usage is above the fairshare target, then the class's start priority for the job decreases. The class's cluster usage is the total percentage of the cluster used by the class.

### **Target**

This field allows an administrator to define the fairshare target for this class. Refer to the Fairshare Policy for an understanding of how fairshare target will be used.

### **Class Priority**

This field allows an administrator to define a class's job priority. A class's job priority will increase or decrease the start priority of this class's jobs. Workload Manager, with some exceptions, will start the jobs with the highest start priority first.

## Comments

### **Comments**

This field allows an administrator to enter comments regarding the class.

## Usage Statistics

This is only visible if a profile is being modified.

**System Utilization**

Shows what percent of the entire system has recently been dedicated to this credential. Each value in this line graph represents the number of dedicated processor seconds used by this credential for the profiling duration divided by the number of dedicated processor seconds in the entire system for the profiling duration. The number of dedicated processor seconds for the entire system for a profiling duration is equal to the size of the profiling duration in seconds multiplied by the number of processors.

## Create/Modify a quality of service profile

Qualities of service are created by the operating system while quality of service profiles are created by Workload Manager. When a quality of service submits a job then that quality of service becomes visible to Workload Manager and at that moment a credential profile is automatically created for the quality of service.

To create a new QoS, you must click **Actions > Create QoS...** in the main menu bar. The following tables describe the fields in the pop-up box. To modify a QoS, you must double-click the QoS profile in the QoS table (located in the Credentials folder of the Navigation pane).

Credential Access**Quality of Service Name**

This field allows an administrator to define the name of the quality of service. Usually this is the login name for the quality of service.

**User Access List**

This field allows an administrator to define which users can access this quality of service.

**Group Access List**

The group access is defined by the operating system and cannot be defined by Workload Manager.

**Account Access List**

This field allows an administrator to define which accounts this quality of service can access.

**Default Account**

This field allows an administrator to define which accounts will automatically be used if the quality of service doesn't specify an account.

Partitions & Reservations**Partitions**

This field allows an administrator to define which partitions this quality of service can access.

**Default Partition**

This field allows an administrator to define which partitions this user can access by default.

**Reservation**

This field allows an administrator to define which reservations jobs that access this quality of service must use.

Fairshare

**Fairshare Policies**

Fairshare is a method of enforcing cluster sharing between credentials. A credential is a user, groups, account, class/queue, or quality of service (QoS). It consists of tracking each credentials usage for a desired amount of time and decreasing a jobs start priority if the fairshare policy is violated. By decreasing a job's start priority the job will wait longer in the queue before it starts allowing other jobs to execute first.

Policy	Description
<b>Fairshare Floor Policy</b>	If the quality of services cluster usage is below the fairshare target the quality of services start priority for the job increases. The quality of services cluster usage is the total percentage of the cluster used by the quality of service.
<b>Fairshare Target Policy</b>	If the quality of services cluster usage is above or below the fairshare target, the quality of services start priority for the job increases or decreases accordingly. The quality of services cluster usage is the total percentage of the cluster used by the quality of service.
<b>Fairshare Ceiling Policy</b>	If the quality of services cluster usage is above the fairshare target, the quality of services start priority for the job decreases. The quality of services cluster usage is the total percentage of the cluster used by the quality of service.

**Target**

This field allows an administrator to define the fairshare target for this quality of service. Refer to the Fairshare Policy for an understanding of how fairshare target will be used.

Comments

**Comments**

This field allows an administrator to enter comments regarding the quality of service.

Job Usage Limits

**Idle Max Jobs**

This field allows an administrator to set the quality of services maximum number of simultaneously idle jobs.

**Max Jobs**

This field allows an administrator to set the quality of services maximum number of simultaneously executing jobs.

**Max Procs**

This field allows an administrator to set the quality of services maximum number of simultaneously utilized processors.

**Max Proc Seconds**

This field allows an administrator to set the quality of services maximum number of simultaneously utilized processor seconds. Processor seconds is the number of processors utilized times the number of seconds they are utilized.

**Max Nodes**

This field allows an administrator to set the quality of services maximum number of simultaneously utilized nodes. A node is a computer consisting of 1 or more processors.

**Max Wallclock**

This field allows an administrator to set the quality of services maximum wallclock time available when submitting a job.

**Min Wallclock**

This field allows an administrator to set the quality of services minimum wallclock time when submitting a job.

**Default Wallclock**

This field allows an administrator to set the quality of services default wallclock time set when submitting a job with no specified wallclock.

**Charging****Dedicated Cost**

The cost to have dedicated access to this resource, regardless of whether it is being utilized.

**Utilized Cost**

The cost to utilize this resource.

**Prioritization****Queue Time Weight**

This field displays the quality of service weight factor. If an idle job is submitted to this quality of service the number of minutes that it has been in the queue will be multiplied by this value. This increases the jobs start priority.

**Expansion Factor Weight**

This field displays the quality of service weight factor. If an idle job is submitted to this quality of service it's expansion factor is multiplied by this value. This increases the job's start priority.

**Quality of Service Priority**

This field affects the priority given to jobs with this quality of service applied.

## Quality of Service Flags

### **Deadline**

This option makes any job with this quality of service with a completion deadline to finish before that deadline.

### **Dedicated**

This option makes any job submitted to this quality of service to require a dedicated node. A dedicated node is a node that is completely reserved for only one job.

### **Enable User Reservation**

This option makes any user that is a member of this quality of service able to create user/personal reservations.

### **Ignore All Policies**

This option makes any job submitted to this quality of service exempt from all resource usage policies.

### **No Backfill**

This option makes any job submitted to this quality of service exempt from the backfill algorithm.

### **No Reservation**

This option makes any job submitted to this quality of service unable to create a job reservation and, therefore, only able to share resources.

### **Next to Run**

This option makes any job submitted to this quality of service run next. This is accomplished by increasing the start priority of a job, than all of the other queued jobs.

### **Preemptee**

This option makes any job submitted to this quality of service preemptable. A preemptable job can be stopped and requeued if a high priority preemptor job needs to execute.

### **Preemptor**

This option makes any job submitted to this quality of service able to preempt any preemptable job.

### **Provision**

This option makes any job submitted to this quality of service that requests unavailable resources such as an operating system or software to have Workload Manager set up a number of nodes with the correct resources.

### **Reserve Always**

This option makes any job submitted to this quality of service create a reservation. Usually job reservations are created when the job starts but with this option enabled the job will create a reservation immediately.

## Usage Statistics

This is only visible if a profile is being modified.

### **System Utilization**

Shows what percent of the entire system has recently been dedicated to this credential. Each value in this line graph represents the number of dedicated processor seconds used by this credential during the profiling duration divided by the number of dedicated processor seconds in the entire system during the profiling duration. The number of dedicated processor seconds for the entire system for a profiling duration is equal to the size of the profiling duration in seconds multiplied by the number of processors.

# Policies

## **Policies Overview**

Moab Workload Manager has many powerful policies that can be managed to effectively handle as large a workload as possible while satisfying other desires. The policies section is intended to give control over Workload Manager's various policies.

## Backfill

Backfill is an optimization policy that allows a scheduler to make better use of available resources by running jobs out of order. When using Backfill, Workload Manager prioritizes the jobs in the queue into a sorted list with the highest priority job first. Beginning at the top of the list, it starts the jobs one by one until it reaches a job that it cannot start because the necessary resources are not available. Using the start times and wallclock limits of the currently running jobs, Workload Manager then calculates when it will be able to start the job. It reserves that spot (in the future) for the job, and attempts to schedule some of the remaining lower-priority jobs in the gaps left over from the higher-priority jobs. This process continues until Workload Manager has attempted to start all the jobs in the list, until all resources are consumed, or until Workload Manager has considered a specific number of jobs. Backfill allows Workload Manager to achieve a higher utilization than would be otherwise possible, while remaining mostly true to the original job priorities.

Backfill Settings**Policy**

In this field you specify the kind of backfill algorithm Workload Manager uses to schedule jobs.

Backfill Algorithm	Description
<b>FirstFit</b>	Considers jobs in the queue sequentially, beginning with the highest priority and moving down the list.
<b>BestFit</b>	Considers all jobs in the queue and selects the job that best fits the available resources (see the <i>Attribute</i> parameter below).
<b>Greedy</b>	Considers all possible combinations of jobs that can run on the available resources and selects the best combination (see the <i>Attribute</i> parameter below).
<b>Optimistic</b>	If any resource manager reports a state of up, that state will be used.
<b>Preempt</b>	Allows the scheduler to start backfill jobs even if the required walltime is not available.
<b>None</b>	Backfill is not enabled.

**Metric**

This is the criteria used by the backfill algorithm to determine the best jobs to backfill. For example, if *Procs* is selected, a job that requires the exact amount of available processors will be considered the best. This parameter only applies to the *BestFit* and *Greedy* backfill policies.

Metric	Description
<b>Procs</b>	This is the number of processors.
<b>ProcSeconds</b>	This is the number of processors multiplied by the duration of the job, in seconds.
<b>Nodes</b>	This is the number of nodes.
<b>Seconds</b>	This is the duration (or wallclock time) of the job, in seconds.

**Depth**

This is the number of jobs in the queue Workload Manager should consider for backfill. By default, all jobs are considered. If Depth is set, Workload Manager will only consider that number of jobs for backfill scheduling. For example, if there are idle jobs in the queue and Depth is set to 10, only 10 jobs would be considered for backfill. If there are fewer than 10 jobs in the queue, all will be considered. Setting this number higher will result in a higher utilization and better turn-around times, especially for smaller jobs, but may result in low-priority jobs being started before medium-priority jobs. This parameter should be tuned for your specific situation.

**Priority Policy**

- DURATION — The length of the jobs determines which backfill job to preempt.
- HWDURATION
- NONE — No priority policy is used.
- RANDOM

**Chunking Duration**

This field allows an administrator to specify the duration during which freed resources will be aggregated for use by larger jobs.

**Chunk Size**

This field allows an administrator to specify the minimum job size which can utilize chunked resources.

**Virtual Walltime Scaling Factor**

This field allows an administrator to specify the factor by which eligible jobs' wallclock time is virtually scaled.

**Min. Virtual Walltime**

This field allows an administrator to specify the minimum job wallclock time for virtual scaling.

## Fairshare

Fairshare allows the cluster to be shared between different individuals and/or organizations without allowing any individual or organization the ability to monopolize the cluster. This is achieved by tracking how the cluster is used over time by each credential or user, group, class, account, and quality of service (QoS) and by increasing or decreasing the start priorities of jobs waiting to execute. It should be noted that the start priority is used by Workload Manager to decide which jobs get executed first. The higher the start priority, the sooner a job will execute. The information collected about each credential is inserted into what is called a usage window. The amount of time tracked in a window is defined by the system administrator.

System administrators often cannot achieve the cluster sharing they desire without using multiple usage windows. Multiple usage windows allow Workload Manager to balance cluster usage differently by making the most recent window more important than more outdated windows. This is achieved by using

the Usage Window Decay Factor. Essentially, the lower the decay factor, the less important outdated usage windows are.

Fairshare Options

**Interval Length**

This field allows an administrator to define how long each window lasts.

**Depth**

This field allows an administrator to define how many windows should exist.

**Usage Metric**

This field allows an administrator to define how credential usage is tracked.

Metric	Description
<b>Dedicated PES</b>	This field tracks credential usage according to the number of processor equivalent seconds reserved for a job.
<b>Dedicated PS</b>	This field tracks credential usage according to the number of processor seconds reserved for a job.
<b>PDEDICATEDPS</b>	This field tracks dedicated processor seconds scaled by the processor speed of the node.
<b>SDEDICATEDPES</b>	This field tracks dedicated processor-equivalent seconds scaled by the speed of the node.
<b>Utilized PS</b>	This field tracks credential usage according to the number of processor seconds used by a job.

### Decay Factor

This field allows an administrator to define how much of an influence outdated usage windows have in calculating a job's start priority. The lower the Usage Window Decay Factor, the less important the outdated usage windows.

### Fairshare Table

Column	Description
<b>Credential</b>	This field displays the credential type (user, group, account, class, or quality of service (QoS)).
<b>ID</b>	This field displays the credential's unique name.
<b>Policy</b>	This field displays the fairshare credentials policy. Consult the create user, group, class, account, or quality of service (QoS) documentation for more information regarding the policies.
<b>Target</b>	This field displays the fairshare credentials policy. Consult the create user, group, class, account, or quality of service (QoS) documentation for more information regarding the targets.
<b>Usage</b>	This field displays the percentage of the cluster that has been used by this credential ID in comparison to the other credential IDs for this Credential Type.
<b>Current Interval</b>	This field displays the first usage window. The decay factor does not affect this window at all.
<b>Interval 1 - 31</b>	This field displays the usage interval windows 1 through 31. The decay factor affects these windows with the most outdated window being window 31 and the most recent window being window 1.

## Job policies and settings

Contained in this section:

### [Job Limit Settings](#)

This window is used to place system wide restrictions on jobs.

#### **Max. Jobs Started per Iteration**

This field allows an administrator to specify the maximum number of times Workload Manager will attempt to start the job.

#### **Max. Jobs Preempted per Iteration**

This field allows an administrator to define the maximum number of times a job can be preempted by Workload Manager for higher priority jobs.

**Max. Processors per Job**

This field allows an administrator to define the maximum number of processors that can be requested by any jobs.

**Max. Processor-Seconds per Job**

This field allows an administrator to define the maximum number of processor-seconds (total number of procs reserved times the amount of time in seconds that the procs are reserved) that can be requested by any jobs.

**Max. Wallclock**

This field allows an administrator to specify the maximum amount of Wallclock time that can be requested by any single job.

**Wallclock Violation Soft Limit**

This field allows an administrator to define the amount of time Workload Manager allows a job to exceed its wallclock limit before Moab sends mail to the primary administrator.

**Wallclock Violation Limit**

This field allows an administrator to define the amount of time Workload Manager allows a job to exceed its wallclock limit before it is terminated.

**Wallclock Violation Action**

This field allows an administrator to define whether Moab should cancel or preempt a job that has exceeded its wallclock limit.

[Job Defer Settings](#)

**Defer Wait Time**

This field allows an administrator to define the amount of time a job will be held in the deferred state before being released back to the idle job queue.

**Starts Before Defer**

This field allows an administrator to define the amount of time a job will be allowed to fail in its start attempts before being deferred.

**Defers Before Hold**

This field allows an administrator to define the number of times a job can be deferred before it will be placed in batch hold.

**Job Sync Time**

This field allows an administrator to define the length of time after which Workload Manager will change a job's expected state to an unexpected reported state. It should be noted that Workload Manager will not allow a job to run as long as its expected state does not match the state reported by the resource manager.

[Global Job Policy Settings](#)

This window contains job-specific global settings.

**Preempt Policy**

This field allows an administrator to specify how Moab should respond to a preempted job.

Policy	Description
<b>CANCEL</b>	The job is terminated and removed from the queue.
<b>CHECKPOINT</b>	The job is terminated, checkpointed, and left in the queue.
<b>REQUEUE</b>	The job is terminated and left in the queue.
<b>SUSPEND</b>	The active job is suspended.

**Node Match Policy**

This field allows an administrator to specify how compute nodes are selected.

Policy	Description
<b>EXACTNODE</b>	Moab selects as many nodes as requested, regardless of how many tasks it assigns to the same node.
<b>EXACTPROC</b>	Moab selects nodes with exactly the same number of processors configured as are requested per node, even if other nodes have more processors available.
<b>EXACTTASK</b>	Moab selects nodes with exactly the same number of tasks configured as are requested per node, even if other nodes have more tasks available.

**Job Priority Policy**

This field allows an administrator to specify how Moab should track the dynamic aspects of a job's priority.

Policy	Description
<b>ACCRUE</b>	The job will accrue queue time based priority from the time it is submitted unless it violates any of the policies not specified in <code>JOBPRIOEXCEPTIONS</code> .
<b>RESET</b>	The job will accrue priority from the time it is submitted unless it violates any of the <code>JOBPRIOEXCEPTIONS</code> . If the job does violate <code>JOBPRIOEXCEPTIONS</code> , its queue time based priority will be reset to 0.

**Use Machine Speed**

By checking this box, an administrator specifies that a job's wallclock should be increased if the job is executing on a slower node and that a job's wallclock should be decreased if the job is executing on a faster node. The speed of the node is assessed by examining the node speed option located in the list nodes window.

**Enable Multiple Node Jobs**

By checking this box, an administrator specifies that resources may be allocated from multiple nodes to a job.

**Enable Multiple Requirement Jobs**

By checking this box, an administrator specifies that jobs may have more than one requirement.

## Node policies

**Node Task Allocation**

A task is a request for resources that must exist on a single compute node. Each job may have one or more tasks. Workload Manager allocates resources to jobs based on the tasks in the job. This is useful because nodes with multiple processors are usually able to support more than one task at a time. For example, if a job has 2 tasks where each task requires 1 processor and 256 MB of memory, Workload Manager may choose to allocate the job to a dual processor node with 512 MB of memory or to 2 single processor nodes with 256 MB of memory each. The node-task allocation policy determines which tasks may run on the same node.

This is the algorithm Workload Manager uses to determine which tasks may run on the same node.

Policy	Description
<b>Shared optional</b>	Tasks from any job and any user may use available resources on any node.
<b>Shared only</b>	Tasks from any job and any user may use available resources on any node.
<b>Single Job</b>	Only tasks from the same job may run for any given node.
<b>Single Task</b>	Only one task may run on each node.
<b>Single User</b>	For any given node, only tasks from jobs submitted by the same user may run.
<b>Unique User</b>	Any number of tasks from a job may allocate resources from a node if the user has no other jobs running on that node.

## Node Allocation Policy

Node allocation is the process of selecting the best resources, from a list of available resources, to assign to a job. Making this decision intelligently is important in environments with heterogeneous resources or nodes that can support multiple jobs at the same time. This is the algorithm Workload Manager uses to allocate nodes.

Policy	Description
<b>FirstAvailable</b>	Nodes are allocated in the order they are presented by the resource manager.
<b>LastAvailable</b>	Resources are selected so as to minimize the amount of time the resources remain unused after the job completes. This minimizes node-time fragmentation and is useful in systems that have a large number of reservations.
<b>MinResource</b>	Nodes that have the smallest amount of resources that meet the job's requirements are selected.
<b>CPULoad</b>	Nodes that have the maximum amount of available, unused CPU power are selected. This is good for timesharing systems, but is only applicable to jobs starting immediately. For future jobs, the MinResource policy is used.
<b>Contiguous</b>	Nodes are allocated in contiguous (linear) blocks. This is required by the Compaq RMS system.
<b>MaxBalance</b>	Nodes that are as similar as possible to each other are allocated to each job. The most important consideration in determining node similarity is node speed.
<b>Fastest</b>	The fastest available nodes are allocated to each job. Workload Manager determines which nodes are fastest based upon first the node speed and then the processor speed of each node. If neither of these values is available, the nodes are selected randomly.

## Node Availability Policy

Workload Manager will start jobs on nodes that are not full and are not considered busy. Workload Manager considers a node busy according to which Node Availability Policy is set. This is the algorithm Workload Manager uses to determine if a node is busy.

Policy	Description
<b>Combined</b>	Either of the above two conditions is met.
<b>Dedicated</b>	The dedicated (assigned or reserved) resources on the node equal or exceed the configured resources.
<b>Utilized</b>	The utilized (in use) resources on the node equal the configured (total available) resources.

**i** Resources may be dedicated to a user, group, or account for a specific period of time. But some of those resources may not be used during the entire period. This setting allows Workload Manager to differentiate between the two possibilities.

## Partition policies

This section deals with policies relating partitions and their behavior. Below is a list of partition policies.

### Partition Allocation Policy

This is a direct way to assign a peer allocation algorithm when multiple partitions are available for a job. Because clusters are considered partitions, this defines how jobs can be migrated to remote resources if multiple remote clusters can be found. Values and their descriptions are listed in the table below.

Policy	Description
<b>BESTFIT</b>	Allocate resources from the eligible peer with the fewest available resources - measured in tasks (minimizes fragmentation of large resource blocks).
<b>BESTPFIT</b>	Allocate resources from the eligible peer with the fewest available resources - measured in percent of configured resources (minimizes fragmentation of large resource blocks).
<b>FIRSTCOMPLETION</b>	Allocate resources from the eligible peer which can complete the job the soonest (takes into account data staging time and job-specific machine speed).
<b>FIRSTSTART</b>	Allocate resources from the eligible peer which can start the job the soonest.
<b>ROUNDROBIN</b>	Allocate resources from the eligible peer which has been least recently allocated.
<b>LOADBALANCE</b>	Allocate resources from the eligible peer with the most available resources - measured in tasks (balances workload distribution across potential peers).
<b>LOADBALANCEP</b>	Allocate resources from the eligible peer with the most available resources - measured in percent of configured resources (balances workload distribution across potential peers).

## Priority

A job has one start priority that determines when a job will start. The higher the start priority, the sooner a job will start. The job start priority can be anywhere between 1,000,000,000 and -1,000,000,000.

## How to read priorities

A job has one start priority that determines when a job will start. The higher the start priority, the sooner a job starts. Workload Manager uses the priority policies to calculate a job's start priority.

A subcomponent priority of 0 means the subcomponent will be ignored. A positive subcomponent priority means the start priority will be increased. A negative subcomponent priority means the start priority will be decreased. Refer to the documentation below for information about Main Components.

## How to understand the priority window layout

Workload Manager uses 39 components to calculate the start priority. These components are grouped into tabs according to their functionality. The Main Component is different from the subcomponents. Refer to the documentation below for further information about Main Components.

The table shows only idle/queued jobs and their start priority. Only idle/queued jobs are displayed because priority policies do not affect running jobs.

## What are components and subcomponents?

The 7 component groupings are crucial to understanding priorities. The Main Component tab is used only to increase or decrease the subcomponents priorities. The subcomponents increase or decrease the job start priority.

## How the job start priority is calculated

A job has one start priority which is used to decide when a job will start. The higher the start priority the sooner a job will start. Workload Manager uses the priority policies to calculate a job's start priority.

The start priority is calculated by adding all the subcomponents in a group together and multiplying the total of these subcomponents by the Main Component priority. This process is repeated 7 times, or once for each main component. The start priority is a summation of these 7 totals.

It should be noted that if the Main Component priority is set to 0, all of the subcomponent priorities for that Main Component will be ignored.

## How to enable a priority

To enable a priority, two priorities must change. The first priority is the sub component priority and the second priority is the Main Component priority.

For example, to apply a priority of 1 for a user's priority, the user priority in the subcomponent credential's priorities and the Credential Priorities in the Main Component must both be set to 1.

## What does a 0 mean?

If the Main Component priority is set to 0, all of the subcomponent priorities for that Main Component will be ignored. A sub component priority of 0 means the sub component will be ignored.

## Main Priority Components

### **Wait Time Job Service**

This field allows an administrator to increase or decrease all of the Wait Time Job Service priorities. If this is set to 0, all of the subcomponent's priorities for Wait Time Job Service are ignored.

### **Quality of Service Target**

This field allows an administrator to increase or decrease all of the Quality of Service Target's priorities. If this is set to 0, all of the subcomponent's priorities for Quality of Service Target will be ignored.

### **Fairshare Usage**

This field allows an administrator to increase or decrease all of the Fairshare Usage priorities. If this is set to 0, all of the subcomponent's priorities for Fairshare Usage will be ignored.

### **Resource Requests**

This field allows an administrator to increase or decrease all of the Resource Request's priorities. If this is set to 0, all of the subcomponent's priorities for Resource Request's will be ignored.

### **Credential Priorities**

This field allows an administrator to increase or decrease all of the Credential Priority's priorities. If this is set to 0, all of the subcomponent's priorities for Credential Priorities will be ignored.

### **Job Attributes**

This field allows an administrator to increase or decrease all of the Job Attributes priorities. If this is set to 0, all of the subcomponent's priorities for Job Attributes will be ignored.

### **Executing Job Usage**

This field allows an administrator to increase or decrease all of the Executing Job Usage priorities. If this is set to 0, all of the subcomponent's priorities for Executing Job Usage will be ignored. Unlike the other components, this component only effects executing jobs and is only applicable when preemption is used.

## Wait Time Job Services

### **Queue Time**

This field allows an administrator to set the priority of a job according to the minutes the job has waited in the queue.

### **X-Factor (Expansion Factor)**

This field allows an administrator to set the priority of a job according to the expansion factor\* of the job.

### **Policy Violation**

This field allows an administrator to set the priority of a job according to whether the job has violated a usage limit. If the job has violated a usage limit, the job is assigned a policy violation value of 1; otherwise, the job is assigned a policy violation value of 0.

### **By Pass**

This field allows an administrator to set the priority of a job according to the number of other jobs that started execution before this job. The other jobs are only counted if Workload Manager started the other jobs because of a backfill policy.

### QoS Targets

#### **Queue Time**

This field allows an administrator to set the priority of a job according to Quality of Service queue time target. The closer the job is to this target, the higher the Queue Time value.

#### **X-Factor (Expansion Factor)**

This field allows an administrator to set the priority of a job according to Quality of Service expansion factor target. The closer the job is to this target, the higher the Expansion Factor value.

### Credential Priority

#### **User**

This field allows an administrator to set the priority of a job according the user's priority.

#### **Group**

This field allows an administrator to set the priority of a job according the group's priority.

#### **Account**

This field allows an administrator to set the priority of a job according the account's priority.

#### **Class**

This field allows an administrator to set the priority of a job according the class's priority.

#### **QoS**

This field allows an administrator to set the priority of a job according the Quality of Service (QoS)'s priority.

### Job Attribute/State Priority

#### **Attribute**

This field allows an administrator to set the priority of a job according a job's attributes. Refer to the Workload Manager Priority Factors documentation for information on how to set the Job Attributes.

#### **State**

This field allows an administrator to set the priority of a job according a job's state.

### Fairshare Usage Priority

#### **User**

This field allows an administrator to set the user's priority of a job according to the fairshare usage.

**Group**

This field allows an administrator to set the group's priority of a job according to the fairshare usage.

**Account**

This field allows an administrator to set the account's priority of a job according to the fairshare usage.

**Class**

This field allows an administrator to set the class's priority of a job according to the fairshare usage.

**Quality of Service (QoS)**

This field allows an administrator to set the qualities of service (QoS)'s priority of a job according to the fairshare usage.

**Jobs Per User**

This field allows an administrator to set the priority of a job according to the number of jobs currently executing for this user.

**Processor Seconds per User**

This field allows an administrator to set the priority of a job according to the number of processor seconds currently being used by this user.

**Processors per User**

This field allows an administrator to set the priority of a job according to the number of processors currently being used by this user.

**Resource Requests Priority****Node**

This field allows an administrator to set the priority of a job according to the total number of nodes requested by the job. The more nodes requested, the higher the Node value.

**Disk**

This field allows an administrator to set the priority of a job according to the total amount of disk space requested by the job. The more disk space requested, the higher the disk value.

**Memory**

This field allows an administrator to set the priority of a job according to the total amount of memory in megabytes requested by the job. The more memory requested, the higher the Memory value.

**Swap**

This field allows an administrator to set the priority of a job according to the total amount of swap in megabytes requested by the job. The more swap requested, the higher the swap value.

**Processor-Equivalent**

This field allows an administrator to set the priority of a job according to the total number of processor equivalents requested by the job. The more processor equivalents requested, the higher the processor equivalent's value.

**Walltime**

This field allows an administrator to set the priority of a job according to the total amount of walltime seconds requested by the job. The more walltime requested, the higher the Walltime value.

Executing Job Usage Priority**Consumed**

This field allows an administrator to set the priority of a job according to the total number of processor seconds it has consumed. Unlike other components, this component only effects executing jobs and is only applicable when preemption is used.

**Remaining**

This field allows an administrator to set the priority of a job according to the total number of processor seconds it has remaining. Unlike other components this component only effects executing jobs and is only applicable when preemption is used.

**Percentage Consumed**

This field allows an administrator to set the priority of a job according to the percentage of the Wallclock that has been consumed. Unlike other components, this component only affects executing jobs and is only applicable when preemption is used.

Priority Chart Options**Display start priority pie chart**

This option displays a pie chart of the priority components. Negative components are not displayed.

**Display start priority bar graph**

This option displays a bar chart of the priority components. Positive and negative components are displayed.

## Reservation policies

Workload Manager uses reservations to guarantee that a specific amount of resources will be available for a given job or set of users at a particular time. For example, Workload Manager can reserve 20 processors and 10 GB of memory for users Bob and John from Friday 6:00 AM to Saturday 10:00 PM. Workload Manager uses reservations internally to manage backfill, protect job resources, allow service guarantees, support deadlines and QoS, and enable grid scheduling. Workload Manager supports infinite, reoccurring, and one-time reservations.

When backfill is enabled, Workload Manager attempts to schedule lower-priority jobs ahead of a higher-priority job that can't start immediately. In order to ensure that those low-priority jobs don't delay the high-priority job's start time, Workload Manager can reserve the resources needed by the high-priority

job. These are called priority reservations. The reservation policy determines how Workload Manager handles priority reservations.

### Reservation Settings

#### Policy

This is the policy Workload Manager uses when creating priority reservations. These reservations protect the resources a job is using until the job completes.

Policy	Description
<b>CurrentHighest</b>	Existent priority reservations will be relinquished to new jobs with higher priority
<b>Highest</b>	All idle jobs that receive a reservation will keep it until they run even if new jobs are higher priority
<b>Never</b>	No idle jobs receive reservations

#### Depth

This is how many priority reservations Workload Manager will create. A higher value protects the start time of high-priority jobs but may decrease backfill efficiency.

#### Reservations Per Node

This is the maximum number of priority reservations that can be created on any single node. On large SMP systems, this value should be set to approximately twice the number of reservations that exist on the system.

#### Retry Time

This is the period of time Workload Manager attempts to restart a job with a priority reservation that originally failed to start.

#### Creation Policy

This determines which users can create one-time reservations (also called Administrative reservations). This setting is unrelated to priority reservations.

## User access

The User Access Settings page, found by clicking **Policies > User Access...** in the main menu bar or **Policies > User Access** in the navigation pane, allows an administrator to assign roles to each user in the system. These settings are saved in Workload Manager and affect command-line operations, as well as permissions within Cluster Manager. The set of default roles available is:

Role	Description
<b>Admin1</b>	Users with this role are called administrators. They have complete control of Workload Manager.
<b>Admin2</b>	Users with this role are called operators. They have complete control of jobs, nodes, reservations, etc., but cannot modify Workload Manager configuration parameters.
<b>Admin3</b>	Users with this role are called help desk personnel. They can control various aspects of Workload Manager, but cannot modify workload.
<b>Admin4</b>	Users with this role are most likely trusted or experienced users. They have a subset of Admin2 permissions that is different from Admin3's.
<b>Admin5</b>	Users with this role can only view workload and resource information.

## Reporting

### Reporting Overview

Cluster Manager offers a wide assortment of customizable statistics whether they be customized charts, graphs, matrix statistics, quick charts, or reports.

### Custom charts/graphs

This window allows you to create charts and graphs showing statistics over a custom time interval. You can create pie, bar, line, and stacked line charts and, if desired, export those charts as PNG files. To export a chart, right click it and select "save as" from the menu. Zoom in on sections of the line charts by using the mouse to drag a box over the area of interest. The domain and range axes will automatically be adjusted. To return to the original zoomed out view, hold down the left mouse button, drag towards the left, and release the mouse button.

Note that, since charts with large time ranges are sampled for efficiency, the zoomed-in chart may not be as detailed as directly creating a chart for the zoomed-in time range. For example, you might create a line chart for all of 2008 and zoom in on September 1st. The zoomed-in portion of this chart will be less detailed than if you specified the time parameters as 12:00 am Sept 1 to 11:59 pm Sept. 1st when initially creating the chart.

## Credential Based Charts

### Select Credentials

The drop down box allows you to select which credential for which Moab Cluster Manager will calculate statistics or if the cluster-wide statistics should be used. The Display All Credentials option displays all the credentials that have been tracked by the statistics regardless of whether they have any activity recorded. The Display Credentials with Statistics option displays only the credentials that have recorded some type of activity. The Display Listed Credentials option displays only the requested credentials.

**Select Metric**

One can select from the following metrics when creating a chart.

Metric	Description
<b>Backlog Hours****</b>	The total number of processor hours of all jobs waiting in the queue that belong to a specific credential. Processor hours are calculated by multiplying requested processors and wallclock; for example, a job that requests 10 hours of wallclock time and 3 processors has 30 backlog hours while the job is waiting in the queue.
<b>Dedicated Processor Hours</b>	The number of processor hours dedicated to jobs run by this credential, regardless of whether those jobs are actually using those processors.
<b>Executed Jobs</b>	The number of jobs belonging to this credential that have finished execution. If a line graph is selected, each y value is the number of jobs that completed during the profiling interval around the value on the x axis.
<b>Jobs That Met QOS Target**</b>	The percentage of completed jobs that met their QOS target to total jobs.
<b>Queue Hours**</b>	The number of hours a credential's jobs waited in the queue before starting. Note that queue hours are floored to the closest lower integer value. For example, 23.8 would be floored to 23. This also means that if there are only .9 queue hours, then 0 will be reported.
<b>Resource Requests</b>	Causes three fields to be charted - processor-seconds, memory, and wallclock per credentials that either exceeded the requested resource or under-utilized the requested resource.
<b>System Utilization*</b>	This field displays the system utilization percentage and should range between 0% and 100%. Each value is calculated as dedicated processor hours for that profiling interval divided by the total number of processor hours available on that system in that profiling interval (times 100). For example, if the profiling interval was 1 hour, there were 10 total processors, and 5 of those processors were in use for the entire profiling interval, the calculation would be $(5 \text{ proc hours} / 10 \text{ procs} * 1 \text{ hour}) * 100 = 50\%$ . This makes sense intuitively as half the processors were in use during the profiling interval.
<b>Utilized Processor Hours</b>	The number of processor hours utilized by this credential. Processors that are idle yet are dedicated to the credential are not counted. It is recommended that one use dedicated instead of utilized processor hours where possible since utilized processor hours are dependent on the accuracy of the resource manager, and some resource managers are known to report inaccurate utilized processor hours. Dedicated processor hours are calculated based on data from within Moab Workload Manager and are a more dependable statistic.
<b>XFactor** (Expansion Factor)</b>	The expansion factor of a job is defined as $((\text{Queue Time} + \text{Execution Time}) / \text{Requested Wallclock Time})$ .

In addition to the above metrics, one can select any generic metrics that are configured in the system. Generic metric charts are line graphs that show the cumulative generic metric for all nodes dedicated to this credential. For example, if at a certain time user Bob used 3 nodes which each used 10 WATTS, where WATTS was defined as a generic metric, the corresponding point on the line graph for that time would be 30 WATTS.

**i** Because Workload Manager operates by averaging usage across its statistical intervals the values displayed can be misleading. For example, if the statistical interval for Workload Manager was set to 10 minutes for a cluster of 256 processors and one job, which used all 256 processors, was submitted that started and ended in 5 minutes, then an administrator would assume the System Utilization would display 100% of the processors used. However, because the interval was 10 minutes long and the job only ran for 5 minutes, the average System Utilization for the 10 minute interval was 50%.

**i** This field can only be calculated when a job finishes execution.

**i** Requires that Moab is running under a dedicated node model where a node can be running only 1 job at a time.

**i** The accuracy of backlog hour charts is somewhat less precise when a **NODEACCESSPOLICY** is being used.

### Select Calculation Parameters

The pie charts and bar graphs can be customized to display averages, maximums, sums, and/or line graphs, depending on what calculation parameters are appropriate to the usage metric. Some calculation parameters make little sense for certain usage metrics and thus are disabled.

#### Average

The charts will display either the average per job or average per profiling interval, depending on the usage metric. For example, average backlog per profiling interval will show the average amount of backlog in any given profiling interval.

#### Max

The charts will display the maximum value of this usage metric that was achieved in a profiling interval. For example, the maximum System Utilization in a Profiling Interval will show you the highest system utilization level achieved in a single profiling interval.

#### Sum/Total

The charts will display the sum of the usage metric for all profiling intervals in the selected time window. For example, a chart that shows Total Executed Jobs for April 2008 will display the total number of jobs that executed for each of the selected credentials in April of 2008.

#### Line Graph

One can see a line graph showing the values of the usage metric at each profile interval in the requested time frame.

## Chart Type

For formatting, you can choose from Pie Chart, 3D Pie Chart, Bar Graph, 3D Bar Graph, and Line Graph.

## Time Frame

Choose a time frame for the graph. Time frames can be chosen from the basis of Month, Week, Day, Hour, or Custom.

Time Frame	Description
<b>Month</b>	Gathers data from the first of the month to the end of the month. For example, if today was the 13th of October selecting Month would cause a chart to display data from the 1st through the 31st of October.
<b>Week</b>	Gathers data from midnight Sunday morning of the current week to the current time.
<b>Day</b>	Gathers data from the midnight this morning to just before midnight tonight.
<b>Hour</b>	Gathers data starting at the 0th second of the current hour. For example, if the current time was 11:15am selecting Hour would cause a chart to be created with data from 11:00am to the 11:15am.
<b>Custom</b>	Gathers data from the start time and ends at the end time.

## Node Based Charts

### Node Categorization Charts

Creates charts that show node categorization over time. For example, one might create a line chart that will show when nodes were in a hardware failure state or create a bar graph to show how much time nodes spent in user reservations. Node categories are a superset of the standard idle, busy, and down states commonly found in batch systems. Some examples include Hardware Failure, Software Failure, Maintenance, etc. For more detailed information, see the [Moab Workload Manager Administrator's Guide](#).

Creating a stacked line graph brings up a chart window that allows one to dynamically make node categories visible or invisible. It shows these node categories in a tree structure where branches corresponding to node categories can be expanded or contracted. As these node categories are expanded or contracted the chart is immediately updated. For example, one might collapse the hardware failure and software failure categories into the parent down time node category.

### Why do only 4 of the node categories appear on the chart?

By default, Moab will only categorize nodes into the states idle, active, hardwareFailure, and [NONE]/Other. Usually [NONE]/Other means that Moab was not running. In order to see the other node categories, one must set a reservation on the node indicating the desired category. For example, for

node001 to appear as being in the hardware maintenance state one would set a reservation on node001 whose duration matched the length of the hardware maintenance. Administrators wanting accurate node categorization charts should consider using triggers to set reservations when nodes change state.

## Generic Metric Charts

Creates charts that show the generic metric values of nodes over time. For example, if there was a generic metric called WATTS one could create a chart that showed the WATTS value for each in a set of selected nodes. For information on how to configure generic metrics, see the [Moab Workload Manager Administrator's Guide](#).

To create a chart, simply select the desired nodes and generic metric and click the create button. A chart should appear. If there are too many nodes in your system to view in a single chart, the paging buttons will be enabled. Click the Next Page button to see the next 10 nodes.

You can also filter out data sequences which are not of interest. To do this, click the Advanced checkbox at the lower left of the chart. A lower panel should appear allowing you to select nodes that either spike or average above or below a certain threshold. Clicking the Apply Filter button causes this change to be reflected in the chart. For example, one might only choose to see nodes that spike above 80 WATTS. The Aggregate Nodes into One Sequence option allows one to see a single line where each point represents the sum of the values for all selected nodes for the corresponding time. This would allow one to see how the total number of WATTS used by all nodes in the cluster changes over time.

## What to do if you see a warning that generic metrics aren't configured

If a chart cannot be created due to a warning informing you that no generic metrics are configured in Moab Workload Manager, you should check to see that your resource manager is returning generic metric information to Moab Workload Manager. Generic Metrics are usually returned to Moab Workload Manager through the **CLUSTERQUERYURL** configured in your `moab.cfg`.

 The accuracy of generic metric charts is dependent on the resource manager, since this is where Moab gets generic metric information.

## Job Template Charts

This window allows one to create charts that show statistics relating to job templates. To create a chart, simply select the desired job templates, usage metric, calculation parameters, chart type, and time frame and click the create button.

## Why am I warned that no job templates are configured?

If you cannot create a chart due to a warning that statistics for job templates is not configured in Moab Workload Manager, modify your `moab.cfg`. Most likely you either have no job templates configured or you did not add the JSTAT attribute. Moab Workload Manager will not collect statistical data for job templates not configured with a JSTAT attribute. For more information on configuring job templates with JSTAT, see the [Moab Workload Manager Administrators Guide](#).

## Event calendar

The events calendar helps you view the events you are interested in while filtering out those you are not interested in. This can be much more convenient than searching through logs and event files. Once you have finished filtering, you can view the details of the remaining events and correlate this with your nodes' state history.

### Filtering

The first filter you should probably apply is the time filter. After setting a start and end time, you can then select what type of events you wish to see. Use the tree control at the top left of this window to click the event types and/or subtypes you desire. For example, you might choose to see all events, all job events, or job end events only. After making your selection, click the Apply Filter button.

If you are looking for events for a specific object, and you know the object's name, you can filter out all other events by specifying the object type and ID in the fields at the lower left. For example, you might wish to see only events relating to the job **moab.2**. To do this, you would specify an object type of "Job" and an object ID of **moab.2**.

### Viewing Event Details

To view the details of desired events, simply click their colored icon representations in the timeline. Note that on busy schedulers, an icon may represent multiple events. You will be able to see the event type, ID, time, object type, object ID, and any messages from the scheduler pertaining to this event.

### The Node State/Node Category Chart

Below the timeline is a colored line chart. Vertically below any point on the timeline one can see the percentage of nodes that were active, idle, down, etc. This can be useful in determining the events you might want to filter. For example, if you see that 30% of your nodes suddenly went idle, yet you know there was a large backlog during that time, you might want to view all reservation start events. This might help you find an unused reservation responsible for the idle nodes.

## Matrix statistics

Matrix statistics are used both to analyze historic workload and to predict future workload. The left column of the table displays different job processor sizes. The top column displays relative time frames in the format Hours:Minutes:Seconds.

For example, the table below would be understood as follows. For jobs using 1 processor, 12 jobs are completed within the first 15 minutes of execution and 8 jobs are completed after the first 15 minutes and before the first hour of execution. For jobs using 4 processors, 5 jobs are completed within the first 15 minutes of execution and 0 jobs are completed after the first 15 minutes and before the first hour of execution.

Total Completed Jobs	00:15:00	01:00:00
1 Processor	12	8

<b>Total Completed Jobs</b>	<b>00:15:00</b>	<b>01:00:00</b>
<b>4 Processors</b>	5	-

## Matrix Statistics Types

Matrix Statistic Type	Description
<b>Estimated Start Time</b>	This field displays the predicted start time of a submitted job according to the number of processors the job would use. This information can help users determine how many processors they should submit a job to for optimal start time. For example, it may take less time to start a four-hour job submitted to four processors, than to one processor for a sixteen-hour job.
<b>Average X-Factor (Expansion Factor)</b>	This field displays the historic average expansion factor of a job according to the number of processors it used. The expansion factor is calculated using the following equation: $((\text{queue time of a job} + \text{job's duration}) / \text{job duration})$ .
<b>Maximum X-Factor (Expansion Factor)</b>	This field displays the historic maximum job expansion factor of a job according to the number of processors it used. The expansion factor is calculated using the following equation: $((\text{queue time of a job} + \text{job's duration}) / \text{job duration})$ .
<b>Average Job Queue Time</b>	This field displays the historic average wait time before a job starts executing, according to the number of processors it used. Queue time is the number of hours a job waited before it began execution.
<b>Average Job By Pass</b>	This field displays the historic average by pass of a job according to the number of processors it used. By pass is the number of jobs that started execution before this job because of backfill policies. This is useful in recognizing which types of jobs are being by passed by backfill.
<b>Maximum Job By Pass</b>	This field displays the historic maximum by pass of a job according to the number of processors it used. Bypass is the number of jobs that started execution before this job because of backfill policies. This is useful in recognizing which types of jobs are being by passed by backfill.
<b>Total Completed Jobs</b>	This field displays the total number of jobs that completed in the time interval according to the number of processors they used.

Matrix Statistic Type	Description
<b>Cluster Proc Hours Requested (%)</b>	This field displays a breakdown of the requested time on the cluster according to the number of processor hours. Processor hours are the number of processors times the number of hours that they were requested. The sum total of the table is 100%. Each cell inside the table gives the percentage of the total cluster processor hours requested by jobs of that size and duration.
<b>Cluster Proc Hours Utilized (%)</b>	This field displays a breakdown of the utilized time on the cluster according to the number of processor hours. Processor hours are the number of processors times the number of hours that they were utilized. The sum total of the entire table is 100%. Each cell inside the table gives the percentage of the total cluster processor hours utilized by jobs of that size and duration.
<b>Wall Clock Accuracy (%)</b>	This field displays the average Wallclock accuracy, or user estimate accuracy of how long a job would execute, according to the number of processors it used. A value greater than 100 indicates the average user overestimates the job Wallclock time. A value less than 100 indicates the average user underestimates the job wallclock time. A value of 100 indicates the average user estimates the job wallclock accurately.
<b>Total Backfill Count (%)</b>	This field displays the percentage of jobs that were delayed in executing because the backfill policy made them execute later.
<b>Backfill Proc Hours Executed (%)</b>	This field displays the percentage of processor hours for jobs that were delayed in executing because of the backfill policy that later executed.
<b>Job Efficiency (%)</b>	This field displays the average percentage of the CPU that jobs used according to the number of processors of each job.
<b>Quality of Service (QoS) Utilized (%)</b>	This field displays the average percentage of jobs that received their desired quality of service (QoS) according to the number of processors they used.

## Processor usage

This graph displays how the cluster's processors are being used over time. The left bar, or y-axis, displays the number of processors. The bottom bar, or x-axis, displays time. The light yellow color displays the total available processors on the cluster. The dark yellow color displays the processors used

by jobs and job reservations. The blue color displays the processors used by reservations other than job reservations.

The switch statistics option allows for the Available Processors and Jobs Reservations colors to be switched.

## Quick charts/graphs

Quick Charts provides a simple interface for viewing the most common statistics. Statistics are gathered from the first day of the current month to the last day of the current day, week, or month.

### Available Charts

1. System Overview
2. Total Processor Hours Per Account
3. Average Job Queue Time Per Account
4. Total Processor Hours Per User
5. Job Queue Time Per Quality of Service

## Reports

The Reports section (**Reporting > Reports**) allows you to generate a custom Basic, Advanced, or Detailed Summary Report. To create a report, you must use the fields described below.

### Basic Report

#### Select Credentials

The drop down box allows you to select which credential for which Moab Cluster Manager will calculate statistics or if the cluster-wide statistics should be used. The **Display All Credentials** option displays all the credentials that have been tracked by the statistics regardless of whether they have any activity recorded. The **Display Credentials with Statistics** option displays only the credentials that have recorded some type of activity. The **Display Listed Credentials** option displays only the requested credentials.

**Select Usage Metric**

You can select from the following metric when you generate a report:

Metric	Description
<b>Executed Jobs</b>	The number of jobs belonging to this credential that have finished execution. If a line graph is selected, each y value is the number of jobs that completed during the profiling interval around the value on the x axis.
<b>Dedicated Proc. Hours</b>	The number of processor hours dedicated to jobs run by this credential, regardless of whether those jobs are actually using those processors.
<b>Utilized Proc. Hours</b>	The number of processor hours utilized by this credential. Processors that are idle yet are dedicated to the credential are not counted. It is recommended that one use dedicated instead of utilized processor hours where possible since utilized processor hours are dependent on the accuracy of the resource manager, and some resource managers are known to report inaccurate utilized processor hours. Dedicated processor hours are calculated based on data from within Moab Workload Manager and are a more dependable statistic.
<b>System Utilization</b>	This field displays the system utilization percentage and should range between 0% and 100%. Each value is calculated as dedicated processor hours for that profiling interval divided by the total number of processor hours available on that system in that profiling interval (times 100). For example, if the profiling interval was 1 hour, there were 10 total processors, and 5 of those processors were in use for the entire profiling interval, the calculation would be $(5 \text{ proc hours} / 10 \text{ procs} * 1 \text{ hour}) * 100 = 50\%$ . This makes sense intuitively as half the processors were in use during the profiling interval.
<b>Queue Hours</b>	The number of hours a credential's jobs waited in the queue before starting. Note that queue hours are floored to the closest lower integer value. For example, 23.8 would be floored to 23. This also means that if there is only .9 queue hours then 0 will be reported.
<b>BackLog Hours</b>	The number of processor hours of the jobs belonging to this credential that are waiting in the queue.
<b>XFactor (Expansion Factor)</b>	The expansion factor of a job is defined as $((\text{Queue Time} + \text{Execution Time}) / \text{Requested Wallclock Time})$ .
<b>Used Wallclock Hours</b>	The total number of wallclock hours used by this credential.

**Select Calculation Parameters**

Field	Description
<b>Avg Per</b>	<p>If you select this option, you may choose from the following options:</p> <ul style="list-style-type: none"> <li>• Job - the average amount of queue hours, xfactor, or used wallclock hours per job.</li> <li>• Profiling Interval - the average amount of backlog or system utilization in any given profiling interval.</li> </ul>
<b>Max In a Profiling Interval</b>	<p>If you select this option, the report will display the maximum value of this usage metric that was achieved in a profiling interval. For example, the maximum system utilization in a profiling interval will show you the highest system utilization level achieved in a single profiling interval.</p>
<b>Sum/Total</b>	<p>If you select this option, the report will display the total of the selected metric for the selected credential.</p>

## Advanced Report

**Select Credentials**

The drop down box allows you to select which credential for which Moab Cluster Manager will calculate statistics or if the cluster-wide statistics should be used. The **Display All Credentials** option displays all the credentials that have been tracked by the statistics regardless of whether they have any activity recorded. The **Display Credentials with Statistics** option displays only the credentials that have recorded some type of activity. The **Display Listed Credentials** option displays only the requested credentials.

**Categorized By**

The drop-down box allows you to select a credential type by which the report will be categorized. For instance, if you selected User in the first drop-down and Class in the second, you can generate a report that displays all metrics submitted or used by a user under certain classes. The **Display All Credentials** option displays all the credentials that have been tracked by the statistics regardless of whether they have any activity recorded. The **Display Listed Credentials** option displays only the requested credentials.

**Select Usage Metric**

You can select any of the metrics described in the [Basic Report](#) section on this page.

## Detailed Summary Report

**Select Credentials**

The drop-down box allows you to select a credential type on which to run the report. Use the textbox and the Select User popup below the drop-down to select only specific credentials for the report.

Since only one option is available, you do not need to select a usage metric before generating the report.

## Command line charts/graphs/reports

### Command Line Charts & Graphs

You can create many of the pie, bar, and line charts available from the credential tab in the Charts & Graphs window using a command line interface, which can be faster than navigating through windows and menus. The command line interface also facilitates scripting. For example, you could create a cron job that generates charts at regular intervals and puts them in a specific directory.

To create charts from the command line, navigate to the scripts directory. There should be a script entitled `createchart.sh` and a sample properties file called `cmdlinechart.cfg`. If you are running on Windows, you will want to use `createchart.bat` instead of `createchart.sh`. The `cmdlinechart.cfg` file is a properties file that lets you specify information about what timeframe, credentials, and metric you would like to see in your chart. It includes comments explaining what each property does and has example values. The properties file lets you specify how to connect to Moab Workload Manager. You can use this script to connect to a Moab Workload Manager running either locally or remotely over SSH.

If running on a Unix based operating system you would run the following:

```
./createchart.sh cmdlinechart.cfg
```

If running Windows you would use:

```
createchart.bat cmdlinechart.cfg
```

If the scripts do not work, export `MCM_HOME` and use the following command to generate graphs and charts:

```
export MCM_HOME=/home/bob/mcm-7.0.0-5313
java -cp $MCM_HOME/mcm.jar com.moab.commandline.statistics.CreateChart
cmdlinechart.cfg [-- password <PASSWORD>]
```

*Explanation...*

### Command Line Reports

You can also use the command line to create many of the phone bill style reports available from the Reports window. Similar to command line charts, there is a `createreport.sh` script for Unix based operating systems and a `createreport.bat` script for Windows users. The `cmdlinereport.cfg` file is a sample properties file that contains parameters on how to connect to Moab Workload Manager.

To create reports on a Unix system:

```
./createreport.sh cmdlinereport.cfg
```

If running Windows you would run:

```
createreport.bat cmdlinereport.cfg
```

# Diagnostics

## Diagnostics Overview

Diagnostics are intended to give an administrator quick and easy system information for diagnosing potential problems.

## Diagnostics support

The diagnostics support features (**Help > Support Diagnostics...** in the main menu bar) allows the user to run a set of commands that will check the status of various parts of the system. These commands are controlled by a script named, `support.diag.pl`. This should be in your `$PREFIX/tools/moab` directory.

 This window will not work without the `support.diag.pl` script.

The diagnostics support screen allows the user to select from the tree what commands to run using a built in script. The script will then package the output of each command into a file. This file is saved in an output directory specified by the user or by default in `/tmp/`.

If anything should go wrong in the support process, a pop-up box will open saying what happened. If this is not sufficient, please consult the `mcm.log` file for more information.

# Miscellaneous

## Miscellaneous Overview

Various Cluster Manager sections that don't fit in other categories are contained here.

## Console

Cluster Manager communicates directly with Workload Manager. This console displays the commands submitted to Workload Manager from Cluster Manager as well as any information returned by Workload Manager. Workload Manager output messages are highlighted in green while error messages are highlighted in red.

**Prepend path to Moab Workload Manager commands**

This checkbox indicates whether the path the Moab client commands should be prepended to the commands being run. For example, if checked, the command `showq` would become `/opt/moab/bin/showq` (assuming the Moab path was `/opt/moab/bin`). If false, it would stay `showq` and might result in an error if the Moab client commands were not in the default `$PATH` environment variable. This should be checked when running Moab commands and unchecked when running anything else. If the path was prepended for a non-Moab command like `pwd`, it would become `/opt/moab/bin/pwd`, which would result in an error.

**Process Commands**

This field will submit to Workload Manager any text in the Commands text window.

## Debugging and log levels

Allows users to select the log level in Moab Cluster Manager, which can be used to help prepare logs to be accompanied with bug reports. Logs are written to the `<MCM_HOME>/logs/mcm.log` file. Higher logging levels create more detailed logging information, which facilitates debugging but may slow performance.

Below are the logging levels available, listed in order of increasing verbosity.

Level	Name	Description
0	Off	Turns off logging.
1	Fatal	Logs only server events that cause the application to abort.
2	Error	Logs all events that Fatal logs plus error events that might allow the application to continue running.
3	Warn	Logs everything that Error logs plus other minor problems.
4	Info	Logs everything that Warn logs does, plus informational messages that highlight the progress of the application at coarse-grained level.
5	Info- With- Moab- Cmd- Debug	Logs everything that Info logs plus all the interaction with Moab Workload Manager except the frequent (defaults to every 2 seconds) commands to determine if Moab Cluster Manager should refresh data from Moab Workload Manager.
6	Debug	Logs everything that Info-With-Moab-Cmd-Debug level logs plus fine-grained informational events that are useful in debugging.

Level	Name	Description
7	Trace	The most verbose logging level. The only level that logs all interaction with Moab Workload Manager, including the frequent refresh checks ignored by other logging levels.

Users can configure extremely fine grained logging information by editing the `<MCM_HOME>/conf/log4j.properties` file. Using this file, one can set the log level on individual classes or packages within Moab Cluster Manager. It should be noted that configuring individual package or class loggers in the `log4j.properties` file other than the root logger or the logger for `com.moab.api.XMLDebuggingTools` may override the settings applied from this window.

**i** Verbose log levels cause a small performance penalty. Because levels 5 and above log all the interaction with Moab Workload Manager, they can use substantially more memory when connected to larger systems.

## MCM preferences

These preferences control Cluster Manager-specific settings. You can access this window by clicking **Configure > Preferences** in the main menu bar.

### Cache Refresh Rate

The more often Cluster Manager communicates with Workload Manager the more up-to-date the information; however, when Cluster Manager communicates with Workload Manager more often, Workload Manager operates at a slower pace.

#### **Fast**

At this refresh rate Cluster Manager updates its information every minute.

#### **Medium**

At this refresh rate, which is the default refresh rate, Cluster Manager updates its information every 10 minutes.

#### **Slow**

At this refresh rate Cluster Manager updates its information every hour.

### Advanced Settings

Check this box to enable more advanced options throughout Cluster Manager. Currently, the plugin Manager is the only option available.

### Font Size

This option specifies the font size used throughout MCM. Valid sizes are from 9 - 14. Default is 11. MCM must be restarted in order for font size changes to take effect.

## Moab Commands

### **Automatically Process Moab Commands**

If checked, all commands submitted to Moab are automatically processed. If unchecked, all commands are displayed in the commands console for review. Unprocessed commands will have to be manually submitted via the Console.

### **Show Command Output in Pop up Window**

If checked, the output of all commands submitted to will be shown in a pop up window after the commands have run. If not checked, no pop up window will display.

## Navigation

Unchecking the Show Navigation box removes the navigation pane on the left of the summary screen. You can easily replace the pane by checking the box again.

# TORQUE Resource Manager

## Introduction

This section contains some basic introduction information to help you get started using TORQUE. It contains these topics:

- [What is a Resource Manager? on page 2541](#)
- [What are Batch Systems? on page 2541](#)
- [Basic Job Flow on page 2542](#)

### **What is a Resource Manager?**

While TORQUE has a built-in scheduler, `pbs_sched`, it is typically used solely as a *resource manager* with a scheduler making requests to it. Resources managers provide the low-level functionality to start, hold, cancel, and monitor jobs. Without these capabilities, a scheduler alone cannot control jobs.

### **What are Batch Systems?**

While TORQUE is flexible enough to handle scheduling a conference room, it is primarily used in batch systems. Batch systems are a collection of computers and other resources (networks, storage systems, license servers, and so forth) that operate under the notion that the whole is greater than the sum of the parts. Some batch systems consist of just a handful of machines running single-processor jobs, minimally managed by the users themselves. Other systems have thousands and thousands of machines executing users' jobs simultaneously while tracking software licenses and access to hardware equipment and storage systems.

Pooling resources in a batch system typically reduces technical administration of resources while offering a uniform view to users. Once configured properly, batch systems abstract away many of the details involved with running and managing jobs, allowing higher resource utilization. For example, users

typically only need to specify the minimal constraints of a job and do not need to know the individual machine names of each host on which they are running. With this uniform abstracted view, batch systems can execute thousands and thousands of jobs simultaneously.

Batch systems are comprised of four different components: (1) Master Node, (2) Submit/Interactive Nodes, (3) Compute Nodes, and (4) Resources.

Component	Description
<b>Master Node</b>	A batch system will have a master node where <code>pbs_server</code> runs. Depending on the needs of the systems, a master node may be dedicated to this task, or it may fulfill the roles of other components as well.
<b>Submit/Interactive Nodes</b>	Submit or interactive nodes provide an entry point to the system for users to manage their workload. For these nodes, users are able to submit and track their jobs. Additionally, some sites have one or more nodes reserved for interactive use, such as testing and troubleshooting environment problems. These nodes have client commands (such as <code>qsub</code> and <code>qhold</code> ).
<b>Computer Nodes</b>	Compute nodes are the workhorses of the system. Their role is to execute submitted jobs. On each compute node, <code>pbs_mom</code> runs to start, kill, and manage submitted jobs. It communicates with <code>pbs_server</code> on the master node. Depending on the needs of the systems, a compute node may double as the master node (or more).
<b>Resources</b>	Some systems are organized for the express purpose of managing a collection of resources beyond compute nodes. Resources can include high-speed networks, storage systems, license managers, and so forth. Availability of these resources is limited and needs to be managed intelligently to promote fairness and increased utilization.

## Basic Job Flow

The life cycle of a job can be divided into four stages: (1) creation, (2) submission, (3) execution, and (4) finalization.

Stage	Description
<b>Creation</b>	<p>Typically, a submit script is written to hold all of the parameters of a job. These parameters could include how long a job should run (<b>walltime</b>), what resources are necessary to run, and what to execute. The following is an example submit file:</p> <pre>#PBS -N localBlast #PBS -S /bin/sh #PBS -l nodes=1:ppn=2,walltime=240:00:00 #PBS -M user@my.organization.com #PBS -m ea source ~/.bashrc cd \$HOME/work/dir sh myBlast.sh -i -v</pre> <p>This submit script specifies the name of the job (<code>localBlast</code>), what environment to use (<code>/bin/sh</code>), that it needs both processors on a single node (<b>nodes=1:ppn=2</b>), that it will run for at most 10 days, and that TORQUE should email "user@my.organization.com" when the job exits or aborts. Additionally, the user specifies where and what to execute.</p>
<b>Submission</b>	A job is submitted with the <code>qsub</code> command. Once submitted, the policies set by the administration and technical staff of the site dictate the priority of the job and therefore, when it will start executing.
<b>Execution</b>	Jobs often spend most of their lifecycle executing. While a job is running, its status can be queried with <code>qstat</code> .
<b>Finalization</b>	When a job completes, by default, the <code>stdout</code> and <code>stderr</code> files are copied to the directory where the job was submitted.

- [Testing server configuration on page 2574](#)

- [TORQUE on NUMA systems on page 2576](#)
- [TORQUE Multi-MOM on page 2580](#)

## TORQUE installation overview

This section contains information about TORQUE architecture and explains how to install TORQUE. It also describes how to install tpackages on compute nodes and how to enable TORQUE as a service.

For details, see these topics:

- [TORQUE architecture on page 2544](#)
- [Installing](#)
- [Compute nodes on page 2549](#)
- [Enabling TORQUE as a service on page 2550](#)

Related topics

- [Troubleshooting on page 2665](#)

## TORQUE architecture

A TORQUE cluster consists of one head node and many compute nodes. The head node runs the `pbs_server` daemon and the compute nodes run the `pbs_mom` daemon. Client commands for submitting and managing jobs can be installed on any host (including hosts not running `pbs_server` or `pbs_mom`).

The head node also runs a scheduler daemon. The scheduler interacts with `pbs_server` to make local policy decisions for resource usage and allocate nodes to jobs. A simple FIFO scheduler, and code to construct more advanced schedulers, is provided in the TORQUE source distribution. Most TORQUE users choose to use a packaged, advanced scheduler such as [Maui](#) or [Moab](#).

Users submit jobs to `pbs_server` using the `qsub` command. When `pbs_server` receives a new job, it informs the scheduler. When the scheduler finds nodes for the job, it sends instructions to run the job with the node list to `pbs_server`. Then, `pbs_server` sends the new job to the first node in the node list and instructs it to launch the job. This node is designated the execution host and is called *Mother Superior*. Other nodes in a job are called *sister MOMs*.

- [TORQUE installation overview on page 2544](#)
- [Installing](#)

## Installing TORQUE

These instructions describe how to install and start TORQUE.

## Requirements

### *Supported Operating Systems*

- CentOS 6.5 or later
- Red Hat 6.5 or later
- Scientific Linux 6.5 or later
- SUSE Linux Enterprise Server 11 SP3 or later

**i** CentOS 5.9, Red Hat 5.9 and Scientific Linux 5.9 are supported, largely to continue support for clusters where the compute nodes operating systems cannot be upgraded. We recommend that the TORQUE head node run on the supported operating systems listed above.

### *Software Requirements*

- libxml2-devel package (package name may vary)
- openssl-devel package (package name may vary)
- Tcl/Tk version 8 or later if you plan to build the GUI portion of TORQUE or use a Tcl based scheduler
- If you use [cpuset](#)s, libhwloc 1.1 or later is required (for TORQUE 4.0.0 and later)

If you build TORQUE from source (i.e. clone from github), the following additional software is required:

- gcc
- gcc-c++
- A posix compatible version of make
- libtool 1.5.22
- boost-devel 1.36.0

## Prerequisites

- TORQUE requires certain ports to be open for essential communication:
  - For client communication to `pbs_server`, all privileged ports must be open (ports under 1024).
  - For `pbs_server` communication to `pbs_mom`, the default port is 15003.
  - For `pbs_mom` to `pbs_server`, the default port is 15001.

For more information on how to configure the ports that TORQUE uses for communication, see [Configuring ports on page 2555](#).

**i Important:** If you intend to use TORQUE 5.0.0 with Moab, you must run Moab version 8.0.0 or later. TORQUE 5.0.0 will not work with versions earlier than Moab 8.0.0.

- Make sure your host (with the correct IP address) is in your `/etc/hosts` file.
- The `libxml2-devel`, `openssl-devel`, and `boost-devel` packages must be installed (These packages should already be installed from following the steps in the [Preparing for installation on page 17](#)).

### RHEL 6.5 and CentOS 6.5, and Scientific Linux 6.5:

```
[root]# yum install openssl-devel libtool-devel libxml2-devel boost-devel gcc gcc-c++
```

### SLES

```
[root]# zypper install openssl-devel libtool-devel libxml2-devel boost-devel gcc gcc-c++
```

### RHEL 5 and CentOS 5, and Scientific Linux 5:

```
[root]# yum install openssl-devel libtool-devel libxml2-devel gcc gcc-c++
```

**i Important:** TORQUE requires Boost version 1.36.0 or greater. The `boost-devel` package provided with RHEL 5, CentOS 5, and Scientific Linux 5 is older than this requirement. A new option, `--with-boost-path` has been added to configure (see [Customizing the install on page 2558](#) in the *TORQUE Administrator Guide* for more information). This allows you to point TORQUE to a specific version of boost during make. One way to compile TORQUE without installing Boost is to simply download the Boost version you plan to use from: <http://www.boost.org/users/history/>. Next, untar Boost—you do not need to build it or install it. When you run TORQUE configure, use the `--with-boost-path` option pointed to the extracted Boost directory.

## To install TORQUE

1. Switch the user to root.

```
[user]$ su -
```

2. Download the latest 5.0.0 build from the [Adaptive Computing](#) website. It can also be downloaded via command line.
  - a. Clone the source from github. If you clone the source from github, the `libtool` package must be installed.

**i** If you are using CentOS 5, use these instructions for installing `libtool`:

```
[root]# cd /tmp
[root]# wget http://ftpmirror.gnu.org/libtool/libtool-2.4.2.tar.gz
[root]# tar -xzvf libtool-2.4.2.tar.gz
[root]# cd libtool-2.4.2
[root]# ./configure --prefix=/usr
[root]# make
[root]# make install
[root]# cd /tmp
[root]# git clone https://github.com/adaptivecomputing/torque.git -b
5.0.0 5.0.0
[root]# cd 5.0.0
[root]# ./autogen.sh
```

```
# RHEL 6 and Scientific Linux 6:
[root]# yum install git libtool
```

```
# SLES:
[root]# zypper install libtool
```

```
[root]# git clone https://github.com/adaptivecomputing/torque.git -b 5.0.0 5.0.0
[root]# cd 5.0.0
[root]# ./autogen.sh
```

- b. Get the tarball source distribution.

```
[root]# wget http://www.adaptivecomputing.com/download/torque/torque-
5.0.0.tar.gz -O torque-5.0.0.tar.gz

[root]# tar -xzvf torque-5.0.0.tar.gz
[root]# cd torque-5.0.0/
```

3. Run each of the following commands in order.

```
[root]# ./configure
[root]# make
[root]# make install
```

For information on what options are available to customize the `./configure` command, see [Customizing the install on page 2558](#).

4. Configure the `trqauthd` daemon to start automatically at system boot.

```

* If RHEL distribution, do the following *
[root]# cp contrib/init.d/trqauthd /etc/init.d/
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start

* If SLES distribution, do the following *
[root]# cp contrib/init.d/suse.trqauthd /etc/init.d/trqauthd
[root]# chkconfig --add trqauthd
[root]# echo /usr/local/lib > /etc/ld.so.conf.d/torque.conf
[root]# ldconfig
[root]# service trqauthd start

```

5. The `make packages` command can be used to create self-extracting packages that can be copied and executed on your nodes. For information on creating packages and deploying them, see [Compute nodes on page 2549](#).

You will also want to scp the `init.d` scripts to the compute nodes and install them there.

6. Verify that the `/var/spool/torque/server_name` file exists and contains the correct name of the server.

```
[root]# echo <pbs_server's_hostname> > /var/spool/torque/server_name
```

7. By default, TORQUE installs all binary files to `/usr/local/bin` and `/usr/local/sbin`. Make sure the path environment variable includes these directories for both the installation user and the root user.

```
[root]# export PATH=/usr/local/bin:/usr/local/sbin:$PATH
```

8. Initialize `serverdb` by executing the `torque.setup` script.

```
[root]# ./torque.setup root
```

9. Add nodes to the `/var/spool/torque/server_priv/nodes` file. For information on syntax and options for specifying compute nodes, see [Specifying compute nodes on page 2553](#).
10. Configure the MOMs if necessary (see [Configuring TORQUE on compute nodes on page 2554](#) in the TORQUE Administrator Guide).
11. Configure `pbs_server` and `pbs_mom` to start automatically at system boot, and then start their daemons.

```

* If RHEL distribution, do the following *
[root]# cp contrib/init.d/pbs_server contrib/init.d/pbs_mom /etc/init.d
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom
[root]# service pbs_server restart
[root]# service pbs_mom start

* If SLES distribution, do the following *
[root]# cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
[root]# cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
[root]# chkconfig --add pbs_server
[root]# chkconfig --add pbs_mom
[root]# service pbs_server restart
[root]# service pbs_mom start

```

- [Component documentation on page 86](#)

## Compute nodes

Use the Adaptive Computing tpackage system to create self-extracting tarballs which can be distributed and installed on compute nodes. The tpackages are customizable. See the `INSTALL` file for additional options and features.

**i** If you installed TORQUE using the RPMs, you must install and configure your nodes manually by modifying the `/var/spool/torque/mom_priv/config` file of each one. This file is identical for all compute nodes and can be created on the head node and distributed in parallel to all systems.

```

[root]# vi /var/spool/torque/mom_priv/config

$pbsserver      headnode      # hostname running pbs server
$logevent       225           # bitmap of which events to log

[root]# service pbs_mom restart

```

### To create tpackages

1. Configure and make as normal, and then run `make packages`.

```

> make packages
Building ./torque-package-clients-linux-i686.sh ...
Building ./torque-package-mom-linux-i686.sh ...
Building ./torque-package-server-linux-i686.sh ...
Building ./torque-package-gui-linux-i686.sh ...
Building ./torque-package-devel-linux-i686.sh ...
Done.

The package files are self-extracting packages that can be copied and executed on
your production machines. Use --help for options.

```

2. Copy the desired packages to a shared location.

```
> cp torque-package-mom-linux-i686.sh /shared/storage/
> cp torque-package-clients-linux-i686.sh /shared/storage/
```

### 3. Install the tpackages on the compute nodes.

Adaptive Computing recommends that you use a remote shell, such as SSH, to install tpackages on remote systems. Set up shared SSH keys if you do not want to supply a password for each host.

**i** The only required package for the compute node is mom-linux. Additional packages are recommended so you can use client commands and submit jobs from compute nodes.

The following is an example of how to copy and install mom-linux in a distributed fashion.

```
> for i in node01 node02 node03 node04 ; do scp torque-package-mom-linux-i686.sh
${i}:/tmp/. ; done
> for i in node01 node02 node03 node04 ; do scp torque-package-clients-linux-
i686.sh ${i}:/tmp/. ; done
> for i in node01 node02 node03 node04 ; do ssh ${i} /tmp/torque-package-mom-linux-
i686.sh --install ; done
> for i in node01 node02 node03 node04 ; do ssh ${i} /tmp/torque-package-clients-
linux-i686.sh --install ; done
```

Alternatively, you can use a tool like xCAT instead of dsh.

### To use a tool like xCAT

#### 1. Copy the tpackage to the nodes.

```
> prcp torque-package-linux-i686.sh noderange:/destinationdirectory/
```

#### 2. Install the tpackage.

```
> psh noderange /tmp/torque-package-linux-i686.sh --install
```

Although optional, it is possible to use the TORQUE server as a compute node and install a pbs\_mom with the pbs\_server daemon.

### Related topics

- [TORQUE installation overview on page 2544](#)

## Enabling TORQUE as a service

**i** Enabling TORQUE as a service is optional. In order to run TORQUE as a service, you must enable trqauthd. (see [Configuring trqauthd for client commands on page 2556](#)).

The method for enabling TORQUE as a service is dependent on the Linux variant you are using. Startup scripts are provided in the contrib/init.d/ directory of the source package. To enable TORQUE as a service, run the following on the host for the appropriate TORQUE daemon:

- RedHat (as root)

```
> cp contrib/init.d/pbs_mom /etc/init.d/pbs_mom
> chkconfig --add pbs_mom
> cp contrib/init.d/pbs_server /etc/init.d/pbs_server
> chkconfig --add pbs_server
```

- SuSE (as root)

```
> cp contrib/init.d/suse.pbs_mom /etc/init.d/pbs_mom
> insserv -d pbs_mom
> cp contrib/init.d/suse.pbs_server /etc/init.d/pbs_server
> insserv -d pbs_server
```

- Debian (as root)

```
> cp contrib/init.d/debian.pbs_mom /etc/init.d/pbs_mom
> update-rc.d pbs_mom defaults
> cp contrib/init.d/debian.pbs_server /etc/init.d/pbs_server
> update-rc.d pbs_server defaults
```

 You will need to customize these scripts to match your system.

These options can be added to the self-extracting packages. For more details, see the `INSTALL` file.

- [Configuring trqauthd for client commands on page 2556](#)

## Initializing/Configuring TORQUE on the server (pbs\_server)

The TORQUE server (`pbs_server`) contains all the information about a cluster. It knows about all of the MOM nodes in the cluster based on the information in the `$TORQUE_HOME/server_priv/nodes` file (See [Configuring TORQUE on compute nodes on page 2554](#)). It also maintains the status of each MOM node through updates from the MOMs in the cluster (see [pbsnodes on page 2705](#)). All jobs are submitted via [qsub](#) to the server, which maintains a master database of all jobs and their states.

Schedulers such as Moab Workload Manager receive job, queue, and node information from `pbs_server` and submit all jobs to be run to `pbs_server`.

The server configuration is maintained in a file named `serverdb`, located in `$TORQUE_HOME/server_priv`. The `serverdb` file contains all parameters pertaining to the operation of TORQUE plus all of the queues which are in the configuration. For `pbs_server` to run, `serverdb` must be initialized.

You can initialize `serverdb` in two different ways, but the recommended way is to use the `./torque.setup` script:

- As root, execute `./torque.setup` from the build directory (see [./torque.setup](#) on page 2552).
- Use `pbs_server -t create` (see [Initializing/Configuring TORQUE on the server \(pbs\\_server\)](#) on page 2551).

Restart `pbs_server` after initializing `serverdb`.

```
> qterm
> pbs_server
```

## ./torque.setup

The `torque.setup` script uses `pbs_server -t create` to initialize `serverdb` and then adds a user as a manager and operator of TORQUE and other commonly used attributes. The syntax is as follows:

`/torque.setup username`

```
> ./torque.setup ken
> qmgr -c 'p s'

#
# Create queues and set their attributes.
#
#
# Create and define queue batch
#
create queue batch
set queue batch queue_type = Execution
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server acl_hosts = kmn
set server managers = ken@kmn
set server operators = ken@kmn
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6
set server mom_job_sync = True
set server keep_completed = 300
```

## pbs\_server -t create

The `-t create` option instructs `pbs_server` to create the `serverdb` file and initialize it with a minimum configuration to run `pbs_server`.

```
> pbs_server -t create
```

To see the configuration and verify that TORQUE is configured correctly, use [qmgr](#):

```

> qmgr -c 'p s'
#
# Set server attributes.
#
set server acl_hosts = kmn
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6

```

A single queue named batch and a few needed server attributes are created.

This section contains these topics:

- [Specifying compute nodes on page 2553](#)
- [Configuring TORQUE on compute nodes on page 2554](#)
- [Finalizing configurations on page 2558](#)

Related topics

- [Appendix C: Node manager \(MOM\) configuration on page 2783](#)
- [Advanced configuration on page 2558](#)

## Specifying compute nodes

The environment variable `TORQUE_HOME` is where configuration files are stored. If you used the default locations during installation, you do not need to specify the `TORQUE_HOME` environment variable.

The `pbs_server` must recognize which systems on the network are its compute nodes. Specify each node on a line in the server's nodes file. This file is located at `TORQUE_HOME/server_priv/nodes`. In most cases, it is sufficient to specify just the names of the nodes on individual lines; however, various properties can be applied to each node.

 Only a root user can access the `server_priv` directory.

Syntax of nodes file:

```
node-name[:ts] [np=] [gpus=] [properties]
```

- The **node-name** must match the hostname on the node itself, including whether it is fully qualified or shortened.
- The **[:ts]** option marks the node as timeshared. Timeshared nodes are listed by the server in the node status report, but the server does not allocate jobs to them.
- The **[np=]** option specifies the number of virtual processors for a given node. The value can be less than, equal to, or greater than the number of physical processors on any given node.
- The **[gpus=]** option specifies the number of GPUs for a given node. The value can be less than, equal to, or greater than the number of physical GPUs on any given node.

- The node processor count can be automatically detected by the TORQUE server if **auto\_node\_np** is set to TRUE. This can be set using this command:

```
qmgr -c set server auto_node_np = True
```

Setting **auto\_node\_np** to TRUE overwrites the value of **np** set in `TORQUE_HOME/server_priv/nodes`.

- The **[properties]** option allows you to specify arbitrary strings to identify the node. Property strings are alphanumeric characters only and must begin with an alphabetic character.
- Comment lines are allowed in the nodes file if the first non-white space character is the pound sign (#).

The following example shows a possible node file listing.

`TORQUE_HOME/server_priv/nodes`:

```
# Nodes 001 and 003-005 are cluster nodes
#

## Configuring TORQUE on compute nodes

If using TORQUE self-extracting packages with default compute node configuration, no additional steps are required and you can skip this section.

If installing manually, or advanced compute node configuration is needed, edit the `TORQUE_HOME/mom_priv/config` file on each node. The recommended settings follow.

`TORQUE_HOME/mom_priv/config`:

```
$pbsserver      headnode      # hostname running pbs server
$logevent       225              # bitmap of which events to log
```

This file is identical for all compute nodes and can be created on the head node and distributed in parallel to all systems.

### Related topics

- [Initializing/Configuring TORQUE on the server \(pbs\\_server\) on page 2551](#)

## Configuring ports

You can optionally configure the various ports that TORQUE uses for communication. Most ports can be configured multiple ways. The ports you can configure are:

- [pbs\\_server listening port](#)
- [pbs\\_mom listening port](#)
- [port pbs\\_server uses to communicate to the pbs\\_mom](#)
- [port pbs\\_mom uses to communicate to the pbs\\_server](#)
- [port client commands use to communicate to the pbs\\_server](#)
- [port trqauthd uses to communicate to the pbs\\_server](#)

If you are running pbspro on the same system, be aware that it uses the same environment variables and `/etc/services` entries.

### Configuring the pbs\_server listening port

To configure the port the `pbs_server` listens on, follow any of these steps:

- Set an environment variable called `PBS_BATCH_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Start `pbs_server` with the `-p` option.

```
$ pbs_server -p port_num
```

- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`
- Start `pbs_server` with the `-H` option.

```
$ pbs_server -H server_name:port_num
```

### Configuring the pbs\_mom listening port

To configure the port the `pbs_mom` listens on, follow any of these steps:

- Set an environment variable called `PBS_MOM_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs_mom port_num/tcp`.
- Start `pbs_mom` with the `-M` option.

```
$ pbs_mom -M port_num
```

- Edit the `nodes` file entry for that list: add `mom_service_port=port_num`.

### Configuring the port pbs\_server uses to communicate with pbs\_mom

To configure the port the `pbs_server` uses to communicate with `pbs_mom`, follow any of these steps:

- Set an environment variable called `PBS_MOM_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs_mom port_num/tcp`.
- Start `pbs_mom` with the `-M` option.

```
$ pbs_server -M port_num
```

## Configuring the port `pbs_mom` uses to communicate with `pbs_server`

To configure the port the `pbs_mom` uses to communicate with `pbs_server`, follow any of these steps:

- Set an environment variable called `PBS_BATCH_SERVICE_PORT` to the port desired.
- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Start `pbs_mom` with the `-S` option.

```
$ pbs_mom -p port_num
```

- Edit the `nodes` file entry for that list: add `mom_service_port=port_num`.

## Configuring the port client commands use to communicate with `pbs_server`

To configure the port client commands use to communicate with `pbs_server`, follow any of these steps:

- Edit the `/etc/services` file and set `pbs port_num/tcp`.
- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`

## Configuring the port `trqauthd` uses to communicate with `pbs_server`

To configure the port `trqauthd` uses to communicate with `pbs_server`, follow any of these steps:

- Edit the `$PBS_HOME/server_name` file and change `server_name` to `server_name:<port_num>`

### Related topics

- [Initializing/Configuring TORQUE on the server \(pbs\\_server\) on page 2551](#)
- [pbs\\_server](#)
- [pbs\\_mom](#)
- [trqauthd](#)
- [client commands](#)

## Configuring `trqauthd` for client commands

`trqauthd` is a daemon used by TORQUE client utilities to authorize user connections to `pbs_server`. Once started, it remains resident. TORQUE client utilities then communicate with `trqauthd` on port 15005 on the loopback interface. It is multi-threaded and can handle large volumes of simultaneous requests.

## Running trqauthd

trqauthd must be run as root. It must also be running on any host where TORQUE client commands will execute.

By default, trqauthd is installed to `/usr/local/bin`.

trqauthd can be invoked directly from the command line or by the use of init.d scripts which are located in the `contrib/init.d` directory of the TORQUE source.

There are three `init.d` scripts for trqauthd in the `contrib/init.d` directory of the TORQUE source tree:

Script	Description
<b>debian.trqauthd</b>	Used for apt-based systems (debian, ubuntu are the most common variations of this)
<b>suse.trqauthd</b>	Used for suse-based systems
<b>trqauthd</b>	An example for other package managers (Redhat, Scientific, CentOS, and Fedora are some common examples)

**i** You should edit these scripts to be sure they will work for your site.

Inside each of the scripts are the variables `PBS_DAEMON` and `PBS_HOME`. These two variables should be updated to match your TORQUE installation. `PBS_DAEMON` needs to point to the location of trqauthd. `PBS_HOME` needs to match your TORQUE installation.

Choose the script that matches your dist system and copy it to `/etc/init.d`. If needed, rename it to **trqauthd**.

### To start the daemon

```
/etc/init.d/trqauthd start
```

### To stop the daemon

```
/etc/init.d/trqauthd stop
```

OR

```
service trqauthd start/stop
```

**i** If you receive an error that says "Could not open socket in trq\_simple\_connect. error 97" and you use a CentOS, RedHat, or Scientific Linux 6+ operating system, check your `/etc/hosts` file for multiple entries of a single host name pointing to the same IP address. Delete the duplicate(s), save the file, and launch trqauthd again.

- [Initializing/Configuring TORQUE on the server \(pbs\\_server\) on page 2551](#)

## Finalizing configurations

After configuring the `serverdb` and the `server_priv/nodes` files, and after ensuring minimal MOM configuration, restart the `pbs_server` on the server node and the `pbs_mom` on the compute nodes.

Compute Nodes:

```
> pbs_mom
```

Server Node:

```
> qterm -t quick
> pbs_server
```

After waiting several seconds, the `pbsnodes -a` command should list all nodes in state `free`.

## Advanced configuration

This section contains information about how you can customize the installation and configure the server to ensure that the server and nodes are communicating correctly. For details, see these topics:

- [Customizing the install on page 2558](#)
- [Server configuration on page 2566](#)

## Related topics

- [Appendix B: Server parameters on page 2766](#)

## Customizing the install

The TORQUE `configure` command has several options available. Listed below are some suggested options to use when running `./configure`.

- By default, TORQUE does not install the admin manuals. To enable this, use `--enable-docs`.
- By default, only children MOM processes use syslog. To enable syslog for all of TORQUE, use `--enable-syslog`.

Table 4-3: Optional Features

Option	Description
<b>--disable-clients</b>	Directs TORQUE not to build and install the TORQUE client utilities such as qsub, qstat, qdel, etc.
<b>--disable-FEATURE</b>	Do not include FEATURE (same as --enable-FEATURE=no).
<b>--disable-lib-tool-lock</b>	Avoid locking (might break parallel builds).
<b>--disable-mom</b>	Do not include the MOM daemon.
<b>--disable-mom-check-spool</b>	Don't check free space on spool directory and set an error.
<b>--disable-posixmemlock</b>	Disable the MOM's use of mlockall. Some versions of OSs seem to have buggy POSIX MEMLOCK.
<b>--disable-priv-ports</b>	Disable the use of privileged ports for authentication. Some versions of OSX have a buggy bind () and cannot bind to privileged ports.
<b>--disable-qsub-keep-override</b>	Do not allow the qsub -k flag to override -o -e.
<b>--disable-server</b>	Do not include server and scheduler.
<b>--disable-shell-pipe</b>	Give the job script file as standard input to the shell instead of passing its name via a pipe.
<b>--disable-spool</b>	If disabled, TORQUE will create output and error files directly in \$HOME/.pbs_spool if it exists or in \$HOME otherwise. By default, TORQUE will spool files in TORQUE_HOME/spool and copy them to the users home directory when the job completes.
<b>--disable-xopen-networking</b>	With HPUX and GCC, don't force usage of XOPEN and libxnet.
<b>--enable-acct-x</b>	Enable adding x attributes to accounting log.

Option	Description
<b>--enable-array</b>	Setting this under IRIX enables the SGI Origin 2000 parallel support. Normally autodetected from the <code>/etc/config/array</code> file.
<b>--enable-blcr</b>	Enable BLCR support.
<b>--enable-cpa</b>	Enable Cray's CPA support.
<b>--enable-cpu-set</b>	Enable Linux 2.6 kernel cpusets. <div style="border: 1px solid black; padding: 5px; margin-top: 10px;">  It is recommended that you turn on this feature to prevent a job from expanding across more CPU cores than it is assigned. </div>
<b>--enable-debug</b>	Prints debug information to the console for <code>pbs_server</code> and <code>pbs_mom</code> while they are running. (This is different than <b>--with-debug</b> which will compile with debugging symbols.)
<b>--enable-dependency-tracking</b>	Do not reject slow dependency extractors.
<b>--enable-fast-install[=PKGS]</b>	Optimize for fast installation [default=yes].
<b>--enable-FEATURE [ARG=yes]</b>	Include FEATURE [ARG=yes].
<b>--enable-file-sync</b>	Open files with sync on each write operation. This has a negative impact on TORQUE performance. This is disabled by default.
<b>--enable-force-nodfile</b>	Forces creation of nodfile regardless of job submission parameters. Not on by default.
<b>--enable-gcc-warnings</b>	Enable gcc strictness and warnings. If using gcc, default is to error on any warning.
<b>--enable-geometry-requests</b>	TORQUE is compiled to use <a href="#">procs_bitmap</a> during job submission.
<b>--enable-gui</b>	Include the GUI-clients.

Option	Description
<b>--enable-main-tainer-mode</b>	This is for the autoconf utility and tells autoconf to enable so called rebuild rules. See <a href="#">maintainer mode</a> for more information.
<b>--enable-maxdefault</b>	<p>Turn on the RESOURCEMAXDEFAULT flag.</p> <div style="border: 1px solid black; padding: 5px;"> <p><b>i</b> Versions of TORQUE earlier than 2.4.5 attempted to apply queue and server defaults to a job that didn't have defaults specified. If a setting still did not have a value after that, TORQUE applied the queue and server maximum values to a job (meaning, the maximum values for an applicable setting were applied to jobs that had no specified or default value).</p> <p>In TORQUE 2.4.5 and later, the queue and server maximum values are no longer used as a value for missing settings. To re-enable this behavior in TORQUE 2.4.5 and later, use <code>--enable-maxdefault</code>.</p> </div>
<b>--enable-nochildsignal</b>	Turn on the NO_SIGCHLD flag.
<b>--enable-nodemask</b>	Enable nodemask-based scheduling on the Origin 2000.
<b>--enable-pemask</b>	Enable pemask-based scheduling on the Cray T3e.
<b>--enable-plock-daemons[=ARG]</b>	Enable daemons to lock themselves into memory: logical-or of 1 for pbs_server, 2 for pbs_scheduler, 4 for pbs_mom (no argument means 7 for all three).
<b>--enable-quick-commit</b>	Turn on the QUICKCOMMIT flag.
<b>--enable-shared[=PKGS]</b>	Build shared libraries [default=yes].
<b>--enable-shell-use-argv</b>	Enable this to put the job script name on the command line that invokes the shell. Not on by default. Ignores --enable-shell-pipe setting.
<b>--enable-sp2</b>	Build PBS for an IBM SP2.
<b>--enable-srfs</b>	Enable support for SRFS on Cray.

Option	Description
<b>--enable-static [=PKGS]</b>	Build static libraries [default=yes].
<b>--enable-syslog</b>	Enable (default) the use of syslog for error reporting.
<b>--enable-tcl-qstat</b>	Setting this builds qstat with Tcl interpreter features. This is enabled if Tcl is enabled.
<b>--enable-unix-sockets</b>	Enable the use of Unix Domain sockets for authentication.

Table 4-4: Optional packages

Option	Description
<b>--with-blcr=DIR</b>	BLCR installation prefix (Available in versions 2.5.6 and 3.0.2 and later).
<b>--with-blcr-include=DIR</b>	Include path for libcr.h (Available in versions 2.5.6 and 3.0.2 and later).
<b>--with-blcr-lib=DIR</b>	Lib path for libcr (Available in versions 2.5.6 and 3.0.2 and later).
<b>--with-blcr-bin=DIR</b>	Bin path for BLCR utilities (Available in versions 2.5.6 and 3.0.2 and later).

Option	Description
<b>--with-boost-path=DIR</b>	<p>Set the path to the Boost header files to be used during make. This option does not require Boost to be built or installed.</p> <p>The <code>--with-boost-path</code> value must be a directory containing a sub-directory called <code>boost</code> that contains the <code>boost.hpp</code> files.</p> <p>For example, if downloading the boost 1.55.0 source tarball to the adaptive user's home directory:</p> <pre data-bbox="586 579 1433 800" style="border: 1px dashed gray; padding: 5px;"> [adaptive]\$ cd ~ [adaptive]\$ wget http://sourceforge.net/projects/boost/files/boost/1.55.0/boost_1_55_0.tar.gz/download [adaptive]\$ tar xzf boost_1_55_0.tar.gz [adaptive]\$ ls boost_1_55_0 boost boost-build.jam ...</pre> <p>In this case use <code>--with-boost-path=/home/adaptive/boost_1_55_0</code> during configure.</p> <p>Another example would be to use an installed version of Boost. If the installed Boost header files exist in <code>/usr/include/boost/*.hpp</code>, use <code>--with-boost-path=/usr/include</code>.</p>
<b>--with-cpa-include=DIR</b>	Include path for <code>cpalib.h</code> .
<b>--with-cpa-lib=DIR</b>	Lib path for <code>libcpalib</code> .
<b>--with-debug=no</b>	Do not compile with debugging symbols.
<b>--with-default-server-r=HOSTNAME</b>	Set the name of the computer that clients will access when no machine name is specified as part of the queue name. It defaults to the hostname of the machine on which PBS is being compiled.
<b>--with-environ=PATH</b>	Set the path containing the environment variables for the daemons. For SP2 and AIX systems, suggested setting is to <code>/etc/environment</code> . Defaults to the file <code>"pbs_environment"</code> in the <code>server-home</code> . Relative paths are interpreted within the context of the <code>server-home</code> .
<b>--with-gnu-ld</b>	Assume the C compiler uses GNU ld [default=no].
<b>--with-mail-domain=MAILDOMAIN</b>	Override the default domain for outgoing mail messages, i.e. <code>"user@maildomain"</code> . The default maildomain is the hostname where the job was submitted from.

Option	Description
<b>--with-modulefiles[=DIR]</b>	Use module files in specified directory [/etc/modulefiles].
<b>--with-momlogdir</b>	Use this directory for MOM logs.
<b>--with-momlogsuffix</b>	Use this suffix for MOM logs.
<b>--without-PACKAGE</b>	Do not use PACKAGE (same as --with-PACKAGE=no).
<b>--without-readline</b>	Do not include readline support (default: included if found).
<b>--with-PACKAGE[=ARG]</b>	Use PACKAGE [ARG=yes].
<b>--with-pam=DIR</b>	Directory that holds the system PAM modules. Defaults to /lib(64)/security on Linux.
<b>--with-pic</b>	Try to use only PIC/non-PIC objects [default=use both].
<b>--with-qstatrc-file=FILE</b>	Set the name of the file that qstat will use if there is no ".qstatrc" file in the directory where it is being invoked. Relative path names will be evaluated relative to the server home directory (see above). If this option is not specified, the default name for this file will be set to "qstatrc" (no dot) in the server home directory.
<b>--with-rcp</b>	One of "scp", "rcp", "mom_rcp", or the full path of a remote file copy program. scp is the default if found, otherwise mom_rcp is used. Some rcp programs don't always exit with valid error codes in case of failure. mom_rcp is a copy of BSD rcp included with this source that has correct error codes, but it is also old, unmaintained, and doesn't have large file support.
<b>--with-sched=TYPE</b>	Sets the scheduler type. If TYPE is "c", the scheduler will be written in C. If TYPE is "tcl" the server will use a Tcl based scheduler. If TYPE is "basl", TORQUE will use the rule based scheduler. If TYPE is "no", then no scheduling is done. "c" is the default.
<b>--with-sched-code=PATH</b>	Sets the name of the scheduler to use. This only applies to BASL schedulers and those written in the C language. For C schedulers this should be a directory name and for BASL schedulers a filename ending in ".basl". It will be interpreted relative to srctree/src/schedulers.SCHD_TYPE/samples. As an example, an appropriate BASL scheduler relative path would be "nas.basl". The default scheduler code for "C" schedulers is "fifo".

Option	Description
<b>--with-scp</b>	In TORQUE 2.1 and later, SCP is the default remote copy protocol. See <a href="#">--with-rcp</a> if a different protocol is desired.
<b>--with-sendmail[=FILE]</b>	Sendmail executable to use.
<b>--with-server-home=DIR</b>	Set the server home/spool directory for PBS use. Defaults to /var/spool/torque.
<b>--with-server-name-file=FILE</b>	Set the file that will contain the name of the default server for clients to use. If this is not an absolute pathname, it will be evaluated relative to the server home directory that either defaults to /usr/spool/PBS or is set using the --with-server-home option to configure. If this option is not specified, the default name for this file will be set to "server_name".
<b>--with-tcl</b>	Directory containing tcl configuration (tclConfig.sh).
<b>--with-tclatrsep=CHAR</b>	Set the Tcl attribute separator character this will default to "." if unspecified.
<b>--with-tclinclude</b>	Directory containing the public Tcl header files.
<b>--with-tclx</b>	Directory containing tclx configuration (tclxConfig.sh).
<b>--with-tk</b>	Directory containing tk configuration (tkConfig.sh).
<b>--with-tkinclude</b>	Directory containing the public Tk header files.
<b>--with-tkx</b>	Directory containing tkx configuration (tkxConfig.sh).
<b>--with-tmpdir=DIR</b>	Set the tmp directory that pbs_mom will use. Defaults to "/tmp". This is a Cray-specific feature.
<b>--with-xauth=PATH</b>	Specify path to xauth program.

## HAVE\_WORDEXP

`Wordxp()` performs a shell-like expansion, including environment variables. By default, `HAVE_WORDEXP` is set to **1** in `src/pbs_config.h`. If set to **1**, will limit the characters that can be used in a job name to those allowed for a file in the current environment, such as BASH. If set to **0**, any valid character for the file system can be used.

If a user would like to disable this feature by setting `HAVE_WORDEXP` to **0** in `src/include/pbs_config.h`, it is important to note that the error and the output file names will not expand environment

variables, including `$PBS_JOBID`. The other important consideration is that characters that BASH dislikes, such as `0`, will not be allowed in the output and error file names for jobs by default.

- [Setting up email on page 2568](#)
- [Using MUNGE authentication on page 2569](#)
- [Setting up the MOM hierarchy on page 2570](#)

## Server configuration overview

There are several steps to ensure that the server and the nodes are completely aware of each other and able to communicate directly. Some of this configuration takes place within TORQUE directly using the `qmgr` command. Other configuration settings are managed using the `pbs_server` nodes file, DNS files such as `/etc/hosts` and the `/etc/hosts.equiv` file.

## Name service configuration

Each node, as well as the server, must be able to resolve the name of every node with which it will interact. This can be accomplished using `/etc/hosts`, DNS, NIS, or other mechanisms. In the case of `/etc/hosts`, the file can be shared across systems in most cases.

A simple method of checking proper name service configuration is to verify that the server and the nodes can "ping" each other.

## Configuring job submission hosts

### Using RCmd authentication

When jobs can be submitted from several different hosts, these hosts should be trusted via the R\* commands (such as `rsh` and `rcp`). This can be enabled by adding the hosts to the `/etc/hosts.equiv` file of the machine executing the `pbs_server` daemon or using other R\* command authorization methods. The

exact specification can vary from OS to OS (see the man page for **ruserok** to find out how your OS validates remote users). In most cases, configuring this file is as simple as adding a line to your `/etc/hosts.equiv` file, as in the following:

`/etc/hosts.equiv:`

```
#[+ | -] [hostname] [username]
mynode.myorganization.com
.....
```

Either of the hostname or username fields may be replaced with a wildcard symbol (+). The (+) may be used as a stand-alone wildcard but not connected to a username or hostname, e.g., `+node01` or `+user01`. However, a (-) may be used in that manner to specifically exclude a user.

Following the Linux man page instructions for `hosts.equiv` may result in a failure. You cannot precede the user or hostname with a (+). To clarify, `node1 +user1` will not work and **user1** will not be able to submit jobs.

For example, the following lines will not work or will not have the desired effect:

```
+node02 user1
node02 +user1
```

These lines will work:

```
node03 +
+ jsmith
node04 -tjones
```

The most restrictive rules must precede more permissive rules. For example, to restrict user `tsmith` but allow all others, follow this format:

```
node01 -tsmith
node01 +
```

Please note that when a hostname is specified, it must be the fully qualified domain name (FQDN) of the host. Job submission can be further secured using the server or queue **acl\_hosts** and **acl\_host\_enabled** parameters (for details, see [Queue attributes on page 2626](#)).

### Using the "submit\_hosts" service parameter

Trusted submit host access may be directly specified without using RCmd authentication by setting the server [submit\\_hosts](#) parameter via **qmgr** as in the following example:

```
> qmgr -c 'set server submit_hosts = host1'
> qmgr -c 'set server submit_hosts += host2'
> qmgr -c 'set server submit_hosts += host3'
```

Use of **submit\_hosts** is potentially subject to DNS spoofing and should not be used outside of controlled and trusted environments.

## Allowing job submission from compute hosts

If preferred, all compute nodes can be enabled as job submit hosts without setting `.rhosts` or `hosts.equiv` by setting the [allow\\_node\\_submit](#) parameter to **true**.

## Configuring TORQUE on a multi-homed server

If the `pbs_server` daemon is to be run on a multi-homed host (a host possessing multiple network interfaces), the interface to be used can be explicitly set using the [SERVERHOST](#) parameter.

## Architecture specific notes

With some versions of Mac OS/X, it is required to add the line `$restricted *.<DOMAIN>` to the `pbs_mom` configuration file. This is required to work around some socket bind bugs in the OS.

## Specifying non-root administrators

By default, only root is allowed to start, configure and manage the `pbs_server` daemon. Additional trusted users can be authorized using the parameters **managers** and **operators**. To configure these parameters use the [qmgr](#) command, as in the following example:

```
> qmgr
Qmgr: set server managers += josh@*.fsc.com
Qmgr: set server operators += josh@*.fsc.com
```

All manager and operator specifications must include a user name and either a fully qualified domain name or a host expression.

**i** To enable all users to be trusted as both operators and administrators, place the + (plus) character on its own line in the `server_priv/acl_svr/operators` and `server_priv/acl_svr/managers` files.

## Setting up email

Moab relies on emails from TORQUE about job events. To set up email, do the following:

### To set up email

1. Use the `--with-sendmail` configure option at configure time. TORQUE needs to know where the email application is. If this option is not used, TORQUE tries to find the `sendmail` executable. If it isn't found, TORQUE cannot send emails.

```
> ./configure --with-sendmail=<path_to_executable>
```

2. Set `mail_domain` in your server settings. If your domain is `clusterresources.com`, execute:

```
> qmgr -c 'set server mail_domain=clusterresources.com'
```

3. (Optional) You can override the default [mail\\_body\\_fmt](#) and [mail\\_subject\\_fmt](#) values via [qmgr](#):

```
> qmgr -c 'set server mail_body_fmt=Job: %i \n Name: %j \n On host: %h \n \n %m \n \n %d'
> qmgr -c 'set server mail_subject_fmt=Job %i - %r'
```

By default, users receive e-mails on job aborts. Each user can select which kind of e-mails to receive by using the `qsub -m` option when submitting the job. If you want to dictate when each user should receive e-mails, use a submit filter (for details, see [Appendix J: Job submission filter \("qsub wrapper"\) on page 2827](#)).

## Using MUNGE authentication

MUNGE is an authentication service that creates and validates user credentials. It was developed by Lawrence Livermore National Laboratory (LLNL) to be highly scalable so it can be used in large environments such as HPC clusters. To learn more about MUNGE and how to install it, see <http://code.google.com/p/munge/>.

Configuring TORQUE to use MUNGE is a compile time operation. When you are building TORQUE, use `-enable-munge-auth` as a command line option with `./configure`.

```
> ./configure -enable-munge-auth
```

You can use only one authorization method at a time. If `-enable-munge-auth` is configured, the privileged port `ruserok` method is disabled.

TORQUE does not link any part of the MUNGE library into its executables. It calls the MUNGE and UNMUNGE utilities which are part of the MUNGE daemon. The MUNGE daemon must be running on the server and all submission hosts. The TORQUE client utilities call MUNGE and then deliver the encrypted credential to `pbs_server` where the credential is then unmunged and the server verifies the user and host against the authorized users configured in `serverdb`.

Authorized users are added to `serverdb` using `qmgr` and the **authorized\_users** parameter. The syntax for **authorized\_users** is `authorized_users=<user>@<host>`. To add an authorized user to the server you can use the following `qmgr` command:

```
> qmgr -c 'set server authorized_users=user1@hosta
> qmgr -c 'set server authorized_users+=user2@hosta'
```

The previous example adds `user1` and `user2` from `hosta` to the list of authorized users on the server. Users can be removed from the list of authorized users by using the `-=` syntax as follows:

```
> qmgr -c 'set server authorized_users-=user1@hosta'
```

Users must be added with the `<user>@<host>` syntax. The user and the host portion can use the `*` wildcard to allow multiple names to be accepted with a single entry. A range of user or host names can be specified using a `[a-b]` syntax where *a* is the beginning of the range and *b* is the end.

```
> qmgr -c 'set server authorized_users=user[1-10]@hosta'
```

This allows `user1` through `user10` on `hosta` to run client commands on the server.

## Setting up the MOM hierarchy

The MOM hierarchy allows you to override the compute nodes' default behavior of reporting status updates directly to the `pbs_server`. Instead, you configure compute nodes so that each node sends its status update information to another compute node. The compute nodes pass the information up a tree or hierarchy until eventually the information reaches a node that will pass the information directly to `pbs_server`. This can significantly reduce traffic and time required to keep the cluster status up to date.

The name of the file that contains the configuration information is named `mom_hierarchy`. By default, it is located in the `/var/spool/torque/server_priv` directory. The file uses syntax similar to XML:

```
<path>
  <level> comma-separated node list </level>
  <level> comma-separated node list </level>
  ...
</path>
...
```

The `<path></path>` tag pair identifies a group of compute nodes. The `<level></level>` tag pair contains a comma-separated list of compute node names. Multiple paths can be defined with multiple levels within each path.

Within a `<path>` tag pair the levels define the hierarchy. All nodes in the top level communicate directly with the server. All nodes in lower levels communicate to the first available node in the level directly above it. If the first node in the upper level goes down, the nodes in the subordinate level will then communicate to the next node in the upper level. If no nodes are available in an upper level then the node will communicate directly to the server.

If an upper level node has fallen out and then becomes available, the lower level nodes will eventually find that the node is available and start sending their updates to that node.

**i** If you want to specify MOMs on a different port than the default, you must list the node in the form: `hostname:mom_manager_port`.

For example:

```
<path>
  <level>hostname:mom_manager_port</level>
  ...
</path>
...
```

## Putting the MOM hierarchy on the MOMs

You can put the MOM hierarchy file directly on the MOMs. This way, the `pbs_server` doesn't have to send the hierarchy to all the MOMs during each `pbs_server` startup. The hierarchy file still has to exist on the `pbs_server` and if the file versions conflict, the `pbs_server` version overwrites the local MOM file. Due to this, it is recommended that the hierarchy file either be symlinked to the MOMs or put on a global NFS share.

Once the hierarchy file exists on the MOMs, start `pbs_server` with the `-n` option which tells `pbs_server` to not send the hierarchy file on startup. Instead, `pbs_server` waits until a MOM requests it.

## Manual setup of initial server configuration

On a new installation of TORQUE, the server database must be initialized using the command `pbs_server -t create`. This command creates a file in `$TORQUEHOME/server_priv` named `serverdb` which contains the server configuration information.

The following output from `qmgr` shows the base configuration created by the command `pbs_server -t create`:

```
qmgr -c 'p s'
#
Set server attributes.
#
set server acl_hosts = kmn
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 6
```

This is a bare minimum configuration and it is not very useful. By using `qmgr`, the server configuration can be modified to set up TORQUE to do useful work. The following `qmgr` commands will create a queue and enable the server to accept and run jobs. These commands must be executed by root.

```
pbs_server -t create
qmgr -c "set server scheduling=true"
qmgr -c "create queue batch queue_type=execution"
qmgr -c "set queue batch started=true"
qmgr -c "set queue batch enabled=true"
qmgr -c "set queue batch resources_default.nodes=1"
qmgr -c "set queue batch resources_default.walltime=3600"
qmgr -c "set server default_queue=batch"
```

When TORQUE reports a new queue to Moab a class of the same name is automatically applied to all nodes.

In this example, the configuration database is initialized and the scheduling interface is activated using (`scheduling=true`). This option allows the scheduler to receive job and node events which allow it to be more responsive (See [scheduling on page 2782](#) for more information). The next command creates a queue and specifies the queue type. Within PBS, the queue must be declared an `execution` queue in order for it to run jobs. Additional configuration (i.e., setting the queue to `started` and `enabled`) allows the queue to *accept* job submissions, and *launch* queued jobs.

The next two lines are optional, setting default `node` and `walltime` attributes for a submitted job. These defaults will be picked up by a job if values are not explicitly set by the submitting user. The final line, `default_queue=batch`, is also a convenience line and indicates that a job should be placed in the batch queue unless explicitly assigned to another queue.

Additional information on configuration can be found in the admin manual and in the [qmgr](#) main page.

## Server node file configuration

This section contains information about configuring server node files. It explains how to specify node virtual processor counts and GPU counts, as well as how to specify node features or properties. For details, see these topics:

- [Basic node specification on page 2572](#)
- [Specifying virtual processor count for a node on page 2572](#)
- [Specifying GPU count for a node on page 2573](#)
- [Specifying node features \(node properties\) on page 2573](#)

## Related topics

- [TORQUE installation overview on page 2544](#)
- [Appendix B: Server parameters on page 2766](#)
- [Moab node feature overview](#)

## Basic node specification

For the `pbs_server` to communicate with each of the MOMs, it needs to know which machines to contact. Each node that is to be a part of the batch system must be specified on a line in the `server nodes` file. This file is located at `TORQUE_HOME/server_priv/nodes`. In most cases, it is sufficient to specify just the node name on a line as in the following example:

`server_priv/nodes:`

```
node001
node002
node003
node004
```

## Related topics

- [Server node file configuration on page 2572](#)

## Specifying virtual processor count for a node

By default each node has one virtual processor. Increase the number using the **np** attribute in the nodes file. The value of `np` can be equal to the number of physical cores on the node or it can be set to a value which represents available "execution slots" for the node. The value used is determined by the administrator based on hardware, system, and site criteria.

The following example shows how to set the `np` value in the nodes file. In this example, we are assuming that `node001` and `node002` have four physical cores. The administrator wants the value of `np` for `node001`

to reflect that it has four cores. However, node002 will be set up to handle multiple virtual processors without regard to the number of physical cores on the system.

server\_priv/nodes:

```
node001 np=4
node002 np=12
...
```

#### Related topics

- [Server node file configuration on page 2572](#)

## Specifying GPU count for a node

Administrators can manually set the number of GPUs on a node or if they are using NVIDIA GPUs and drivers, they can have them detected automatically. For more information about how to set up TORQUE with GPUS, see [Accelerators on page 815](#).

To manually set the number of GPUs on a node, use the `gpus` attribute in the nodes file. The value of GPUs is determined by the administrator based on hardware, system, and site criteria.

The following example shows how to set the GPU value in the nodes file. In the example, we assume node001 and node002 each have two physical GPUs. The administrator wants the value of node001 to reflect the physical GPUs available on that system and adds `gpus=2` to the nodes file entry for node001. However, node002 will be set up to handle multiple virtual GPUs without regard to the number of physical GPUs on the system.

server\_priv/nodes:

```
node001 gpus=1
node002 gpus=4
...
```

#### Related topics

- [Server node file configuration on page 2572](#)

## Specifying node features (node properties)

Node features can be specified by placing one or more white space-delimited strings on the line for the associated host as in the following example:

server\_priv/nodes:

```
node001 np=2 fast ia64
node002 np=4 bigmem fast ia64 smp
...
```

These features can be used by users to request specific nodes when submitting jobs. For example:

```
qsub -l nodes=1:bigmem+1:fast job.sh
```

This job submission will look for a node with the bigmem feature (node002) and a node with the fast feature (either node001 or node002).

## Testing server configuration

If you have initialized TORQUE using the `torque.setup` script or started TORQUE using `pbs_server -t create` and `pbs_server` is still running, terminate the server by calling `qterm`. Next, start `pbs_server` again without the `-t create` arguments. Follow the script below to verify your server configuration. The output for the examples below is based on the nodes file example in [Specifying node features](#) and [Server configuration](#).

```

# verify all queues are properly configured
> qstat -q

server:kmn

Queue   Memory   CPU Time   Walltime   Node   Run   Que   Lm   State
-----
batch   --       --         --         --     0     0    --   ER
                                     ---
                                     0     0

# view additional server configuration
> qmgr -c 'p s'
#
# Create queues and set their attributes
#
# Create and define queue batch
#
create queue batch
set queue batch queue_type = Execution
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server acl_hosts = kmn
set server managers = user1@kmn
set server operators = user1@kmn
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server node_check_rate = 150
set server tcp_timeout = 300
set server job_stat_rate = 45
set server poll_jobs = True
set server mom_job_sync = True
set server keep_completed = 300
set server next_job_number = 0

# verify all nodes are correctly reporting
> pbsnodes -a
node001
  state=free
  np=2
  properties=bigmem,fast,ia64,smp
  ntype=cluster
  status=rectime=1328810402,varattr=,jobs=,state=free,netload=6814326158,gres=,loadave
=0.21,ncpus=6,physmem=8193724kb,
availmem=13922548kb,totmem=16581304kb,idletime=3,nusers=3,nsessions=18,sessions=1876
1120 1912 1926 1937 1951 2019 2057 28399 2126 2140 2323 5419 17948 19356 27726 22254
29569,uname=Linux kmn 2.6.38-11-generic #48-Ubuntu SMP Fri Jul 29 19:02:55 UTC 2011
x86_64,opsys=linux
  mom_service_port = 15002
  mom_manager_port = 15003
  gpus = 0
# submit a basic job - DO NOT RUN AS ROOT
> su - testuser
> echo "sleep 30" | qsub

# verify jobs display
> qstat

Job id   Name   User   Time Use   S   Queue
-----

```

```
0.kmn STDIN knielson 0 Q batch
```

At this point, the job should be in the **Q** state and will not run because a scheduler is not running yet. TORQUE can use its native scheduler by running `pbs_sched` or an advanced scheduler (such as Moab Workload Manager). See [Integrating schedulers for TORQUE on page 2653](#) for details on setting up an advanced scheduler.

## TORQUE on NUMA systems

Starting in TORQUE version 3.0, TORQUE can be configured to take full advantage of Non-Uniform Memory Architecture (NUMA) systems. The following instructions are a result of development on SGI Altix and UV hardware.

For details, see these topics:

- [TORQUE NUMA configuration on page 2576](#)
- [Building TORQUE with NUMA support on page 2576](#)

### TORQUE NUMA configuration

There are three steps to configure TORQUE to take advantage of NUMA architectures:

1. Configure TORQUE with `--enable-numa-support`.
2. Create the `mom_priv/mom.layout` file.
3. Configure `server_priv/nodes`.

#### Related topics

- [TORQUE on NUMA systems on page 2576](#)

### Building TORQUE with NUMA support

To turn on NUMA support for TORQUE the `--enable-numa-support` option must be used during the configure portion of the installation. In addition to any other configuration options, add the `--enable-numa-support` option as indicated in the following example:

```
$ ./configure --enable-numa-support
```

 Don't use MOM hierarchy with NUMA.

When TORQUE is enabled to run with NUMA support, there is only a single instance of `pbs_mom` (MOM) that is run on the system. However, TORQUE will report that there are multiple nodes running in the cluster. While `pbs_mom` and `pbs_server` both know there is only one instance of `pbs_mom`, they manage the cluster as if there were multiple separate MOM nodes.

The `mom.layout` file is a virtual mapping between the system hardware configuration and how the administrator wants TORQUE to view the system. Each line in `mom.layout` equates to a node in the cluster and is referred to as a NUMA node.

## Automatically Creating `mom.layout` (Recommended)

A perl script named `mom_gencfg` is provided in the `contrib/` directory that generates the `mom.layout` file for you. The script can be customized by setting a few variables in it. To automatically create the `mom.layout` file, follow these instructions (these instructions are also included in the script):

1. Verify `hwloc` version 1.1 or higher is installed - see `contrib/hwloc_install.sh`.
2. Install `Sys::Hwloc` from CPAN.
3. Verify `$PBS_HOME` is set to the proper value.
4. Update the variables in the 'Config Definitions' section of the script. Especially update `firstNodeId` and `nodesPerBoard` if desired. The `firstNodeId` variable should be set above 0 if you have a root `cpuset` that you wish to exclude and the `nodesPerBoard` variable is the number of NUMA nodes per board. Each node is defined in `/sys/devices/system/node`, in a subdirectory `node<node index>`
5. Back up your current file in case a variable is set incorrectly or neglected.
6. Run the script.

7. 

```
$ ./mom_gencfg
```

## Manually Creating `mom.layout`

To properly set up the `mom.layout` file, it is important to know how the hardware is configured. Use the `topology` command line utility and inspect the contents of `/sys/devices/system/node`. The `hwloc` library can also be used to create a custom discovery tool.

Typing `topology` on the command line of a NUMA system produces something similar to the following:

```

Partition number: 0
6 Blades
72 CPUs
378.43 Gb Memory Total

```

Blade	ID	asic	NASID	Memory
0	r001i01b00	UVHub 1.0	0	67089152 kB
1	r001i01b01	UVHub 1.0	2	67092480 kB
2	r001i01b02	UVHub 1.0	4	67092480 kB
3	r001i01b03	UVHub 1.0	6	67092480 kB
4	r001i01b04	UVHub 1.0	8	67092480 kB
5	r001i01b05	UVHub 1.0	10	67092480 kB

CPU	Blade	PhysID	CoreID	APIC-ID	Family	Model	Speed	L1 (KiB)	L2 (KiB)	L3 (KiB)
0	r001i01b00	00	00	0	6	46	2666	32d/32i	256	18432
1	r001i01b00	00	02	4	6	46	2666	32d/32i	256	18432
2	r001i01b00	00	03	6	6	46	2666	32d/32i	256	18432
3	r001i01b00	00	08	16	6	46	2666	32d/32i	256	18432
4	r001i01b00	00	09	18	6	46	2666	32d/32i	256	18432
5	r001i01b00	00	11	22	6	46	2666	32d/32i	256	18432
6	r001i01b00	01	00	32	6	46	2666	32d/32i	256	18432
7	r001i01b00	01	02	36	6	46	2666	32d/32i	256	18432
8	r001i01b00	01	03	38	6	46	2666	32d/32i	256	18432
9	r001i01b00	01	08	48	6	46	2666	32d/32i	256	18432
10	r001i01b00	01	09	50	6	46	2666	32d/32i	256	18432
11	r001i01b00	01	11	54	6	46	2666	32d/32i	256	18432
12	r001i01b01	02	00	64	6	46	2666	32d/32i	256	18432
13	r001i01b01	02	02	68	6	46	2666	32d/32i	256	18432
14	r001i01b01	02	03	70	6	46	2666	32d/32i	256	18432

From this partial output, note that this system has 72 CPUs on 6 blades. Each blade has 12 CPUs grouped into clusters of 6 CPUs. If the entire content of this command were printed you would see each Blade ID and the CPU ID assigned to each blade.

The topology command shows how the CPUs are distributed, but you likely also need to know where memory is located relative to CPUs, so go to `/sys/devices/system/node`. If you list the node directory you will see something similar to the following:

```

# ls -al
total 0
drwxr-xr-x 14 root root 0 Dec 3 12:14 .
drwxr-xr-x 14 root root 0 Dec 3 12:13 ..
-r--r--r-- 1 root root 4096 Dec 3 14:58 has_cpu
-r--r--r-- 1 root root 4096 Dec 3 14:58 has_normal_memory
drwxr-xr-x 2 root root 0 Dec 3 12:14 node0
drwxr-xr-x 2 root root 0 Dec 3 12:14 node1
drwxr-xr-x 2 root root 0 Dec 3 12:14 node10
drwxr-xr-x 2 root root 0 Dec 3 12:14 node11
drwxr-xr-x 2 root root 0 Dec 3 12:14 node2
drwxr-xr-x 2 root root 0 Dec 3 12:14 node3
drwxr-xr-x 2 root root 0 Dec 3 12:14 node4
drwxr-xr-x 2 root root 0 Dec 3 12:14 node5
drwxr-xr-x 2 root root 0 Dec 3 12:14 node6
drwxr-xr-x 2 root root 0 Dec 3 12:14 node7
drwxr-xr-x 2 root root 0 Dec 3 12:14 node8
drwxr-xr-x 2 root root 0 Dec 3 12:14 node9
-r--r--r-- 1 root root 4096 Dec 3 14:58 online
-r--r--r-- 1 root root 4096 Dec 3 14:58 possible

```

The directory entries `node0`, `node1`, ..., `node11` represent groups of memory and CPUs local to each other. These groups are a node board, a grouping of resources that are close together. In most cases, a node board is made up of memory and processor cores. Each bank of memory is called a memory node by the

operating system, and there are certain CPUs that can access that memory very rapidly. Note under the directory for node board node0 that there is an entry called `cpulist`. This contains the CPU IDs of all CPUs local to the memory in node board 0.

Now create the `mom.layout` file. The content of `cpulist` 0-5 are local to the memory of node board 0, and the memory and `cpus` for that node are specified in the layout file by saying `nodes=0`. The `cpulist` for node board 1 shows 6-11 and memory node index 1. To specify this, simply write `nodes=1`. Repeat this for all twelve node boards and create the following `mom.layout` file for the 72 CPU system.

```
nodes=0
nodes=1
nodes=2
nodes=3
nodes=4
nodes=5
nodes=6
nodes=7
nodes=8
nodes=9
nodes=10
nodes=11
```

Each line in the `mom.layout` file is reported as a node to `pbs_server` by the `pbs_mom` daemon.

The `mom.layout` file does not need to match the hardware layout exactly. It is possible to combine node boards and create larger NUMA nodes. The following example shows how to do this:

```
nodes=0-1
```

The memory nodes can be combined the same as CPUs. The memory nodes combined must be contiguous. You cannot combine mem 0 and 2.

## Configuring `server_priv/nodes`

The `pbs_server` requires awareness of how the MOM is reporting nodes since there is only one MOM daemon and multiple MOM nodes. So, configure the `server_priv/nodes` file with the **`num_node_boards`** and **`numa_board_str`** attributes. The attribute `num_node_boards` tells `pbs_server` how many numa nodes are reported by the MOM. Following is an example of how to configure the `nodes` file with `num_node_boards`:

```
numa-10 np=72 num_node_boards=12
```

This line in the `nodes` file tells `pbs_server` there is a host named `numa-10` and that it has 72 processors and 12 nodes. The `pbs_server` divides the value of `np` (72) by the value for `num_node_boards` (12) and determines there are 6 CPUs per NUMA node.

In this example, the NUMA system is uniform in its configuration of CPUs per node board, but a system does not need to be configured with the same number of CPUs per node board. For systems with non-uniform CPU distributions, use the attribute **`numa_board_str`** to let `pbs_server` know where CPUs are located in the cluster.

The following is an example of how to configure the `server_priv/nodes` file for non-uniformly distributed CPUs:

```
Numa-11 numa_board_str=6,8,12
```

In this configuration, `pbs_server` knows it has three MOM nodes and the nodes have 6, 8, and 12 CPUs respectively. Note that the attribute `np` is not used. The `np` attribute is ignored because the number of CPUs per node is expressly given.

## Enforcement of memory resource limits

TORQUE can better enforce memory limits with the use of the utility **memacctd**. The `memacctd` utility is provided by SGI on SuSe Linux Enterprise Edition (SLES). It is a daemon that caches memory footprints when it is queried. When configured to use the memory monitor, TORQUE queries `memacctd`. It is up to the user to make sure `memacctd` is installed. See the [SGI memacctd man page](#) for more information.

### To configure TORQUE to use memacctd for memory enforcement

1. Start **memacctd** as instructed by SGI.
2. Reconfigure TORQUE with `--enable-memacct`. This will link in the necessary library when TORQUE is recompiled.
3. Recompile and reinstall TORQUE.
4. Restart all MOM nodes.
5. (Optional) Alter the [gsub](#) filter to include a default memory limit for all jobs that are not submitted with memory limit.

- [TORQUE on NUMA systems on page 2576](#)

## TORQUE Multi-MOM

Starting in TORQUE version 3.0 users can run multiple MOMs on a single node. The initial reason to develop a multiple MOM capability was for testing purposes. A small cluster can be made to look larger since each MOM instance is treated as a separate node.

When running multiple MOMs on a node each MOM must have its own service and manager ports assigned. The default ports used by the MOM are 15002 and 15003. With the multi-mom alternate ports can be used without the need to change the default ports for `pbs_server` even when running a single instance of the MOM.

For details, see these topics:

- [Multi-MOM configuration on page 2580](#)
- [Stopping pbs\\_mom in Multi-MOM mode on page 2582](#)

## Multi-MOM configuration

There are three steps to setting up multi-MOM capability:

1. [Configure server\\_priv/nodes on page 2581](#)
2. [/etc/hosts file on page 2581](#)
3. [Starting pbs\\_mom with multi-MOM options on page 2581](#)

## Configure server\_priv/nodes

The attributes **mom\_service\_port** and **mom\_manager\_port** were added to the nodes file syntax to accommodate multiple MOMs on a single node. By default `pbs_mom` opens ports 15002 and 15003 for the service and management ports respectively. For multiple MOMs to run on the same IP address they need to have their own port values so they can be distinguished from each other. `pbs_server` learns about the port addresses of the different MOMs from entries in the `server_priv/nodes` file. The following is an example of a nodes file configured for multiple MOMs:

```
hosta    np=2
hosta-1  np=2 mom_service_port=30001 mom_manager_port=30002
hosta-2  np=2 mom_service_port=31001 mom_manager_port=31002
hosta-3  np=2 mom_service_port=32001 mom_manager_port=32002
```

Note that all entries have a unique host name and that all port values are also unique. The entry `hosta` does not have a `mom_service_port` or `mom_manager_port` given. If unspecified, then the MOM defaults to ports 15002 and 15003.

## /etc/hosts file

Host names in the `server_priv/nodes` file must be resolvable. Creating an alias for each host enables the server to find the IP address for each MOM; the server uses the port values from the `server_priv/nodes` file to contact the correct MOM. An example `/etc/hosts` entry for the previous `server_priv/nodes` example might look like the following:

```
192.65.73.10 hosta hosta-1 hosta-2 hosta-3
```

Even though the host name and all the aliases resolve to the same IP address, each MOM instance can still be distinguished from the others because of the unique port value assigned in the `server_priv/nodes` file.

## Starting pbs\_mom with multi-MOM options

To start multiple instances of `pbs_mom` on the same node, use the following syntax (see [pbs\\_mom on page 2693](#) for details):

```
pbs_mom -m -M <port value of MOM_service_port> -R <port value of MOM_manager_port> -A
<name of MOM alias>
```

Continuing based on the earlier example, if you want to create four MOMs on `hosta`, type the following at the command line:

```
# pbs_mom -m -M 30001 -R 30002 -A hosta-1
# pbs_mom -m -M 31001 -R 31002 -A hosta-2
# pbs_mom -m -M 32001 -R 32002 -A hosta-3
# pbs_mom
```

Notice that the last call to `pbs_mom` uses no arguments. By default `pbs_mom` opens on ports 15002 and 15003. No arguments are necessary because there are no conflicts.

- [Stopping pbs\\_mom in Multi-MOM mode on page 2582](#)

## Stopping pbs\_mom in Multi-MOM mode

Terminate `pbs_mom` by using the `momctl -s` command (for details, see [momctl](#)). For any MOM using the default manager port 15003, the `momctl -s` command stops the MOM. However, to terminate MOMs with a manager port value not equal to 15003, you must use the following syntax:

```
momctl -s -p <port value of MOM_manager_port>
```

The `-p` option sends the terminating signal to the MOM manager port and the MOM is terminated.

# Submitting and managing jobs

This section contains information about how you can submit and manage jobs with TORQUE. For details, see the following topics:

- [Job submission on page 2583](#)
- [Monitoring jobs on page 2599](#)
- [Canceling jobs on page 2599](#)
- [Job preemption on page 2600](#)
- [Keeping completed jobs on page 2600](#)
- [Job checkpoint and restart on page 2601](#)
- [Job exit status on page 2611](#)
- [Service jobs on page 2615](#)

## Job submission

Job submission is accomplished using the **qsub** command, which takes a number of command line arguments and integrates such into the specified PBS command file. The PBS command file may be specified as a filename on the **qsub** command line or may be entered via STDIN.

- The PBS command file does not need to be executable.
- The PBS command file may be *piped* into **qsub** (i.e., `cat pbs.cmd | qsub`).
- In the case of parallel jobs, the PBS command file is staged to, and executed on, the first allocated compute node only. (Use **pbsdsh** to run actions on multiple nodes.)
- The command script is executed from the user's home directory in all cases. (The script may determine the submission directory by using the `$PBS_O_WORKDIR` environment variable)
- The command script will be executed using the default set of user environment variables unless the **-V** or **-v** flags are specified to include aspects of the job submission environment.
- PBS directives should be declared first in the job script.

```
#PBS -S /bin/bash
#PBS -m abe
#PBS -M <yourEmail@company.com>
echo sleep 300
```

*This is an example of properly declared PBS directives.*

```
#PBS -S /bin/bash
SOMEVARIABLE=42
#PBS -m abe
#PBS -M <yourEmail@company.com>
echo sleep 300
```

*This is an example of improperly declared PBS directives. PBS directives below "SOMEVARIABLE=42" are ignored.*

**i** By default, job submission is allowed only on the TORQUE server host (host on which **pbs\_server** is running). Enablement of job submission from other hosts is documented in [Server configuration on page 2566](#).

**i** Versions of TORQUE earlier than 2.4.5 attempted to apply queue and server defaults to a job that didn't have defaults specified. If a setting still did not have a value after that, TORQUE applied the queue and server maximum values to a job (meaning, the maximum values for an applicable setting were applied to jobs that had no specified or default value).

In TORQUE 2.4.5 and later, the queue and server maximum values are no longer used as a value for missing settings.

- [Appendix J: Job submission filter \("qsub wrapper"\)](#) on page 2827 – Allow local checking and modification of submitted job

## Multiple job submission

Sometimes users will want to submit large numbers of jobs based on the same job script. Rather than using a script to repeatedly call `qsub`, a feature known as job arrays now exists to allow the creation of multiple jobs with one `qsub` command. Additionally, this feature includes a new job naming convention that allows users to reference the entire set of jobs as a unit, or to reference one particular job from the set.

Job arrays are submitted through the `-t` option to `qsub`, or by using `#PBS -t` in your batch script. This option takes a comma-separated list consisting of either a single job ID number, or a pair of numbers separated by a dash. Each of these jobs created will use the same script and will be running in a nearly identical environment.

```
> qsub -t 0-4 job_script
1098[0].hostname

> qstat -t
1098[0].hostname ...
1098[1].hostname ...
1098[2].hostname ...
1098[3].hostname ...
1098[4].hostname ...
```

**i** Versions of TORQUE earlier than 2.3 had different semantics for the `-t` argument. In these versions, `-t` took a single integer number—a count of the number of jobs to be created.

Each `1098[x]` job has an environment variable called `PBS_ARRAYID`, which is set to the value of the array index of the job, so `1098[0].hostname` would have `PBS_ARRAYID` set to 0. This allows you to create job arrays where each job in the array performs slightly different actions based on the value of this variable, such as performing the same tasks on different input files. One other difference in the environment between jobs in the same array is the value of the `PBS_JOBNAME` variable.

```
# These two examples are equivalent in TORQUE 2.2
> qsub -t 0-99
> qsub -t 100

# You can also pass comma delimited lists of ids and ranges:
> qsub -t 0,10,20,30,40
> qsub -t 0-50,60,70,80
```

Running `qstat` displays a job summary, which provides an overview of the array's state. To see each job in the array, run `qstat -t`.

The `qalter`, `qdel`, `qhold`, and `qrls` commands can operate on arrays—either the entire array or a range of that array. Additionally, any job in the array may be accessed normally by using that job's ID, just as you would with any other job. For example, running the following command would run only the specified job:

```
qrun 1098[0].hostname
```

## Slot Limit

The slot limit is a way for administrators to limit the number of jobs from a job array that can be eligible for scheduling at the same time. When a slot limit is used, TORQUE puts a hold on all jobs in the array that exceed the slot limit. When an eligible job in the array completes, TORQUE removes the hold flag from the next job in the array. Slot limits can be declared globally with the [max\\_slot\\_limit](#) parameter, or on a per-job basis with [qsub -t](#).

- [Job submission on page 2583](#)

## Managing multi-node jobs

By default, when a multi-node job runs, the Mother Superior manages the job across all the sister nodes by communicating with each of them and updating `pbs_server`. Each of the sister nodes sends its updates and stdout and stderr directly to the Mother Superior. When you run an extremely large job using hundreds or thousands of nodes, you may want to reduce the amount of network traffic sent from the sisters to the Mother Superior by specifying a job radix. Job radix sets a maximum number of nodes with which the Mother Superior and resulting intermediate MOMs communicate and is specified using the [-W on page 2755](#) option for `qsub`.

For example, if you submit a smaller, 12-node job and specify `job_radix=3`, Mother Superior and each resulting intermediate MOM is only allowed to receive communication from 3 subordinate nodes.

Image 4-1: Job radix example

The Mother Superior picks three sister nodes with which to communicate the job information. Each of those nodes (intermediate MOMs) receives a list of all sister nodes that will be subordinate to it. They each contact up to three nodes and pass the job information on to those nodes. This pattern continues until the bottom level is reached. All communication is now passed across this new hierarchy. The stdout and stderr data is aggregated and sent up the tree until it reaches the Mother Superior, where it is saved and copied to the `.o` and `.e` files.

**i** Job radix is meant for extremely large jobs only. It is a tunable parameter and should be adjusted according to local conditions in order to produce the best results.

## Requesting resources

Various resources can be requested at the time of job submission. A job can request a particular node, a particular node attribute, or even a number of nodes with particular attributes. Either native TORQUE resources or external scheduler resource extensions may be specified. The native TORQUE resources are listed in the following table:

Resource	Format	Description
<b>arch</b>	string	Specifies the administrator defined system architecture required. This defaults to whatever the <b>PBS_MACH</b> string is set to in "local.mk".
<b>cpus</b>	seconds, or [[HH:]MM:]SS	Maximum amount of CPU time used by all processes in the job.

Resource	Format	Description
<b>cpuclock</b>	string	<p>Specify the CPU clock frequency for each node requested for this job. A <b>cpuclock</b> request applies to every processor on every node in the request. Specifying varying CPU frequencies for different nodes or different processors on nodes in a single job request is not supported.</p> <p>Not all processors support all possible frequencies or ACPI states. If the requested frequency is not supported by the CPU, the nearest frequency is used.</p> <p>ALPS 1.4 or later is required when using <b>cpuclock</b> on Cray.</p> <p>The clock frequency can be specified via:</p> <ul style="list-style-type: none"> <li>a number that indicates the clock frequency (with or without the SI unit suffix).</li> </ul> <pre>qsub -l cpuclock=1800,nodes=2 script.sh qsub -l cpuclock=1800mhz,nodes=2 script.sh</pre> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to 1800 MHz.</i></p> <ul style="list-style-type: none"> <li>a Linux power governor policy name. The governor names are: <ul style="list-style-type: none"> <li><b>performance</b>: This governor instructs Linux to operate each logical processor at its maximum clock frequency. This setting consumes the most power and workload executes at the fastest possible speed.</li> <li><b>powersave</b>: This governor instructs Linux to operate each logical processor at its minimum clock frequency. This setting executes workload at the slowest possible speed. This setting does not necessarily consume the least amount of power since applications execute slower, and may actually consume more energy because of the additional time needed to complete the workload's execution.</li> <li><b>ondemand</b>: This governor dynamically switches the logical processor's clock frequency to the maximum value when system load is high and to the minimum value when the system load is low. This setting causes workload to execute at the fastest possible speed or the slowest possible speed, depending on OS load. The system switches between consuming the most power and the least power.</li> </ul> </li> </ul>

Resource	Format	Description
		<div data-bbox="764 317 1409 709" style="border: 1px solid #ccc; padding: 10px; margin-bottom: 10px;"> <p><b>i</b> The power saving benefits of <i>ondemand</i> might be non-existent due to frequency switching latency if the system load causes clock frequency changes too often. This has been true for older processors since changing the clock frequency required putting the processor into the C3 "sleep" state, changing its clock frequency, and then waking it up, all of which required a significant amount of time. Newer processors, such as the Intel Xeon E5-2600 Sandy Bridge processors, can change clock frequency dynamically and much faster.</p> </div> <ul style="list-style-type: none"> <li data-bbox="732 720 1409 947"> <p>o <i>conservative</i>: This governor operates like the <i>ondemand</i> governor but is more conservative in switching between frequencies. It switches more gradually and uses all possible clock frequencies. This governor can switch to an intermediate clock frequency if it seems appropriate to the system load and usage, which the <i>ondemand</i> governor does not do.</p> </li> </ul> <div data-bbox="683 961 1409 1010" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <pre>qsub -l cpuclock=performance,nodes=2 script.sh</pre> </div> <div data-bbox="732 1024 1360 1108" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to the performance power governor policy.</i></p> </div> <ul style="list-style-type: none"> <li data-bbox="651 1136 1409 1346"> <p>• an ACPI performance state (or P-state) with or without the P prefix. P-states are a special range of values (0-15) that map to specific frequencies. Not all processors support all 16 states, however, they all start at P0. P0 sets the CPU clock frequency to the highest performance state which runs at the maximum frequency. P15 sets the CPU clock frequency to the lowest performance state which runs at the lowest frequency.</p> </li> </ul> <div data-bbox="683 1371 1409 1440" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <pre>qsub -l cpuclock=3,nodes=2 script.sh qsub -l cpuclock=p3,nodes=2 script.sh</pre> </div> <div data-bbox="732 1455 1360 1539" style="border: 1px dashed #ccc; padding: 5px; margin-bottom: 10px;"> <p><i>This job requests 2 nodes and specifies their CPU frequencies should be set to a performance state of 3.</i></p> </div> <p>When reviewing job or node properties when <b>cpuclock</b> was used, be mindful of unit conversion. The OS reports frequency in Hz, not MHz or GHz.</p>

Resource	Format	Description
<b>epilogue</b>	string	Specifies a user owned epilogue script which will be run before the system epilogue and epilogue.user scripts at the completion of a job. The syntax is <code>epilogue=&lt;file&gt;</code> . The file can be designated with an absolute or relative path. For more information, see <a href="#">Appendix G: Prologue and epilogue scripts on page 2817</a> .
<b>feature</b>	string	Specifies a property or feature for the job. Feature corresponds to TORQUE node properties and Moab features. <pre>qsub script.sh -l procs=10,feature=bigmem</pre>
<b>file</b>	<a href="#">size</a>	The amount of total disk requested for the job. (Ignored on Unicos.)
<b>host</b>	string	Name of the host on which the job should be run. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent.
<b>mem</b>	<a href="#">size</a>	Maximum amount of physical memory used by the job. Ignored on Darwin, Digital Unix, Free BSD, HPUX 11, IRIX, NetBSD, and SunOS. Not implemented on AIX and HPUX 10. The <code>mem</code> resource will only work for single-node jobs. If your job requires multiple nodes, use <code>pmem</code> instead.
<b>ncpus</b>	integer	The number of processors in one task where a task cannot span nodes.  You cannot request both <code>ncpus</code> and <code>nodes</code> in the same job.
<b>nice</b>	integer	Number between -20 (highest priority) and 19 (lowest priority). Adjust the process execution priority.

Resource	Format	Description
<b>nodes</b>	{<node_count>   <hostname>} [:ppn=<ppn>] [:gpus=<gpu>] [:<property>] [:<property>...] [+ ...]	<p>Number and/or type of nodes to be reserved for exclusive use by the job. The value is one or more node_specs joined with the + (plus) character: node_spec [+node_spec...]. Each node_spec is a number of nodes required of the type declared in the node_spec and a name of one or more properties desired for the nodes. The number, the name, and each property in the node_spec are separated by a : (colon). If no number is specified, one (1) is assumed. The name of a node is its hostname. The properties of nodes are:</p> <ul style="list-style-type: none"> <li>• <b>ppn=#</b> - Specify the number of virtual processors per node requested for this job. The number of virtual processors available on a node by default is 1, but it can be configured in the \$TORQUE_HOME/server_priv/nodes file using the <b>np</b> attribute (see <a href="#">Server node file configuration on page 2572</a>). The virtual processor can relate to a physical core on the node or it can be interpreted as an "execution slot" such as on sites that set the node np value greater than the number of physical cores (or hyper-thread contexts). The ppn value is a characteristic of the hardware, system, and site, and its value is to be determined by the administrator.</li> <li>• <b>gpus=#</b> - Specify the number of GPUs per node requested for this job. The number of GPUs available on a node can be configured in the \$TORQUE_HOME/server_priv/nodes file using the <b>gpu</b> attribute (see <a href="#">Server node file configuration on page 2572</a>). The GPU value is a characteristic of the hardware, system, and site, and its value is to be determined by the administrator.</li> <li>• <b>property</b> - A string assigned by the system administrator specifying a node's features. Check with your administrator as to the node names and properties available to you.</li> </ul> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> TORQUE does not have a TPN (tasks per node) property. You can specify TPN in Moab Workload Manager with TORQUE as your resource manager, but TORQUE does not recognize the property when it is submitted directly to it via <code>qsub</code>.</p> </div> <p>See <a href="#">qsub -l nodes on page 2592</a> for examples.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> By default, the node resource is mapped to a virtual node (that is, directly to a processor, not a full physical compute node). This behavior can be changed within Maui or Moab by setting the <code>JOBNODEMATCHPOLICY</code> parameter. See <a href="#">Appendix A: Moab Parameters on page 923</a> for more information.</p> </div>
<b>opsys</b>	string	Specifies the administrator defined operating system as defined in the MOM configuration file.

Resource	Format	Description
<b>other</b>	string	Allows a user to specify site specific information. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent.   This does not work for <code>msub</code> using Moab and Maui.
<b>pccput</b>	seconds, or [[HH:]MM:]SS	Maximum amount of CPU time used by any single process in the job.
<b>pmem</b>	<a href="#">size</a>	Maximum amount of physical memory used by any single process of the job. (Ignored on Fujitsu. Not implemented on Digital Unix and HPUNIX.)
<b>procs</b>	procs=<integer>	<i>(Applicable in version 2.5.0 and later.)</i> The number of processors to be allocated to a job. The processors can come from one or more qualified node(s). Only one procs declaration may be used per submitted <a href="#">qsub</a> command.  > qsub -l nodes=3 -l procs=2
<b>procs_bitmap</b>	string	A string made up of 1's and 0's in reverse order of the processor cores requested. A <b>procs_bitmap=1110</b> means the job requests a node that has four available cores, but the job runs exclusively on cores two, three, and four. With this bitmap, core one is not used.  For more information, see <a href="#">Scheduling cores on page 2624</a> .
<b>prologue</b>	string	Specifies a user owned prologue script which will be run after the system prologue and prologue.user scripts at the beginning of a job. The syntax is <code>prologue=&lt;file&gt;</code> . The file can be designated with an absolute or relative path.  For more information, see <a href="#">Appendix G: Prologue and epilogue scripts on page 2817</a> .
<b>pvmem</b>	<a href="#">size</a>	Maximum amount of virtual memory used by any single process in the job. (Ignored on Unicos.)
<b>size</b>	integer	For TORQUE, this resource has no meaning. It is passed on to the scheduler for interpretation. In the Moab scheduler, the size resource is intended for use in Cray installations only.
<b>software</b>	string	Allows a user to specify software required by the job. This is useful if certain software packages are only available on certain systems in the site. This resource is provided for use by the site's scheduling policy. The allowable values and effect on job placement is site dependent. (See <a href="#">License Management on page 663</a> for more information.)

Resource	Format	Description
<b>vmem</b>	<a href="#">size</a>	Maximum amount of virtual memory used by all concurrent processes in the job. (Ignored on Unicors.)
<b>walltime</b>	seconds, or [[HH:]MM:]SS	Maximum amount of real time during which the job can be in the running state.

### size

The size format specifies the maximum amount in terms of bytes or words. It is expressed in the form *integer[suffix]*. The suffix is a multiplier defined in the following table ("b" means bytes [the default] and "w" means words). The size of a word is calculated on the execution server as its word size.

Suffix		Multiplier
b	w	1
kb	kw	1024
mb	mw	1,048,576
gb	gw	1,073,741,824
tb	tw	1,099,511,627,776

### Example 4-10: `qsub -l nodes`

Usage	Description
<code>&gt; qsub -l nodes=12</code>	Request 12 nodes of any type
<code>&gt; qsub -l nodes=2:server+14</code>	Request 2 "server" nodes and 14 other nodes (a total of 16) - this specifies two node_specs, "2:server" and "14"
<code>&gt; qsub -l nodes=s=server:hippi+10:noserver+3:bigmem:hippi</code>	Request (a) 1 node that is a "server" and has a "hippi" interface, (b) 10 nodes that are not servers, and (c) 3 nodes that have a large amount of memory and have hipp
<code>&gt; qsub -l nodes=b2005+b1803+b1813</code>	Request 3 specific nodes by hostname

Usage	Description
> qsub -l nodes=4:ppn=2	Request 2 processors on each of four nodes
> qsub -l nodes=1:ppn=4	Request 4 processors on one node
> qsub -l nodes=2:blue:ppn=2+red:ppn=3+b1014	Request 2 processors on each of two blue nodes, three processors on one red node, and the compute node "b1014"

**Example 4-11:**

This job requests a node with 200MB of available memory:

```
> qsub -l mem=200mb /home/user/script.sh
```

**Example 4-12:**

This job will wait until node01 is free with 200MB of available memory:

```
> qsub -l nodes=node01,mem=200mb /home/user/script.sh
```

## Related topics

- [Job submission on page 2583](#)

## Requesting generic resources

When **generic** resources have been assigned to nodes using the server's nodes file, these resources can be requested at the time of job submission using the *other* field. (See [Managing Shared Cluster Resources \(Floating Resources\) on page 567](#) for details on configuration within Moab).

**Example 4-13: Generic**

This job will run on any node that has the generic resource **matlab**.

```
> qsub -l other=matlab /home/user/script.sh
```

This can also be requested at the time of job submission using the `-W x=GRES:matlab` flag.

## Related topics

- [Requesting resources on page 2586](#)
- [Job submission on page 2583](#)

## Requesting floating resources

When **floating** resources have been set up inside Moab, they can be requested in the same way as **generic** resources. Moab will automatically understand that these resources are floating and will

schedule the job accordingly. (See [Managing Shared Cluster Resources \(Floating Resources\)](#) on page 567 for details on configuration within Moab.)

#### Example 4-14: Floating

This job will run on any node when there are enough floating resources available.

```
> qsub -l other=matlab /home/user/script.sh
```

 This can also be requested at the time of job submission using the `-W x=GRES:matlab` flag.

#### Related topics

- [Requesting resources on page 2586](#)
- [Job submission on page 2583](#)

## Requesting other resources

Many other resources can be requested at the time of job submission using the Moab Workload Manager. See [Resource Manager Extensions on page 618](#) for a list of these supported requests and correct syntax.

#### Related topics

- [Requesting resources on page 2586](#)
- [Job submission on page 2583](#)

## Exported batch environment variables

When a batch job is started, a number of variables are introduced into the job's environment that can be used by the batch script in making decisions, creating output files, and so forth. These variables are listed in the following table:

Variable	Description
<b>PBS_JOBNAME</b>	User specified jobname
<b>PBS_ARRAYID</b>	Zero-based value of job array index for this job (in version 2.2.0 and later)
<b>PBS_GPUFILE</b>	Line-delimited list of GPUs allocated to the job located in <code>\$TORQUE_HOME/aux/jobidgpu</code> . Each line follows the following format: <code>&lt;host&gt;-gpu&lt;number&gt;</code> For example, <code>myhost-gpu1</code> .
<b>PBS_O_WORKDIR</b>	Job's submission directory

Variable	Description
<b>PBS_ENVIRONMENT</b>	N/A
<b>PBS_TASKNUM</b>	Number of tasks requested
<b>PBS_O_HOME</b>	Home directory of submitting user
<b>PBS_MOMPORT</b>	Active port for MOM daemon
<b>PBS_O_LOGNAME</b>	Name of submitting user
<b>PBS_O_LANG</b>	Language variable for job
<b>PBS_JOBCOOKIE</b>	Job cookie
<b>PBS_JOBID</b>	Unique pbs job id
<b>PBS_NODENUM</b>	Node offset number
<b>PBS_NUM_NODES</b>	Number of nodes allocated to the job
<b>PBS_NUM_PPN</b>	Number of procs per node allocated to the job
<b>PBS_O_SHELL</b>	Script shell
<b>PBS_O_HOST</b>	Host on which job script is currently running
<b>PBS_QUEUE</b>	Job queue
<b>PBS_NODEFILE</b>	File containing line delimited list of nodes allocated to the job
<b>PBS_NP</b>	Number of execution slots (cores) for the job
<b>PBS_O_PATH</b>	Path variable used to locate executables within job script

## Related topics

- [Job submission on page 2583](#)

## Enabling trusted submit hosts

By default, only the node running the `pbs_server` daemon is allowed to submit jobs. Additional nodes can be trusted as submit hosts by taking any of the following steps:

- Set the `allow_node_submit` server parameter (see [Allowing job submission from compute hosts on page 2568](#)).  
Allows any host trusted as a compute host to also be trusted as a submit host.
- Set the `submit_hosts` server parameter (see [Using the "submit\\_hosts" service parameter on page 2567](#)).  
Allows specified hosts to be trusted as a submit host.
- Use `.rhosts` to enable `ruserok()` based authentication (see [Using RCmd authentication on page 2566](#)).

See [Configuring job submission hosts on page 2566](#) for more information.

**i** When you enable `allow_node_submit` on page 2767, you must also enable the `allow_proxy_user` on page 2767 parameter to allow user proxying when submitting and running jobs.

## Related topics

## Job files

TORQUE 4.5.0 was updated to accept XML-based job files in addition to the binary job files. The change allows job files to be more human-readable and easier to parse. Below is a sample job file in the new XML format:

```

<?xml version="1.0"?>
<job>
  <version>131842</version>
  <state>1</state>
  <substate>10</substate>
  <server_flags>33</server_flags>
  <start_time>0</start_time>
  <jobid>340</jobid>
  <fileprefix>340</fileprefix>
  <queue>batch</queue>
  <destination_queue></destination_queue>
  <record_type>1</record_type>
  <mom_address>0</mom_address>
  <mom_port>11</mom_port>
  <mom_rmpport>0</mom_rmpport>
  <attributes>
    <Job_Name flags="1">job2.sh</Job_Name>
    <Job_Owner flags="1">echan@moabServer.cn</Job_Owner>
    <job_state flags="1">Q</job_state>
    <queue flags="3">batch</queue>
    <server flags="1">company.com</server>
    <Checkpoint flags="1">u</Checkpoint>
    <ctime flags="1">1384292754</ctime>
    <Error_Path flags="1">moabServer.cn:/home/echan/work/job2.sh.e340</Error_Path>
    <Hold_Types flags="1">n</Hold_Types>
    <Join_Path flags="1">n</Join_Path>
    <Keep_Files flags="1">n</Keep_Files>
    <Mail_Points flags="1">a</Mail_Points>
    <mtime flags="1">1384292754</mtime>
    <Output_Path flags="1">moabServer.cn:/home/echan/work/job2.sh.o340</Output_Path>
    <Priority flags="1">0</Priority>
    <qtime flags="1">1384292754</qtime>
    <Rerunable flags="1">True</Rerunable>
    <Resource_List>
      <epilogue flags="1">/tmp/epilogue.sh</epilogue>
      <neednodes flags="1">moabServer:ppn=1</neednodes>
      <nodect flags="1">1</nodect>
      <nodes flags="1">moabServer:ppn=1</nodes>
    </Resource_List>
    <substate flags="1">10</substate>
    <Variable_List flags="1">PBS_O_QUEUE=batch
PBS_O_HOME=/home/echan
PBS_O_LOGNAME=echan
PBS_O_
PATH=/home/echan/eclipse:/usr/lib/lightdm/lightdm:/usr/local/sbin:/usr/local/bin:/usr/
sbin:/usr/bin:/sbin:/bin:/usr/games:/opt/moab/bin:/opt/moab/sbin
PBS_O_SHELL=/bin/bash
PBS_O_LANG=en_US
PBS_O_WORKDIR=/home/echan/work
PBS_O_HOST=moabServer.cn
PBS_O_SERVER=moabServer
</Variable_List>
    <euser flags="1">echan</euser>
    <egroup flags="5">company</egroup>
    <hop_count flags="1">1</hop_count>
    <queue_rank flags="1">2</queue_rank>
    <queue_type flags="1">E</queue_type>
    <etime flags="1">1384292754</etime>
    <submit_args flags="1">-l nodes=lei:ppn=1 -l epilogue=/tmp/epilogue.sh
./job2.sh</submit_args>
    <fault_tolerant flags="1">False</fault_tolerant>
    <job_radix flags="1">0</job_radix>
  </attributes>
</job>

```

```
<submit_host flags="1">lei.ac</submit_host>
</attributes>
</job>
```

The above job was submitted with this submit command:

```
qsub -l nodes=moabServer:ppn=1 -l epilogue=/tmp/epilogue.sh ./job2.sh
```

Related topics

- [Job submission on page 2583](#)

## Monitoring jobs

TORQUE allows users and administrators to monitor submitted jobs with the [qstat](#) command. If the command is run by a non-administrative user, it will output just that user's jobs. For example:

```
> qstat
Job id      Name      User      Time Use S Queue
-----
4807       scatter  user01    12:56:34 R batch
...
```

Related topics

- [Submitting and managing jobs on page 2582](#)

## Canceling jobs

TORQUE allows users and administrators to cancel submitted jobs with the [qdel](#) command. The job will be sent TERM and KILL signals killing the running processes. When the top-level job script exits, the job will exit. The only parameter is the ID of the job to be canceled.

If a job is canceled by an operator or manager, an email notification will be sent to the user. Operators and managers may add a comment to this email with the `-m` option.

```
$ qstat
Job id      Name      User      Time Use S Queue
-----
4807       scatter  user01    12:56:34 R batch
...
$ qdel -m "hey! Stop abusing the NFS servers" 4807
$
```

## Job preemption

TORQUE supports job preemption by allowing authorized users to suspend and resume jobs. This is supported using one of two methods. If the node supports OS-level preemption, TORQUE will recognize that during the configure process and enable it. Otherwise, the MOM may be configured to launch a custom *checkpoint script* in order to support preempting a job. Using a custom checkpoint script requires that the job understand how to resume itself from a checkpoint after the preemption occurs.

### Configuring a checkpoint script on a MOM

To configure the MOM to support a checkpoint script, the `$checkpoint_script` parameter must be set in the MOM's configuration file found in `TORQUE_HOME/mom_priv/config`. The checkpoint script should have execute permissions set. A typical configuration file might look as follows:

mom\_priv/config:

```
$pbsserver      node06
$logevent       255
$restricted     *.mycluster.org
$checkpoint_script /opt/moab/tools/mom-checkpoint.sh
```

The second thing that must be done to enable the checkpoint script is to change the value of `MOM_CHECKPOINT` to **1** in `/src/include/pbs_config.h`. (In some instances, `MOM_CHECKPOINT` may already be defined as 1.) The new line should be as follows:

/src/include/pbs\_config.h:

```
#define MOM_CHECKPOINT 1
```

## Keeping completed jobs

TORQUE provides the ability to report on the status of completed jobs for a configurable duration after the job has completed. This can be enabled by setting the [keep\\_completed on page 2631](#) attribute on the job execution queue or the [keep\\_completed on page 2772](#) parameter on the server. This should be set to the number of seconds that jobs should be held in the queue. If you set `keep_completed` on the job execution queue, completed jobs will be reported in the **C** state and the exit status is seen in the `exit_status` job attribute.

- i** If the Mother Superior and TORQUE server are on the same server, expect the following behavior:
- When `keep_completed` is set, the job spool files will be deleted when the specified time arrives and TORQUE purges the job from memory.
  - When `keep_completed` is not set, TORQUE deletes the job spool files upon job completion.
  - If you manually purge a job (`qdel -p`) before the job completes or time runs out, TORQUE will never delete the spool files.

By maintaining status information about completed (or canceled, failed, etc.) jobs, administrators can better track failures and improve system performance. This allows TORQUE to better communicate with Moab Workload Manager and track the status of jobs. This gives Moab the ability to track specific failures and to schedule the workload around possible hazards. (See [NODEFAILURERESERVETIME](#) for more information.)

## Job checkpoint and restart

While TORQUE has had a job checkpoint and restart capability for many years, this was tied to machine specific features. Now TORQUE supports BLCR—an architecture independent package that provides for process checkpoint and restart.

- i** The support for BLCR is only for serial jobs, not for any MPI type jobs.

This section contains these topics:

## Introduction to BLCR

BLCR is a kernel level package. It must be downloaded and installed from [BLCR](#).

After building and making the package, it must be installed into the kernel with commands as follows. These can be installed into the file `/etc/modules` but all of the testing was done with explicit invocations of **modprobe**.

Installing BLCR into the kernel:

```
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr_imports.ko
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr_vmadump.ko
# /sbin/insmod /usr/local/lib/blcr/2.6.12-1.234/blcr.ko
```

The BLCR system provides four command line utilities:

- `cr_checkpoint`
- `cr_info`
- `cr_restart`
- `cr_run`

For more information about BLCR, see the [BLCR Administrator's Guide](#).

## Configuration files and scripts

Configuring and Building TORQUE for BLCR:

```
> ./configure --enable-unixsockets=no --enable-blcr
> make
> sudo make install
```

Depending on where BLCR is installed you may also need to use the following configure options to specify BLCR paths:

Option	Description
<code>--with-blcr-include=DIR</code>	include path for <code>libcr.h</code>
<code>--with-blcr-lib=DIR</code>	lib path for <code>libcr</code>
<code>--with-blcr-bin=DIR</code>	bin path for BLCR utilities

The `pbs_mom` configuration file located in `/var/spool/torque/mom_priv` must be modified to identify the script names associated with invoking the BLCR commands. The following variables should be used in the configuration file when using BLCR checkpointing.

Variable	Description
<code>\$checkpoint_interval</code>	How often periodic job checkpoints will be taken (minutes)
<code>\$checkpoint_script</code>	The name of the script file to execute to perform a job checkpoint
<code>\$restart_script</code>	The name of the script file to execute to perform a job restart
<code>\$checkpoint_run_exe</code>	The name of an executable program to be run when starting a checkpointable job (for BLCR, <code>cr_run</code> )

The following example shows the contents of the configuration file used for testing the BLCR feature in TORQUE.

 The script files below must be executable by the user. Be sure to use `chmod` to set the permissions to 754.

#### Example 4-15: Script file permissions

```
# chmod 754 blcr*
# ls -l
total 20
-rwxr-xr-- 1 root root 2112 2008-03-11 13:14 blcr_checkpoint_script
-rwxr-xr-- 1 root root 1987 2008-03-11 13:14 blcr_restart_script
-rw-r--r-- 1 root root 215 2008-03-11 13:13 config
drwxr-x--x 2 root root 4096 2008-03-11 13:21 jobs
-rw-r--r-- 1 root root 7 2008-03-11 13:15 mom.lock
```

#### Example 4-16: `mom_priv/config`

```
$checkpoint_script /var/spool/torque/mom_priv/blcr_checkpoint_script
$restart_script /var/spool/torque/mom_priv/blcr_restart_script
$checkpoint_run_exe /usr/local/bin/cr_run
$pbsserver makuu.cridomain
$loglevel 7
```

*Example 4-17: mom\_priv/blcr\_checkpoint\_script*

```

#!/usr/bin/perl
#####
#
# Usage: checkpoint_script
#
# This script is invoked by pbs_mom to checkpoint a job.
#
#####
use strict;
use Sys::Syslog;

# Log levels:
# 0 = none -- no logging
# 1 = fail -- log only failures
# 2 = info -- log invocations
# 3 = debug -- log all subcommands
my $logLevel = 3;

logPrint(2, "Invoked: $0 " . join(' ', @ARGV) . "\n");

my ($sessionId, $jobId, $userId, $signalNum, $checkpointDir, $checkpointName);

## Starting a checkpointable job

Not every job is checkpointable. A job for which checkpointing is desirable must be started with the `-c` command line option. This option takes a comma-separated list of arguments that are used to control checkpointing behavior. The list of valid options available in the 2.4 version of TORQUE is show below.

Option	Description
<b>none</b>	No checkpointing (not highly useful, but included for completeness).
<b>enabled</b>	Specify that checkpointing is allowed, but must be explicitly invoked by either the <code>qhold</code> or <code>qchkpt</code> commands.
<b>shutdown</b>	Specify that checkpointing is to be done on a job at <code>pbs_mom</code> shutdown.
<b>periodic</b>	Specify that periodic checkpointing is enabled. The default interval is 10 minutes and can be changed by the <code>\$checkpoint_interval</code> option in the MOM configuration file, or by specifying an interval when the job is submitted.
<b>interval=minutes</b>	Specify the checkpoint interval in minutes.
<b>depth=number</b>	Specify a number (depth) of checkpoint images to be kept in the checkpoint directory.
<b>dir=path</b>	Specify a checkpoint directory (default is <code>/var/spool/torque/checkpoint</code> ).

### Example 4-19: Sample test program

```
#include "stdio.h"
int main( int argc, char *argv[] )
{
  int i;
  for (i=0; i<100; i++)
  {
    printf("i = %d\n", i);
    fflush(stdout);
    sleep(1);
  }
}
```

### Example 4-20: Instructions for building test program

```
> gcc -o test test.c
```

**Example 4-21: Sample test script**

```
#!/bin/bash ./test
```

**Example 4-22: Starting the test job**

```
> qstat
> qsub -c enabled,periodic,shutdown,interval=1 test.sh
77.jakaa.cridomain
> qstat
Job id          Name          User          Time Use S Queue
-----
77.jakaa       test.sh       jsmith        0 Q batch
>
```

If you have no scheduler running, you might need to start the job with [grun](#).

As this program runs, it writes its output to a file in `/var/spool/torque/spool`. This file can be observed with the command `tail -f`.

**Related topics**

- [Job checkpoint and restart on page 2601](#)

## Checkpointing a job

Jobs are checkpointed by issuing a [ghold](#) command. This causes an image file representing the state of the process to be written to disk. The directory by default is `/var/spool/torque/checkpoint`.

This default can be altered at the queue level with the `qmgr` command. For example, the command `qmgr -c set queue batch checkpoint_dir=/tmp` would change the checkpoint directory to `/tmp` for the queue 'batch'.

The default directory can also be altered at job submission time with the `-c dir=/tmp` command line option.

The name of the checkpoint directory and the name of the checkpoint image file become attributes of the job and can be observed with the command `qstat -f`. Notice in the output the names **checkpoint\_dir** and **checkpoint\_name**. The variable `checkpoint_name` is set when the image file is created and will not exist if no checkpoint has been taken.

A job can also be checkpointed without stopping or holding the job with the command [gchkpt](#).

**Related topics**

- [Job checkpoint and restart on page 2601](#)

## Restarting a job

### Restarting a job in the Held state

The [grls](#) command is used to restart the hibernated job. If you were using the `tail -f` command to watch the output file, you will see the test program start counting again.

It is possible to use the [galter](#) command to change the name of the checkpoint file associated with a job. This could be useful if there were several job checkpoints and it restarting the job from an older image was specified.

## Restarting a job in the Completed state

In this case, the job must be moved to the Queued state with the [grerun](#) command. Then the job must go to the Run state either by action of the scheduler or if there is no scheduler, through using the [grun](#) command.

- [Job checkpoint and restart on page 2601](#)

## Acceptance tests

A number of tests were made to verify the functioning of the BLCR implementation. See [Appendix M: BLCR acceptance tests on page 2836](#) for a description of the testing.

Related topics

- [Job checkpoint and restart on page 2601](#)

## Job exit status

Once a job under TORQUE has completed, the `exit_status` attribute will contain the result code returned by the job script. This attribute can be seen by submitting a `qstat -f` command to show the entire set of information associated with a job. The `exit_status` field is found near the bottom of the set of output lines.

**Example 4-23: qstat -f (job failure)**

```

Job Id: 179.host
Job_Name = STDIN
Job_Owner = user@host
job_state = C
queue = batchq server = host
Checkpoint = u ctime = Fri Aug 29 14:55:55 2008
Error_Path = host:/opt/moab/STDIN.e179
exec_host = node1/0
Hold_Types = n
Join_Path = n
Keep_Files = n
Mail_Points = a
mtime = Fri Aug 29 14:55:55 2008
Output_Path = host:/opt/moab/STDIN.o179
Priority = 0
qtime = Fri Aug 29 14:55:55 2008
Rerunable = True Resource_List.ncpus = 2
Resource_List.nodect = 1
Resource_List.nodes = node1
Variable_List = PBS_O_HOME=/home/user,PBS_O_LOGNAME=user,
PBS_O_PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:,PBS_O_
SHELL=/bin/bash,PBS_O_HOST=host,
PBS_O_WORKDIR=/opt/moab,PBS_O_QUEUE=batchq
sched_hint = Post job file processing error; job 179.host on host node1/0Ba
d UID for job execution REJHOST=pala.cridomain MSG=cannot find user 'user' in
password file
etime = Fri Aug 29 14:55:55 2008
exit_status = -1
    
```

**i** The value of `Resource_List.*` is the amount of resources requested.

This code can be useful in diagnosing problems with jobs that may have unexpectedly terminated.

If TORQUE was unable to start the job, this field will contain a negative number produced by the `pbs_mom`. Otherwise, if the job script was successfully started, the value in this field will be the return value of the script.

**Example 4-24: TORQUE supplied exit codes**

Name	Value	Description
<b>JOB_EXEC_OK</b>	0	Job execution successful
<b>JOB_EXEC_FAIL1</b>	-1	Job execution failed, before files, no retry
<b>JOB_EXEC_FAIL2</b>	-2	Job execution failed, after files, no retry
<b>JOB_EXEC_RETRY</b>	-3	Job execution failed, do retry
<b>JOB_EXEC_INITABT</b>	-4	Job aborted on MOM initialization
<b>JOB_EXEC_INITRST</b>	-5	Job aborted on MOM init, chkpt, no migrate

Name	Value	Description
<b>JOB_EXEC_INITRMG</b>	-6	Job aborted on MOM init, chkpt, ok migrate
<b>JOB_EXEC_BADRESRT</b>	-7	Job restart failed
<b>JOB_EXEC_CMDFAIL</b>	-8	Exec() of user command failed
<b>JOB_EXEC_STDOUTFAIL</b>	-9	Could not create/open stdout stderr files
<b>JOB_EXEC_OVERLIMIT_MEM</b>	-10	Job exceeded a memory limit
<b>JOB_EXEC_OVERLIMIT_WT</b>	-11	Job exceeded a walltime limit
<b>JOB_EXEC_OVERLIMIT_CPUT</b>	-12	Job exceeded a CPU time limit

## Example 4-25: Exit code from C program

```

$ cat error.c
#include
#include

int
main(int argc, char *argv)
{
    exit(256+11);
}

$ gcc -o error error.c

$ echo ./error | qsub
180.xxx.yyy

$ qstat -f
Job Id: 180.xxx.yyy
  Job_Name = STDIN
  Job_Owner = test.xxx.yyy
  resources_used.cput = 00:00:00
  resources_used.mem = 0kb
  resources_used.vmem = 0kb
  resources_used.walltime = 00:00:00
  job_state = C
  queue = batch
  server = xxx.yyy
  Checkpoint = u
  ctime = Wed Apr 30 11:29:37 2008
  Error_Path = xxx.yyy:/home/test/STDIN.e180
  exec_host = node01/0
  Hold_Types = n
  Join_Path = n
  Keep_Files = n
  Mail_Points = a
  mtime = Wed Apr 30 11:29:37 2008
  Output_Path = xxx.yyy:/home/test/STDIN.o180
  Priority = 0
  qtime = Wed Apr 30 11:29:37 2008
  Rerunnable = True
  Resource_List.needsnodes = 1
  Resource_List.nodect = 1
  Resource_List.nodes = 1
  Resource_List.walltime = 01:00:00
  session_id = 14107
  substate = 59
  Variable_List = PBS_O_HOME=/home/test,PBS_O_LANG=en_US.UTF-8,
    PBS_O_LOGNAME=test,
    PBS_O_PATH=/usr/local/perltests/bin:/home/test/bin:/usr/local/s
    bin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/games,
    PBS_O_SHELL=/bin/bash,PBS_SERVER=xxx.yyy,
    PBS_O_HOST=xxx.yyy,PBS_O_WORKDIR=/home/test,
    PBS_O_QUEUE=batch
  euser = test
  egroup = test
  hashname = 180.xxx.yyy
  queue_rank = 8
  queue_type = E
  comment = Job started on Wed Apr 30 at 11:29
  etime = Wed Apr 30 11:29:37 2008
  exit_status = 11
  start_time = Wed Apr 30 11:29:37 2008
  start_count = 1

```

Notice that the C routine `exit` passes only the low order byte of its argument. In this case, `256+11` is really `267` but the resulting exit code is only `11` as seen in the output.

## Service jobs

TORQUE service jobs are a special kind of job that is treated differently by TORQUE than normal batch jobs. TORQUE service jobs are *not* related to Moab's dynamic service jobs. A TORQUE service job cannot dynamically grow and shrink in size over time.

Jobs are marked as service jobs at the time they are submitted to Moab or TORQUE. Just like a normal job, a script file is specified with the job. In a batch job, the contents of the script file are taken by TORQUE and executed on the compute nodes. For a service job, however, the script file is assumed to respond to certain command-line arguments. Instead of just executing the script, TORQUE will use these command-line arguments to start, stop, and check on the status of the job. Listed below are the three command-line arguments that must be supported by any script submitted as part of a TORQUE service job:

- `start`: The script should take this argument and launch its service/workload. The script should remain executing/running until the service stops.
- `stop`: The script should take this argument and stop the service/workload that was earlier started.
- `status`: The script should take this argument and return, via standard out, either "running" if the service/workload is running as expected or "stopped" if the service is not running.

This feature was created with long-running services in mind. The command-line arguments should be familiar to users who interact with Unix services, as each of the service scripts found in `/etc/init.d/` also accept and respond to the arguments as explained above.

For example, if a user wants to start the Apache 2 server on a compute node, they can use a TORQUE service job and specify a script which will start, stop, and check on the status of the "httpd" daemon--possibly by using the already present `/etc/init.d/httpd` script.

If you wish to submit service jobs only through TORQUE, no special version of Moab is required. If you wish to submit service jobs using Moab's `msub`, then Moab 5.4 is required.

For details, see these topics:

- [Submitting service jobs on page 2616](#)
- [Submitting service jobs in MCM on page 2616](#)
- [Managing service jobs on page 2616](#)

## Submitting service jobs

There is a new option to `qsub`, "-s" which can take either a 'y' or 'n' (yes or no, respectively). When "-s y" is present, then the job is marked as a service job.

```
qsub -l walltime=100:00:00,nodes=1 -s y service_job.py
```

The example above submits a job to TORQUE with a walltime of 100 hours, one node, and it is marked as a service job. The script "service\_job.py" will be used to start, stop, and check the status of the service/workload started on the compute nodes.

Moab, as of version 5.4, is able to accept the "-s y" option when `mbsub` is used for submission. Moab will then pass this information to TORQUE when the job is migrated.

### Related topics

- [Service jobs on page 2615](#)

## Submitting service jobs in MCM

Submitting a service job in MCM requires the latest Adaptive Computing Suite snapshot of MCM. It also requires MCM to be started with the "`--future=2`" option.

Once MCM is started, open the **Create Workload** window and verify **Show Advanced Options** is checked. Notice that there is a **Service** checkbox that can be selected in the **Flags/Options** area. Use this to specify the job is a service job.

### Related topics

- [Service jobs on page 2615](#)

## Managing service jobs

Managing a service job is done much like any other job; only a few differences exist.

Examining the job with `qstat -f` will reveal that the job has the `service = True` attribute. Non-service jobs will not make any mention of the "service" attribute.

Canceling a service job is done with `qdel`, `mjobctl -c`, or through any of the GUI's as with any other job. TORQUE, however, cancels the job by calling the service script with the "stop" argument instead of killing it directly. This behavior also occurs if the job runs over its wallclock and TORQUE/Moab is configured to cancel the job.

If a service job completes when the script exits after calling it with "start," or if TORQUE invokes the script with "status" and does not get back "running," it will *not* be terminated by using the "stop" argument.

# Managing nodes

This section contains information about adding and configuring compute nodes. It explains how to work with host security for systems that require dedicated access to compute nodes. It also contains information about scheduling specific cores on a node at job submission.

For details, see these topics:

- [Adding nodes on page 2617](#)
- [Node properties on page 2618](#)
- [Changing node state on page 2618](#)
- [Host security on page 2621](#)
- [Linux cpuset support on page 2623](#)
- [Scheduling cores on page 2624](#)

## Adding nodes

TORQUE can add and remove nodes either dynamically with [qmgr](#) or by manually editing the `TORQUE_HOME/server_priv/nodes` file (see [Initializing/Configuring TORQUE on the server \(pbs\\_server\) on page 2551](#)).

### Run-time node changes

TORQUE can dynamically add nodes with the `qmgr` command. For example, the following command will add node **node003**:

```
> qmgr -c "create node node003"
```

The above command appends the `$TORQUE_HOME/server_priv/nodes` file with:

```
node003
```

Nodes can also be removed with a similar command:

```
> qmgr -c "delete node node003"
```

**i** Typically, an administrator will want to change the state of a node instead of remove it (for details, see [Changing node state on page 2618](#)).

**i** When you make changes to nodes – whether by using `qmgr` or directly editing the `nodes` file – you must restart `pbs_server` for those changes to take effect.

Related topics

- [Managing nodes on page 2617](#)

## Node properties

TORQUE can associate properties with nodes to aid in identifying groups of nodes. It's typical for a site to conglomerate a heterogeneous set of resources. To identify the different sets, properties can be given to each node in a set. For example, a group of nodes that has a higher speed network connection could have the property "ib". TORQUE can set, update, or remove properties either dynamically with [qmgr](#) or by manually editing the `nodes` file.

### Run-time node changes

TORQUE can dynamically change the properties of a node with the `qmgr` command. For example, note the following to give **node001** the properties of "bigmem" and "dualcore":

```
> qmgr -c "set node node001 properties = bigmem"
> qmgr -c "set node node001 properties += dualcore"
```

To relinquish a stated property, use the "-" operator.

### Manual node changes

The properties of each node are enumerated in `TORQUE_HOME/server_priv/nodes`. The feature(s) must be in a space delimited list after the node name. For example, to give **node001** the properties of "bigmem" and "dualcore" and **node002** the properties of "bigmem" and "matlab," edit the `nodes` file to contain the following:

`server_priv/nodes:`

```
node001 bigmem dualcore
node002 np=4 bigmem matlab
```

For changes to the `nodes` file to be activated, `pbs_server` must be restarted.

For a full description of this file, please see the *PBS Administrator Guide*.

#### Related topics

- [Job submission on page 2583](#)
- [Managing nodes on page 2617](#)

## Changing node state

A common task is to prevent jobs from running on a particular node by marking it *offline* with `pbsnodes -o nodename`. Once a node has been marked offline, the scheduler will no longer consider it available for new jobs. Simply use `pbsnodes -c nodename` when the node is returned to service.

Also useful is `pbsnodes -l`, which lists all nodes with an interesting state, such as down, unknown, or offline. This provides a quick glance at nodes that might be having a problem. (See [pbsnodes](#) for details.)

## Related topics

- [Managing nodes on page 2617](#)

## Changing node power states

In TORQUE 5.0.0 and later, the `pbsnodes -m` command can modify the power state of nodes. Node cannot go from one low-power state to another low-power state. They must be brought up to the Running state and then moved to the new low-power state. The supported power states are:

State	Description
<b>Running</b>	<ul style="list-style-type: none"> <li>• Physical machine is actively working</li> <li>• Power conservation is on a per-device basis</li> <li>• Processor power consumption controlled by P-states</li> </ul>
<b>Standby</b>	<ul style="list-style-type: none"> <li>• System appears off</li> <li>• Processor halted (OS executes a "halt" instruction)</li> <li>• Processor maintains CPU and system cache state</li> <li>• RAM refreshed to maintain memory state</li> <li>• Machine in low-power mode</li> <li>• Requires interrupt to exit state</li> <li>• Lowest-latency sleep state - has no effect on software</li> </ul>
<b>Suspend</b>	<ul style="list-style-type: none"> <li>• System appears off</li> <li>• Processor and support chipset have no power</li> <li>• OS maintains CPU, system cache, and support chipset state in memory</li> <li>• RAM in slow refresh</li> <li>• Machine in lowest-power state</li> <li>• Usually requires specific interrupt (keyboard, mouse) to exit state</li> <li>• Third lowest-latency sleep state - system must restore power to processor and support chipset</li> </ul>
<b>Hibernate</b>	<ul style="list-style-type: none"> <li>• System is off</li> <li>• Physical machine state and memory saved to disk</li> <li>• Requires restoration of power and machine state to exit state</li> <li>• Second highest-latency sleep state - system performs faster boot using saved machine state and copy of memory</li> </ul>
<b>Shutdown</b>	<ul style="list-style-type: none"> <li>• Equivalent to <code>shutdown now</code> command as root</li> </ul>

In order to wake nodes and bring them up to a running state:

- the nodes must support, and be configured to use, Wake-on-LAN (WOL).
- the pbsnodes command must report the node's MAC address correctly.

### To configure nodes to use Wake-on-LAN

1. Enable WOL in the BIOS for each node. If needed, contact your hardware manufacturer for details.
2. Use the `ethtool` command to determine what types of WOL packets your hardware supports. TORQUE uses the `g` packet. If the `g` packet is not listed, you cannot use WOL with TORQUE.

```
[root]# ethtool eth0
Settings for eth0:
    Supported ports: [ TP ]
    Supported link modes:   10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full

    Supported pause frame use: No
    Supports auto-negotiation: Yes
    Advertised link modes:  10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full

    Advertised pause frame use: No
    Advertised auto-negotiation: Yes
    Speed: 100Mb/s
    Duplex: Full
    Port: Twisted Pair
    PHYAD: 2
    Transceiver: internal
    Auto-negotiation: on
    MDI-X: off
    Supports Wake-on: pumbg
    Wake-on: p
    Current message level: 0x00000007 (7)
                           drv probe link

    Link detected: yes
```

*This Ethernet interface supports the `g` WOL packet, but is currently set to use the `p` packet.*

3. If your Ethernet interface supports the `g` packet, but is configured for a different packet, use `ethtool -s <interface> wol g` to configure it to use `g`.

```

[root]# ethtool -s eth0 wol g
[root]# ethtool eth0
Settings for eth0:
    Supported ports: [ TP ]
    Supported link modes:   10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full

    Supported pause frame use: No
    Supports auto-negotiation: Yes
    Advertised link modes:  10baseT/Half 10baseT/Full
                           100baseT/Half 100baseT/Full
                           1000baseT/Full

    Advertised pause frame use: No
    Advertised auto-negotiation: Yes
    Speed: 100Mb/s
    Duplex: Full
    Port: Twisted Pair
    PHYAD: 2
    Transceiver: internal
    Auto-negotiation: on
    MDI-X: off
    Supports Wake-on: pumbg
    Wake-on: g
    Current message level: 0x00000007 (7)
                           drv probe link

    Link detected: yes

```

Now the power state of your nodes can be modified and they can be woken up from power-saving states.

## Host security

### Enabling PAM with TORQUE

TORQUE is able to take advantage of the authentication services provided through Pluggable Authentication Modules (PAM) to help administrators manage access to compute nodes by users. The PAM module available in TORQUE is located in the PAM security directory. This module, when used in conjunction with other PAM modules, restricts access to the compute node unless the user has a job currently running on the node. The following configurations are examples only. For more information about PAM, see the [PAM \(Pluggable Authentication Modules\) documentation](#) from LinuxDocs.

To enable TORQUE PAM configure TORQUE using the `--with-pam` option. Using `--with-pam` is sufficient but if your PAM security modules are not in the default `/lib/security` or `/lib64/security` directory, you can specify the location using `--with-pam=<DIR>` where `<DIR>` is the directory where you want the modules to be installed. When TORQUE is installed the files `pam_pbssimpleauth.la` and `pam_pbssimpleauth.so` appear in `/lib/security`, `/lib64/security`, or the directory designated on the configuration line.

PAM is very flexible and policies vary greatly from one site to another. The following example restricts users trying to access a node using SSH. Administrators need to assess their own installations and decide how to apply the TORQUE PAM restrictions.

In this example, after installing TORQUE with PAM enabled, you would add the following two lines to `/etc/pam.d/sshd`:

```
account required pam_pbssimpleauth.so
account required pam_access.so
```

In `/etc/security/access.conf` make sure all users who access the compute node are added to the configuration. This is an example which allows the users `root`, `george`, `allen`, and `michael` access.

```
 -:ALL EXCEPT root george allen michael torque:ALL
```

With this configuration, if user `george` has a job currently running on the compute node, `george` can use `ssh` to login to the node. If there are currently no jobs running, `george` is disconnected when attempting to login.

TORQUE PAM is good at keeping users out who do not have jobs running on a compute node. However, it does not have the ability to force a user to log out once they are in. To accomplish this use epilogue or prologue scripts to force users off the system.

## Legacy TORQUE PAM configuration

There is an alternative PAM configuration for TORQUE that has been available since 2006. It can be found in the `contrib/pam_authuser` directory of the source tree. Adaptive Computing does not currently support this method but the instructions are given here for those who are currently using it and for those who wish to use it.

For systems requiring dedicated access to compute nodes (for example, users with sensitive data), TORQUE prologue and epilogue scripts provide a vehicle to leverage the authentication provided by linux-PAM modules. (See [Appendix G: Prologue and epilogue scripts on page 2817](#) for more information.)

### To allow only users with running jobs (and root) to access compute nodes

1. Untar `contrib/pam_authuser.tar.gz` (found in the src tar ball).
2. Compile `pam_authuser.c` with `make` and `make install` on every compute node.
3. Edit `/etc/system-auth` as described in `README.pam_authuser`, again on every compute node.
4. Either make a tarball of the epilogue\* and prologue\* scripts (to preserve the symbolic link) and untar it in the `mom_priv` directory, or just copy epilogue\* and prologue\* to `mom_priv/`.

The prologue\* scripts are Perl scripts that add the user of the job to `/etc/authuser`. The epilogue\* scripts then remove the first occurrence of the user from `/etc/authuser`. File locking is employed in all scripts to eliminate the chance of race conditions. There is also some commented code in the epilogue\* scripts, which, if uncommented, kills all processes owned by the user (using `pkill`), provided that the user doesn't have another valid job on the same node.

[prologue](#) and [epilogue](#) scripts were added to the `pam_authuser` tarball in version 2.1 of TORQUE.

## Linux cpuset support

- [Cpuset overview on page 2623](#)
- [Cpuset support on page 2623](#)
- [Cpuset configuration on page 2623](#)
- [Cpuset advantages / disadvantages on page 2624](#)

### Cpuset overview

Linux kernel 2.6 Cpusets are logical, hierarchical groupings of CPUs and units of memory. Once created, individual processes can be placed within a cpuset. The processes will only be allowed to run/access the specified CPUs and memory. Cpusets are managed in a virtual file system mounted at `/dev/cpuset`. New cpusets are created by simply making new directories. Cpusets gain CPUs and memory units by simply writing the unit number to files within the cpuset.

### Cpuset support

**i** All nodes using cpusets must have the `hwloc` library version 1.2 or higher installed.

When started, `pbs_mom` will create an initial top-level cpuset at `/dev/cpuset/torque`. This cpuset contains all CPUs and memory of the host machine. If this "torqueset" already exists, it will be left unchanged to allow the administrator to override the default behavior. All subsequent cpusets are created within the torqueset.

When a job is started, the jobset is created at `/dev/cpuset/torque/$jobid` and populated with the CPUs listed in the `exec_host job` attribute. Also created are individual tasksets for each CPU within the jobset. This happens before prologue, which allows it to be easily modified, and it happens on all nodes.

The top-level batch script process is executed in the jobset. Tasks launched through the TM interface (`pbsdsh` and PW's `mpiexec`) will be executed within the appropriate taskset.

On job exit, all tasksets and the jobset are deleted.

### Cpuset configuration

#### To configure cpuset

1. As root, mount the virtual filesystem for cpusets:

```
mkdir /dev/cpuset
mount -t cpuset none /dev/cpuset
```

**i** Do this for each MOM that is to use cpusets.

2. Because `cpuset` usage is a build-time option in TORQUE, you must add `--enable-cpuset` to your configure options:

```
./configure --enable-cpuset
```

3. Use this configuration for the MOMs across your system.

## Cpuset advantages / disadvantages

Presently, any job can request a single CPU and proceed to use everything available in the machine. This is occasionally done to circumvent policy, but most often is simply an error on the part of the user. Cpuset support will easily constrain the processes to not interfere with other jobs.

Jobs on larger NUMA systems may see a performance boost if jobs can be intelligently assigned to specific CPUs. Jobs may perform better if striped across physical processors, or contained within the fewest number of memory controllers.

TM tasks are constrained to a single core, thus a multi-threaded process could seriously suffer.

### Related topics

- [Managing nodes on page 2617](#)
- [Geometry request configuration on page 2624](#)

## Scheduling cores

In TORQUE 2.4 and later, you can request specific cores on a node at job submission by using geometry requests. To use this feature, specify the [procs\\_bitmap](#) resource request of `qsub-1` (see [qsub](#)) at job submission.

For details about scheduling cores, see these topics:

- [Geometry request configuration on page 2624](#)
- [Geometry request usage on page 2625](#)
- [Geometry request considerations on page 2625](#)

## Geometry request configuration

A Linux kernel of 2.6 or later is required to use geometry requests, because this feature uses Linux cpusets in its implementation. In order to use this feature, the `cpuset` directory has to be mounted. For more information on how to mount the `cpuset` directory, see [Linux cpuset support on page 2623](#). If the operating environment is suitable for geometry requests, configure TORQUE with the `--enable-geometry-requests` option.

```
> ./configure --prefix=/home/john/torque --enable-geometry-requests
```

TORQUE is configured to install to `/home/john/torque` and to enable the geometry requests feature.

**i** The geometry request feature uses a subset of the cpusets feature. When you configure TORQUE using `--enable-cpuset` and `--enable-geometry-requests` at the same time, and use `-l procs_bitmap=X`, the job will get the requested cpuset. Otherwise, the job is treated as if only `--enable-cpuset` was configured.

#### Related topics

- [Scheduling cores on page 2624](#)

## Geometry request usage

Once enabled, users can submit jobs with a geometry request by using the `procs_bitmap=<string>` resource request. [procs\\_bitmap](#) requires a numerical string made up of 1's and 0's. A 0 in the bitmap means the job cannot run on the core that matches the 0's index in the bitmap. The index is in reverse order of the number of cores available. If a job is submitted with `procs_bitmap=1011`, then the job requests a node with four free cores, and uses only cores one, two, and four.

**i** The geometry request feature requires a node that has all cores free. A job with a geometry request cannot run on a node that has cores that are busy, even if the node has more than enough cores available to run the job.

```
qsub -l procs_bitmap=0011 ossl.sh
```

The job **ossl.sh** is submitted with a geometry request of **0011**.

In the above example, the submitted job can run only on a node that has four cores. When a suitable node is found, the job runs exclusively on cores one and two.

#### Related topics

- [Scheduling cores on page 2624](#)

## Geometry request considerations

As previously stated, jobs with geometry requests require a node with all of its cores available. After the job starts running on the requested cores, the node cannot run other jobs, even if the node has enough free cores to meet the requirements of the other jobs. Once the geometry requesting job is done, the node is available to other jobs again.

#### Related topics

- [Scheduling cores on page 2624](#)

## Scheduling accelerator hardware

TORQUE works with accelerators (such as NVIDIA GPUs and Intel MICs) and can collect and report metrics from them or submit workload to them. This feature requires the use of the Moab scheduler. Refer to the [Accelerators on page 815](#) for information on configuring accelerators in TORQUE.

## Setting server policies

This section explains how to set up and configure your queue. It lists the queue attributes and describes how to set up a routing queue. This section also explains how to set up TORQUE to run in high availability mode. For details, see these topics:

- [Queue configuration on page 2626](#)
- [Server high availability on page 2640](#)

### Queue configuration

Under TORQUE, queue configuration is accomplished using the [Server high availability](#) command. With this tool, the first step is to create the queue. This is accomplished using the `create` subcommand of `qmgr` as in the following example:

```
> qmgr -c "create queue batch queue_type=execution"
```

Once created, the queue must be configured to be operational. At a minimum, this includes setting the options **started** and **enabled**. Further configuration is possible using any combination of the attributes listed in what follows.

For Boolean attributes, *T*, *t*, *1*, *Y*, and *y* are all synonymous with "TRUE," and *F*, *f*, *0*, *N*, and *n* all mean "FALSE."

For [queue\\_type](#), *E* and *R* are synonymous with "Execution" and "Routing" (respectively).

See these topics for more details:

- [Queue attributes on page 2626](#)
- [Example queue configuration on page 2637](#)
- [Setting a default queue on page 2638](#)
- [Mapping a queue to subset of resources on page 2638](#)
- [Creating a routing queue on page 2638](#)

Related topics

- [max\\_running](#) on page 2632
- [max\\_user\\_queueable](#) on page 2632
- [max\\_user\\_run](#) on page 2633
- [priority](#) on page 2633
- [queue\\_type](#) on page 2633
- [required\\_login\\_property](#) on page 2633
- [resources\\_available](#) on page 2634
- [resources\\_default](#) on page 2634
- [resources\\_max](#) on page 2634
- [resources\\_min](#) on page 2635
- [route\\_destinations](#) on page 2635
- [started](#) on page 2635

This section also lists some queue resource limits (see [Assigning queue resource limits](#) on page 2636).

For Boolean attributes, *T*, *t*, *1*, *Y*, and *y* are all synonymous with "TRUE," and *F*, *f*, *0*, *N*, and *n* all mean "FALSE."

acl_groups	
<b>Format</b>	<GROUP>[@<HOST>][+<USER>[@<HOST>]]...
<b>Default</b>	---

acl_groups	
<b>Description</b>	Specifies the list of groups which may submit jobs to the queue. If <code>acl_group_enable</code> is set to true, only users with a primary group listed in <code>acl_groups</code> may utilize the queue. <p><b>i</b> If the <code>PBSACLUSEGROUPLIST</code> variable is set in the <code>pbs_server</code> environment, <code>acl_groups</code> checks against all groups of which the job user is a member.</p>
<b>Example</b>	<pre>&gt; qmgr -c "set queue batch acl_groups=staff" &gt; qmgr -c "set queue batch acl_groups+=ops@h1" &gt; qmgr -c "set queue batch acl_groups+=staff@h1"</pre> <p><b>i</b> Used in conjunction with <a href="#">acl_group_enable</a>.</p>

acl_group_enable	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If <b>TRUE</b> , constrains TORQUE to only allow jobs submitted from groups specified by the <a href="#">acl_groups</a> parameter.
<b>Example</b>	<pre>qmgr -c "set queue batch acl_group_enable=true"</pre>

acl_group_sloppy	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If <b>TRUE</b> , <a href="#">acl_groups</a> will be checked against all groups of which the job users is a member.
<b>Example</b>	---

acl_hosts	
<b>Format</b>	<HOST>[+<HOST>]...
<b>Default</b>	---

acl_hosts	
<b>Description</b>	Specifies the list of hosts that may submit jobs to the queue.
<b>Example</b>	<pre>qmgr -c "set queue batch acl_hosts=h1+h1+h1"</pre> <p> Used in conjunction with <a href="#">acl_host_enable</a>.</p>

acl_host_enable	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If <b>TRUE</b> , constrains TORQUE to only allow jobs submitted from hosts specified by the <a href="#">acl_hosts</a> parameter.
<b>Example</b>	<pre>qmgr -c "set queue batch acl_host_enable=true"</pre>

acl_logic_or	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	If <b>TRUE</b> , user and group acls are logically OR'd together, meaning that either acl may be met to allow access. If FALSE or unset, then both acls are AND'd, meaning that both acls must be satisfied.
<b>Example</b>	<pre>qmgr -c "set queue batch acl_logic_or=true"</pre>

acl_users	
<b>Format</b>	<USER> [@<HOST>][+<USER>[@<HOST>]]...
<b>Default</b>	---
<b>Description</b>	Specifies the list of users who may submit jobs to the queue. If <a href="#">acl_user_enable</a> is set to <b>TRUE</b> , only users listed in <code>acl_users</code> may use the queue.

## acl\_users

## Example

```
> qmgr -c "set queue batch acl_users=john"
> qmgr -c "set queue batch acl_users+=steve@h1"
> qmgr -c "set queue batch acl_users+=stevek@h1"
```

Used in conjunction with [acl\\_user\\_enable](#).

## acl\_user\_enable

## Format

&lt;BOOLEAN&gt;

## Default

FALSE

## Description

If **TRUE**, constrains TORQUE to only allow jobs submitted from users specified by the [acl\\_users](#) parameter.

## Example

```
qmgr -c "set queue batch acl_user_enable=true"
```

## disallowed\_types

## Format

&lt;type&gt;[+&lt;type&gt;]...

## Default

---

## Description

Specifies classes of jobs that are not allowed to be submitted to this queue. Valid types are interactive, batch, rerunable, nonrerunable, fault\_tolerant (as of version 2.4.0 and later), fault\_intolerant (as of version 2.4.0 and later), and job\_array (as of version 2.4.1 and later).

## Example

```
qmgr -c "set queue batch disallowed_types = interactive"
qmgr -c "set queue batch disallowed_types += job_array"
```

## enabled

## Format

&lt;BOOLEAN&gt;

## Default

FALSE

## Description

Specifies whether the queue accepts new job submissions.

## enabled

### Example

```
qmgr -c "set queue batch enabled=true"
```

## features\_required

### Format

feature1[feature2[,feature3...]]

### Default

---

### Description

Specifies that all jobs in this queue will require these features in addition to any they may have requested. A feature is a synonym for a property.

### Example

```
qmgr -c 's q batch features_required=fast'
```

## keep\_completed

### Format

<INTEGER>

### Default

0

### Description

Specifies the number of seconds jobs should be held in the Completed state after exiting. For more information, see [Keeping completed jobs on page 2600](#).

### Example

```
qmgr -c "set queue batch keep_completed=120"
```

## kill\_delay

### Format

<INTEGER>

### Default

2

### Description

Specifies the number of seconds between sending a SIGTERM and a SIGKILL to a job in a specific queue that you want to cancel. It is possible that the job script, and any child processes it spawns, can receive several SIGTERM signals before the SIGKILL signal is received.

All MOMs must be configured with `$exec with exec true` in order for `kill_delay` to work, even when relying on default `kill_delay` settings.

**kill\_delay****Example**

```
qmgr -c "set queue batch kill_delay=30"
```

**max\_queuable****Format**

&lt;INTEGER&gt;

**Default**

unlimited

**Description**

Specifies the maximum number of jobs allowed in the queue at any given time (includes idle, running, and blocked jobs).

**Example**

```
qmgr -c "set queue batch max_queuable=20"
```

**max\_running****Format**

&lt;INTEGER&gt;

**Default**

unlimited

**Description**

Specifies the maximum number of jobs in the queue allowed to run at any given time.

**Example**

```
qmgr -c "set queue batch max_running=20"
```

**max\_user\_queuable****Format**

&lt;INTEGER&gt;

**Default**

unlimited

**Description**

Specifies the maximum number of jobs, per user, allowed in the queue at any given time (includes idle, running, and blocked jobs). Version 2.1.3 and greater.

**Example**

```
qmgr -c "set queue batch max_user_queuable=20"
```

max_user_run	
<b>Format</b>	<INTEGER>
<b>Default</b>	unlimited
<b>Description</b>	Specifies the maximum number of jobs, per user, in the queue allowed to run at any given time.
<b>Example</b>	<pre>qmgr -c "set queue batch max_user_run=10"</pre>

priority	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the priority value associated with the queue.
<b>Example</b>	<pre>qmgr -c "set queue batch priority=20"</pre>

queue_type	
<b>Format</b>	One of <i>e</i> , <i>execution</i> , <i>r</i> , or <i>route</i> (see <a href="#">Creating a routing queue on page 2638</a> )
<b>Default</b>	---
<b>Description</b>	Specifies the queue type. <div style="border: 1px solid red; background-color: #ffe6e6; padding: 5px; margin-top: 10px;">  This value must be explicitly set for all queues. </div>
<b>Example</b>	<pre>qmgr -c "set queue batch queue_type=execution"</pre>

required_login_property	
<b>Format</b>	<STRING>
<b>Default</b>	---

## required\_login\_property

**Description** Adds the specified login property as a requirement for all jobs in this queue.

**Example** `qmgr -c 's q <queuename> required_login_property=INDUSTRIAL'`

## resources\_available

**Format** <STRING>

**Default** ---

**Description** Specifies cumulative resources available to all jobs running in the queue. See [qsub will not allow the submission of jobs requesting many processors on page 2675](#) for more information.

**Example** `qmgr -c "set queue batch resources_available.nodect=20"`

You must restart pbs\_server for changes to take effect.

Also, resources\_available is constrained by the smallest of queue.resources\_available and server.resources\_available.

## resources\_default

**Format** <STRING>

**Default** ---

**Description** Specifies default resource requirements for jobs submitted to the queue.

**Example** `qmgr -c "set queue batch resources_default.walltime=3600"`

## resources\_max

**Format** <STRING>

**Default** ---

resources_max	
<b>Description</b>	Specifies the maximum resource limits for jobs submitted to the queue.
<b>Example</b>	<pre>qmgr -c "set queue batch resources_max.nodect=16"</pre>

resources_min	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies the minimum resource limits for jobs submitted to the queue.
<b>Example</b>	<pre>qmgr -c "set queue batch resources_min.nodect=2"</pre>

route_destinations	
<b>Format</b>	<queue>[@<host>]
<b>Default</b>	---
<b>Description</b>	Specifies the potential destination queues for jobs submitted to the associated routing queue. <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;">  This attribute is only valid for routing queues (see <a href="#">Creating a routing queue on page 2638</a>). </div>
<b>Example</b>	<pre>&gt; qmgr -c "set queue route route_destinations=fast" &gt; qmgr -c "set queue route route_destinations+=slow" &gt; qmgr -c "set queue route route_destinations+=medium@hostname"</pre> <p>To set multiple queue specifications, use multiple commands:</p> <pre>&gt; qmgr -c 's s route_destinations=batch' &gt; qmgr -c 's s route_destinations+=long' &gt; qmgr -c 's s route_destinations+=short'</pre>

started	
<b>Format</b>	<BOOLEAN>

started	
<b>Default</b>	FALSE
<b>Description</b>	Specifies whether jobs in the queue are allowed to execute.
<b>Example</b>	<pre>qmgr -c "set queue batch started=true"</pre>

## Assigning queue resource limits

Administrators can use resources limits to help direct what kind of jobs go to different queues. There are four queue attributes where resource limits can be set: [resources\\_available](#), [resources\\_default](#), [resources\\_max](#), and [resources\\_min](#). The list of supported resources that can be limited with these attributes are *arch*, *mem*, *nodect*, *nodes*, *procct*, *pvmem*, *vmem*, and *walltime*.

Resource	Format	Description
<b>arch</b>	string	Specifies the administrator defined system architecture required.
<b>mem</b>	<a href="#">size</a>	Amount of physical memory used by the job. (Ignored on Darwin, Digital Unix, Free BSD, HPUX 11, IRIX, NetBSD, and SunOS. Also ignored on Linux if number of nodes is not 1. Not implemented on AIX and HPUX 10.)
<b>ncpus</b>	integer	Sets the number of processors in one task where a task cannot span nodes. <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; background-color: #E6F2FF; margin-top: 10px;"><b>i</b> You cannot request both <code>ncpus</code> and <code>nodes</code> in the same queue.</div>
<b>nodect</b>	integer	Sets the number of nodes available. By default, TORQUE will set the number of nodes available to the number of nodes listed in the <code>\$TORQUE_HOME/server_priv/nodes</code> file. <code>nodect</code> can be set to be greater than or less than that number. Generally, it is used to set the node count higher than the number of physical nodes in the cluster.
<b>nodes</b>	integer	Specifies the number of nodes.
<b>procct</b>	integer	Sets limits on the total number of execution slots (procs) allocated to a job. The number of procs is calculated by summing the products of all node and ppn entries for a job. For example <code>qsub -l nodes=2:ppn=2+3:ppn=4 job.sh</code> would yield a <code>procct</code> of 16. $2*2$ (2:ppn=2) + $3*4$ (3:ppn=4).
<b>pvmem</b>	<a href="#">size</a>	Amount of virtual memory used by any single process in a job.

Resource	Format	Description
<b>vmem</b>	<a href="#">size</a>	Amount of virtual memory used by all concurrent processes in the job.
<b>walltime</b>	seconds, or [[HH:] MM:]SS	Amount of real time during which a job can be in a running state.

### *size*

The size format specifies the maximum amount in terms of bytes or words. It is expressed in the form *integer[suffix]*. The suffix is a multiplier defined in the following table ("b" means bytes [the default] and "w" means words). The size of a word is calculated on the execution server as its word size.

Suffix		Multiplier
b	w	1
kb	kw	1024
mb	mw	1,048,576
gb	gw	1,073,741,824
tb	tw	1,099,511,627,776

### Related topics

- [Example queue configuration on page 2637](#)

## Example queue configuration

The following series of **qmgr** commands will create and configure a queue named batch:

```
qmgr -c "create queue batch queue_type=execution"
qmgr -c "set queue batch started=true"
qmgr -c "set queue batch enabled=true"
qmgr -c "set queue batch resources_default.nodes=1"
qmgr -c "set queue batch resources_default.walltime=3600"
```

This queue will accept new jobs and, if not explicitly specified in the job, will assign a nodecount of 1 and a walltime of 1 hour to each job.

### Related topics

- [Queue configuration on page 2626](#)

## Setting a default queue

By default, a job must explicitly specify which queue it is to run in. To change this behavior, the server parameter [default\\_queue](#) may be specified as in the following example:

```
qmgr -c "set server default_queue=batch"
```

### Related topics

- [Queue configuration on page 2626](#)

## Mapping a queue to subset of resources

TORQUE does not currently provide a simple mechanism for mapping queues to nodes. However, schedulers such as [Moab](#) and [Maui](#) can provide this functionality.

The simplest method is using `default_resources.neednodes` on an execution queue, setting it to a particular node attribute. Maui/Moab will use this information to ensure that jobs in that queue will be assigned nodes with that attribute. For example, suppose we have some nodes bought with money from the chemistry department, and some nodes paid by the biology department.

```
$TORQUE_HOME/server_priv/nodes:
node01 np=2 chem
node02 np=2 chem
node03 np=2 bio
node04 np=2 bio
qmgr:
set queue chem resources_default.neednodes=chem
set queue bio resources_default.neednodes=bio
```

**i** This example does not preclude other queues from accessing those nodes. One solution is to use some other generic attribute with all other nodes and queues.

More advanced configurations can be made with standing reservations and QoSs.

## Creating a routing queue

A routing queue will steer a job to a destination queue based on job attributes and queue constraints. It is set up by creating a queue of [queue\\_type](#) "Route" with a [route\\_destinations](#) attribute set, as in the following example.

```

qmgr

# routing queue
create queue route
set queue route queue_type = Route
set queue route route_destinations = reg_64
set queue route route_destinations += reg_32
set queue route route_destinations += reg_
set queue route enabled = True
set queue route started = True

# queue for jobs using 1-15 nodes
create queue reg
set queue reg queue_type = Execution
set queue reg resources_min.ncpus = 1
set queue reg resources_min.nodect = 1
set queue reg resources_default.ncpus = 1
set queue reg resources_default.nodes = 1
set queue reg enabled = True
set queue reg started = True

# queue for jobs using 16-31 nodes
create queue reg_32
set queue reg_32 queue_type = Execution
set queue reg_32 resources_min.ncpus = 31
set queue reg_32 resources_min.nodes = 16
set queue reg_32 resources_default.walltime = 12:00:00
set queue reg_32 enabled = True
set queue reg_32 started = True

# queue for jobs using 32+ nodes
create queue reg_64
set queue reg_64 queue_type = Execution
set queue reg_64 resources_min.ncpus = 63
set queue reg_64 resources_min.nodes = 32
set queue reg_64 resources_default.walltime = 06:00:00
set queue reg_64 enabled = True
set queue reg_64 started = True

# have all jobs go through the routing queue
set server default_queue = batch
set server resources_default.ncpus = 1
set server resources_default.walltime = 24:00:00
...

```

In this example, the compute nodes are dual processors and default walltimes are set according to the number of processors/nodes of a job. Jobs with 32 nodes (63 processors) or more will be given a default walltime of 6 hours. Also, jobs with 16-31 nodes (31-62 processors) will be given a default walltime of 12 hours. All other jobs will have the server default walltime of 24 hours.

The ordering of the `route_destinations` is important. In a routing queue, a job is assigned to the first possible destination queue based on the [resources\\_max](#), [resources\\_min](#), [acl\\_users](#), and [acl\\_groups](#) attributes. In the preceding example, the attributes of a single processor job would first be checked against the `reg_64` queue, then the `reg_32` queue, and finally the `reg` queue.

Adding the following settings to the earlier configuration elucidates the queue resource requirements:

```

qmgr

set queue reg resources_max.ncpus = 30
set queue reg resources_max.nodect = 15
set queue reg_16 resources_max.ncpus = 62
set queue reg_16 resources_max.nodect = 31

```

The time of enforcement of server and queue defaults is important in this example. TORQUE applies server and queue defaults differently in job centric and queue centric modes. For job centric mode, TORQUE waits to apply the server and queue defaults until the job is assigned to its final execution queue. For queue centric mode, it enforces server defaults before it is placed in the routing queue. In either mode, queue defaults override the server defaults. TORQUE defaults to job centric mode. To set queue centric mode, set `queue_centric_limits`, as in what follows:

```
qmgr
set server queue_centric_limits = true
```

An artifact of job centric mode is that if a job does not have an attribute set, the server and routing queue defaults are not applied when queue resource limits are checked. Consequently, a job that requests 32 nodes (not `ncpus=32`) will not be checked against a `min_resource.ncpus` limit. Also, for the preceding example, a job without any attributes set will be placed in the `reg_64` queue, since the server `ncpus` default will be applied after the job is assigned to an execution queue.

**i** Routine queue defaults are not applied to job attributes in versions 2.1.0 and before.

**i** If the error message "qsub: Job rejected by all possible destinations" is reported when submitting a job, it may be necessary to add queue location information, (i.e., in the routing queue's `route_destinations` attribute, change "batch" to "batch@localhost").

## Server high availability

You can now run TORQUE in a redundant or high availability mode. This means that there can be multiple instances of the server running and waiting to take over processing in the event that the currently running server fails.

**i** The high availability feature is available in the 2.3 and later versions of TORQUE. TORQUE 2.4 includes several enhancements to high availability (see [Server high availability on page 2640](#)).

**i** Contact Adaptive Computing before attempting to implement any type of high availability.

For more details, see these sections:

- [Redundant server host machines on page 2641](#)
- [Server high availability on page 2640](#)
- [Enhanced high availability with Moab on page 2642](#)
- [How commands select the correct server host on page 2642](#)

- [Job names on page 2643](#)
- [Persistence of the pbs\\_server process on page 2643](#)
- [High availability of the NFS server on page 2643](#)
- [Installing TORQUE in high availability mode on page 2643](#)
- [Installing TORQUE in high availability mode on headless nodes on page 2648](#)
- [Example setup of high availability on page 2652](#)

## Redundant server host machines

High availability enables TORQUE to continue running even if pbs\_server is brought down. This is done by running multiple copies of pbs\_server which have their torque/server\_priv directory mounted on a shared file system. The torque/server\_name must include the host names of all nodes that run pbs\_server. All MOM nodes also must include the host names of all nodes running pbs\_server in their torque/server\_name file. The syntax of the torque/server\_name is a comma delimited list of host names.

For example:

```
host1,host2,host3
```

When configuring high availability, do not use \$pbsserver to specify the host names. You must use the \$TORQUEHOMEDIR/server\_name file.

All instances of pbs\_server need to be started with the --ha command line option that allows the servers to run at the same time. Only the first server to start will complete the full startup. The second server to start will block very early in the startup when it tries to lock the file torque/server\_priv/server.lock. When the second server cannot obtain the lock, it will spin in a loop and wait for the lock to clear. The sleep time between checks of the lock file is one second.

Notice that not only can the servers run on independent server hardware, there can also be multiple instances of the pbs\_server running on the same machine. This was not possible before as the second one to start would always write an error and quit when it could not obtain the lock.

## Enabling high availability

To use high availability, you must start each instance of pbs\_server with the --ha option.

Prior to version 4.0, TORQUE with HA was configured with an --enable-high-availability option. That option is no longer required.

Three server options help manage high availability. The server parameters are [lock\\_file](#), [lock\\_file\\_update\\_time](#), and [lock\\_file\\_check\\_time](#).

The lock\_file option allows the administrator to change the location of the lock file. The default location is torque/server\_priv. If the lock\_file option is used, the new location must be on the shared partition so all servers have access.

The `lock_file_update_time` and `lock_file_check_time` parameters are used by the servers to determine if the primary server is active. The primary `pbs_server` will update the lock file based on the `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs, the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
> qmgr -c "set server lock_file_check_time=5"
```

In the above example, after the primary `pbs_server` goes down, the backup `pbs_server` takes up to 5 seconds to take over. It takes additional time for all MOMs to switch over to the new `pbs_server`.

**i** The clock on the primary and redundant servers must be synchronized in order for high availability to work. Use a utility such as NTP to ensure your servers have a synchronized time.

**i** Do not use anything but a plain simple NFS fileshare that is not used by anybody or anything else (i.e., only Moab can use the fileshare).

**i** Do not use any general-purpose NAS, do not use any parallel file system, and do not use company-wide shared infrastructure to set up Moab high availability using "native" high availability.

## Enhanced high availability with Moab

When TORQUE is run with an external scheduler such as Moab, and the `pbs_server` is not running on the same host as Moab, `pbs_server` needs to know where to find the scheduler. To do this, use the `-l` option as demonstrated in the example below (the port is required and the default is 15004).

```
> pbs_server -l <moabhost:port>
```

If Moab is running in HA mode, add a `-l` option for each redundant server.

```
> pbs_server -l <moabhost1:port> -l <moabhost2:port>
```

If `pbs_server` and Moab run on the same host, use the `--ha` option as demonstrated in the example below.

```
> pbs_server --ha
```

The root user of each Moab host must be added to the [operators](#) and [managers](#) lists of the server. This enables Moab to execute root level operations in TORQUE.

## How commands select the correct server host

The various commands that send messages to `pbs_server` usually have an option of specifying the server name on the command line, or if none is specified will use the default server name. The default server name comes either from the environment variable `PBS_DEFAULT` or from the file `torque/server_name`.

When a command is executed and no explicit server is mentioned, an attempt is made to connect to the first server name in the list of hosts from `PBS_DEFAULT` or `torque/server_name`. If this fails, the next server name is tried. If all servers in the list are unreachable, an error is returned and the command fails.

Note that there is a period of time after the failure of the current server during which the new server is starting up where it is unable to process commands. The new server must read the existing configuration and job information from the disk, so the length of time that commands cannot be received varies. Commands issued during this period of time might fail due to timeouts expiring.

## Job names

Job names normally contain the name of the host machine where `pbs_server` is running. When job names are constructed, only the server name in `$PBS_DEFAULT` or the first name from the server specification list, `$TORQUE_HOME/server_name`, is used in building the job name.

## Persistence of the `pbs_server` process

The system administrator must ensure that `pbs_server` continues to run on the server nodes. This could be as simple as a *cron* job that counts the number of `pbs_server`'s in the process table and starts some more if needed.

## High availability of the NFS server

Before installing a specific NFS HA solution please contact Adaptive Computing Support for a detailed discussion on NFS HA type and implementation path.

One consideration of this implementation is that it depends on NFS file system also being redundant. NFS can be set up as a redundant service. See the following.

- [Setting Up A Highly Available NFS Server](#)
- [Making NFS Work On Your Network](#)
- [Sourceforge Linux NFS FAQ](#)
- [NFS v4 main site](#)

There are also other ways to set up a shared file system. See the following:

- [Red Hat Global File System](#)
- [Data sharing with a GFS storage cluster](#)

## Installing TORQUE in high availability mode

The following procedure demonstrates a TORQUE installation in high availability (HA) mode.

## Requirements

- gcc (GCC) 4.1.2
- BASH shell
- Servers configured the following way:
  - 2 main servers with identical architecture:
    - server1 — Primary server running TORQUE with a shared file system (this example uses NFS)
    - server2 — Secondary server running with TORQUE with a shared file system (this example uses NFS)
  - fileServer — Shared file system (this example uses NFS)
  - Compute nodes

## To install TORQUE in HA mode

1. Stop all firewalls or update your firewall to allow traffic from TORQUE services.

```
> service iptables stop
> chkconfig iptables off
```

If you are unable to stop the firewall due to infrastructure restriction, open the following ports:

- 15001 [tcp,udp]
- 15002 [tcp,udp]
- 15003 [tcp,udp]

2. Disable SELinux

```
> vi /etc/sysconfig/selinux
SELINUX=disabled
```

3. Update your main ~/.bashrc profile to ensure you are always referencing the applications to be installed on all servers.

```
# TORQUE
export TORQUEHOME=/var/spool/torque

# Library Path
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:${TORQUEHOME}/lib

# Update system paths
export PATH=${TORQUEHOME}/bin:${TORQUEHOME}/sbin:${PATH}
```

4. Verify server1 and server2 are resolvable via either DNS or looking for an entry in the /etc/hosts file.
5. Configure the NFS Mounts by following these steps:

- a. Create mount point folders on fileServer.

```
fileServer# mkdir -m 0755 /var/spool/torque
fileServer# mkdir -m 0750 /var/spool/torque/server_priv
```

- b. Update /etc/exports on fileServer. The IP addresses should be that of server2.

```
/var/spool/torque/server_priv 192.168.0.0/255.255.255.0(rw, sync, no_root_squash)
```

- c. Update the list of NFS exported file systems.

```
fileServer# exportfs -r
```

6. If the NFS daemons are not already running on fileServer, start them.

```
> systemctl restart rpcbind.service
> systemctl start nfs-server.service
> systemctl start nfs-lock.service
> systemctl start nfs-idmap.service
```

7. Mount the exported file systems on server1 by following these steps:

- a. Create the directory reference and mount them.

```
server1# mkdir /var/spool/torque/server_priv
```

Repeat this process for server2.

- b. Update /etc/fstab on server1 to ensure that NFS mount is performed on startup.

```
fileServer:/var/spool/torque/server_priv /var/spool/torque/server_priv nfs
rsize= 8192, wsize=8192, timeo=14, intr
```

Repeat this step for server2.

8. Install TORQUE by following these steps:

- a. Download and extract TORQUE 5.0.0 on server1.

```
server1# wget http://github.com/adaptivecomputing/torque/ branches/5.0.0/torque-
5.0.0.tar.gz
server1# tar -xvzf torque-5.0.0.tar.gz
```

- b. Navigate to the TORQUE directory and compile TORQUE on server1.

```
server1# configure
server1# make
server1# make install
server1# make packages
```

- c. If the installation directory is shared on both head nodes, then run `make install` on server1.

```
server1# make install
```

If the installation directory is not shared, repeat step 8a-b (downloading and installing TORQUE) on server2.

9. Start `trqauthd`.

```
server1# /etc/init.d/trqauthd start
```

## 10. Configure TORQUE for HA.

- a. List the host names of all nodes that run `pbs_server` in the `torque/server_name` file. You must also include the host names of all nodes running `pbs_server` in the `torque/server_name` file of each MOM node. The syntax of `torque/server_name` is a comma-delimited list of host names.

```
server1
server2
```

- b. Create a simple queue configuration for TORQUE job queues on server1.

```
server1# pbs_server -t create
server1# qmgr -c "set server scheduling=true"
server1# qmgr -c "create queue batch queue_type=execution"
server1# qmgr -c "set queue batch started=true"
server1# qmgr -c "set queue batch enabled=true"
server1# qmgr -c "set queue batch resources_default.nodes=1"
server1# qmgr -c "set queue batch resources_default.walltime=3600"
server1# qmgr -c "set server default_queue=batch"
```

**i** Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- c. Add the root users of TORQUE to the TORQUE configuration as an operator and manager.

```
server1# qmgr -c "set server managers += root@server1"
server1# qmgr -c "set server managers += root@server2"
server1# qmgr -c "set server operators += root@server1"
server1# qmgr -c "set server operators += root@server2"
```

**i** Because `server_priv/*` is a shared drive, you do not need to repeat this step on `Server 2`.

- d. You must update the lock file mechanism for TORQUE in order to determine which server is the primary. To do so, use the `lock_file_update_time` and `lock_file_check_time` parameters. The primary `pbs_server` will update the lock file based on the specified `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs, the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
server1# qmgr -c "set server lock_file_check_time=5"
server1# qmgr -c "set server lock_file_update_time=3"
```

**i** Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- e. List the servers running `pbs_server` in the TORQUE `acl_hosts` file.

```
server1# qmgr -c "set server acl_hosts += server1"
server1# qmgr -c "set server acl_hosts += server2"
```

**i** Because `server_priv/*` is a shared drive, you do not need to repeat this step on `server2`.

- f. Restart the running `pbs_server` in HA mode.

```
server1# qterm
```

- g. Start the `pbs_server` on the secondary server.

```
server1# pbs_server --ha -l server2:port
server2# pbs_server --ha -l server1:port
```

11. Check the status of TORQUE in HA mode.

```
server1# qmgr -c "p s"
server2# qmgr -c "p s"
```

*The commands above returns all settings from the active TORQUE server from either node.*

Drop one of the `pbs_servers` to verify that the secondary server picks up the request.

```
server1# qterm
server2# qmgr -c "p s"
```

Stop the `pbs_server` on `server2` and restart `pbs_server` on `server1` to verify that both nodes can handle a request from the other.

12. Install a `pbs_mom` on the compute nodes.

- a. Copy the install scripts to the compute nodes and install.
- b. Navigate to the shared source directory of TORQUE and run the following:

```
node1# torque-package-mom-linux-x86_64.sh --install
node2# torque-package-clients-linux-x86_64.sh --install
```

Repeat this for each compute node. Verify that the `/var/pool/ torque/server-name` file shows all your compute nodes.

- c. On `server1` or `server2`, configure the `nodes` file to identify all available MOMs. To do so, edit the `/var/spool/torque/server_priv/nodes` file.

```
node1 np=2
node2 np=2
```

**i** Change the `np` flag to reflect number of available processors on that node.

- d. Recycle the `pbs_servers` to verify that they pick up the MOM configuration.

```
server1# qterm; pbs_server --ha -l server2:port
server2# qterm; pbs_server --ha -l server1:port
```

- e. Start the `pbs_mom` on each execution node.

```
node5# pbs_mom
node6# pbs_mom
```

## Installing TORQUE in high availability mode on headless nodes

The following procedure demonstrates a TORQUE installation in high availability (HA) mode on nodes with no local hard drive.

### Requirements

- gcc (GCC) 4.1.2
- BASH shell
- Servers (these cannot be two VMs on the same hypervisor) configured the following way:
  - 2 main servers with identical architecture
    - `server1` — Primary server running TORQUE with a file system share (this example uses NFS)
    - `server2` — Secondary server running with TORQUE with a file system share (this example uses NFS)
  - Compute nodes
  - `fileServer` — A shared file system server (this example uses NFS)

### To install TORQUE in HA mode on a node with no local hard drive

1. Stop all firewalls or update your firewall to allow traffic from TORQUE services.

```
> service iptables stop
> chkconfig iptables off
```

If you are unable to stop the firewall due to infrastructure restriction, open the following ports:

- 15001 [tcp,udp]
- 15002 [tcp,udp]
- 15003 [tcp,udp]

2. Disable SELinux

```
> vi /etc/sysconfig/selinux
SELINUX=disabled
```

3. Update your main `~/ .bashrc` profile to ensure you are always referencing the applications to be installed on all servers.

```
# TORQUE
export TORQUEHOME=/var/spool/torque

# Library Path

export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:${TORQUEHOME}/lib

# Update system paths
export PATH=${TORQUEHOME}/bin:${TORQUEHOME}/sbin:${PATH}
```

4. Verify `server1` and `server2` are resolvable via either DNS or looking for an entry in the `/etc/hosts` file.

5. Configure the NFS Mounts by following these steps:

a. Create mount point folders on `fileServer`.

```
fileServer# mkdir -m 0755 /var/spool/torque
```

b. Update `/etc/exports` on `fileServer`. The IP addresses should be that of `server2`.

```
/var/spool/torque/ 192.168.0.0/255.255.255.0(rw,sync,no_root_squash)
```

c. Update the list of NFS exported file systems.

```
fileServer# exportfs -r
```

6. If the NFS daemons are not already running on `fileServer`, start them.

```
> systemctl restart rpcbind.service
> systemctl start nfs-server.service
> systemctl start nfs-lock.service
> systemctl start nfs-idmap.service
```

7. Mount the exported file systems on `server1` by following these steps:

a. Create the directory reference and mount them.

```
server1# mkdir /var/spool/torque
```

Repeat this process for `server2`.

b. Update `/etc/fstab` on `server1` to ensure that NFS mount is performed on startup.

```
fileServer:/var/spool/torque/server_priv /var/spool/torque/server_priv nfs
rsize= 8192, wsize=8192, timeo=14, intr
```

Repeat this step for `server2`.

8. Install TORQUE by following these steps:

a. Download and extract TORQUE 5.0.0 on `server1`.

```
server1# wget http://github.com/adaptivecomputing/torque/branches/5.0.0/torque-5.0.0.tar.gz
server1# tar -xvzf torque-5.0.0.tar.gz
```

b. Navigate to the TORQUE directory and compile TORQUE with the HA flag on `server1`.

```
server1# configure --prefix=/var/spool/torque
server1# make
server1# make install
server1# make packages
```

- c. If the installation directory is shared on both head nodes, then run `make install` on `server1`.

```
server1# make install
```

If the installation directory is not shared, repeat step 8a-b (downloading and installing TORQUE) on `server2`.

9. Start `trqauthd`.

```
server1# /etc/init.d/trqauthd start
```

10. Configure TORQUE for HA.

- a. List the host names of all nodes that run `pbs_server` in the `torque/server_name` file. You must also include the host names of all nodes running `pbs_server` in the `torque/server_name` file of each MOM node. The syntax of `torque/server_name` is a comma-delimited list of host names.

```
server1,server2
```

- b. Create a simple queue configuration for TORQUE job queues on `server1`.

```
server1# pbs_server -t create
server1# qmgr -c "set server scheduling=true"
server1# qmgr -c "create queue batch queue_type=execution"
server1# qmgr -c "set queue batch started=true"
server1# qmgr -c "set queue batch enabled=true"
server1# qmgr -c "set queue batch resources_default.nodes=1"
server1# qmgr -c "set queue batch resources_default.walltime=3600"
server1# qmgr -c "set server default_queue=batch"
```

**i** Because `TORQUEHOME` is a shared drive, you do not need to repeat this step on `server2`.

- c. Add the root users of TORQUE to the TORQUE configuration as an operator and manager.

```
server1# qmgr -c "set server managers += root@server1"
server1# qmgr -c "set server managers += root@server2"
server1# qmgr -c "set server operators += root@server1"
server1# qmgr -c "set server operators += root@server2"
```

**i** Because `TORQUEHOME` is a shared drive, you do not need to repeat this step on `server2`.

- d. You must update the lock file mechanism for TORQUE in order to determine which server is the primary. To do so, use the `lock_file_update_time` and `lock_file_check_time` parameters. The primary `pbs_server` will update the lock file based on the specified `lock_file_update_time` (default value of 3 seconds). All backup `pbs_servers` will check the lock file as

indicated by the `lock_file_check_time` parameter (default value of 9 seconds). The `lock_file_update_time` must be less than the `lock_file_check_time`. When a failure occurs, the backup `pbs_server` takes up to the `lock_file_check_time` value to take over.

```
server1# qmgr -c "set server lock_file_check_time=5"
server1# qmgr -c "set server lock_file_update_time=3"
```

**i** Because `TORQUEHOME` is a shared drive, you do not need to repeat this step on `server2`.

- e. List the servers running `pbs_server` in the TORQUE `acl_hosts` file.

```
server1# qmgr -c "set server acl_hosts += server1"
server1# qmgr -c "set server acl_hosts += server2"
```

**i** Because `TORQUEHOME` is a shared drive, you do not need to repeat this step on `server2`.

- f. Restart the running `pbs_server` in HA mode.

```
server1# qterm
```

- g. Start the `pbs_server` on the secondary server.

```
server1# pbs_server --ha -l server2:port
server2# pbs_server --ha -l server1:port
```

11. Check the status of TORQUE in HA mode.

```
server1# qmgr -c "p s"
server2# qmgr -c "p s"
```

*The commands above returns all settings from the active TORQUE server from either node.*

Drop one of the `pbs_servers` to verify that the secondary server picks up the request.

```
server1# qterm
server2# qmgr -c "p s"
```

Stop the `pbs_server` on `server2` and restart `pbs_server` on `server1` to verify that both nodes can handle a request from the other.

12. Install a `pbs_mom` on the compute nodes.

- a. On `server1` or `server2`, configure the nodes file to identify all available MOMs. To do so, edit the `/var/spool/torque/server_priv/nodes` file.

```
node1 np=2
node2 np=2
```

**i** Change the `np` flag to reflect number of available processors on that node.

- b. Recycle the `pbs_servers` to verify that they pick up the MOM configuration.

```
server1# qterm; pbs_server --ha -l server2:port
server2# qterm; pbs_server --ha -l server1:port
```

- c. Start the pbs\_mom on each execution node.

```
server1# pbs_mom -d <mom-server1>
server2# pbs_mom -d <mom-server2>
```

## Example setup of high availability

1. The machines running pbs\_server must have access to a shared server\_priv/ directory (usually an NFS share on a MoM).
2. All MoMs must have the same content in their server\_name file. This can be done manually or via an NFS share. The server\_name file contains a comma-delimited list of the hosts that run pbs\_server.

```
# List of all servers running pbs_server
server1,server2
```

3. The machines running pbs\_server must be listed in [acl\\_hosts](#).

```
> qmgr -c "set server acl_hosts += server1"
> qmgr -c "set server acl_hosts += server2"
```

4. Start pbs\_server with the --ha option.

```
[root@server1]$ pbs_server --ha
[root@server2]$ pbs_server --ha
```

## Setting min\_threads and max\_threads

There are two threadpools in TORQUE, one for background tasks and one for incoming requests from the MOMs and through the API (client commands, Moab, and so forth). The [min\\_threads on page 2778](#) and [max\\_threads on page 2777](#) parameters control the number of total threads used for both, not for each individually. The incoming requests' threadpool has three-quarters of [min\\_threads](#) for its minimum, and three-quarters of [max\\_threads](#) for its maximum, with the background pool receiving the other one-quarter.

Additionally, pbs\_server no longer allows incoming requests to pile up indefinitely. When the threadpool is too busy for incoming requests, it indicates such, returning PBSE\_SERVER\_BUSY with the accompanying message that "Pbs Server is currently too busy to service this request. Please retry this request." The threshold for this message, if the request is from a manager, is that at least two threads be available in the threadpool. If the request comes from a non-manager, 5% of the threadpool must be available for the request to be serviced. Note that availability is calculated based on the maximum threads and not based on the current number of threads allocated.

If an undesirably large number of requests are given a busy response, one option is to increase the number of maximum threads for the threadpool. If the load on the server is already very high, then this is probably not going to help, but if the CPU load is lower, then it may help. Remember that by default the threadpool shrinks down once the extra threads are no longer needed. This is controlled via the [thread\\_idle\\_seconds](#) on [page 2783](#) server parameter.

**i** Any change in the [min\\_threads](#), [max\\_threads](#), or [thread\\_idle\\_seconds](#) parameters requires a restart of `pbs_server` to take effect.

## Integrating schedulers for TORQUE

Selecting the cluster scheduler is an important decision and significantly affects cluster utilization, responsiveness, availability, and intelligence. The default TORQUE scheduler, `pbs_sched`, is very basic and will provide poor utilization of your cluster's resources. Other options, such as Maui Scheduler or Moab Workload Manager, are highly recommended. If you are using [Maui](#) or [Moab](#), see [Moab-TORQUE Integration Guide](#) on [page 1228](#). If using `pbs_sched`, simply start the `pbs_sched` daemon.

**i** If you are installing Moab Cluster Suite, TORQUE and Moab were configured at installation for interoperability and no further action is required.

## Configuring data management

This section contains information about SCP-based data management with TORQUE. It describes how to use TORQUE with NFS and other networked filesystems. It also outlines file staging requirements. For details, see these topics:

- [SCP setup](#) on [page 2653](#)
- [NFS and other networked filesystems](#) on [page 2656](#)
- [File stage-in/stage-out](#) on [page 2657](#)

### SCP setup

To use SCP-based data management, TORQUE must be authorized to migrate data to any of the compute nodes. If this is not already enabled within the cluster, this can be achieved with the process described below. This process enables uni-directional access for a particular user from a *source* host to a *destination* host.

**i** These directions were written using [OpenSSH version 3.6](#) and may not transfer correctly to older versions.

To set up TORQUE for SCP, follow the directions in each of these topics:

- [Generating SSH key on source host on page 2654](#)
- [Copying public SSH key to each destination host on page 2654](#)
- [Configuring the SSH daemon on each destination host on page 2655](#)
- [Validating correct SSH configuration on page 2655](#)
- [Enabling bi-directional SCP access on page 2655](#)
- [Compiling TORQUE to support SCP on page 2656](#)
- [Troubleshooting on page 2656](#)

#### Related topics

- [Configuring data management on page 2653](#)

## Generating SSH key on source host

On the source host as the transfer user, execute the following:

```
> ssh-keygen -t rsa
```

This will prompt for a passphrase (optional) and create two files (`id_rsa` and `id_rsa.pub`) inside `~/.ssh/`.

#### Related topics

- [SCP setup on page 2653](#)
- [Copying public SSH key to each destination host on page 2654](#)

## Copying public SSH key to each destination host

Transfer public key to each destination host as the transfer user:

Easy key copy:

```
ssh-copy-id [-i [identity_file]] [user@]machine
```

Manual steps to copy keys:

```
> scp ~/.ssh/id_rsa.pub destHost:~ (enter password)
```

Create an `authorized_keys` file on each destination host:

```
> ssh destHost (enter password)
> cat id_rsa.pub >> .ssh/authorized_keys
```

If the `.ssh` directory does not exist, create it with 700 privileges (`mkdir .ssh; chmod 700 .ssh`):

```
> chmod 700 .ssh/authorized_keys
```

## Related topics

- [Generating SSH key on source host on page 2654](#)
- [SCP setup on page 2653](#)

## Configuring the SSH daemon on each destination host

Some configuration of the SSH daemon may be required on the destination host. (Because this is not always the case, see [Validating correct SSH configuration on page 2655](#) and test the changes made to this point. If the tests fail, proceed with this step and then try testing again.) Typically, this is done by editing the `/etc/ssh/sshd_config` file (root access needed). To verify correct configuration, see that the following attributes are set (not commented):

```
RSAAuthentication yes
PubkeyAuthentication yes
```

If configuration changes were required, the SSH daemon will need to be restarted (root access needed):

```
> /etc/init.d/sshd restart
```

## Related topics

- [SCP setup on page 2653](#)

## Validating correct SSH configuration

If all is properly configured, the following command issued on the *source* host should succeed and not prompt for a password:

```
> scp destHost:/etc/motd /tmp
```

**i** If this is your first time accessing *destination* from *source*, it may ask you if you want to add the fingerprint to a file of known hosts. If you specify yes, this message should no longer appear and should not interfere with scp copying via TORQUE. Also, it is important that the full hostname appear in the `known_hosts` file. To do this, use the full hostname for *destHost*, as in `machine.domain.org` instead of just `machine`.

## Related topics

- [SCP setup on page 2653](#)

## Enabling bi-directional SCP access

The preceding steps allow *source* access to *destination* without prompting for a password. The reverse, however, is not true. Repeat the steps, but this time using the *destination* as the *source*, etc. to enable bi-directional SCP access (i.e. *source* can send to *destination* and *destination* can send to *source* without password prompts.)

## Related topics

- [SCP setup on page 2653](#)

## Compiling TORQUE to support SCP

**i** In TORQUE 2.1 and later, SCP is the default remote copy protocol. These instructions are only necessary for earlier versions.

TORQUE must be re-configured (and then rebuilt) to use SCP by passing in the `--with-scp` flag to the configure script:

```
> ./configure --prefix=xxx --with-scp
> make
```

**i** If special SCP flags are required in your local setup, these can be specified using the `$rcpcmd` parameter.

## Related topics

- [SCP setup on page 2653](#)

## Troubleshooting

If, after following all of the instructions in this section (see [SCP setup on page 2653](#)), TORQUE is still having problems transferring data with SCP, set the `PBSDEBUG` environment variable and restart the `pbs_mom` for details about copying. Also check the MOM log files for more details.

## Related topics

- [SCP setup on page 2653](#)

## NFS and other networked filesystems

When a batch job starts, its `stdin` file (if specified) is copied from the submission directory on the remote submission host. This file is placed in the `$PBSMOMHOME` directory on the mother superior node (i.e., `/usr/spool/PBS/spool`). As the job runs, `stdout` and `stderr` files are generated and placed in this directory using the naming convention `$JOBID.OU` and `$JOBID.ER`.

When the job completes, the MOM copies the files into the directory from which the job was submitted. By default, this file copying will be accomplished using a remote copy facility such as `rcp` or `scp`.

If a shared file system such as NFS, DFS, or AFS is available, a site can specify that the MOM should take advantage of this by specifying the `$usecp` directive inside the MOM configuration file (located in the `$PBSMOMHOME/mom_priv` directory) using the following format:

```
$usecp <HOST>:<SRCDIR> <DSTDIR>
```

<HOST> can be specified with a leading wildcard (\*) character. The following example demonstrates this directive:

```
mom_priv/config
# /home is NFS mounted on all hosts
$usecp */:/home /home
# submission hosts in domain fte.com should map '/data' directory on submit host to
# '/usr/local/data' on compute host
$usecp *.fte.com:/data /usr/local/data
```

If for any reason the MOM daemon is unable to copy the output or error files to the submission directory, these files are instead copied to the `undelivered` directory also located in `$PBSMOMHOME`.

### Related topics

- [Configuring data management on page 2653](#)

## File stage-in/stage-out

File staging requirements are specified using the `stagein` and `stageout` directives of the [qsub](#) command. Stagein requests occur before the job starts execution, while stageout requests happen after a job completes.

On completion of the job, all staged-in and staged-out files are removed from the execution system. The `file_list` is in the form `local_file@hostname:remote_file[,...]` regardless of the direction of the copy. The name `local_file` is the name of the file on the system where the job executed. It may be an absolute path or relative to the home directory of the user. The name `remote_file` is the destination name on the host specified by `hostname`. The name may be absolute or relative to the user's home directory on the destination host. The use of wildcards in the file name is not recommended.

The file names map to a remote copy program (`rcp/scp/cp`, depending on configuration) called on the execution system in the following manner:

For stagein: `rcp/scp hostname:remote_file local_file`

For stageout: `rcp/scp local_file hostname:remote_file`

### Examples

```
# stage /home/john/input_source.txt from node13.fsc to /home/john/input_
destination.txt on master compute node
> qsub -l nodes=1,walltime=100 -W stagein=input_
source.txt@node13.fsc:/home/john/input_destination.txt
```

```
# stage /home/bill/output_source.txt on master compute node to /tmp/output_
destination.txt on node15.fsc
> qsub -l nodes=1,walltime=100 -W stageout=/tmp/output_
source.txt@node15.fsc:/home/bill/output_destination.txt
```

```
$ fortune >xxx;echo cat xxx|qsub -W stagein=xxx@`hostname`:xxx
199.myhost.mydomain
$ cat STDIN*199
Anyone who has had a bull by the tail knows five or six more things
than someone who hasn't.

# MPI (Message Passing Interface) support

A message passing library is used by parallel jobs to augment communication between the tasks distributed across the cluster. TORQUE can run with any message passing library and provides limited integration with some [MPI](#) libraries.

For more information, see these topics:

- [MPICH on page 2658](#)
- [Open MPI on page 2659](#)

## MPICH

One of the most popular MPI libraries is [MPICH](#) available from [Argonne National Lab](#). If using this release, you may want to consider also using the [mpiexec](#) tool for launching MPI applications. Support for `mpiexec` has been integrated into TORQUE.

## MPIExec Overview

`mpiexec` is a replacement program for the script `mpirun`, which is part of the `mpich` package. It is used to initialize a parallel job from within a PBS batch or interactive environment. `mpiexec` uses the task manager library of PBS to spawn copies of the executable on the nodes in a PBS allocation.

Reasons to use `mpiexec` rather than a script (`mpirun`) or an external daemon (`mpd`):

- Starting tasks with the task manager (TM) interface is much faster than invoking a separate `rsh` \* once for each process.
- Resources used by the spawned processes are accounted correctly with `mpiexec`, and reported in the PBS logs, because all the processes of a parallel job remain under the control of PBS, unlike when using `mpirun`-like scripts.
- Tasks that exceed their assigned limits of CPU time, wallclock time, memory usage, or disk space are killed cleanly by PBS. It is quite hard for processes to escape control of the resource manager when using `mpiexec`.
- You can use `mpiexec` to enforce a security policy. If all jobs are forced to spawn using `mpiexec` and the PBS execution environment, it is not necessary to enable `rsh` or `ssh` access to the compute nodes in the cluster.

For more information, see the [mpiexec](#) homepage.

## MPIExec Troubleshooting

Although problems with `mpiexec` are rare, if issues do occur, the following steps may be useful:

- Determine current version using `mpiexec --version` and review the [change log](#) available on the [MPI homepage](#) to determine if the reported issue has already been corrected.
- Send email to the mpiexec mailing list at [mpiexec@osc.edu](mailto:mpiexec@osc.edu).
- Browse the mpiexec user list [archives](#) for similar problems and resolutions.
- Read the FAQ contained in the README file and the mpiexec man pages contained within the mpiexec distribution.
- Increase the logging of mpiexec operation with `mpiexec --verbose` (reports messages to `stderr`).
- Increase logging of the master and slave resource manager execution daemons associated with the job (with TORQUE, use `$loglevel` to 5 or higher in `$TORQUEROOT/mom_priv/config` and look for 'tm' messages after associated `join` job messages).
- Use `tracejob` (included with TORQUE) or `qtracejob` (included with OSC's pbstools package) to isolate failures within the cluster.
- If the message 'exec: Error: get\_hosts: pbs\_connect: Access from host not allowed, or unknown host' appears, this indicates that mpiexec cannot communicate with the `pbs_server` daemon. In most cases, this indicates that the `$TORQUEROOT/server_name` file points to the wrong server or the node cannot resolve the server's name. The [qstat](#) command can be run on the node to test this.

## General MPI Troubleshooting

When using MPICH, some sites have issues with orphaned MPI child processes remaining on the system after the master MPI process has been terminated. To address this, TORQUE epilogue scripts can be created that properly clean up the orphaned processes (see [Appendix G: Prologue and epilogue scripts on page 2817](#)).

Related topics

- [MPI \(Message Passing Interface\) support on page 2658](#)

## Open MPI

[Open MPI](#) is a new MPI implementation that combines technologies from multiple projects to create the best possible library. It supports the TM interface for integration with TORQUE. More information is available in the [FAQ](#).

Related topics

- [MPI \(Message Passing Interface\) support on page 2658](#)

# Resources

A primary task of any resource manager is to monitor the state, health, configuration, and utilization of managed resources. TORQUE is specifically designed to monitor compute hosts for use in a batch environment. TORQUE is not designed to monitor non-compute host resources such as software licenses, networks, file systems, and so forth, although these resources can be integrated into the cluster using some scheduling systems.

With regard to monitoring compute nodes, TORQUE reports about a number of attributes broken into three major categories:

- [Configuration on page 2660](#)
- [Utilization on page 2661](#)
- [Node states on page 2661](#)

## Configuration

Configuration includes both detected hardware configuration and specified batch attributes.

Attribute	Description	Details
<b>Architecture (arch)</b>	operating system of the node	The value reported is a derivative of the operating system installed.
<b>Node Features (properties)</b>	arbitrary string attributes associated with the node	No node features are specified by default. If required, they are set using the <code>nodes</code> file located in the <code>TORQUE_HOME/server_priv</code> directory. They may specify any string and are most commonly used to allow users to request certain subsets of nodes when submitting jobs.
<b>Local Disk (size)</b>	configured local disk	By default, local disk space is not monitored. If the MOM configuration <a href="#">size [fs=&lt;FS&gt;]</a> parameter is set, TORQUE will report, in kilobytes, configured disk space within the specified directory.
<b>Memory (physmem)</b>	local memory/RAM	Local memory/RAM is monitored and reported in kilobytes.

Attribute	Description	Details
<b>Processors (ncpus/np)</b>	real/virtual processors	The number of processors detected by TORQUE is reported via the <i>ncpus</i> attribute. However, for scheduling purposes, other factors are taken into account. In its default configuration, TORQUE operates in "dedicated" mode with each node possessing a single virtual processor. In dedicated mode, each job task will consume one virtual processor and TORQUE will accept workload on each node until all virtual processors on that node are in use. While the number of virtual processors per node defaults to 1, this may be configured using the <i>nodes</i> file located in the <code>TORQUE_HOME/server_priv</code> directory. An alternative to dedicated mode is "timeshared" mode. If TORQUE's time-shared mode is enabled, TORQUE will accept additional workload on each node until the node's <i>maxload</i> limit is reached.
<b>Swap (totmem)</b>	virtual memory/Swap	Virtual memory/Swap is monitored and reported in kilobytes.

## Utilization

Utilization includes information regarding the amount of node resources currently in use as well as information about who or what is consuming it.

Attribute	Description	Details
<b>Disk (size)</b>	local disk availability	By default, local disk space is not monitored. If the MOM configuration <a href="#">size [fs=&lt;FS&gt;]</a> parameter is set, TORQUE will report configured and currently available disk space within the specified directory in kilobytes.
<b>Memory (availmem)</b>	real memory/RAM	Available real memory/RAM is monitored and reported in kilobytes.
<b>Network (netload)</b>	local network adapter usage	Reports total number of bytes transferred in or out by the network adapter.
<b>Processor Utilization (loadave)</b>	node's cpu load average	Reports the node's 1 minute bsd load average.

## Node states

State information includes administrative status, general node health information, and general usage status.

Attribute	Description	Details
<b>Idle Time (idletime)</b>	time since local keyboard/mouse activity has been detected	Time in seconds since local keyboard/mouse activity has been detected.
<b>State (state)</b>	monitored/admin node state	<p>A node can be in one or more of the following states:</p> <ul style="list-style-type: none"> <li>• <i>busy</i> - node is full and will not accept additional work</li> <li>• <i>down</i> - node is failing to report, is detecting local failures with node</li> <li>• <i>free</i> - node is ready to accept additional work</li> <li>• <i>job-exclusive</i> - all available virtual processors are assigned to jobs</li> <li>• <i>job-sharing</i> - node has been allocated to run multiple shared jobs and will remain in this state until jobs are complete</li> <li>• <i>offline</i> - node has been instructed by an admin to no longer accept work</li> <li>• <i>reserve</i> - node has been reserved by the server</li> <li>• <i>time-shared</i> - node always allows multiple jobs to run concurrently</li> <li>• <i>unknown</i> - node has not been detected</li> </ul>

## Accounting records

TORQUE maintains accounting records for batch jobs in the following directory:

```
$TORQUEROOT/server_priv/accounting/<TIMESTAMP>
```

\$TORQUEROOT defaults to /usr/spool/PBS and <TIMESTAMP> is in the format: YYYYMMDD.

These records include events, time stamps, and information on resources requested and used.

Records for four different event types are produced and are described in the following table:

Record marker	Record type	Description
<b>A</b>	abort	Job has been aborted by the server
<b>C</b>	checkpoint	Job has been checkpointed and held
<b>D</b>	delete	Job has been deleted

Record marker	Record type	Description
<b>E</b>	exit	Job has exited (either successfully or unsuccessfully)
<b>Q</b>	queue	Job has been submitted/queued
<b>R</b>	rerun	Attempt to rerun the job has been made
<b>S</b>	start	Attempt to start the job has been made (if the job fails to properly start, it may have multiple job start records)
<b>T</b>	restart	Attempt to restart the job (from checkpoint) has been made (if the job fails to properly start, it may have multiple job start records)

## Accounting Variables

The following table offers accounting variable descriptions. Descriptions for accounting variables not indicated in the table, particularly those prefixed with **Resources\_List**, are available at [Job submission on page 2583](#).

Variable	Description
<b>ctime</b>	Time job was created
<b>etime</b>	Time job became eligible to run
<b>qtime</b>	Time job was queued
<b>start</b>	Time job started to run

A sample record in this file can look like the following:

```
06/06/2005 14:04:25;D;408.ign1.zeta2.org;requestor=guest@ign1.zeta2.org
06/06/2005 14:04:35;Q;409.ign1.zeta2.org;queue=batch
06/06/2005 14:04:44;Q;410.ign1.zeta2.org;queue=batch
06/06/2005 14:06:06;S;407.ign1.zeta2.org;user=guest group=guest jobname=STDIN
queue=batch ctime=1118087915 qtime=1118087915 etime=1118087915 start=1118088366 exec_
host=ign1.zeta2.org/0 Resource_List.neednodes=ign1.zeta2.org Resource_List.nodect=1
Resource_List.nodes=1 Resource_List.walltime=00:16:40
06/06/2005 14:07:17;D;407.ign1.zeta2.org;requestor=guest@ign1.zeta2.org
06/06/2005 14:07:17;E;407.ign1.zeta2.org;user=guest group=guest jobname=STDIN
queue=batch ctime=1118087915 qtime=1118087915 etime=1118087915 start=1118088366 exec_
host=ign1.zeta2.org/0 Resource_List.nodect=1 Resource_List.nodes=1 Resource_
List.walltime=00:16:40 session=6365 end=1118088437 Exit_status=271 resources_
used.cput=00:00:00 resources_used.mem=3068kb resources_used.vmem=16080kb resources_
used.walltime=00:01:11
```

**i** The value of `Resource_List.*` is the amount of resources requested, and the value of `resources_used.*` is the amount of resources actually used.

## Job logging

New in TORQUE 2.5.3 is the ability to log job information for completed jobs. The information stored in the log file is the same information produced with the command `qstat -f`. The log file data is stored using an XML format. Data can be extracted from the log using the utility `showjobs` found in the `contrib/` directory of the TORQUE source tree. Custom scripts that can parse the XML data can also be used.

For details about job logging, see these topics:

- [Job log location and name on page 2664](#)
- [Enabling job logs on page 2664](#)

### Job log location and name

When job logging is enabled (see [Enabling job logs on page 2664](#)), the job log is kept at `$TORQUE_HOME/job_logs`. The naming convention for the job log is the same as for the server log or MOM log. The log name is created from the current year/month/day.

For example, if today's date is 26 October, 2010 the log file is named 20101026.

A new log file is created each new day that data is written to the log.

Related topics

- [Job logging on page 2664](#)

### Enabling job logs

There are five new server parameters used to enable job logging. These parameters control what information is stored in the log and manage the log files.

Parameter	Description
<b>record_job_info</b>	This must be set to true in order for job logging to be enabled. If not set to true, the remaining server parameters are ignored.

Parameter	Description
<b>record_job_script</b>	If set to true, this adds the contents of the script executed by a job to the log.
<b>job_log_file_max_size</b>	This specifies a soft limit (in kilobytes) for the job log's maximum size. The file size is checked every five minutes and if the <i>current day</i> file size is greater than or equal to this value, it is rolled from <i>&lt;filename&gt;</i> to <i>&lt;filename.1&gt;</i> and a new empty log is opened. If the current day file size exceeds the maximum size a second time, the <i>&lt;filename.1&gt;</i> log file is rolled to <i>&lt;filename.2&gt;</i> , the current log is rolled to <i>&lt;filename.1&gt;</i> , and a new empty log is opened. Each new log causes all other logs to roll to an extension that is one greater than its current number. Any value less than 0 is ignored by pbs_server (meaning the log will not be rolled).
<b>job_log_file_roll_depth</b>	This sets the maximum number of new log files that are kept in a day if the <a href="#">job_log_file_max_size</a> parameter is set. For example, if the roll depth is set to 3, no file can roll higher than <i>&lt;filename.3&gt;</i> . If a file is already at the specified depth, such as <i>&lt;filename.3&gt;</i> , the file is deleted so it can be replaced by the incoming file roll, <i>&lt;filename.2&gt;</i> .
<b>job_log_keep_days</b>	This maintains logs for the number of days designated. If set to 4, any log file older than 4 days old is deleted.

## Troubleshooting

There are a few general strategies that can be followed to determine the cause of unexpected behavior. These are a few of the tools available to help determine where problems occur. See these topics for details:

- [Host resolution](#) on page 2666
- [Firewall configuration](#) on page 2666
- [TORQUE log files](#) on page 2666
- [Using "tracejob" to locate job failures](#) on page 2668
- [Using GDB to locate job failures](#) on page 2670
- [Other diagnostic options](#) on page 2670
- [Stuck jobs](#) on page 2671
- [Frequently asked questions \(FAQ\)](#) on page 2672

- [Compute node health check on page 2677](#)
- [Debugging on page 2679](#)

## Host resolution

The TORQUE server host must be able to perform both forward and reverse name lookup on itself and on all compute nodes. Likewise, each compute node must be able to perform forward and reverse name lookup on itself, the TORQUE server host, and all other compute nodes. In many cases, name resolution is handled by configuring the node's `/etc/hosts` file although *DNS* and *NIS* services may also be used. Commands such as `nslookup` or `dig` can be used to verify proper host resolution.

**i** Invalid host resolution may exhibit itself with compute nodes reporting as down within the output of `pbsnodes-a` and with failure of the `momctl -d3` command.

### Related topics

- [Troubleshooting on page 2665](#)

## Firewall configuration

Be sure that, if you have firewalls running on the server or node machines, you allow connections on the appropriate ports for each machine. TORQUE `pbs_mom` daemons use UDP ports 1023 and below if privileged ports are configured (privileged ports is the default). The `pbs_server` and `pbs_mom` daemons use TCP and UDP ports 15001-15004 by default.

Firewall based issues are often associated with server to MOM communication failures and messages such as 'premature end of message' in the log files.

Also, the `tcpdump` program can be used to verify the correct network packets are being sent.

### Related topics

- [Troubleshooting on page 2665](#)

## TORQUE log files

### pbs\_server and pbs\_mom log files

The `pbs_server` keeps a daily log of all activity in the `TORQUE_HOME/server_logs` directory. The `pbs_mom` also keeps a daily log of all activity in the `TORQUE_HOME/mom_logs/` directory. These logs contain information on communication between server and MOM as well as information on jobs as they enter the queue and as they are dispatched, run, and terminated. These logs can be very helpful in determining general job failures. For MOM logs, the verbosity of the logging can be adjusted by setting the `$loglevel` parameter in the `mom_priv/config` file. For server logs, the verbosity of the logging can be adjusted by setting the server `log_level` attribute in `qmgr`.

For both `pbs_mom` and `pbs_server` daemons, the log verbosity level can also be adjusted by setting the environment variable **PBSLOGLEVEL** to a value between 0 and 7. Further, to dynamically change the log level of a running daemon, use the `SIGUSR1` and `SIGUSR2` signals to increase and decrease the active loglevel by one. Signals are sent to a process using the `kill` command.

For example, `kill -USR1 `pgrep pbs_mom`` would raise the log level up by one.

The current loglevel for `pbs_mom` can be displayed with the command `momctl -d3`.

## trqauthd log files

As of TORQUE 4.1.3, `trqauthd` logs its events in the `$TORQUE_HOME/client_logs` directory. It names the log files in the format `<YYYYMMDD>`, creating a new log daily as events occur.

**i** You might see some peculiar behavior if you mount the `client_logs` directory for shared access via network-attached storage.

When `trqauthd` first gets access on a particular day, it writes an "open" message to the day's log file. It also writes a "close" message to the last log file it accessed prior to that, which is usually the previous day's log file, but not always. For example, if it is Monday and no client commands were executed over the weekend, `trqauthd` writes the "close" message to Friday's file.

Since the various `trqauthd` binaries on the submit hosts (and potentially, the compute nodes) each write an "open" and "close" message on the first access of a new day, you'll see multiple (seemingly random) accesses when you have a shared log.

The `trqauthd` records the following events along with the date and time of the occurrence:

- When `trqauthd` successfully starts. It logs the event with the IP address and port.
- When a user successfully authenticates with `trqauthd`.
- When a user fails to authenticate with `trqauthd`.
- When `trqauthd` encounters any unexpected errors.

### Example 4-26: trqauthd logging sample

```
2012-10-05 15:05:51.8404 Log opened
2012-10-05 15:05:51.8405 TORQUE authd daemon started and listening on IP:port
101.0.1.0:12345
2012-10-10 14:48:05.5688 User hfrye at IP:port abc:12345 logged in
```

## Using "tracejob" to locate job failures

### Overview

The *tracejob* utility extracts job status and job events from accounting records, MOM log files, server log files, and scheduler log files. Using it can help identify where, how, a why a job failed. This tool takes a job id as a parameter as well as arguments to specify which logs to search, how far into the past to search, and other conditions.

### Syntax

```
tracejob [-a|s|l|m|q|v|z] [-c count] [-w size] [-p path] [ -n <DAYS>] [-f
filter_type] <JOBID>
```

```
-p : path to PBS_SERVER_HOME
-w : number of columns of your terminal
-n : number of days in the past to look for job(s) [default 1]
-f : filter out types of log entries, multiple -f's can be specified
    error, system, admin, job, job_usage, security, sched, debug,
    debug2, or absolute numeric hex equivalent
-z : toggle filtering excessive messages
-c : what message count is considered excessive
-a : don't use accounting log files
-s : don't use server log files
-l : don't use scheduler log files
-m : don't use MOM log files
-q : quiet mode - hide all error messages
-v : verbose mode - show more error messages
```

## Example

```

> tracejob -n 10 1131
Job: 1131.icluster.org

03/02/2005 17:58:28 S enqueueing into batch, state 1 hop 1
03/02/2005 17:58:28 S Job Queued at request of dev@icluster.org, owner =

resources_used.mem=3544kb resources_used.vmem=10632kb
resources_used.walltime=00:07:46
...

```

**i** The `tracejob` command operates by searching the `pbs_server` accounting records and the `pbs_server`, `MOM`, and scheduler logs. To function properly, it must be run on a node and as a user which can access these files. By default, these files are all accessible by the user `root` and only available on the cluster management node. In particular, the files required by `tracejob` are located in the following directories:

```
TORQUE_HOME/server_priv/accounting
```

```
TORQUE_HOME/server_logs
```

```
TORQUE_HOME/mom_logs
```

```
TORQUE_HOME/sched_logs
```

**i** `tracejob` may only be used on systems where these files are made available. Non-root users may be able to use this command if the permissions on these directories or files are changed appropriately.

**i** The value of `Resource_List.*` is the amount of resources requested, and the value of `resources_used.*` is the amount of resources actually used.

### Related topics

- [Troubleshooting on page 2665](#)

## Using GDB to locate job failures

If either the `pbs_mom` or `pbs_server` fail unexpectedly (and the log files contain no information on the failure) `gdb` can be used to determine whether or not the program is crashing. To start `pbs_mom` or `pbs_server` under [GDB](#) export the environment variable `PBSDEBUG=yes` and start the program (i.e., `gdb pbs_mom` and then issue the `run` subcommand at the `gdb` prompt).

`GDB` may run for some time until a failure occurs and at which point, a message will be printed to the screen and a `gdb` prompt again made available. If this occurs, use the `gdb where` subcommand to determine the exact location in the code. The information provided may be adequate to allow local diagnosis and correction. If not, this output may be sent to the mailing list or to [help](#) for further assistance.

**i** See the `PBSCOREDUMP` parameter for enabling creation of core files (see [Using "tracejob" to locate job failures on page 2668](#)).

### Related topics

- [Troubleshooting on page 2665](#)

## Other diagnostic options

When `PBSDEBUG` is set, some client commands will print additional diagnostic information.

```
$ export PBSDEBUG=yes
$ cmd
```

To debug different kinds of problems, it can be useful to see where in the code time is being spent. This is called profiling and there is a Linux utility "gprof" that will output a listing of routines and the amount of time spent in these routines. This does require that the code be compiled with special options to instrument the code and to produce a file, `gmon.out`, that will be written at the end of program execution.

The following listing shows how to build TORQUE with profiling enabled. Notice that the output file for `pbs_mom` will end up in the `mom_priv` directory because its startup code changes the default directory to this location.

```
# ./configure "CFLAGS=-pg -lgcov -fPIC"
# make -j5
# make install
# pbs_mom ... do some stuff for a while ...
# momctl -s
# cd /var/spool/torque/mom_priv
# gprof -b `which pbs_mom` gmon.out |less
#
```

Another way to see areas where a program is spending most of its time is with the `valgrind` program. The advantage of using `valgrind` is that the programs do not have to be specially compiled.

```
# valgrind --tool=callgrind pbs_mom
```

#### Related topics

- [Troubleshooting on page 2665](#)

## Stuck jobs

If a job gets stuck in TORQUE, try these suggestions to resolve the issue:

- Use the [qdel](#) command to cancel the job.
- Force the MOM to send an obituary of the job ID to the server.

```
> qsig -s 0 <JOBID>
```

- You can try clearing the stale jobs by using the [momctl](#) command on the compute nodes where the jobs are still listed.

```
> momctl -c 58925 -h compute-5-20
```

- Setting the [qmgr](#) server setting `mom_job_sync` to *True* might help prevent jobs from hanging.

```
> qmgr -c "set server mom_job_sync = True"
```

To check and see if this is already set, use:

```
> qmgr -c "p s"
```

- If the suggestions above cannot remove the stuck job, you can try [qdel](#) `-p`. However, since the `-p` option purges all information generated by the job, this is not a recommended option unless the above suggestions fail to remove the stuck job.

```
> qdel -p <JOBID>
```

- The last suggestion for removing stuck jobs from compute nodes is to restart the `pbs_mom`.

For additional troubleshooting, run a `tracejob` on one of the stuck jobs. You can then create an [online support ticket](#) with the full server log for the time period displayed in the trace job.

- [My build fails attempting to use the TCL library on page 2676](#)
- [My job will not start, failing with the message 'cannot send job to mom, state=PRERUN' on page 2676](#)
- [How do I determine what version of TORQUE I am using? on page 2676](#)
- [How do I resolve autogen.sh errors that contain "error: possibly undefined macro: AC\\_MSG\\_ERROR"? on page 2676](#)
- [How do I resolve compile errors with libssl or libcrypto for TORQUE 4.0 on Ubuntu 10.04? on page 2677](#)
- [Why are there so many error messages in the client logs \(trqauthd logs\) when I don't notice client commands failing? on page 2677](#)

### Cannot connect to server: error=15034

This error occurs in TORQUE clients (or their APIs) because TORQUE cannot find the `server_name` file and/or the `PBS_DEFAULT` environment variable is not set. The `server_name` file or `PBS_DEFAULT` variable indicate the `pbs_server`'s hostname that the client tools should communicate with. The `server_name` file is usually located in TORQUE's local state directory. Make sure the file exists, has proper permissions, and that the version of TORQUE you are running was built with the proper directory settings. Alternatively you can set the `PBS_DEFAULT` environment variable. Restart TORQUE daemons if you make changes to these settings.

### Deleting 'stuck' jobs

To manually delete a "stale" job which has no process, and for which the mother superior is still alive, sending a sig 0 with `qsig` will often cause MOM to realize the job is stale and issue the proper JobObit notice. Failing that, use `momctl -c` to forcefully cause MOM to purge the job. The following process should never be necessary:

- Shut down the MOM on the mother superior node.
- Delete all files and directories related to the job from `TORQUE_HOME/mom_priv/jobs`.
- Restart the MOM on the mother superior node.

If the mother superior MOM has been lost and cannot be recovered (i.e. hardware or disk failure), a job running on that node can be purged from the output of [qstat](#) using the [qdel on page 2720](#) `-p` command or can be removed manually using the following steps:

### To remove job X

1. Shut down `pbs_server`.

```
> qterm
```

2. Remove job spool files.

```
> rm TORQUE_HOME/server_priv/jobs/X.SC TORQUE_HOME/server_priv/jobs/X.JB
```

3. Restart `pbs_server`

```
> pbs_server
```

## Which user must run TORQUE?

TORQUE (`pbs_server` & `pbs_mom`) must be started by a user with root privileges.

## Scheduler cannot run jobs - rc: 15003

For a scheduler, such as [Moab](#) or [Maui](#), to control jobs with TORQUE, the scheduler needs to be run by a user in the server operators / managers list (see [qmgr](#)). The default for the server operators / managers list is `root@localhost`. For TORQUE to be used in a grid setting with Silver, the scheduler needs to be run as `root`.

## PBS\_Server: pbsd\_init, Unable to read server database

If this message is displayed upon starting `pbs_server` it means that the local database cannot be read. This can be for several reasons. The most likely is a version mismatch. Most versions of TORQUE can read each other's databases. However, there are a few incompatibilities between OpenPBS and TORQUE. Because of enhancements to TORQUE, it cannot read the job database of an OpenPBS server (job structure sizes have been altered to increase functionality). Also, a compiled in 32-bit mode cannot read a database generated by a 64-bit `pbs_server` and vice versa.

## To reconstruct a database (excluding the job database)

1. First, print out the old data with this command:

```
%> qmgr -c "p s"
#
# Create queues and set their attributes.
#
#
# Create and define queue batch
# create queue batch
set queue batch queue_type = Execution
set queue batch acl_host_enable = False
set queue batch resources_max.nodect = 6
set queue batch resources_default.nodes = 1
set queue batch resources_default.walltime = 01:00:00
set queue batch resources_available.nodect = 18
set queue batch enabled = True
set queue batch started = True
#
# Set server attributes.
#
set server scheduling = True
set server managers = griduser@oahu.icluster.org
set server managers += scott@*.icluster.org
set server managers += wightman@*.icluster.org
set server operators = griduser@oahu.icluster.org
set server operators += scott@*.icluster.org
set server operators += wightman@*.icluster.org
set server default_queue = batch
set server log_events = 511
set server mail_from = adm
set server resources_available.nodect = 80
set server node_ping_rate = 300
set server node_check_rate = 600
set server tcp_timeout = 6
```

2. Copy this information somewhere.
3. Restart pbs\_server with the following command:

```
> pbs_server -t create
```

4. When you are prompted to overwrite the previous database, enter *y*, then enter the data exported by the `qmgr` command as in this example:

```
> cat data | qmgr
```

5. Restart pbs\_server without the flags:

```
> qterm
> pbs_server
```

This will reinitialize the database to the current version.

**i** Reinitializing the server database will reset the next jobid to 1

## qsub will not allow the submission of jobs requesting many processors

TORQUE's definition of a node is context sensitive and can appear inconsistent. The `qsub -l nodes=<X>` expression can at times indicate a request for X processors and other time be interpreted as a request for X nodes. While `qsub` allows multiple interpretations of the keyword nodes, aspects of the TORQUE server's logic are not so flexible. Consequently, if a job is using `-l nodes` to specify processor count and the requested number of processors exceeds the available number of physical nodes, the server daemon will reject the job.

To get around this issue, the server can be told it has an inflated number of nodes using the `resources_available` attribute. To take effect, this attribute should be set on both the server and the associated queue as in the example below. (See [resources\\_available](#) for more information.)

```
> qmgr
Qmgr: set server resources_available.nodect=2048
Qmgr: set queue batch resources_available.nodect=2048
```

**i** The `pbs_server` daemon will need to be restarted before these changes will take effect.

## qsub reports 'Bad UID for job execution'

```
[guest@login2]$ qsub test.job
qsub: Bad UID for job execution
```

Job submission hosts must be explicitly specified within TORQUE or enabled via RCmd security mechanisms in order to be trusted. In the example above, the host 'login2' is not configured to be trusted. This process is documented in [Configuring job submission hosts on page 2566](#).

## Why does my job keep bouncing from running to queued?

There are several reasons why a job will fail to start. Do you see any errors in the MOM logs? Be sure to increase the loglevel on MOM if you don't see anything. Also be sure TORQUE is configured with `--enable-syslog` and look in `/var/log/messages` (or wherever your syslog writes).

Also verify the following on all machines:

- DNS resolution works correctly with matching forward and reverse
- Time is synchronized across the head and compute nodes
- User accounts exist on all compute nodes
- User home directories can be mounted on all compute nodes
- Prologue scripts (if specified) exit with 0

If using a scheduler such as [Moab](#) or [Mauai](#), use a scheduler tool such as `checkjob` to identify job start issues.

## How do I use PVM with TORQUE?

- Start the master pvm on a compute node and then add the slaves
- mpiexec can be used to launch slaves using rsh or ssh (use `export PVM_RSH=/usr/bin/ssh` to use ssh)

**i** Access can be managed by rsh/ssh without passwords between the batch nodes, but denying it from anywhere else, including the interactive nodes. This can be done with xinetd and sshd configuration (root is allowed to ssh everywhere). This way, the pvm daemons can be started and killed from the job script.

The problem is that this setup allows the users to bypass the batch system by writing a job script that uses rsh/ssh to launch processes on the batch nodes. If there are relatively few users and they can more or less be trusted, this setup can work.

## My build fails attempting to use the TCL library

TORQUE builds can fail on TCL dependencies even if a version of TCL is available on the system. TCL is only utilized to support the xpbsmon client. If your site does not use this tool (most sites do not use xpbsmon), you can work around this failure by rerunning `configure` with the `--disable-gui` argument.

## My job will not start, failing with the message 'cannot send job to mom, state=PRERUN'

If a node crashes or other major system failures occur, it is possible that a job may be stuck in a corrupt state on a compute node. TORQUE 2.2.0 and higher automatically handle this when the `mom_job_sync` parameter is set via [qmgr](#) (the default). For earlier versions of TORQUE, set this parameter and restart the `pbs_mom` daemon.

This error can also occur if not enough free space is available on the partition that holds TORQUE.

## How do I determine what version of TORQUE I am using?

There are times when you want to find out what version of TORQUE you are using. An easy way to do this is to run the following command:

```
qmgr
> qmgr -c "p s" | grep pbs_ver
```

## How do I resolve autogen.sh errors that contain "error: possibly undefined macro: AC\_MSG\_ERROR"?

Verify the `pkg-config` package is installed.

## How do I resolve compile errors with libssl or libcrypto for TORQUE 4.0 on Ubuntu 10.04?

When compiling TORQUE 4.0 on Ubuntu 10.04 the following errors might occur:

```
libtool: link: gcc -Wall -pthread -g -D_LARGEFILE64_SOURCE -o .libs/trqauthd trq_auth_
daemon.o trq_main.o -ldl -lssl -lcrypto -L/home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs /home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs/libtorque.so -lpthread -lrt -pthread
/usr/bin/ld: cannot find -lssl
collect2: ld returned 1 exit status
make[3]: *** [trqauthd] Error 1

libtool: link: gcc -Wall -pthread -g -D_LARGEFILE64_SOURCE -o .libs/trqauthd trq_auth_
daemon.o trq_main.o -ldl -lssl -lcrypto -L/home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs /home/adaptive/torques/torque-
4.0.0/src/lib/Libpbs/.libs/libtorque.so -lpthread -lrt -pthread
/usr/bin/ld: cannot find -lcrypto
collect2: ld returned 1 exit status
make[3]: *** [trqauthd] Error 1
```

To resolve the compile issue, use these commands:

```
> cd /usr/lib
> ln -s /lib/libcrypto.so.0.9.8 libcrypto.so
> ln -s /lib/libssl.so.0.9.8 libssl.so
```

## Why are there so many error messages in the client logs (trqauthd logs) when I don't notice client commands failing?

If a client makes a connection to the server and the trqauthd connection for that client command is authorized *before* the client's connection, the trqauthd connection is rejected. The connection is retried, but if all retry attempts are rejected, trqauthd logs a message indicating a failure. Some client commands then open a new connection to the server and try again. The client command fails only if all its retries fail.

## Compute node health check

TORQUE provides the ability to perform health checks on each compute node. If these checks fail, a failure message can be associated with the node and routed to the scheduler. Schedulers (such as [Moab](#)) can forward this information to administrators by way of scheduler triggers, make it available through scheduler diagnostic commands, and automatically mark the node down until the issue is resolved. (See the RMMMSGIGNORE parameter in [Appendix A: Moab Parameters on page 923](#) for more information.)

Additionally, Michael Jennings at LBNL has authored an open-source bash node health check script project. It offers an easy way to perform some of the most common node health checking tasks, such as verifying network and filesystem functionality. More information is available on the [project's page](#).

For more information about node health checks, see these topics:

- [Configuring MOMs to launch a health check on page 2678](#)
- [Creating the health check script on page 2678](#)
- [Adjusting node state based on the health check output on page 2679](#)
- [Example health check script on page 2679](#)

## Configuring MOMs to launch a health check

The health check feature is configured via the `mom_priv/config` file using the parameters described below:

Parameter	Format	Default	Description
<code>\$node_check_script</code>	<STRING>	N/A	(Required) Specifies the fully qualified pathname of the health check script to run
<code>\$node_check_interval</code>	<INTEGER>	1	(Optional) Specifies the number of MOM intervals between health checks (by default, each MOM interval is 45 seconds long - this is controlled via the <a href="#">\$status_update_time on page 2798</a> node parameter. The integer may be followed by a list of event names (currently supported are <code>jobstart</code> and <code>jobend</code> ). (For more information, see <a href="#">pbs_mom</a> .)

#### Related topics

- [Compute node health check on page 2677](#)

## Creating the health check script

The health check script is executed directly by the `pbs_mom` daemon under the root user id. It must be accessible from the compute node and may be a script or compile executable program. It may make any needed system calls and execute any combination of system utilities but should not execute resource manager client commands. Also, as of TORQUE 1.0.1, the `pbs_mom` daemon blocks until the health check is completed and does not possess a built-in timeout. Consequently, it is advisable to keep the launch script execution time short and verify that the script will not block even under failure conditions.

If the script detects a failure, it should return the keyword **ERROR** to stdout followed by an error message. When a failure is detected, the **ERROR** keyword should be printed to stdout before any other data. The message (up to 1024 characters) immediately following the **ERROR** keyword must all be contained on the same line. The message is assigned to the node attribute 'message' of the associated node.

## Related topics

- [Compute node health check on page 2677](#)

## Adjusting node state based on the health check output

If the health check reports an error, the node attribute "message" is set to the error string returned. Cluster schedulers can be configured to adjust a given node's state based on this information. For example, by default, [Moab](#) sets a node's state to down if a node error message is detected. The node health script continues to run at the configured interval (see [Configuring MOMs to launch a health check on page 2678](#) for more information), and if it does not generate the error message again during one of its later executions, Moab picks that up at the beginning of its next iteration and restores the node to an online state.

## Related topics

- [Compute node health check on page 2677](#)

## Example health check script

As mentioned, the health check can be a shell script, PERL, Python, C-executable, or anything which can be executed from the command line capable of setting STDOUT. The example below demonstrates a very simple health check:

```
#!/bin/sh
/bin/mount | grep global
if [ $? != "0" ]
then
echo "ERROR cannot locate filesystem global"
fi
```

## Debugging

TORQUE supports a number of diagnostic and debug options including the following:

*PBSDEBUG* environment variable - If set to 'yes', this variable will prevent *pbs\_server*, *pbs\_mom*, and/or *pbs\_sched* from backgrounding themselves allowing direct launch under a debugger. Also, some client commands will provide additional diagnostic information when this value is set.

*PBSLOGLEVEL* environment variable - Can be set to any value between 0 and 7 and specifies the logging verbosity level (default = 0)

*PBSCOREDUMP* environment variable - If set, it will cause the offending resource manager daemon to create a core file if a *SIGSEGV*, *SIGILL*, *SIGFPE*, *SIGSYS*, or *SIGTRAP* signal is received. The core dump will be placed in the daemon's home directory (*\$PBSHOME/mom\_priv* for *pbs\_mom* and *\$PBSHOME/server\_priv* for *pbs\_server*).

**i** To enable core dumping in a Red Hat system, you must add the following line to the `/etc/init.d/pbs_mom` and `/etc/init.d/pbs_server` scripts:

```
export DAEMON_COREFILE_LIMIT=unlimited
```

`NDEBUG #define` - if set at build time, will cause additional low-level logging information to be output to stdout for `pbs_server` and `pbs_mom` daemons.

`tracejob` reporting tool - can be used to collect and report logging and accounting information for specific jobs (for more information, see [Using "tracejob" to locate job failures on page 2668](#)).

**i** `PBSLOGLEVEL` and `PBSCOREDUMP` must be added to the `$PBSHOME/pbs_environment` file, not just the current environment. To set these variables, add a line to the `pbs_environment` file as either "variable=value" or just "variable". In the case of "variable=value", the environment variable is set up as the value specified. In the case of "variable", the environment variable is set based upon its value in the current environment.

## TORQUE error codes

Error code name	Number	Description
<b>PBSE_FLOOR</b>	15000	No error
<b>PBSE_UNKJOBID</b>	15001	Unknown job identifier
<b>PBSE_NOATTR</b>	15002	Undefined attribute
<b>PBSE_ATTRRO</b>	15003	Attempt to set READ ONLY attribute
<b>PBSE_IVALREQ</b>	15004	Invalid request
<b>PBSE_UNKREQ</b>	15005	Unknown batch request
<b>PBSE_TOOMANY</b>	15006	Too many submit retries
<b>PBSE_PERM</b>	15007	No permission
<b>PBSE_IFF_NOT_FOUND</b>	15008	"pbs_iff" not found; unable to authenticate
<b>PBSE_MUNGE_NOT_FOUND</b>	15009	"munge" executable not found; unable to authenticate
<b>PBSE_BADHOST</b>	15010	Access from host not allowed

Error code name	Number	Description
<b>PBSE_JOBEXIST</b>	15011	Job already exists
<b>PBSE_SYSTEM</b>	15012	System error occurred
<b>PBSE_INTERNAL</b>	15013	Internal server error occurred
<b>PBSE_REGROUTE</b>	15014	Parent job of dependent in rte queue
<b>PBSE_UNKSIG</b>	15015	Unknown signal name
<b>PBSE_BADATVAL</b>	15016	Bad attribute value
<b>PBSE_MODATRRUN</b>	15017	Cannot modify attribute in run state
<b>PBSE_BADSTATE</b>	15018	Request invalid for job state
<b>PBSE_UNKQUE</b>	15020	Unknown queue name
<b>PBSE_BADCRED</b>	15021	Invalid credential in request
<b>PBSE_EXPIRED</b>	15022	Expired credential in request
<b>PBSE_QUNOENB</b>	15023	Queue not enabled
<b>PBSE_QACCESS</b>	15024	No access permission for queue
<b>PBSE_BADUSER</b>	15025	Bad user - no password entry
<b>PBSE_HOPCOUNT</b>	15026	Max hop count exceeded
<b>PBSE_QUEEXIST</b>	15027	Queue already exists
<b>PBSE_ATTRRYPE</b>	15028	Incompatible queue attribute type
<b>PBSE_QUEBUSY</b>	15029	Queue busy (not empty)
<b>PBSE_QUENBIG</b>	15030	Queue name too long
<b>PBSE_NOSUP</b>	15031	Feature/function not supported

Error code name	Number	Description
<b>PBSE_QUENOEN</b>	15032	Cannot enable queue,needs add def
<b>PBSE_PROTOCOL</b>	15033	Protocol (ASN.1) error
<b>PBSE_BADATLST</b>	15034	Bad attribute list structure
<b>PBSE_NOCONNECTS</b>	15035	No free connections
<b>PBSE_NOSERVER</b>	15036	No server to connect to
<b>PBSE_UNKRESC</b>	15037	Unknown resource
<b>PBSE_EXCQRESC</b>	15038	Job exceeds queue resource limits
<b>PBSE_QUENODFLT</b>	15039	No default queue defined
<b>PBSE_NORERUN</b>	15040	Job not rerunnable
<b>PBSE_ROUTEREJ</b>	15041	Route rejected by all destinations
<b>PBSE_ROUTEEXPD</b>	15042	Time in route queue expired
<b>PBSE_MOMREJECT</b>	15043	Request to MOM failed
<b>PBSE_BADSCRIPT</b>	15044	(qsub) Cannot access script file
<b>PBSE_STAGEIN</b>	15045	Stage-In of files failed
<b>PBSE_RESCUNAV</b>	15046	Resources temporarily unavailable
<b>PBSE_BADGRP</b>	15047	Bad group specified
<b>PBSE_MAXQUED</b>	15048	Max number of jobs in queue
<b>PBSE_CKPBYSY</b>	15049	Checkpoint busy, may be retries
<b>PBSE_EXLIMIT</b>	15050	Limit exceeds allowable
<b>PBSE_BADACCT</b>	15051	Bad account attribute value

Error code name	Number	Description
<b>PBSE_ALRDYEXIT</b>	15052	Job already in exit state
<b>PBSE_NOCOPYFILE</b>	15053	Job files not copied
<b>PBSE_CLEANEOUT</b>	15054	Unknown job id after clean init
<b>PBSE_NOSYNCMSTR</b>	15055	No master in sync set
<b>PBSE_BADDEPEND</b>	15056	Invalid dependency
<b>PBSE_DUPLIST</b>	15057	Duplicate entry in list
<b>PBSE_DISPROTO</b>	15058	Bad DIS based request protocol
<b>PBSE_EXECTHERE</b>	15059	Cannot execute there
<b>PBSE_SISREJECT</b>	15060	Sister rejected
<b>PBSE_SISCOMM</b>	15061	Sister could not communicate
<b>PBSE_SVRDOWN</b>	15062	Requirement rejected -server shutting down
<b>PBSE_CKPSHORT</b>	15063	Not all tasks could checkpoint
<b>PBSE_UNKNODE</b>	15064	Named node is not in the list
<b>PBSE_UNKNODEATR</b>	15065	Node-attribute not recognized
<b>PBSE_NONODES</b>	15066	Server has no node list
<b>PBSE_NODENBIG</b>	15067	Node name is too big
<b>PBSE_NODEEXIST</b>	15068	Node name already exists
<b>PBSE_BADNDATVAL</b>	15069	Bad node-attribute value
<b>PBSE_MUTUALEX</b>	15070	State values are mutually exclusive
<b>PBSE_GMODERR</b>	15071	Error(s) during global modification of nodes

Error code name	Number	Description
<b>PBSE_NORELYMOM</b>	15072	Could not contact MOM
<b>PBSE_NOTSNODE</b>	15073	No time-shared nodes
<b>PBSE_JOBTYPE</b>	15074	Wrong job type
<b>PBSE_BADACLHOST</b>	15075	Bad ACL entry in host list
<b>PBSE_MAXUSERQUED</b>	15076	Maximum number of jobs already in queue for user
<b>PBSE_BADDISALLOWTYPE</b>	15077	Bad type in "disallowed_types" list
<b>PBSE_NOINTERACTIVE</b>	15078	Interactive jobs not allowed in queue
<b>PBSE_NOBATCH</b>	15079	Batch jobs not allowed in queue
<b>PBSE_NORERUNABLE</b>	15080	Rerunable jobs not allowed in queue
<b>PBSE_NONONRERUNABLE</b>	15081	Non-rerunable jobs not allowed in queue
<b>PBSE_UNKARRAYID</b>	15082	Unknown array ID
<b>PBSE_BAD_ARRAY_REQ</b>	15083	Bad job array request
<b>PBSE_TIMEOUT</b>	15084	Time out
<b>PBSE_JOBNOTFOUND</b>	15085	Job not found
<b>PBSE_NOFAULTTOLERANT</b>	15086	Fault tolerant jobs not allowed in queue
<b>PBSE_NOFAULTINTOLERANT</b>	15087	Only fault tolerant jobs allowed in queue
<b>PBSE_NOJOBARRAYS</b>	15088	Job arrays not allowed in queue
<b>PBSE_RELAYED_TO_MOM</b>	15089	Request was relayed to a MOM
<b>PBSE_MEM_MALLOC</b>	15090	Failed to allocate memory for memmgr
<b>PBSE_MUTEX</b>	15091	Failed to allocate controlling mutex (lock/unlock)

Error code name	Number	Description
<b>PBSE_TRHEADATTR</b>	15092	Failed to set thread attributes
<b>PBSE_THREAD</b>	15093	Failed to create thread
<b>PBSE_SELECT</b>	15094	Failed to select socket
<b>PBSE_SOCKET_FAULT</b>	15095	Failed to get connection to socket
<b>PBSE_SOCKET_WRITE</b>	15096	Failed to write data to socket
<b>PBSE_SOCKET_READ</b>	15097	Failed to read data from socket
<b>PBSE_SOCKET_CLOSE</b>	15098	Socket closed
<b>PBSE_SOCKET_LISTEN</b>	15099	Failed to listen in on socket
<b>PBSE_AUTH_INVALID</b>	15100	Invalid auth type in request
<b>PBSE_NOT_IMPLEMENTED</b>	15101	Functionality not yet implemented
<b>PBSE_QUEENOTAVAILABLE</b>	15102	Queue is not available

## Appendix A: Commands overview

### Client commands

Command	Description
<a href="#"><u>momctl</u></a>	Manage/diagnose MOM (node execution) daemon
<a href="#"><u>pbsdsh</u></a>	Launch tasks within a parallel job
<a href="#"><u>pbsnodes</u></a>	View/modify batch status of compute nodes
<a href="#"><u>qalter</u></a>	Modify queued batch jobs
<a href="#"><u>qchkpt</u></a>	Checkpoint batch jobs
<a href="#"><u>qdel</u></a>	Delete/cancel batch jobs
<a href="#"><u>qgpumode</u></a>	Specifies new mode for GPU
<a href="#"><u>qgpureset</u></a>	Reset the GPU
<a href="#"><u>qhold</u></a>	Hold batch jobs
<a href="#"><u>qmgr</u></a>	Manage policies and other batch configuration
<a href="#"><u>qmove on page 2729</u></a>	Move batch jobs

Command	Description
<a href="#">qorder</a> on page 2730	Exchange order of two batch jobs in any queue
<a href="#">qrerun</a>	Rerun a batch job
<a href="#">qrls</a>	Release batch job holds
<a href="#">qrun</a>	Start a batch job
<a href="#">qsig</a>	Send a signal to a batch job
<a href="#">qstat</a>	View queues and jobs
<a href="#">qsub</a>	Submit jobs
<a href="#">qterm</a>	Shutdown pbs server daemon
<b>tracejob</b>	Trace job actions and states recorded in TORQUE logs (see <a href="#">Using "tracejob" to locate job failures</a> on page 2668)

## Binary executables

Command	Description
<b>pbs_iff</b>	Interprocess authentication service
<a href="#">pbs_mom</a>	Start MOM (node execution) daemon
<a href="#">pbs_server</a>	Start server daemon
<a href="#">pbs_track</a>	Tell pbs_mom to track a new process

## momctl

(PBS MOM Control)

## Synopsis

```

momctl -c { <JOBID> | all }
momctl -C
momctl -d { <INTEGER> | <JOBID> }
momctl -f <FILE>
momctl -h <HOST>[,<HOST>]...
momctl -p <PORT NUMBER>
momctl -q <ATTRIBUTE>
momctl -r { <FILE> | LOCAL:<FILE> }
momctl -s

```

## Overview

The `momctl` command allows remote shutdown, reconfiguration, diagnostics, and querying of the `pbs_mom` daemon.

## Format

<b>-c — Clear</b>	
<b>Format</b>	{ <JOBID>   <i>all</i> }
<b>Default</b>	---
<b>Description</b>	Makes the MOM unaware of the job's existence. It does not clean up any processes associated with the job.
<b>Example</b>	<code>momctl - node1 -c 15406</code>

<b>-C — Cycle</b>	
<b>Format</b>	---
<b>Default</b>	---
<b>Description</b>	Cycle <code>pbs_mom(s)</code>
<b>Example</b>	<code>momctl - node1 -C</code> Cycle <code>pbs_mom</code> on node1.

<b>-d — Diagnose</b>	
<b>Format</b>	{ <INTEGER>   <JOBID> }
<b>Default</b>	0
<b>Description</b>	Diagnose MOM(s) (For more details, see <a href="#">Diagnose detail on page 2692</a> below.)
<b>Example</b>	<pre>momctl - node1 -d 2</pre> Print level 2 and lower diagnose information for the MOM on node1.

<b>-f — Host File</b>	
<b>Format</b>	<FILE>
<b>Default</b>	---
<b>Description</b>	A file containing only comma or whitespace (space, tab, or new line) delimited hostnames
<b>Example</b>	<pre>momctl -f hosts.txt -d</pre> Print diagnose information for the MOMs running on the hosts specified in <code>hosts.txt</code> .

<b>-h — Host List</b>	
<b>Format</b>	<HOST>[,<HOST>]..
<b>Default</b>	localhost
<b>Description</b>	A comma separated list of hosts
<b>Example</b>	<pre>momctl -h node1,node2,node3 -d</pre> Print diagnose information for the MOMs running on node1, node2, and node3.

<b>-p — Port</b>	
<b>Format</b>	<PORT_NUMBER>

**-p — Port**

<b>Default</b>	TORQUE's default port number
<b>Description</b>	The port number for the specified MOM(s)
<b>Example</b>	<pre>momctl -p 5455 -h node1 -d</pre> <p>Request diagnose information over port 5455 on node1.</p>

**-q — Query**

<b>Format</b>	<ATTRIBUTE>
<b>Default</b>	---
<b>Description</b>	Query <ATTRIBUTE> on specified MOM, where <ATTRIBUTE> is a property listed by <a href="#">pbsnodes -a</a> (see <a href="#">Query attributes on page 2691</a> for a list of attributes)
<b>Example</b>	<pre>momctl -q phymem</pre> <p>Print the amount of phymem on localhost.</p>

**-r — Reconfigure**

<b>Format</b>	{ <FILE>   LOCAL:<FILE> }
<b>Default</b>	---
<b>Description</b>	Reconfigure MOM(s) with remote or local config file, <FILE>. This does not work if \$remote_reconf is not set to true when the MOM is started.
<b>Example</b>	<pre>momctl -r /home/user1/new.config -h node1</pre> <p>Reconfigure MOM on node1 with /home/user1/new.cofig on node1.</p>

**-s — Shutdown**

<b>Format</b>	
<b>Default</b>	---

<b>-s — Shutdown</b>	
<b>Description</b>	Shutdown pbs_mom
<b>Example</b>	<pre>momctl -s</pre> Terminates pbs_mom process on localhost.

## Query attributes

<b>Attribute</b>	<b>Description</b>
<b>arch</b>	node hardware architecture
<b>availmem</b>	available RAM
<b>loadave</b>	1 minute load average
<b>ncpus</b>	number of CPUs available on the system
<b>netload</b>	total number of bytes transferred over all network interfaces
<b>nsessions</b>	number of sessions active
<b>nusers</b>	number of users active
<b>physmem</b>	configured RAM
<b>sessions</b>	list of active sessions
<b>totmem</b>	configured RAM plus configured swap

## Diagnose detail

Level	Description
0	<p>Display the following information:</p> <ul style="list-style-type: none"> <li>• Local hostname</li> <li>• Expected server hostname</li> <li>• Execution version</li> <li>• MOM home directory</li> <li>• MOM config file version (if specified)</li> <li>• Duration MOM has been executing</li> <li>• Duration since last request from pbs_server daemon</li> <li>• Duration since last request to pbs_server daemon</li> <li>• RM failure messages (if any)</li> <li>• Log verbosity level</li> <li>• Local job list</li> </ul>
1	<p>All information for level 0 plus the following:</p> <ul style="list-style-type: none"> <li>• Interval between updates sent to server</li> <li>• Number of initialization messages sent to pbs_server daemon</li> <li>• Number of initialization messages received from pbs_server daemon</li> <li>• Prolog/epilog alarm time</li> <li>• List of trusted clients</li> </ul>
2	<p>All information from level 1 plus the following:</p> <ul style="list-style-type: none"> <li>• PID</li> <li>• Event alarm status</li> </ul>
3	<p>All information from level 2 plus the following:</p> <ul style="list-style-type: none"> <li>• syslog enabled</li> </ul>

**Example 4-27: MOM diagnostics**

```

momctl -d 1

Host: nsrc/nsrc.fllcl.com      Server: 10.10.10.113      Version: torque_1.1.0p4
HomeDirectory:                /usr/spool/PBS/mom_priv
ConfigVersion:                147
MOM active:                   7390 seconds
Last Msg From Server:        7389 seconds (CLUSTER_ADDRS)
Server Update Interval:      20 seconds
Server Update Interval:      20 seconds
Init Msgs Received:          0 hellos/1 cluster-addr
Init Msgs Sent:              1 hellos
LOGLEVEL:                    0 (use SIGUSR1/SIGUSR2 to adjust)
Prolog Alarm Time:           300 seconds
Trusted Client List:         12.14.213.113,127.0.0.1
JobList:                     NONE

diagnostics complete

```

**Example 4-28: System shutdown**

```

> momctl -s -f /opt/clusterhostfile

shutdown request successful on node001
shutdown request successful on node002
shutdown request successful on node003
shutdown request successful on node004
shutdown request successful on node005
shutdown request successful on node006

```

## pbs\_mom

Start a pbs batch execution mini-server.

### Synopsis

```

pbs_mom [-a alarm] [-A alias] [-C chkdiritory] [-c config] [-d directory] [-h
hostname]
[-L logfile] [-M MOMport] [-R RPPport] [-p|-r] [-P purge] [-w] [-x]

```

### Description

The `pbs_mom` command is located within the `TORQUE_HOME` directory and starts the operation of a batch Machine Oriented Mini-server (MOM) on the execution host. To ensure that the `pbs_mom` command is not runnable by the general user community, the server will only execute if its real and effective uid is zero.

The first function of `pbs_mom` is to place jobs into execution as directed by the server, establish resource usage limits, monitor the job's usage, and notify the server when the job completes. If they exist, `pbs_mom` will execute a prologue script before executing a job and an epilogue script after executing the job.

The second function of `pbs_mom` is to respond to resource monitor requests. This was done by a separate process in previous versions of PBS but has now been combined into one process. It provides information about the status of running jobs, memory available, etc.

The last function of `pbs_mom` is to respond to task manager requests. This involves communicating with running tasks over a TCP socket as well as communicating with other MOMs within a job (a.k.a. a "sisterhood").

`pbs_mom` will record a diagnostic message in a log file for any error occurrence. The log files are maintained in the `mom_logs` directory below the home directory of the server. If the log file cannot be opened, the diagnostic message is written to the system console.

## Options

Flag	Name	Description
<b>-a</b>	alarm	Used to specify the alarm timeout in seconds for computing a resource. Every time a resource request is processed, an alarm is set for the given amount of time. If the request has not completed before the given time, an alarm signal is generated. The default is 5 seconds.
<b>-A</b>	alias	Used to specify this multimom's alias name. The alias name needs to be the same name used in the <code>mom.hierarchy</code> file. It is only needed when running multiple MOMs on the same machine. For more information, see <a href="#">TORQUE Multi-MOM on page 2580</a> .
<b>-C</b>	chkdirectory	Specifies The path of the directory used to hold checkpoint files. (Currently this is only valid on Cray systems.) The default directory is <code>TORQUE_HOME/spool/checkpoint</code> (see the <b>-d</b> option). The directory specified with the <b>-C</b> option must be owned by root and accessible (rwx) only by root to protect the security of the checkpoint files.
<b>-c</b>	config	Specifies an alternative configuration file, see description below. If this is a relative file name it will be relative to <code>TORQUE_HOME/mom_priv</code> , (see the <b>-d</b> option). If the specified file cannot be opened, <code>pbs_mom</code> will abort. If the <b>-C</b> option is not supplied, <code>pbs_mom</code> will attempt to open the default configuration file "config" in <code>TORQUE_HOME/mom_priv</code> . If this file is not present, <code>pbs_mom</code> will log the fact and continue.
<b>-d</b>	directory	Specifies the path of the directory which is the home of the server's working files, <code>TORQUE_HOME</code> . This option is typically used along with <b>-M</b> when debugging MOM. The default directory is given by <code>\$PBS_SERVER_HOME</code> which is typically <code>/usr/spool/PBS</code> .
<b>-h</b>	hostname	Set MOM's hostname. This can be useful on multi-homed networks.
<b>-L</b>	logfile	Specify an absolute path name for use as the log file. If not specified, MOM will open a file named for the current date in the <code>TORQUE_HOME/mom_logs</code> directory (see the <b>-d</b> option).
<b>-M</b>	port	Specifies the port number on which the mini-server (MOM) will listen for batch requests.

Flag	Name	Description
<b>-p</b>	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. On any restart of MOM, the new mini-server will not be the parent of any running jobs, MOM has lost control of her offspring (not a new situation for a mother). With the <b>-p</b> option, MOM will allow the jobs to continue to run and monitor them indirectly via polling. This flag is redundant in that this is the default behavior when starting the server. The <b>-p</b> option is mutually exclusive with the <b>-R</b> and <b>-q</b> options.
<b>-P</b>	purge	Specifies the impact on jobs which were in execution when the mini-server shut down. With the <b>-P</b> option, it is assumed that either the entire system has been restarted or the MOM has been down so long that it can no longer guarantee that the pid of any running process is the same as the recorded job process pid of a recovering job. Unlike the <b>-p</b> option, no attempt is made to try and preserve or recover running jobs. All jobs are terminated and removed from the queue.
<b>-q</b>	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. With the <b>-q</b> option, MOM will allow the processes belonging to jobs to continue to run, but will not attempt to monitor them. The <b>-q</b> option is mutually exclusive with the <b>-p</b> and <b>-R</b> options.
<b>-R</b>	port	Specifies the port number on which the mini-server (MOM) will listen for resource monitor requests, task manager requests and inter-MOM messages. Both a UDP and a TCP port of this number will be used.
<b>-r</b>	n/a	Specifies the impact on jobs which were in execution when the mini-server shut down. With the <b>-r</b> option, MOM will kill any processes belonging to jobs, mark the jobs as terminated, and notify the batch server which owns the job. The <b>-r</b> option is mutually exclusive with the <b>-p</b> and <b>-q</b> options.  Normally the mini-server is started from the system boot file without the <b>-p</b> or the <b>-r</b> option. The mini-server will make no attempt to signal the former session of any job which may have been running when the mini-server terminated. It is assumed that on reboot, all processes have been killed. If the <b>-r</b> option is used following a reboot, process IDs (pids) may be reused and MOM may kill a process that is not a batch session.
<b>-w</b>	wait_for_server	When started with <b>-w</b> , pbs_moms wait until they get their MOM hierarchy file from <a href="#">pbs_server</a> to send their first update, or until 10 minutes pass. This reduces network traffic on startup and can bring up clusters faster.
<b>-x</b>	n/a	Disables the check for privileged port resource monitor connections. This is used mainly for testing since the privileged port is the only mechanism used to prevent any ordinary user from connecting.

## Configuration file

The configuration file, located at `mom_priv/config` by default, can be specified on the command line at program start with the `-C` flag. The use of this file is to provide several types of run time information to `pbs_mom`: static resource names and values, external resources provided by a program to be run on request via a shell escape, and values to pass to internal set up functions at initialization (and re-initialization).

See the [Parameters on page 2784](#) page for a full list of `pbs_mom` parameters.

Each item type is on a single line with the component parts separated by white space. If the line starts with a hash mark (pound sign, #), the line is considered to be a comment and is skipped.

### *Static Resources*

For static resource names and values, the configuration file contains a list of resource names/values pairs, one pair per line and separated by white space. An example of static resource names and values could be the number of tape drives of different types and could be specified by:

- tape3480 4
- tape3420 2
- tapedat 1
- tape8mm 1

### *Shell Commands*

If the first character of the value is an exclamation mark (!), the entire rest of the line is saved to be executed through the services of the `system(3)` standard library routine.

The shell escape provides a means for the resource monitor to yield arbitrary information to the scheduler. Parameter substitution is done such that the value of any qualifier sent with the query, as explained below, replaces a token with a percent sign (%) followed by the name of the qualifier. For example, here is a configuration file line which gives a resource name of "escape":

```
escape !echo %xxx %yyy
```

If a query for "escape" is sent with no qualifiers, the command executed would be `echo %xxx %yyy`.

If one qualifier is sent, `escape[xxx=hi there]`, the command executed would be `echo hi there %yyy`.

If two qualifiers are sent, `escape[xxx=hi][yyy=there]`, the command executed would be `echo hi there`.

If a qualifier is sent with no matching token in the command line, `escape[zzz=snafu]`, an error is reported.

## Resources

Resource Manager queries can be made with `momctl -q` options to retrieve and set `pbs_mom` options. Any configured static resource may be retrieved with a request of the same name. These are resource requests not otherwise documented in the PBS ERS.

Request	Description
<b>cycle</b>	Forces an immediate MOM cycle.
<b>status_update_time</b>	Retrieve or set the \$status_update_time parameter.
<b>check_poll_time</b>	Retrieve or set the \$check_poll_time parameter.
<b>configversion</b>	Retrieve the config version.
<b>jobstartblocktime</b>	Retrieve or set the \$jobstartblocktime parameter.
<b>enablemomrestart</b>	Retrieve or set the \$enablemomrestart parameter.
<b>loglevel</b>	Retrieve or set the \$loglevel parameter.
<b>down_on_error</b>	Retrieve or set the EXPERIMENTAL \$down_on_error parameter.
<b>diag0 - diag4</b>	Retrieves varied diagnostic information.
<b>rcpcmd</b>	Retrieve or set the \$rcpcmd parameter.
<b>version</b>	Retrieves the pbs_mom version.

## Health check

The health check script is executed directly by the pbs\_mom daemon under the root user id. It must be accessible from the compute node and may be a script or compiled executable program. It may make any needed system calls and execute any combination of system utilities but should not execute resource manager client commands. Also, the pbs\_mom daemon blocks until the health check is completed and does not possess a built-in timeout. Consequently, it is advisable to keep the launch script execution time short and verify that the script will not block even under failure conditions.

If the script detects a failure, it should return the keyword "Error" to `stdout` followed by an error message. The message (up to 256 characters) immediately following the Error string will be assigned to the node attribute message of the associated node.

If the script detects a failure when run from "jobstart", then the job will be rejected. You can use this behavior with an advanced scheduler, such as Moab Workload Manager, to cause the job to be routed to another node. TORQUE currently ignores Error messages by default, but you can configure an advanced scheduler to react appropriately.

If the experimental \$down\_on\_error MOM setting is enabled, the MOM will set itself to state down and report to pbs\_server. Additionally, the experimental \$down\_on\_error server attribute can be enabled which has the same effect but moves the decision to pbs\_server. It is redundant to have MOM's

`$down_on_error` and `pbs_servers down_on_error` features enabled. See "down\_on\_error" in `pbs_server_attributes(7B)`.

## Files

File	Description
<code>\$PBS_SERVER_HOME/server_name</code>	Contains the hostname running <code>pbs_server</code>
<code>\$PBS_SERVER_HOME/mom_priv</code>	The default directory for configuration files, typically <code>(/usr/spool/pbs)/mom_priv</code>
<code>\$PBS_SERVER_HOME/mom_logs</code>	Directory for log files recorded by the server
<code>\$PBS_SERVER_HOME/mom_priv/-prologue</code>	The administrative script to be run before job execution
<code>\$PBS_SERVER_HOME/mom_priv/e-epilogue</code>	The administrative script to be run after job execution

## Signal handling

`pbs_mom` handles the following signals:

Signal	Description
<b>SIGHUP</b>	Causes <code>pbs_mom</code> to re-read its configuration file, close and reopen the log file, and reinitialize resource structures.
<b>SIGALRM</b>	Results in a log file entry. The signal is used to limit the time taken by certain children processes, such as the prologue and epilogue.
<b>SIGINT and SIGTERM</b>	Results in <code>pbs_mom</code> exiting without terminating any running jobs. This is the action for the following signals as well: <code>SIGXCPU</code> , <code>SIGXFSZ</code> , <code>SIGCPULIM</code> , and <code>SIGSHUTDN</code> .
<b>SIGUSR1, SIGUSR2</b>	Causes the MOM to increase and decrease logging levels, respectively.
<b>SIGPIPE, SIGINFO</b>	Are ignored.
<b>SIGBUS, SIGFPE, SIGILL, SIGTRAP, and SIGSYS</b>	Cause a core dump if the <code>PBSCOREDUMP</code> environmental variable is defined.

All other signals have their default behavior installed.

## Exit status

If the `pbs_mom` command fails to begin operation, the server exits with a value greater than zero.

## pbs\_server

(*PBS Server*) pbs batch system manager

### Synopsis

```
pbs_server [-a active] [-c] [-d config_path] [-f force overwrite] [-p port] [-A acctfile]
[-l location] [-L logfile] [-S scheduler_port]
[-h hostname] [-t type] [--ha]
[-n don't send hierarchy] [--about] [-v] [--version]
```

### Description

The `pbs_server` command starts the operation of a batch server on the local host. Typically, this command will be in a local boot file such as `/etc/rc.local`. If the batch server is already in execution, `pbs_server` will exit with an error. To ensure that the `pbs_server` command is not runnable by the general user community, the server will only execute if its real and effective uid is zero.

The server will record a diagnostic message in a log file for any error occurrence. The log files are maintained in the `server_logs` directory below the home directory of the server. If the log file cannot be opened, the diagnostic message is written to the system console.

As of TORQUE 4.0, the `pbs_server` is multi-threaded which leads to quicker response to client commands, is more robust, and allows for higher job throughput.

## Options

Option	Name	Description
<b>-A</b>	acctfile	Specifies an absolute path name of the file to use as the accounting file. If not specified, the file name will be the current date in the <code>PBS_HOME/server_priv/accounting</code> directory.
<b>-a</b>	active	Specifies if scheduling is active or not. This sets the server attribute <code>scheduling</code> . If the option argument is "true" ("True", "t", "T", or "1"), the server is active and the PBS job scheduler will be called. If the argument is "false" ("False", "f", "F", or "0"), the server is idle, and the scheduler will not be called and no jobs will be run. If this option is not specified, the server will retain the prior value of the scheduling attribute.
<b>-c</b>	wait_for_moms	This directs <code>pbs_server</code> to send the MOM hierarchy only to MOMs that request it for the first 10 minutes. After 10 minutes, it attempts to send the MOM hierarchy to MOMs that haven't requested it already. This greatly reduces traffic on start up.
<b>-d</b>	config_directory	Specifies the path of the directory which is home to the server's configuration files, <code>PBS_HOME</code> . A host may have multiple servers. Each server must have a different configuration directory. The default configuration directory is given by the symbol <code>\$PBS_SERVER_HOME</code> which is typically <code>var/spool/torque</code> .
<b>-f</b>	force overwrite	Forces an overwrite of the server database. This can be useful to bypass the <code>yes/no</code> prompt when running something like <code>pbs_server -t create</code> and can ease installation and configuration of TORQUE via scripts.
<b>-h</b>	hostname	Causes the server to start under a different hostname as obtained from <code>gethostname(2)</code> . Useful for servers with multiple network interfaces to support connections from clients over an interface that has a hostname assigned that differs from the one that is returned by <code>gethostname(2)</code> .
<b>--ha</b>	high_availability	Starts server in high availability mode (for details, see <a href="#">Server high availability on page 2640</a> ).
<b>-L</b>	logfile	Specifies an absolute path name of the file to use as the log file. If not specified, the file will be the current date in the <code>PBS_HOME/server_logs</code> directory (see the <a href="#">-d</a> option).
<b>-l</b>	location	Specifies where to find Moab when it does not reside on the same host as TORQUE.
<b>-n</b>	no send	This directs <code>pbs_server</code> to not send the hierarchy to all the MOMs on startup. Instead, the hierarchy is only sent if a MOM requests it. This flag works only in conjunction with the <a href="#">local MOM hierarchy</a> feature.

Option	Name	Description
<b>-p</b>	port	Specifies the port number on which the server will listen for batch requests. If multiple servers are running on a single host, each must have its own unique port number. This option is for use in testing with multiple batch systems on a single host.
<b>-S</b>	scheduler_ port	Specifies the port number to which the server should connect when contacting the scheduler. The argument scheduler_conn is of the same syntax as under the -M option.
<b>-t</b>	type	<p>Specifies the impact on jobs which were in execution, running, when the server shut down. If the running job is not rerunnable or restartable from a checkpoint image, the job is aborted. If the job is rerunnable or restartable, then the actions described below are taken. When the type argument is:</p> <ul style="list-style-type: none"> <li>• <i>hot</i> – All jobs are queued except non-rerunnable jobs that were executing. Any rerunnable job which was executing when the server went down will be run immediately. This returns the server to the same state as when it went down. After those jobs are restarted, then normal scheduling takes place for all remaining queued jobs.</li> </ul> <p>If a job cannot be restarted immediately because of a missing resource, such as a node being down, the server will attempt to restart it periodically for up to 5 minutes. After that period, the server will revert to a normal state, as if warm started, and will no longer attempt to restart any remaining jobs which were running prior to the shutdown.</p> <ul style="list-style-type: none"> <li>• <i>warm</i> – All rerunnable jobs which were running when the server went down are queued. All other jobs are maintained. New selections are made for which jobs are placed into execution. Warm is the default if <i>-t</i> is not specified.</li> <li>• <i>cold</i> – All jobs are deleted. Positive confirmation is required before this direction is accepted.</li> <li>• <i>create</i> – The server will discard any existing configuration files, queues and jobs, and initialize configuration files to the default values. The server is idled.</li> </ul>

## Files

File	Description
<b>TORQUE_HOME/server_ priv</b>	Default directory for configuration files, typically /usr/spool/pbs/server_ priv
<b>TORQUE_HOME/server_ logs</b>	Directory for log files recorded by the server

## Signal handling

On receipt of the following signals, the server performs the defined action:

Action	Description
<b>SIGHUP</b>	The current server log and accounting log are closed and reopened. This allows for the prior log to be renamed and a new log started from the time of the signal.
<b>SIGINT</b>	Causes an orderly shutdown of pbs_server.
<b>SIGUSR1, SIGUSR2</b>	Causes server to increase and decrease logging levels, respectively.
<b>SIGTERM</b>	Causes an orderly shutdown of pbs_server.
<b>SIGSHUTDN</b>	On systems (Unicos) where SIGSHUTDN is defined, it also causes an orderly shutdown of the server.
<b>SIGPIPE</b>	This signal is ignored.

All other signals have their default behavior installed.

## Exit status

If the server command fails to begin batch operation, the server exits with a value greater than zero.

## pbs\_track

Starts a new process and informs pbs\_mom to start tracking it.

## Synopsis

```
pbs_track -j <JOBID> [-b] <executable> [args]
```

## Description

The `pbs_track` command tells a `pbs_mom` daemon to monitor the lifecycle and resource usage of the process that it launches using `exec()`. The `pbs_mom` is told about this new process via the Task Manager API, using `tm_adopt()`. The process must also be associated with a job that already exists on the `pbs_mom`.

By default, `pbs_track` will send its PID to TORQUE via `tm_adopt()`. It will then perform an `exec()`, causing `<executable>` to run with the supplied arguments. `pbs_track` will not return until the launched process has completed because it becomes the launched process.

This command can be considered related to the [pbsdsh](#) command which uses the `tm_spawn()` API call. The `pbsdsh` command asks a `pbs_mom` to launch and track a new process on behalf of a job. When it is not desirable or possible for the `pbs_mom` to spawn processes for a job, `pbs_track` can be used to allow an external entity to launch a process and include it as part of a job.

This command improves integration with TORQUE and SGI's MPT MPI implementation.

## Options

Option	Description
<b>-j</b> <b>&lt;JOBID&gt;</b>	Job ID the new process should be associated with.
<b>-b</b>	Instead of having <code>pbs_track</code> send its PID to TORQUE, it will <code>fork()</code> first, send the child PID to TORQUE, and then execute from the forked child. This essentially "backgrounds" <code>pbs_track</code> so that it will return after the new process is launched.

## Operands

The `pbs_track` command accepts a path to a program/executable (`<executable>`) and, optionally, one or more arguments to pass to that program.

## Exit status

Because the `pbs_track` command becomes a new process (if used without **-b**), its exit status will match that of the new process. If the **-b** option is used, the exit status will be zero if no errors occurred before launching the new process.

If `pbs_track` fails, whether due to a bad argument or other error, the exit status will be set to a non-zero value.

## pbsdsh

The `pbsdsh` command distributes tasks to nodes under `pbs`.

## Synopsis

```
pbsdsh [-c copies] [-o] [-s] [-u] [-v] program [args]
pbsdsh [-n node] [-o] [-s] [-u] [-v] program [args]
pbsdsh [-h nodename] [-o] [-v] program [args]
```

## Description

Executes (spawns) a normal Unix program on one or more nodes under control of the Portable Batch System, PBS. Pbsdsh uses the Task Manager API (see `tm_spawn(3)`) to distribute the program on the allocated nodes.

When run without the `-c` or the `-n` option, `pbsdsh` will spawn the program on all nodes allocated to the PBS job. The spawns take place concurrently – all execute at (about) the same time.

Users will find the `PBS_TASKNUM`, `PBS_NODENUM`, and the `PBS_VNODENUM` environmental variables useful. They contain the TM task id, the node identifier, and the `cpu` (virtual node) identifier.

**i** Note that under particularly high workloads, the `pbsdsh` command may not function properly.

## Options

Option	Name	Description
<code>-c</code>	<code>copies</code>	The program is spawned on the first <code>Copies</code> nodes allocated. This option is mutually exclusive with <code>-n</code> .
<code>-h</code>	<code>hostname</code>	The program is spawned on the node specified.
<code>-n</code>	<code>node</code>	The program is spawned on one node which is the <code>n</code> -th node allocated. This option is mutually exclusive with <code>-c</code> .
<code>-o</code>	<code>---</code>	Capture stdout of the spawned program. Normally stdout goes to the job's output.

Option	Name	Description
<b>-s</b>	---	If this option is given, the program is run in turn on each node, one after the other.
<b>-u</b>	---	The program is run once on each node (unique). This ignores the number of allocated processors on a given node.
<b>-v</b>	---	Verbose output about error conditions and task exit status is produced.

## Operands

The first operand, `program`, is the program to execute.

Additional operands are passed as arguments to the program.

## Standard error

The `pbsdsh` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the command, the exit status will be a value of zero.

If the `pbsdsh` command fails to process any operand, or fails to contact the MOM daemon on the localhost the command exits with a value greater than zero.

## pbsnodes

PBS node manipulation.

## Synopsis

```
pbsnodes [-{a|x}] [-q] [-s server] [node:property]
pbsnodes -l [-q] [-s server] [state] [nodename:property ...]
pbsnodes -m <running|standby|suspend|hibernate|shutdown> <host list>
pbsnodes [-{c|d|o|r}] [-q] [-s server] [-n -l] [-N "note"] [node:property]
```

## Description

The `pbsnodes` command is used to mark nodes down, free or offline. It can also be used to list nodes and their state. Node information is obtained by sending a request to the PBS job server. Sets of nodes can be operated on at once by specifying a node property prefixed by a colon. (For more information, see Node states.)

Nodes do not exist in a single state, but actually have a set of states. For example, a node can be simultaneously "busy" and "offline". The "free" state is the absence of all other states and so is never combined with other states.

In order to execute `pbsnodes` with other than the `-a` or `-l` options, the user must have PBS Manager or Operator privilege.

## Options

	Description
-a	All attributes of a node or all nodes are listed. This is the default if no flag is given.
-x	Same as <code>-a</code> , but the output has an XML-like format.
-c	Clear OFFLINE from listed nodes.
-C	Print MOM diagnosis on the listed nodes. Not yet implemented. Use <code>momctl</code> instead.

## Description

- Set the hosts in the specified host list to the requested power state. If a compute node does not support the energy-saving power state you request, the command returns an error and leaves the state unchanged. In order for the command to wake a node from a low-power state, Wake-on-LAN (WOL) must be enabled for the node.

**i** In order for the command to wake a node from a low-power state, Wake-on-LAN must be enabled for the node and it must support the `g` WOL packet. For more information, see [Changing node power states](#) on page 2619.

The allowable power states are:

- **Running:** The node is up and running.
- **Standby:** CPU is halted but still powered. Moderate power savings but low latency entering and leaving this state.
- **Suspend:** Also known as Suspend-to-RAM. Machine state is saved to RAM. RAM is put into self-refresh mode. Much more significant power savings with longer latency entering and leaving state.
- **Hibernate:** Also known as Suspend-to-disk. Machine state is saved to disk and then powered down. Significant power savings but very long latency entering and leaving state.
- **Shutdown:** Equivalent to `shutdown now` command as root.

The host list is a space-delimited list of node host names.

## Description

```
pbsnodes -m shutdown node01 node02 node03 node04
```

*With this command, pbs\_server tells the pbs\_mom associated with nodes01-04 to shut down the node.*

The `pbsnodes` output shows the current power state of nodes. In this example, note that `pbsnodes` returns the MAC addresses of the nodes.

```
pbsnodes
nuc1

```

- Add the OFFLINE state. This is different from being marked DOWN. OFFLINE prevents new jobs from running on the specified nodes. This gives the administrator a tool to hold a node out of service without changing anything else. The OFFLINE state will never be set or cleared automatically by `pbs_server`; it is purely for the manager or operator.
- Purge the node record from `pbs_server`. Not yet implemented.
- Reset the listed nodes by clearing OFFLINE and adding DOWN state. `pbs_server` will ping the node and, if they communicate correctly, free the node.

	Description
I	<ul style="list-style-type: none"> <li>- List node names and their state. If no state is specified, only nodes in the DOWN, OFFLINE, or UNKNOWN states are listed. Specifying a state string acts as an output filter. Valid state strings are "active", "all", "busy", "down", "free", "job-exclusive", "job-sharing", "offline", "reserve", "state-unknown", "time-shared", and "up". <ul style="list-style-type: none"> <li>• Using <i>all</i> displays all nodes and their attributes.</li> <li>• Using <i>active</i> displays all nodes which are job-exclusive, job-sharing, or busy.</li> <li>• Using <i>up</i> displays all nodes in an "up state". Up states include job-exclusive, job-sharing, reserve, free, busy and time-shared.</li> <li>• All other strings display the nodes which are currently in the state indicated by the string.</li> </ul> </li> </ul>
M	<ul style="list-style-type: none"> <li>- Specify a "note" attribute. This allows an administrator to add an arbitrary annotation to the listed nodes. To clear a note, use <code>-N ""</code> or <code>-N n</code>.</li> </ul>
I	<ul style="list-style-type: none"> <li>- Show the "note" attribute for nodes that are DOWN, OFFLINE, or UNKNOWN. This option requires <a href="#">-l</a>.</li> </ul>
C	<ul style="list-style-type: none"> <li>- Suppress all error messages.</li> </ul>
s	<ul style="list-style-type: none"> <li>- Specify the PBS server's hostname or IP address.</li> </ul>

## qalter

Alter batch job.

### Synopsis

```
qalter [-a date_time] [-A account_string] [-c interval] [-e path_name]
[-h hold_list] [-j join_list] [-k keep_list] [-l resource_list]
[-m mail_options] [-M mail_list] [-n] [-N name] [-o path_name]
[-p priority] [-r y|n] [-S path_name_list] [-u user_list]
[-v variable_list] [-W additional_attributes]
```

```
[-t array_range]
job_identifier ...
```

## Description

The `qalter` command modifies the attributes of the job or jobs specified by `job_identifier` on the command line. Only those attributes listed as options on the command will be modified. If any of the specified attributes cannot be modified for a job for any reason, none of that job's attributes will be modified.

The `qalter` command accomplishes the modifications by sending a Modify Job batch request to the batch server which owns each job.

## Options

Option	Name	Description
<b>-a</b>	date_time	<p>Replaces the time at which the job becomes eligible for execution. The <code>date_time</code> argument syntax is:</p> <pre>[[ [ [CC] YY] MM] DD] hhmm [ .SS]</pre> <p>If the month, <code>MM</code>, is not specified, it will default to the current month if the specified day <code>DD</code>, is in the future. Otherwise, the month will be set to next month. Likewise, if the day, <code>DD</code>, is not specified, it will default to today if the time <code>hhmm</code> is in the future. Otherwise, the day will be set to tomorrow.</p> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
<b>-A</b>	account_string	<p>Replaces the account string associated with the job. This attribute cannot be altered once the job has begun execution.</p>

Option	Name	Description
-c	checkpoint_interval	<p>Replaces the interval at which the job will be checkpointed. If the job executes upon a host which does not support checkpointing, this option will be ignored.</p> <p>The interval argument is specified as:</p> <ul style="list-style-type: none"> <li>• <i>n</i> – No checkpointing is to be performed.</li> <li>• <i>s</i> – Checkpointing is to be performed only when the server executing the job is shutdown.</li> <li>• <i>c</i> – Checkpointing is to be performed at the default minimum cpu time for the queue from which the job is executing.</li> <li>• <i>c=minutes</i> – Checkpointing is performed at intervals of the specified amount of time in minutes. Minutes are the number of minutes of CPU time used, not necessarily clock time.</li> </ul> <div style="border: 1px solid black; border-radius: 10px; padding: 5px; margin: 10px 0;"> <p> This value must be greater than zero. If the number is less than the default checkpoint time, the default time will be used.</p> </div> <p>This attribute can be altered once the job has begun execution, but the new value does not take effect unless the job is rerun.</p>
-e	path_name	<p>Replaces the path to be used for the standard error stream of the batch job. The path argument is of the form:</p> <p>[hostname:]path_name</p> <p>where <i>hostname</i> is the name of a host to which the file will be returned and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX 1003.1. The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> <li>• <i>path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the <i>hostname</i> component.</li> <li>• <i>hostname:path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will not expand the path name. The execution server will expand it relative to the home directory of the user on the system specified by <i>hostname</i>.</li> </ul> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>

Option	Name	Description
<b>-h</b>	hold_list	<p>Updates the types of holds on the job. The hold_list argument is a string of one or more of the following characters:</p> <ul style="list-style-type: none"> <li>• <i>u</i> – Add the USER type hold.</li> <li>• <i>s</i> – Add the SYSTEM type hold if the user has the appropriate level of privilege. (Typically reserved to the batch administrator.)</li> <li>• <i>o</i> – Add the OTHER (or OPERATOR ) type hold if the user has the appropriate level of privilege. (Typically reserved to the batch administrator and batch operator.)</li> <li>• <i>n</i> – Set to none and clear the hold types which could be applied with the user's level of privilege. Repetition of characters is permitted, but "n" may not appear in the same option argument with the other three characters.</li> </ul> <p>This attribute can be altered once the job has begun execution, but the hold will not take effect unless the job is rerun.</p>
<b>-j</b>	join	<p>Declares which standard streams of the job will be merged together. The join argument value may be the characters "oe" and "eo", or the single character "n".</p> <p>An argument value of oe directs that the standard output and standard error streams of the job will be merged, intermixed, and returned as the standard output. An argument value of eo directs that the standard output and standard error streams of the job will be merged, intermixed, and returned as the standard error.</p> <p>A value of n directs that the two streams will be two separate files. This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> If using either the <code>-e</code> or the <code>-o</code> option and the <code>-j eo oe</code> option, the <code>-j</code> option takes precedence and all standard error and output messages go to the chosen output file.</p> </div>

Option	Name	Description
<b>-k</b>	keep	<p>Defines which if either of standard output or standard error of the job will be retained on the execution host. If set for a stream, this option overrides the path name for that stream.</p> <p>The argument is either the single letter "e", "o", or "n", or one or more of the letters "e" and "o" combined in either order.</p> <ul style="list-style-type: none"> <li>• <i>n</i> – No streams are to be retained.</li> <li>• <i>e</i> – The standard error stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by:  <code>job_name.e<sub>sequence</sub></code>            where <code>job_name</code> is the name specified for the job, and <code>sequence</code> is the sequence number component of the job identifier.</li> <li>• <i>o</i> – The standard output stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by:  <code>job_name.o<sub>sequence</sub></code>            where <code>job_name</code> is the name specified for the job, and <code>sequence</code> is the sequence number component of the job identifier.</li> <li>• <i>eo</i> – Both the standard output and standard error streams will be retained.</li> <li>• <i>oe</i> – Both the standard output and standard error streams will be retained.</li> </ul> <p>This attribute cannot be altered once the job has begun execution.</p>
<b>-l</b>	resource_ list	<p>Modifies the list of resources that are required by the job. The <code>resource_list</code> argument is in the following syntax:</p> <pre>resource_name [= [value]] [, resource_name [= [value]], ... ]</pre> <p>For the complete list of resources that can be modified, see <a href="#">Requesting resources on page 2586</a>.</p> <p>If a requested modification to a resource would exceed the resource limits for jobs in the current queue, the server will reject the request.</p> <p>If the job is running, only certain resources can be altered. Which resources can be altered in the run state is system dependent. A user may only lower the limit for those resources.</p>
<b>-m</b>	mail_ options	<p>Replaces the set of conditions under which the execution server will send a mail message about the job. The <code>mail_options</code> argument is a string which consists of the single character "n", or one or more of the characters "a", "b", and "e".</p> <p>If the character "n" is specified, no mail will be sent.</p> <p>For the letters "a", "b", and "e":</p> <ul style="list-style-type: none"> <li>• <i>a</i> – Mail is sent when the job is aborted by the batch system.</li> <li>• <i>b</i> – Mail is sent when the job begins execution.</li> <li>• <i>e</i> – Mail is sent when the job ends.</li> </ul>

Option	Name	Description
<b>-M</b>	user_list	Replaces the list of users to whom mail is sent by the execution server when it sends mail about the job. The user_list argument is of the form: user[@host] [, user[@host], ...]
<b>-n</b>	node-exclusive	Sets or unsets exclusive node allocation on a job. Use the y and n options to enable or disable the feature. This affects only cpusets and compatible schedulers. <pre>&gt; qalter ... -n y #enables exclusive node allocation on a job &gt; qalter ... -n n #disables exclusive node allocation on a job</pre>
<b>-N</b>	name	Renames the job. The name specified may be up to and including 15 characters in length. It must consist of printable, nonwhite space characters with the first character alphabetic.
<b>-o</b>	path	Replaces the path to be used for the standard output stream of the batch job. The path argument is of the form: [hostname:]path_name where <i>hostname</i> is the name of a host to which the file will be returned and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX. The argument will be interpreted as follows: <ul style="list-style-type: none"> <li><i>path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the <i>hostname</i> component.</li> <li><i>hostname:path_name</i> – Where <i>path_name</i> is not an absolute path name, then the <code>qalter</code> command will not expand the path name. The execution server will expand it relative to the home directory of the user on the system specified by <i>hostname</i>.</li> </ul> This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.
<b>-p</b>	priority	Replaces the priority of the job. The priority argument must be an integer between -1024 and +1023 inclusive. This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.
<b>-r</b>	[y/n]	Declares whether the job is rerunable (see the <code>qrerun</code> command). The option argument <i>c</i> is a single character. PBS recognizes the following characters: y and n. If the argument is "y", the job is marked rerunable. If the argument is "n", the job is marked as not rerunable.

Option	Name	Description
<b>-S</b>	path	<p>Declares the shell that interprets the job script.</p> <p>The option argument path_list is in the form:</p> <pre>path[@host] [,path[@host], ...]</pre> <p>Only one path may be specified for any host named. Only one path may be specified without the corresponding host name. The path selected will be the one with the host name that matched the name of the execution host. If no matching host is found, then the path specified (without a host) will be selected.</p> <p>If the <code>-S</code> option is not specified, the option argument is the null string, or no entry from the path_list is selected, the execution will use the login shell of the user on the execution host.</p> <p>This attribute can be altered once the job has begun execution, but it will not take effect unless the job is rerun.</p>
<b>-t</b>	array_range	<p>The array_range argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: <code>-t 1-100</code> or <code>-t 1, 10, 50-100</code></p> <p>If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.</p> <p>An optional "slot limit" can be specified to limit the amount of jobs that can run concurrently in the job array. The default value is unlimited. The slot limit must be the last thing specified in the array_request and is delimited from the array by a percent sign (%).</p> <pre>qalter weatherSimulationArray[] -t %20</pre> <p>Here, the array weatherSimulationArray[] is configured to allow a maximum of 20 concurrently running jobs.</p> <p>Slot limits can be applied at job submit time with <a href="#">qsub</a>, or can be set in a global server parameter policy with <a href="#">max_slot_limit</a>.</p>
<b>-u</b>	user_list	<p>Replaces the user name under which the job is to run on the execution system.</p> <p>The user_list argument is of the form:</p> <pre>user[@host] [,user[@host], ...]</pre> <p>Only one user name may be given for per specified host. Only one of the user specifications may be supplied without the corresponding host specification. That user name will be used for execution on any host not named in the argument list.</p> <p>This attribute cannot be altered once the job has begun execution.</p>
<b>-W</b>	additional_attributes	<p>The <code>-w</code> option allows for the modification of additional job attributes.</p> <p>Note if white space occurs anywhere within the option argument string or the equal sign, "=", occurs within an attribute_value string, then the string must be enclosed with either single or double quote marks.</p> <p>To see the attributes PBS currently supports within the <code>-w</code> option, see <a href="#">Table 4-5: -W additional_attributes on page 2716</a>.</p>

Table 4-5: -W additional\_attributes

Attribute	Description
<b>depend=dependency_list</b>	<p>Redefines the dependencies between this and other jobs. The <code>dependency_list</code> is in the form:</p> <pre>type [:argument[:argument...]] [, type:argument...]</pre> <p>The argument is either a numeric count or a PBS job id according to type. If argument is a count, it must be greater than 0. If it is a job id and is not fully specified in the form: <code>seq_number.server.name</code>, it will be expanded according to the default server rules. If argument is null (the preceding colon need not be specified), the dependency of the corresponding type is cleared (unset).</p> <ul style="list-style-type: none"> <li>• <i>synccount:count</i> – This job is the first in a set of jobs to be executed at the same time. Count is the number of additional jobs in the set.</li> <li>• <i>syncwith:jobid</i> – This job is an additional member of a set of jobs to be executed at the same time. In the above and following dependency types, jobid is the job identifier of the first job in the set.</li> <li>• <i>after:jobid [:jobid...]</i> – This job may be scheduled for execution at any point after jobs jobid have started execution.</li> <li>• <i>afterok:jobid [:jobid...]</i> – This job may be scheduled for execution only after jobs jobid have terminated with no errors. See the csh warning under "Extended Description".</li> <li>• <i>afternotok:jobid [:jobid...]</i> – This job may be scheduled for execution only after jobs jobid have terminated with errors. See the csh warning under "Extended Description".</li> <li>• <i>afterany:jobid [:jobid...]</i> – This job may be scheduled for execution after jobs jobid have terminated, with or without errors.</li> <li>• <i>on:count</i> – This job may be scheduled for execution after count dependencies on other jobs have been satisfied. This dependency is used in conjunction with any of the 'before' dependencies shown below. If job A has <i>on:2</i>, it will wait for two jobs with 'before' dependencies on job A to be fulfilled before running.</li> <li>• <i>before:jobid [:jobid...]</i> – When this job has begun execution, then jobs jobid... may begin.</li> <li>• <i>beforeok:jobid [:jobid...]</i> – If this job terminates execution without errors, then jobs jobid... may begin. See the csh warning under "Extended Description".</li> <li>• <i>beforenotok:jobid [:jobid...]</i> – If this job terminates execution with errors, then jobs jobid... may begin. See the csh warning under "Extended Description".</li> <li>• <i>beforeany:jobid [:jobid...]</i> – When this job terminates execution, jobs jobid... may begin.</li> </ul> <p>If any of the before forms are used, the job referenced by jobid must have been submitted with a dependency type of on.</p> <p>If any of the before forms are used, the jobs referenced by jobid must have the same owner as the job being altered. Otherwise, the dependency will not take effect.</p> <p>Error processing of the existence, state, or condition of the job specified to qalter is a deferred service, i.e. the check is performed after the job is queued. If an error is detected, the job will be deleted by the server. Mail will be sent to the job submitter stating the error.</p>

Attribute	Description
<b>group_list=g_list</b>	<p>Alters the group name under which the job is to run on the execution system.</p> <p>The <code>g_list</code> argument is of the form:</p> <pre>group[@host] [,group[@host], ...]</pre> <p>Only one group name may be given per specified host. Only one of the group specifications may be supplied without the corresponding host specification. That group name will be used for execution on any host not named in the argument list.</p>
<b>stagein=file_list</b> <b>stageout=file_list</b>	<p>Alters which files are staged (copied) in before job start or staged out after the job completes execution. The <code>file_list</code> is in the form:</p> <pre>local_file@hostname:remote_file[,...]</pre> <p>The name <code>local_file</code> is the name on the system where the job executes. It may be an absolute path or a path relative to the home directory of the user. The name <code>remote_file</code> is the destination name on the host specified by <code>hostname</code>. The name may be absolute or relative to the user's home directory on the destination host.</p>

## Operands

The `qalter` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name][@server]
```

## Standard error

Any error condition, either in processing the options or the operands, or any error received in reply to the batch requests will result in an error message being written to standard error.

## Exit status

Upon successful processing of all the operands presented to the `qalter` command, the exit status will be a value of zero.

If the `qalter` command fails to process any operand, the command exits with a value greater than zero.

## qchkpt

Checkpoint pbs batch jobs.

## Synopsis

```
qchkpt <JOBID> [ <JOBID> ] ...
```

## Description

The `qchkpt` command requests that the PBS MOM generate a checkpoint file for a running job.

This is an extension to POSIX.2d.

The `qchkpt` command sends a Chkpt Job batch request to the server as described in the general section.

## Options

None.

## Operands

The `qchkpt` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

## Examples

```
> qchkpt 3233 request a checkpoint for job 3233
```

## Standard error

The `qchkpt` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qchkpt` command, the exit status will be a value of zero.

If the `qchkpt` command fails to process any operand, the command exits with a value greater than zero.

## qdel

*(delete job)*

### Synopsis

```
qdel [{-a <asynchronous delete>|-m <message>|-p|-W <delay>|-t <array_range>}]
<JOBID>[ <JOBID>]... | 'all' | 'ALL'
```

### Description

The `qdel` command deletes jobs in the order in which their job identifiers are presented to the command. A job is deleted by sending a Delete Job batch request to the batch server that owns the job. A job that has been deleted is no longer subject to management by batch services.

A batch job may be deleted by its owner, the batch operator, or the batch administrator.

A batch job being deleted by a server will be sent a SIGTERM signal following by a SIGKILL signal. The time delay between the two signals is an attribute of the execution queue from which the job was run (set table by the administrator). This delay may be overridden by the `-W` option.

See the PBS ERS section 3.1.3.3, "Delete Job Request", for more information.

## Options

Option	Name	Description
<b>-a</b>	asynchronous delete	Performs an asynchronous delete. The server responds to the user before contacting the MOM. The option <code>qdel -a all</code> performs <code>qdel all</code> due to restrictions from being single-threaded.
<b>-W</b>	delay	Specifies the wait delay between the sending of the SIGTERM and SIGKILL signals. The argument is the length of time in seconds of the delay.
<b>-p</b>	purge	Forcibly purges the job from the server. This should only be used if a running job will not exit because its allocated nodes are unreachable. The admin should make every attempt at resolving the problem on the nodes. If a job's mother superior recovers after purging the job, any epilogue scripts may still run. This option is only available to a batch operator or the batch administrator.
<b>-m</b>	message	Specify a comment to be included in the email. The argument message specifies the comment to send. This option is only available to a batch operator or the batch administrator.
<b>-t</b>	array_range	The <code>array_range</code> argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list (examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code> ).  If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.

## Operands

The `qdel` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

or

```
all
```

## Examples

```
> qdel 1324
> qdel 1324-3 To delete one job of a job array
> qdel all To delete all jobs (Version 2.3.0 and later)
```

## Standard error

The `qdel` command will write a diagnostic messages to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qdel` command, the exit status will be a value of zero.

If the `qdel` command fails to process any operand, the command exits with a value greater than zero.

## qgpumode

*(GPU mode)*

## Synopsis

```
qgpumode -H host -g gpuid -m mode
```

## Description

The `qgpumode` command specifies the mode for the GPU. This command triggers an immediate update of the `pbs_server`.

For additional information about options for configuring GPUs, see [NVIDIA GPUs on page 817](#).

## Options

Option	Description
<b>-H</b>	Specifies the host where the GPU is located.
<b>-g</b>	Specifies the ID of the GPU. This varies depending on the version of the Nvidia driver used. For driver 260.x, it is 0, 1, and so on. For driver 270.x, it is the PCI bus address, i.e., 0:5:0.

Option	Description
<b>-m</b>	<p>Specifies the new mode for the GPU:</p> <ul style="list-style-type: none"> <li>• <b>0 (Default/Shared)</b>: Default/shared compute mode. Multiple threads can use <code>cudaSetDevice()</code> with this device.</li> <li>• <b>1 (Exclusive Thread)</b>: Compute-exclusive-thread mode. Only one thread in one process is able to use <code>cudaSetDevice()</code> with this device.</li> <li>• <b>2 (Prohibited)</b>: Compute-prohibited mode. No threads can use <code>cudaSetDevice()</code> with this device.</li> <li>• <b>3 (Exclusive Process)</b>: Compute-exclusive-process mode. Many threads in one process are able to use <code>cudaSetDevice()</code> with this device.</li> </ul> <pre>qgpumode -H node01 -g 0 -m 1</pre> <p><i>This puts the first GPU on node01 into mode 1 (exclusive)</i></p> <pre>qgpumode -H node01 -g 0 -m 0</pre> <p><i>This puts the first GPU on node01 into mode 0 (shared)</i></p>

#### Related topics

- [qgpureset on page 2723](#)

## qgpureset

(reset GPU)

### Synopsis

```
qgpureset -H host -g gpuid -p -v
```

### Description

The `qgpureset` command resets the GPU.

### Options

Option	Description
<b>-H</b>	Specifies the host where the GPU is located.
<b>-g</b>	Specifies the ID of the GPU. This varies depending on the version of the Nvidia driver used. For driver 260.x, it is 0, 1, and so on. For driver 270.x, it is the PCI bus address, i.e., 0:5:0.

Option	Description
<b>-p</b>	Specifies to reset the GPU's permanent ECC error count.
<b>-v</b>	Specifies to reset the GPU's volatile ECC error count.

## qhold

*(hold job)*

## Synopsis

```
qhold [{"-h" <HOLD LIST>|"-t" <array_range>}] <JOBID>[ <JOBID>] ...
```

## Description

The `qhold` command requests that the server place one or more holds on a job. A job that has a hold is not eligible for execution. There are three supported holds: USER, OTHER (also known as operator), and SYSTEM.

A user may place a USER hold upon any job the user owns. An "operator", who is a user with "operator privilege," may place either an USER or an OTHER hold on any job. The batch administrator may place any hold on any job.

If no `-h` option is given, the USER hold will be applied to the jobs described by the `job_identifier` operand list.

If the job identified by `job_identifier` is in the queued, held, or waiting states, then the hold type is added to the job. The job is then placed into held state if it resides in an execution queue.

If the job is in running state, then the following additional action is taken to interrupt the execution of the job. If checkpoint/restart is supported by the host system, requesting a hold on a running job will (1) cause the job to be checkpointed, (2) the resources assigned to the job will be released, and (3) the job is placed in the held state in the execution queue.

If checkpoint/restart is not supported, `qhold` will only set the requested hold attribute. This will have no effect unless the job is rerun with the [qrerun](#) command.

## Options

Option	Name	Description
<b>-h</b>	hold_list	The hold_list argument is a string consisting of one or more of the letters "u", "o", or "s" in any combination. The hold type associated with each letter is: <ul style="list-style-type: none"> <li>• <i>u</i> - USER</li> <li>• <i>o</i> - OTHER</li> <li>• <i>s</i> - SYSTEM</li> </ul>
<b>-t</b>	array_range	The array_range argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list (examples: -t 1-100 or -t 1,10,50-100) . If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.

## Operands

The `qhold` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

## Example

```
> qhold -h u 3233 place user hold on job 3233
```

## Standard error

The `qhold` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qhold` command, the exit status will be a value of zero.

If the `qhold` command fails to process any operand, the command exits with a value greater than zero.

## qmgr

(PBS Queue Manager) PBS batch system manager.

### Synopsis

```
qmgr [-a] [-c command] [-e] [-n] [-z] [server...]
```

### Description

The `qmgr` command provides an administrator interface to query and configure batch system parameters (see [Appendix B: Server parameters on page 2766](#)).

The command reads directives from standard input. The syntax of each directive is checked and the appropriate request is sent to the batch server or servers.

The list or print subcommands of `qmgr` can be executed by general users. Creating or deleting a queue requires PBS Manager privilege. Setting or unsetting server or queue attributes requires PBS Operator or Manager privilege.

**i** By default, the user `root` is the only PBS Operator and Manager. To allow other users to be privileged, the server attributes `operators` and `managers` will need to be set (i.e., as `root`, issue `'qmgr -c 'set server managers += <USER1>@<HOST>'`). See [TORQUE/PBS Integration Guide - RM Access Control on page 1231](#).

If `qmgr` is invoked without the `-c` option and standard output is connected to a terminal, `qmgr` will write a prompt to standard output and read a directive from standard input.

Commands can be abbreviated to their minimum unambiguous form. A command is terminated by a new line character or a semicolon, ";", character. Multiple commands may be entered on a single line. A command may extend across lines by escaping the new line character with a back-slash "\".

Comments begin with the "#" character and continue to end of the line. Comments and blank lines are ignored by `qmgr`.

### Options

Option	Name	Description
<code>-a</code>	---	Abort <code>qmgr</code> on any syntax errors or any requests rejected by a server.
<code>-c</code>	command	Execute a single command and exit <code>qmgr</code> .

Option	Name	Description
<b>-e</b>	---	Echo all commands to standard output.
<b>-n</b>	---	No commands are executed, syntax checking only is performed.
<b>-z</b>	---	No errors are written to standard error.

## Operands

The *server* operands identify the name of the batch server to which the administrator requests are sent. Each *server* conforms to the following syntax:

```
host_name[:port]
```

where *host\_name* is the network name of the host on which the server is running and *port* is the port number to which to connect. If *port* is not specified, the default port number is used.

If *server* is not specified, the administrator requests are sent to the local server.

## Standard input

The `qmgr` command reads standard input for directives until end of file is reached, or the exit or quit directive is read.

## Standard output

If Standard Output is connected to a terminal, a command prompt will be written to standard output when `qmgr` is ready to read a directive.

If the `-e` option is specified, `qmgr` will echo the directives read from standard input to standard output.

## Standard error

If the `-z` option is not specified, the `qmgr` command will write a diagnostic message to standard error for each error occurrence.

## Directive syntax

A `qmgr` directive is one of the following forms:

```
command server [names] [attr OP value[,attr OP value,...]]
command queue [names] [attr OP value[,attr OP value,...]]
command node [names] [attr OP value[,attr OP value,...]]
```

where *command* is the command to perform on an object.

Commands are:

Command	Description
<b>active</b>	Sets the active objects. If the active objects are specified, and the name is not given in a <code>qmgr cmd</code> the active object names will be used.
<b>create</b>	Is to create a new object, applies to queues and nodes.
<b>delete</b>	Is to destroy an existing object, applies to queues and nodes.
<b>set</b>	Is to define or alter attribute values of the object.
<b>unset</b>	Is to clear the value of attributes of the object. <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;">  This form does not accept an OP and value, only the attribute name. </div>
<b>list</b>	Is to list the current attributes and associated values of the object.
<b>print</b>	Is to print all the queue and server attributes in a format that will be usable as input to the <code>qmgr</code> command.
<b>names</b>	Is a list of one or more names of specific objects The name list is in the form: <code>[name] [@server] [, queue_name [@server] . . . ]</code> with no intervening white space. The name of an object is declared when the object is first created. If the name is <code>@server</code> , then all the objects of specified type at the server will be affected.
<b>attr</b>	Specifies the name of an attribute of the object which is to be set or modified. If the attribute is one which consist of a set of resources, then the attribute is specified in the form: <code>attribute_name.resource_name</code>
<b>OP</b>	Operation to be performed with the attribute and its value: <ul style="list-style-type: none"> <li>• "=" – set the value of the attribute. If the attribute has an existing value, the current value is replaced with the new value.</li> <li>• "+=" – increase the current value of the attribute by the amount in the new value.</li> <li>• "-=" – decrease the current value of the attribute by the amount in the new value.</li> </ul>
<b>value</b>	The value to assign to an attribute. If the value includes white space, commas or other special characters, such as the "#" character, the value string must be enclosed in quote marks ("").

The following are examples of `qmgr` directives:

```

create queue fast priority=10,queue_type=e,enabled = true,max_running=0
set queue fast max_running +=2
create queue little
set queue little resources_max.mem=8mw,resources_max.cput=10
unset queue fast max_running
set node state = "down,offline"
active server s1,s2,s3
list queue @server1
set queue max_running = 10          - uses active queues

```

## Exit status

Upon successful processing of all the operands presented to the `qmgr` command, the exit status will be a value of zero.

If the `qmgr` command fails to process any operand, the command exits with a value greater than zero.

## qmove

Move PBS batch jobs.

## Synopsis

```
qmove destination jobId [jobId ...]
```

## Description

To move a job is to remove the job from the queue in which it resides and instantiate the job in another queue. The `qmove` command issues a Move Job batch request to the batch server that currently owns each job specified by *jobId*.

A job in the **Running**, **Transiting**, or **Exiting** state cannot be moved.

## Operands

The first operand, the new *destination*, is one of the following:

queue

@server

queue@server

If the *destination* operand describes only a queue, then `qmove` will move jobs into the queue of the specified name at the job's current server. If the *destination* operand describes only a batch server, then `qmove` will move jobs into the default queue at that batch server. If the *destination* operand describes both a queue and a batch server, then `qmove` will move the jobs into the specified queue at the specified server.

All following operands are *joblds* which specify the jobs to be moved to the new *destination*. The `qmove` command accepts one or more *jobld* operands of the form: `sequenceNumber [.serverName] [@server]`

## Standard error

The `qmove` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qmove` command, the exit status will be a value of zero.

If the `qmove` command fails to process any operand, the command exits with a value greater than zero.

## qorder

Exchange order of two PBS batch jobs in any queue.

## Synopsis

```
qorder job1_identifier job2_identifier
```

## Description

To order two jobs is to exchange the jobs' positions in the queue(s) in which the jobs reside. The two jobs must be located on the same server. No attribute of the job, such as priority, is changed. The impact of changing the order in the queue(s) is dependent on local job schedule policy. For information about your local job schedule policy, contact your systems administrator.

 A job in the **running** state cannot be reordered.

## Operands

Both operands are `job_identifiers` that specify the jobs to be exchanged. The `qorder` command accepts two `job_identifier` operands of the following form:  
`sequence_number [.server_name] [@server]`

The two jobs must be in the same location, so the server specification for the two jobs must agree.

## Standard error

The `qorder` command will write diagnostic messages to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qorder` command, the exit status will be a value of zero.

If the `qorder` command fails to process any operand, the command exits with a value greater than zero.

## qrerun

*(Rerun a batch job)*

## Synopsis

```
qrerun [{-f}] <JOBID>[ <JOBID>] ...
```

## Description

The `qrerun` command directs that the specified jobs are to be rerun if possible. To rerun a job is to terminate the session leader of the job and return the job to the queued state in the execution queue in which the job currently resides.

If a job is marked as not rerunable then the rerun request will fail for that job. If the mini-server running the job is down, or it rejects the request, the Rerun Job batch request will return a failure unless `-f` is used.

Using `-f` violates IEEE Batch Processing Services Standard and should be handled with great care. It should only be used under exceptional circumstances. The best practice is to fix the problem mini-server host and let `qrerun` run normally. The nodes may need manual cleaning (see the `-r` option on the [qsub](#) and [qalter](#) commands).

## Options

Option	Description
<b>-f</b>	Force a rerun on a job

```
qrerun -f 15406
```

**i** The `qrerun` all command is meant to be run if all of the compute nodes go down. If the machines have actually crashed, then we know that all of the jobs need to be restarted. The behavior if you don't run this would depend on how you bring up the `pbs_mom` daemons, but by default would be to cancel all of the jobs.

Running the command makes it so that all jobs are requeued without attempting to contact the moms on which they should be running.

## Operands

The `qrerun` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name][@server]
```

## Standard error

The `qrerun` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qrerun` command, the exit status will be a value of zero.

If the `qrerun` command fails to process any operand, the command exits with a value greater than zero.

## Examples

```
> qrerun 3233
```

(Job 3233 will be re-run.)

## qrlls

*(Release hold on PBS batch jobs)*

## Synopsis

```
qrlls [{"-h" <HOLD LIST>|"-t" <array_range>}] <JOBID>[ <JOBID>] ...
```

## Description

The `qrlls` command removes or releases holds which exist on batch jobs.

A job may have one or more types of holds which make the job ineligible for execution. The types of holds are USER, OTHER, and SYSTEM. The different types of holds may require that the user issuing the `qrlls` command have special privileges. A user may always remove a USER hold on their own jobs, but only privileged users can remove OTHER or SYSTEM holds. An attempt to release a hold for which the user does not have the correct privilege is an error and no holds will be released for that job.

If no `-h` option is specified, the USER hold will be released.

If the job has no execution\_time pending, the job will change to the queued state. If an execution\_time is still pending, the job will change to the waiting state.

## Options

Command	Name	Description
<code>-h</code>	hold_list	<p>Defines the types of hold to be released from the jobs. The hold_list option argument is a string consisting of one or more of the letters "u", "o", and "s" in any combination. The hold type associated with each letter is:</p> <ul style="list-style-type: none"> <li>• <i>u</i> - USER</li> <li>• <i>o</i> - OTHER</li> <li>• <i>s</i> - SYSTEM</li> </ul>
<code>-t</code>	array_range	<p>The array_range argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code></p> <p>If an array range isn't specified, the command tries to operate on the entire array. The command acts on the array (or specified range of the array) just as it would on an individual job.</p>

## Operands

The `qrls` command accepts one or more `job_identifier` operands of the form:

```
sequence_number [.server_name] [@server]
```

## Examples

```
> qrls -h u 3233 release user hold on job 3233
```

## Standard error

The `qrls` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qrls` command, the exit status will be a value of zero.

If the `qrls` command fails to process any operand, the command exits with a value greater than zero.

## qrun

*(Run a batch job)*

## Synopsis

```
qrun [{"-H <HOST>|_a"}] <JOBID>[ <JOBID>] ...
```

## Overview

The `qrun` command runs a job.

## Format

-H	
<b>Format</b>	<STRING> Host Identifier
<b>Default</b>	---
<b>Description</b>	Specifies the host within the cluster on which the job(s) are to be run. The host argument is the name of a host that is a member of the cluster of hosts managed by the server. If the option is not specified, the server will select the "worst possible" host on which to execute the job.
<b>Example</b>	<pre>qrun -H hostname 15406</pre>

-a	
<b>Format</b>	---
<b>Default</b>	---
<b>Description</b>	Run the job(s) asynchronously.
<b>Example</b>	<pre>qrun -a 15406</pre>

## Command details

The `qrun` command is used to force a batch server to initiate the execution of a batch job. The job is run regardless of scheduling position or resource requirements.

In order to execute `qrun`, the user must have PBS Operation or Manager privileges.

## Examples

```
> qrun 3233
```

(Run job 3233.)

`qsig`

(Signal a job)

## Synopsis

```
qsig [{-s <SIGNAL>}] <JOBID>[ <JOBID>] ...
[-a]
```

## Description

The `qsig` command requests that a signal be sent to executing batch jobs. The signal is sent to the session leader of the job. If the `-s` option is not specified, `SIGTERM` is sent. The request to signal a batch job will be rejected if:

- The user is not authorized to signal the job.
- The job is not in the running state.
- The requested signal is not supported by the system upon which the job is executing.

The `qsig` command sends a Signal Job batch request to the server which owns the job.

## Options

Option	Name	Description
<code>-s</code>	signal	<p>Declares which signal is sent to the job.</p> <p>The signal argument is either a signal name, e.g. <code>SIGKILL</code>, the signal name without the <code>SIG</code> prefix, e.g. <code>KILL</code>, or an unsigned signal number, e.g. <code>9</code>. The signal name <code>SIGNULL</code> is allowed; the server will send the signal <code>0</code> to the job which will have no effect on the job, but will cause an obituary to be sent if the job is no longer executing. Not all signal names will be recognized by <code>qsig</code>. If it doesn't recognize the signal name, try issuing the signal number instead.</p> <p>Two special signal names, "suspend" and "resume", are used to suspend and resume jobs. Cray systems use the Cray-specific <code>suspend()/resume()</code> calls.</p> <p>On non-Cray system, <code>suspend</code> causes a <code>SIGTSTP</code> to be sent to all processes in the job's top task, wait 5 seconds, and then send a <code>SIGSTOP</code> to all processes in all tasks on all nodes in the job. This differs from TORQUE 2.0.0 which did not have the ability to propagate signals to sister nodes. <code>Resume</code> sends a <code>SIGCONT</code> to all processes in all tasks on all nodes.</p> <p>When suspended, a job continues to occupy system resources but is not executing and is not charged for walltime. The job will be listed in the "S" state. Manager or operator privilege is required to suspend or resume a job.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p> Interactive jobs may not resume properly because the top-level shell will background the suspended child process.</p> </div>
<code>-a</code>	asynchronously	Makes the command run asynchronously.

## Operands

The `qsig` command accepts one or more `job_identifier` operands of the form:

```
sequence_number[.server_name] [@server]
```

## Examples

```
> qsig -s SIGKILL 3233      send a SIGKILL to job 3233
> qsig -s KILL 3233        send a SIGKILL to job 3233
> qsig -s 9 3233           send a SIGKILL to job 3233
```

## Standard error

The `qsig` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qsig` command, the exit status will be a value of zero.

If the `qsig` command fails to process any operand, the command exits with a value greater than zero.

## qstat

Show status of PBS batch jobs.

## Synopsis

```
qstat [-c on page 2738] [-f [-1]] [-W site_specific] [job_identifier... |
destination...] [time]
qstat [-a|-i|-r|-e] [-c on page 2738] [-n [-1]] [-s] [-G|-M] [-R] [-u user_
list]
[job_identifier... | destination...]
qstat -Q [-f [-1]] [-c on page 2738] [-W site_specific] [destination...]
qstat -q [-c on page 2738] [-G|-M] [destination...]
qstat -B [-c on page 2738] [-f [-1]] [-W site_specific] [server_name...]
qstat -t [-c on page 2738]
```

## Description

The `qstat` command is used to request the status of jobs, queues, or a batch server. The requested status is written to standard out.

When requesting job status, synopsis format 1 or 2, `qstat` will output information about each job\_ identifier or all jobs at each destination. Jobs for which the user does not have status privilege are not displayed.

When requesting queue or server status, synopsis format 3 through 5, `qstat` will output information about each destination.

**i** You can configure TORQUE with `CFLAGS='DTXT'` to change the alignment of text in `qstat` output. This noticeably improves `qstat -r` output.

## Options

Option	Description
<b>-c</b>	Completed jobs are not displayed in the output. If desired, you can set the <code>PBS_QSTAT_NO_COMPLETE</code> environment variable to cause all <code>qstat</code> requests to not show completed jobs by default.
<b>-f</b>	Specifies that a full status display be written to standard out. The [time] value is the amount of wall-time, in seconds, remaining for the job. [time] does not account for walltime multipliers.
<b>-a</b>	All jobs are displayed in the alternative format (see <a href="#">Standard output on page 2740</a> ). If the operand is a destination id, all jobs at that destination are displayed. If the operand is a job id, information about that job is displayed.
<b>-e</b>	If the operand is a job id or not specified, only jobs in executable queues are displayed. Setting the <code>PBS_QSTAT_EXEONLY</code> environment variable will also enable this option.
<b>-i</b>	Job status is displayed in the alternative format. For a destination id operand, statuses for jobs at that destination which are not running are displayed. This includes jobs which are queued, held or waiting. If an operand is a job id, status for that job is displayed regardless of its state.
<b>-r</b>	If an operand is a job id, status for that job is displayed. For a destination id operand, statuses for jobs at that destination which are running are displayed; this includes jobs which are suspended. Note that if there is no walltime given for a job, then elapsed time does not display.
<b>-n</b>	In addition to the basic information, nodes allocated to a job are listed.
<b>-1</b>	In combination with <a href="#">-n</a> , the <code>-1</code> option puts all of the nodes on the same line as the job ID. In combination with <a href="#">-f</a> attributes are not folded to fit in a terminal window. This is intended to ease the parsing of the <code>qstat</code> output.
<b>-s</b>	In addition to the basic information, any comment provided by the batch administrator or scheduler is shown.

Option	Description
<b>-G</b>	Show size information in giga-bytes.
<b>-M</b>	Show size information, disk or memory in mega-words. A word is considered to be 8 bytes.
<b>-R</b>	In addition to other information, disk reservation information is shown. Not applicable to all systems.
<b>-t</b>	Normal <code>qstat</code> output displays a summary of the array instead of the entire array, job for job. <code>qstat -t</code> expands the output to display the entire array. Note that arrays are now named with brackets following the array name; for example: <pre>dbbeer@napali:~/dev/torque/array_changes\$ echo sleep 20   qsub -t 0-299 189 []].napali</pre> Individual jobs in the array are now also noted using square brackets instead of dashes; for example, here is part of the output of <code>qstat -t</code> for the preceding array: <pre>189[299].napali STDIN[299] dbbeer 0 Q batch</pre>
<b>-u</b>	Job status is displayed in the alternative format. If an operand is a job id, status for that job is displayed. For a destination id operand, statuses for jobs at that destination which are owned by the user(s) listed in <code>user_list</code> are displayed. The syntax of the <code>user_list</code> is: <pre>user_name[@host] [, user_name[@host], ...]</pre> Host names may be wild carded on the left end, e.g. <code>*.nasa.gov</code> . User_name without a <code>@host</code> is equivalent to <code>"user_name@*"</code> , that is at any host.
<b>-Q</b>	Specifies that the request is for queue status and that the operands are destination identifiers.
<b>-q</b>	Specifies that the request is for queue status which should be shown in the alternative format.
<b>-B</b>	Specifies that the request is for batch server status and that the operands are the names of servers.

## Operands

If neither the **-Q** nor the **-B** option is given, the operands on the `qstat` command must be either job identifiers or destinations identifiers.

If the operand is a job identifier, it must be in the following form:

```
sequence_number[.server_name] [@server]
```

where `sequence_number.server_name` is the job identifier assigned at submittal time (see [qsub](#)). If the `.server_name` is omitted, the name of the default server will be used. If `@server` is supplied, the request will be for the job identifier currently at that Server.

If the operand is a destination identifier, it is one of the following three forms:

- queue
- @server
- queue@server

If queue is specified, the request is for status of all jobs in that queue at the default server. If the @server form is given, the request is for status of all jobs at that server. If a full destination identifier, queue@server, is given, the request is for status of all jobs in the named queue at the named server.

If the **-Q** option is given, the operands are destination identifiers as specified above. If queue is specified, the status of that queue at the default server will be given. If queue@server is specified, the status of the named queue at the named server will be given. If @server is specified, the status of all queues at the named server will be given. If no destination is specified, the status of all queues at the default server will be given.

If the **-B** option is given, the operand is the name of a server.

## Standard output

### Displaying job status

If job status is being displayed in the default format and the **-f** option is not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the job identifier assigned by PBS.
- the job name given by the submitter.
- the job owner.
- the CPU time used.
- the job state:

Item	Description
<b>C</b>	Job is completed after having run.
<b>E</b>	Job is exiting after having run.
<b>H</b>	Job is held.
<b>Q</b>	Job is queued, eligible to run or routed.
<b>R</b>	Job is running.
<b>T</b>	Job is being moved to new location.

Item	Description
<b>W</b>	Job is waiting for its execution time ( <a href="#">-a</a> option) to be reached.
<b>S</b>	(Unicos only) Job is suspended.

- the queue in which the job resides.

If job status is being displayed and the [-f](#) option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See [Configuration on page 2743](#) for details. If Tcl is not being used, full display for each job consists of the header line:

```
Job Id: job identifier
```

Followed by one line per job attribute of the form:

```
attribute_name = value
```

If any of the options [-a](#), [-i](#), [-r](#), [-u](#), [-n](#), [-s](#), [-G](#), or [-M](#) are provided, the alternative display format for jobs is used. The following items are displayed on a single line, in the specified order, separated by white space:

- the job identifier assigned by PBS
- the job owner
- the queue in which the job currently resides
- the job name given by the submitter
- the session id (if the job is running)
- the number of nodes requested by the job
- the number of cpus or tasks requested by the job
- the amount of memory requested by the job
- either the cpu time, if specified, or wall time requested by the job, (hh:mm)
- the jobs current state
- the amount of cpu time or wall time used by the job (hh:mm)

If the [-r](#) option is provided, the line contains:

- the job identifier assigned by PBS
- the job owner
- the queue in which the job currently resides
- the number of nodes requested by the job
- the number of cpus or tasks requested by the job
- the amount of memory requested by the job
- either the cpu time or wall time requested by the job

- the jobs current state
- the amount of cpu time or wall time used by the job
- the amount of SRFS space requested on the big file system
- the amount of SRFS space requested on the fast file system
- the amount of space requested on the parallel I/O file system

The last three fields may not contain useful information at all sites or on all systems

## Displaying queue status

If queue status is being displayed and the `-f` option was not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the queue name
- the maximum number of jobs that may be run in the queue concurrently
- the total number of jobs in the queue
- the enable or disabled status of the queue
- the started or stopped status of the queue
- for each job state, the name of the state and the number of jobs in the queue in that state
- the type of queue, execution or routing

If queue status is being displayed and the `-f` option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See [Configuration on page 2743](#) for details. If Tcl is not being used, the full display for each queue consists of the header line:

```
Queue: queue_name
```

Followed by one line per queue attribute of the form:

```
attribute_name = value
```

If the `-Q` option is specified, queue information is displayed in the alternative format: The following information is displayed on a single line:

- the queue name
- the maximum amount of memory a job in the queue may request
- the maximum amount of cpu time a job in the queue may request
- the maximum amount of wall time a job in the queue may request
- the maximum amount of nodes a job in the queue may request
- the number of jobs in the queue in the running state
- the number of jobs in the queue in the queued state
- the maximum number (limit) of jobs that may be run in the queue concurrently

- the state of the queue given by a pair of letters:
  - either the letter *E* if the queue is Enabled or *D* if Disabled
  - and
  - either the letter *R* if the queue is Running (started) or *S* if Stopped.

### Displaying server status

If batch server status is being displayed and the `-f` option is not specified, the following items are displayed on a single line, in the specified order, separated by white space:

- the server name
- the maximum number of jobs that the server may run concurrently
- the total number of jobs currently managed by the server
- the status of the server
- for each job state, the name of the state and the number of jobs in the server in that state

If server status is being displayed and the `-f` option is specified, the output will depend on whether `qstat` was compiled to use a Tcl interpreter. See [Configuration on page 2743](#) for details. If Tcl is not being used, the full display for the server consists of the header line:

```
Server: server name
```

Followed by one line per server attribute of the form:

```
attribute_name = value
```

### Standard error

The `qstat` command will write a diagnostic message to standard error for each error occurrence.

### Configuration

If `qstat` is compiled with an option to include a Tcl interpreter, using the `-f` flag to get a full display causes a check to be made for a script file to use to output the requested information. The first location checked is `$HOME/.qstatrc`. If this does not exist, the next location checked is administrator configured. If one of these is found, a Tcl interpreter is started and the script file is passed to it along with three global variables. The command line arguments are split into two variable named flags and operands. The status information is passed in a variable named `objects`. All of these variables are Tcl lists. The flags list contains the name of the command (usually "qstat") as its first element. Any other elements are command line option flags with any options they use, presented in the order given on the command line. They are broken up individually so that if two flags are given together on the command line, they are separated in the list. For example, if the user typed:

```
qstat -QfWbigdisplay
```

the flags list would contain

```
qstat -Q -f -W bigdisplay
```

The operands list contains all other command line arguments following the flags. There will always be at least one element in operands because if no operands are typed by the user, the default destination or server name is used. The objects list contains all the information retrieved from the server(s) so the Tcl interpreter can run once to format the entire output. This list has the same number of elements as the operands list. Each element is another list with two elements.

The first element is a string giving the type of objects to be found in the second. The string can take the values "server", "queue", "job" or "error".

The second element will be a list in which each element is a single batch status object of the type given by the string discussed above. In the case of "error", the list will be empty. Each object is again a list. The first element is the name of the object. The second is a list of attributes.

The third element will be the object text.

All three of these object elements correspond with fields in the structure `batch_status` which is described in detail for each type of object by the man pages for `pbs_statjob(3)`, `pbs_statque(3)`, and `pbs_statsserver(3)`. Each attribute in the second element list whose elements correspond with the `attr1` structure. Each will be a list with two elements. The first will be the attribute name and the second will be the attribute value.

## Exit status

Upon successful processing of all the operands presented to the `qstat` command, the exit status will be a value of zero.

If the `qstat` command fails to process any operand, the command exits with a value greater than zero.

## qsub

Submit PBS job.

## Synopsis

```
qsub [-a date_time] [-A account_string] [-b secs] [-c checkpoint_options]
[-C directive_prefix] [-d path] [-D path] [-e path] [-f] [-F] [-h]
[-I ] [-j join ] [-k keep ] [-l resource_list ]
[-m mail_options] [-M user_list] [-n] [-N name] [-o path]
[-p priority] [-P user[:group]] [-q destination] [-r c] [-S path_to_shell(s)]
[-t array_request] [-u user_list]
[-v variable_list] [-V] [-W additional_attributes] [-x] [-X] [-z] [script]
```

## Description

To create a job is to submit an executable script to a batch server. The batch server will be the default server unless the **-q** option is specified. The command parses a script prior to the actual script execution; it does not execute a script itself. All script-writing rules remain in effect, including the **"#!"** at the head of the file (see discussion of **PBS\_DEFAULT** under [Environment variables on page 2760](#)). Typically, the script is a shell script which will be executed by a command shell such as **sh** or **csh**.

Options on the **qsub** command allow the specification of attributes which affect the behavior of the job.

The **qsub** command will pass certain environment variables in the **Variable\_List** attribute of the job. These variables will be available to the job. The value for the following variables will be taken from the environment of the **qsub** command: **HOME**, **LANG**, **LOGNAME**, **PATH**, **MAIL**, **SHELL**, and **TZ**. These values will be assigned to a new name which is the current name prefixed with the string **"PBS\_O\_"**. For example, the job will have access to an environment variable named **PBS\_O\_HOME** which have the value of the variable **HOME** in the **qsub** command environment.

In addition to the above, the following environment variables will be available to the batch job:

Variable	Description
<b>PBS_O_HOST</b>	The name of the host upon which the <b>qsub</b> command is running.
<b>PBS_SERVER</b>	The hostname of the <b>pbs_server</b> which <b>qsub</b> submits the job to.
<b>PBS_O_QUEUE</b>	The name of the original queue to which the job was submitted.
<b>PBS_O_WORKDIR</b>	The absolute path of the current working directory of the <b>qsub</b> command.
<b>PBS_ARRAYID</b>	Each member of a job array is assigned a unique identifier (see <b>-t</b> option).
<b>PBS_ENVIRONMENT</b>	Set to <b>PBS_BATCH</b> to indicate the job is a batch job, or to <b>PBS_INTERACTIVE</b> to indicate the job is a PBS interactive job (see <b>-I</b> option).
<b>PBS_GPUFILE</b>	The name of the file containing the list of assigned GPUs. For more information about how to set up TORQUE with GPUS, see <a href="#">Accelerators on page 815</a> .

Variable	Description
<b>PBS_JOBID</b>	The job identifier assigned to the job by the batch system. It can be used in the stdout and stderr paths. TORQUE replaces <code>\$PBS_JOBID</code> with the job's jobid (for example, <code>#PBS -o /tmp/\$PBS_JOBID.output</code> ).
<b>PBS_JOBNAME</b>	The job name supplied by the user.
<b>PBS_NODEFILE</b>	The name of the file contains the list of nodes assigned to the job (for parallel and cluster systems).
<b>PBS_QUEUE</b>	The name of the queue from which the job is executed.

## Options

Option	Name	Description
<b>-a</b>	date_time	<p>Declares the time after which the job is eligible for execution.</p> <p>The <code>date_time</code> argument is in the form:</p> <pre>[[ [CC] YY] MM] DD] hhmm [ . SS]</pre> <p>where <i>CC</i> is the first two digits of the year (the century), <i>YY</i> is the second two digits of the year, <i>MM</i> is the two digits for the month, <i>DD</i> is the day of the month, <i>hh</i> is the hour, <i>mm</i> is the minute, and the optional <i>SS</i> is the seconds.</p> <p>If the month (<i>MM</i>) is not specified, it will default to the current month if the specified day (<i>DD</i>) is in the future. Otherwise, the month will be set to next month. Likewise, if the day (<i>DD</i>) is not specified, it will default to today if the time (<i>hhmm</i>) is in the future. Otherwise, the day will be set to tomorrow.</p> <p>For example, if you submit a job at 11:15 am with a time of <code>-a 1110</code>, the job will be eligible to run at 11:10 am tomorrow.</p>
<b>-A</b>	account_string	<p>Defines the account string associated with the job. The <code>account_string</code> is an undefined string of characters and is interpreted by the server which executes the job. See section 2.7.1 of the PBS ERS.</p>
<b>-b</b>	seconds	<p>Defines the maximum number of seconds <code>qsub</code> will block attempting to contact <code>pbs_server</code>. If <code>pbs_server</code> is down, or for a variety of communication failures, <code>qsub</code> will continually retry connecting to <code>pbs_server</code> for job submission.</p> <p>This value overrides the <code>CLIENTRETRY</code> parameter in <code>torque.cfg</code>. This is a non-portable TORQUE extension. Portability-minded users can use the <code>PBS_CLIENTRETRY</code> environmental variable. A negative value is interpreted as infinity. The default is 0.</p>

Option	Name	Description
<b>-c</b>	checkpoint_options	<p>Defines the options that will apply to the job. If the job executes upon a host which does not support checkpoint, these options will be ignored.</p> <p>Valid checkpoint options are:</p> <ul style="list-style-type: none"> <li>• <i>none</i> – No checkpointing is to be performed.</li> <li>• <i>enabled</i> – Specify that checkpointing is allowed but must be explicitly invoked by either the <a href="#">ghold</a> or <a href="#">gchkpt</a> commands.</li> <li>• <i>shutdown</i> – Specify that checkpointing is to be done on a job at pbs_mom shutdown.</li> <li>• <i>periodic</i> – Specify that periodic checkpointing is enabled. The default interval is 10 minutes and can be changed by the \$checkpoint_interval option in the MOM config file or by specifying an interval when the job is submitted</li> <li>• <i>interval=minutes</i> – Checkpointing is to be performed at an interval of minutes, which is the integer number of minutes of wall time used by the job. This value must be greater than zero.</li> <li>• <i>depth=number</i> – Specify a number (depth) of checkpoint images to be kept in the checkpoint directory.</li> <li>• <i>dir=path</i> – Specify a checkpoint directory (default is /var/spool/torque/checkpoint).</li> </ul>
<b>-C</b>	directive_prefix	<p>Defines the prefix that declares a directive to the qsub command within the script file. (See the paragraph on script directives under <a href="#">Extended description on page 2761</a>.)</p> <p>If the -C option is presented with a directive_prefix argument that is the null string, qsub will not scan the script file for directives.</p>
<b>-d</b>	path	<p>Defines the working directory path to be used for the job. If the -d option is not specified, the default working directory is the home directory. This option sets the environment variable PBS_O_INITDIR.</p>
<b>-D</b>	path	<p>Defines the root directory to be used for the job. This option sets the environment variable PBS_O_ROOTDIR.</p>

Option	Name	Description
<b>-e</b>	path	<p>Defines the path to be used for the standard error stream of the batch job. The path argument is of the form:</p> <pre>[hostname:]path_name</pre> <p>where <i>hostname</i> is the name of a host to which the file will be returned, and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX.</p> <div data-bbox="516 495 1409 585" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <p> When specifying a directory for the location you need to include a trailing slash.</p> </div> <p>The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> <li>• <i>path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component.</li> <li>• <i>hostname:path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will not expand the path name relative to the current working directory of the command. On delivery of the standard error, the path name will be expanded relative to the user's home directory on the hostname system.</li> <li>• <i>path_name</i> – where <i>path_name</i> specifies an absolute path name, then the <code>qsub</code> will supply the name of the host on which it is executing for the hostname.</li> <li>• <i>hostname:path_name</i> – where <i>path_name</i> specifies an absolute path name, the path will be used as specified.</li> </ul> <p>If the <code>-e</code> option is not specified, the default file name for the standard error stream will be used. The default name has the following form:</p> <ul style="list-style-type: none"> <li>• <i>job_name.esquence_number</i> – where <i>job_name</i> is the name of the job (see the <code>-n</code> name option) and <i>sequence_number</i> is the job number assigned when the job is submitted.</li> </ul>
<b>-f</b>	---	<p>Job is made fault tolerant. Jobs running on multiple nodes are periodically polled by mother superior. If one of the nodes fails to report, the job is canceled by mother superior and a failure is reported. If a job is fault tolerant, it will not be canceled based on failed polling (no matter how many nodes fail to report). This may be desirable if transient network failures are causing large jobs not to complete, where ignoring one failed polling attempt can be corrected at the next polling attempt.</p> <div data-bbox="516 1478 1409 1602" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <p> If TORQUE is compiled with <code>PBS_NO_POSIX_VIOLATION</code> (there is no config option for this), you have to use <code>-W fault_tolerant=true</code> to mark the job as fault tolerant.</p> </div>

Option	Name	Description
<b>-F</b>	---	<p>Specifies the arguments that will be passed to the job script when the script is launched. The accepted syntax is:</p> <pre>qsub -F "myarg1 myarg2 myarg3=myarg3value" myscript2.sh</pre> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> Quotation marks are required. <code>qsub</code> will fail with an error message if the argument following <code>-F</code> is not a quoted value. The <code>pbs_mom</code> server will pass the quoted value as arguments to the job script when it launches the script.</p> </div>
<b>-h</b>	---	Specifies that a user hold be applied to the job at submission time.
<b>-i</b>	---	<p>Declares that the job is to be run "interactively". The job will be queued and scheduled as any PBS batch job, but when executed, the standard input, output, and error streams of the job are connected through <code>qsub</code> to the terminal session in which <code>qsub</code> is running. Interactive jobs are forced to not rerunable. See <a href="#">Extended description on page 2761</a> for additional information of interactive jobs.</p>
<b>-j</b>	join	<p>Declares if the standard error stream of the job will be merged with the standard output stream of the job.</p> <p>An option argument value of <code>oe</code> directs that the two streams will be merged, intermixed, as standard output. An option argument value of <code>eo</code> directs that the two streams will be merged, intermixed, as standard error.</p> <p>If the join argument is <code>n</code> or the option is not specified, the two streams will be two separate files.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p><b>i</b> If using either the <code>-e</code> or the <code>-o</code> option and the <code>-j eo oe</code> option, the <code>-j</code> option takes precedence and all standard error and output messages go to the chosen output file.</p> </div>

Option	Name	Description
<b>-k</b>	keep	<p>Defines which (if either) of standard output or standard error will be retained on the execution host. If set for a stream, this option overrides the path name for that stream. If not set, neither stream is retained on the execution host.</p> <p>The argument is either the single letter "e" or "o", or the letters "e" and "o" combined in either order. Or the argument is the letter "n".</p> <ul style="list-style-type: none"> <li>• <i>e</i> – The standard error stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.esquence</code> where <i>job_name</i> is the name specified for the job, and <i>sequence</i> is the sequence number component of the job identifier.</li> <li>• <i>o</i> – The standard output stream is to be retained on the execution host. The stream will be placed in the home directory of the user under whose user id the job executed. The file name will be the default file name given by: <code>job_name.osequence</code> where <i>job_name</i> is the name specified for the job, and <i>sequence</i> is the sequence number component of the job identifier.</li> <li>• <i>eo</i> – Both the standard output and standard error streams will be retained.</li> <li>• <i>oe</i> – Both the standard output and standard error streams will be retained.</li> <li>• <i>n</i> – Neither stream is retained.</li> </ul>
<b>-l</b>	resource_list	<p>Defines the resources that are required by the job and establishes a limit to the amount of resource that can be consumed. If not set for a generally available resource, such as CPU time, the limit is infinite. The <b>resource_list</b> argument is of the form: <code>resource_name [= [value]] [, resource_name [= [value]] , ...]</code></p> <div data-bbox="516 1199 1409 1291" style="border: 1px solid #0070C0; border-radius: 10px; padding: 10px; background-color: #E6F2FF;"> <p> In this situation, you should request the more inclusive resource first. For example, a request for procs should come before a gres request.</p> </div> <p>In TORQUE 3.0.2 or later, <code>qsub</code> supports the mapping of <code>-l gpus=X to -l gres=gpus:X</code>. This allows users who are using NUMA systems to make requests such as <code>-l ncpus=20:gpus=5</code> indicating they are not concerned with the GPUs in relation to the NUMA nodes they request, they only want a total of 20 cores and 5 GPUs. For more information, see <a href="#">Requesting resources on page 2586</a>.</p> <p>For information on specifying multiple types of resources for allocation, see .</p>

Option	Name	Description
<b>-m</b>	mail_options	<p>Defines the set of conditions under which the execution server will send a mail message about the job. The mail_options argument is a string which consists of either the single character "n", or one or more of the characters "a", "b", and "e".</p> <p>If the character "n" is specified, no normal mail is sent. Mail for job cancels and other events outside of normal job processing are still sent.</p> <p>For the letters "a", "b", and "e":</p> <ul style="list-style-type: none"> <li>• <i>a</i> – Mail is sent when the job is aborted by the batch system.</li> <li>• <i>b</i> – Mail is sent when the job begins execution.</li> <li>• <i>e</i> – Mail is sent when the job terminates.</li> </ul> <p>If the <code>-m</code> option is not specified, mail will be sent if the job is aborted.</p>
<b>-M</b>	user_list	<p>Declares the list of users to whom mail is sent by the execution server when it sends mail about the job.</p> <p>The user_list argument is of the form:</p> <pre>user[@host] [, user[@host] , ... ]</pre> <p>If unset, the list defaults to the submitting user at the qsub host, i.e. the job owner.</p>
<b>-n</b>	node-exclusive	<p>Allows a user to specify an exclusive-node access/allocation request for the job. This affects only cpusets and compatible schedulers (see <a href="#">Linux cpuset support on page 2623</a>).</p>
<b>-N</b>	name	<p>Declares a name for the job. The name specified may be an unlimited number of characters in length. It must consist of printable, nonwhite space characters with the first character alphabetic.</p> <p>If the <code>-N</code> option is not specified, the job name will be the base name of the job script file specified on the command line. If no script file name was specified and the script was read from the standard input, then the job name will be set to STDIN.</p>

Option	Name	Description
<b>-o</b>	path	<p>Defines the path to be used for the standard output stream of the batch job. The path argument is of the form:</p> <pre>[hostname:]path_name</pre> <p>where <i>hostname</i> is the name of a host to which the file will be returned, and <i>path_name</i> is the path name on that host in the syntax recognized by POSIX.</p> <div style="border: 1px solid black; border-radius: 10px; padding: 5px; margin: 10px 0;">  When specifying a directory for the location you need to include a trailing slash. </div> <p>The argument will be interpreted as follows:</p> <ul style="list-style-type: none"> <li>• <i>path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will expand the path name relative to the current working directory of the command. The command will supply the name of the host upon which it is executing for the hostname component.</li> <li>• <i>hostname:path_name</i> – where <i>path_name</i> is not an absolute path name, then the <code>qsub</code> command will not expand the path name relative to the current working directory of the command. On delivery of the standard output, the path name will be expanded relative to the user's home directory on the hostname system.</li> <li>• <i>path_name</i> – where <i>path_name</i> specifies an absolute path name, then the <code>qsub</code> will supply the name of the host on which it is executing for the hostname.</li> <li>• <i>hostname:path_name</i> where <i>path_name</i> specifies an absolute path name, the path will be used as specified.</li> </ul> <p>If the <code>-o</code> option is not specified, the default file name for the standard output stream will be used. The default name has the following form:</p> <ul style="list-style-type: none"> <li>• <i>job_name.osequence_number</i> – where <i>job_name</i> is the name of the job (see the <a href="#">-n</a> name option) and <i>sequence_number</i> is the job number assigned when the job is submitted.</li> </ul>
<b>-p</b>	priority	<p>Defines the priority of the job. The priority argument must be a integer between -1024 and +1023 inclusive. The default is no priority which is equivalent to a priority of zero.</p>
<b>-P</b>	user [:group]	<p>Allows a root user or manager to submit a job as another user. TORQUE treats proxy jobs as though the jobs were submitted by the supplied username. This feature is available in TORQUE 2.4.7 and later, however, TORQUE 2.4.7 does not have the ability to supply the <code>[:group]</code> option; it is available in TORQUE 2.4.8 and later.</p>

Option	Name	Description
<b>-q</b>	destination	<p>Defines the destination of the job. The destination names a queue, a server, or a queue at a server.</p> <p>The <code>qsub</code> command will submit the script to the server defined by the destination argument. If the destination is a routing queue, the job may be routed by the server to a new destination.</p> <p>If the <code>-q</code> option is not specified, the <code>qsub</code> command will submit the script to the default server. (See <a href="#">Environment variables on page 2760</a> and the PBS ERS section 2.7.4, "Default Server".)</p> <p>If the <code>-q</code> option is specified, it is in one of the following three forms:</p> <ul style="list-style-type: none"> <li>• queue</li> <li>• @server</li> <li>• queue@server</li> </ul> <p>If the destination argument names a queue and does not name a server, the job will be submitted to the named queue at the default server.</p> <p>If the destination argument names a server and does not name a queue, the job will be submitted to the default queue at the named server.</p> <p>If the destination argument names both a queue and a server, the job will be submitted to the named queue at the named server.</p>
<b>-r</b>	y/n	<p>Declares whether the job is rerunnable (see the <a href="#">qrerun</a> command). The option argument is a single character, either y or n.</p> <p>If the argument is "y", the job is rerunnable. If the argument is "n", the job is not rerunnable. The default value is y, rerunnable.</p>
<b>-S</b>	path_list	<p>Declares the path to the desired shell for this job.</p> <pre>qsub script.sh -S /bin/tcsh</pre> <p>If the shell path is different on different compute nodes, use the following syntax:</p> <pre>path[@host] [,path[@host], ...]</pre> <pre>qsub script.sh -S /bin/tcsh@node1,/usr/bin/tcsh@node2</pre> <p>Only one path may be specified for any host named. Only one path may be specified without the corresponding host name. The path selected will be the one with the host name that matched the name of the execution host. If no matching host is found, then the path specified without a host will be selected, if present.</p> <p>If the <code>-S</code> option is not specified, the option argument is the null string, or no entry from the <code>path_list</code> is selected, the execution will use the user's login shell on the execution host.</p>

Option	Name	Description
<b>-t</b>	array_request	<p>Specifies the task ids of a job array. Single task arrays are allowed.</p> <p>The <code>array_request</code> argument is an integer id or a range of integers. Multiple ids or id ranges can be combined in a comma delimited list. Examples: <code>-t 1-100</code> or <code>-t 1,10,50-100</code></p> <p>An optional <i>slot limit</i> can be specified to limit the amount of jobs that can run concurrently in the job array. The default value is unlimited. The slot limit must be the last thing specified in the <code>array_request</code> and is delimited from the array by a percent sign (%).</p> <pre>qsub script.sh -t 0-299%5</pre> <p>This sets the slot limit to 5. Only 5 jobs from this array can run at the same time.</p> <p>You can use <a href="#">qalter</a> to modify slot limits on an array. The server parameter <a href="#">max_slot_limit</a> can be used to set a global slot limit policy.</p>
<b>-u</b>	user_list	<p>Defines the user name under which the job is to run on the execution system.</p> <p>The <code>user_list</code> argument is of the form:</p> <pre>user[@host] [,user[@host],...]</pre> <p>Only one user name may be given per specified host. Only one of the user specifications may be supplied without the corresponding host specification. That user name will be used for execution on any host not named in the argument list. If unset, the user list defaults to the user who is running <code>qsub</code>.</p>
<b>-v</b>	variable_list	<p>Expands the list of environment variables that are exported to the job.</p> <p>In addition to the variables described in the "Description" section above, <code>variable_list</code> names environment variables from the <code>qsub</code> command environment which are made available to the job when it executes. The <code>variable_list</code> is a comma separated list of strings of the form <code>variable</code> or <code>variable=value</code>. These variables and their values are passed to the job. Note that <code>-v</code> has a higher precedence than <code>-V</code>, so identically named variables specified via <code>-v</code> will provide the final value for an environment variable in the job.</p>
<b>-V</b>	---	<p>Declares that all environment variables in the <code>qsub</code> commands environment are to be exported to the batch job.</p>

Option	Name	Description
-W	additional_attributes	<p>The <code>-W</code> option allows for the specification of additional job attributes. The general syntax of <code>-W</code> is in the form:</p> <pre>-W attr_name=attr_value.</pre> <p>You can use multiple <code>-W</code> options with this syntax:</p> <pre>-W attr_name1=attr_value1 -W attr_name2=attr_value2.</pre> <div data-bbox="544 499 1432 625" style="border: 1px solid black; padding: 5px; margin: 10px 0;"> <p><b>i</b> If white space occurs anywhere within the option argument string or the equal sign, "=", occurs within an attribute_value string, then the string must be enclosed with either single or double quote marks.</p> </div> <p>PBS currently supports the following attributes within the <code>-W</code> option:</p> <ul style="list-style-type: none"> <li>• <code>depend=dependency_list</code> – Defines the dependency between this and other jobs. The <code>dependency_list</code> is in the form: <pre>type[:argument[:argument...]][,type:argument...]</pre> <p>The argument is either a numeric count or a PBS job id according to type. If argument is a count, it must be greater than 0. If it is a job id and not fully specified in the form <code>seq_number.server.name</code>, it will be expanded according to the default server rules which apply to job IDs on most commands. If argument is null (the preceding colon need not be specified), the dependency of the corresponding type is cleared (unset). For more information, see <a href="#">depend=dependency_list valid dependencies on page 2756</a>.</p> </li> <li>• <code>group_list=g_list</code> – Defines the group name under which the job is to run on the execution system. The <code>g_list</code> argument is of the form: <pre>group[@host][,group[@host],...]</pre> <p>Only one group name may be given per specified host. Only one of the group specifications may be supplied without the corresponding host specification. That group name will used for execution on any host not named in the argument list. If not set, the <code>group_list</code> defaults to the primary group of the user under which the job will be run.</p> </li> <li>• <code>interactive=true</code> – If the interactive attribute is specified, the job is an interactive job. The <code>-I</code> option is an alternative method of specifying this attribute.</li> <li>• <code>job_radix=&lt;int&gt;</code> – To be used with parallel jobs. It directs the Mother Superior of the job to create a distribution radix of size <code>&lt;int&gt;</code> between sisters. See <a href="#">Managing multi-node jobs on page 2585</a>.</li> <li>• <code>stagein=file_list</code></li> <li>• <code>stageout=file_list</code> – Specifies which files are staged (copied) in before job start or staged out after the job completes execution. On completion of the job, all staged-in and staged-out files are removed from the execution system. The <code>file_list</code> is in the form: <pre>local_file@hostname:remote_file[,...]</pre> <p>regardless of the direction of the copy. The name <code>local_file</code> is the name of the file on the system where the job executed. It may be an absolute path or relative to the home directory of the user. The name <code>remote_file</code> is the destination name on the host specified by <code>hostname</code>. The name may be</p> </li> </ul>

Option	Name	Description
		<p>absolute or relative to the user's home directory on the destination host. The use of wildcards in the file name is not recommended. The file names map to a remote copy program (rcp) call on the execution system in the follow manner:</p> <ul style="list-style-type: none"> <li>◦ For stagein: <code>rcp hostname:remote_file local_file</code></li> <li>◦ For stageout: <code>rcp local_file hostname:remote_file</code></li> </ul> <p>Data staging examples:</p> <pre>-W stagein=/tmp/input.txt@headnode:/home/user/input.txt -W stageout=/tmp/output.txt@headnode:/home/user/output.txt</pre> <p>If TORQUE has been compiled with wordexp support, then variables can be used in the specified paths. Currently only \$PBS_JOBID, \$HOME, and \$TMPDIR are supported for stagein.</p> <ul style="list-style-type: none"> <li>• <code>umask=XXX</code> – Sets umask used to create stdout and stderr spool files in pbs_mom spool directory. Values starting with 0 are treated as octal values, otherwise the value is treated as a decimal umask value.</li> </ul>
<b>-x</b>	---	<p>By default, if you submit an interactive job with a script, the script will be parsed for PBS directives but the rest of the script will be ignored since it's an interactive job. The <code>-x</code> option allows the script to be executed in the interactive job and then the job completes. For example:</p> <pre>script.sh #!/bin/bash ls ---end script---</pre> <pre>qsub -I script.sh qsub: waiting for job 5.napali to start dbeer@napali:~# &lt;displays the contents of the directory, because of the ls command&gt; qsub: job 5.napali completed</pre>
<b>-X</b>	---	Enables X11 forwarding. The DISPLAY environment variable must be set.
<b>-z</b>	---	Directs that the <code>qsub</code> command is not to write the job identifier assigned to the job to the commands standard output.

### depend=dependency\_list valid dependencies

For job dependencies to work correctly, you must set the [keep\\_completed](#) on page 2772 server parameter.

Dependency	Description
<code>synccount:count</code>	This job is the first in a set of jobs to be executed at the same time. Count is the number of additional jobs in the set.
<code>syncwith:jobid</code>	This job is an additional member of a set of jobs to be executed at the same time. In the above and following dependency types, jobid is the job identifier of the first job in the set.
<code>after:jobid[:jobid...]</code>	This job may be scheduled for execution at any point after jobs jobid have started execution.
<code>afterok:jobid[:jobid...]</code>	This job may be scheduled for execution only after jobs jobid have terminated with no errors. See the csh warning under <a href="#">Extended description on page 2761</a> .
<code>afternotok:jobid[:jobid...]</code>	This job may be scheduled for execution only after jobs jobid have terminated with errors. See the csh warning under <a href="#">Extended description on page 2761</a> .
<code>afterany:jobid[:jobid...]</code>	This job may be scheduled for execution after jobs jobid have terminated, with or without errors.
<code>on:count</code>	This job may be scheduled for execution after count dependencies on other jobs have been satisfied. This form is used in conjunction with one of the "before" forms (see below).
<code>before:jobid[:jobid...]</code>	When this job has begun execution, then jobs jobid... may begin.
<code>beforeok:jobid[:jobid...]</code>	If this job terminates execution without errors, then jobs jobid... may begin. See the csh warning under <a href="#">Extended description on page 2761</a> .
<code>beforenotok:jobid[:jobid...]</code>	If this job terminates execution with errors, then jobs jobid... may begin. See the csh warning under <a href="#">Extended description on page 2761</a> .

Dependency	Description
beforeany:jobid[:jobid...]	<p>When this job terminates execution, jobs jobid... may begin.</p> <p>If any of the before forms are used, the jobs referenced by jobid must have been submitted with a dependency type of on.</p> <p>If any of the before forms are used, the jobs referenced by jobid must have the same owner as the job being submitted. Otherwise, the dependency is ignored.</p>
<p><b>i</b> Array dependencies make a job depend on an array or part of an array. If no count is given, then the entire array is assumed. For examples, see <a href="#">Dependency examples on page 2759</a>.</p>	
afterstartarray:arrayid[count]	<p>After this many jobs have started from arrayid, this job may start.</p>
afterokarray:arrayid[count]	<p>This job may be scheduled for execution only after jobs in arrayid have terminated with no errors.</p>
afternotokarray:arrayid[count]	<p>This job may be scheduled for execution only after jobs in arrayid have terminated with errors.</p>
afteranyarray:arrayid[count]	<p>This job may be scheduled for execution after jobs in arrayid have terminated, with or without errors.</p>
beforestartarray:arrayid[count]	<p>Before this many jobs have started from arrayid, this job may start.</p>
beforeokarray:arrayid[count]	<p>If this job terminates execution without errors, then jobs in arrayid may begin.</p>
beforenotokarray:arrayid[count]	<p>If this job terminates execution with errors, then jobs in arrayid may begin.</p>
beforeanyarray:arrayid[count]	<p>When this job terminates execution, jobs in arrayid may begin.</p> <p>If any of the before forms are used, the jobs referenced by arrayid must have been submitted with a dependency type of on.</p> <p>If any of the before forms are used, the jobs referenced by arrayid must have the same owner as the job being submitted. Otherwise, the dependency is ignored.</p>

Dependency	Description
<p><b>i</b> Error processing of the existence, state, or condition of the job on which the newly submitted job is a deferred service, i.e. the check is performed after the job is queued. If an error is detected, the new job will be deleted by the server. Mail will be sent to the job submitter stating the error.</p>	

## Dependency examples

```
qsub -W depend=afterok:123.big.iron.com /tmp/script
```

```
qsub -W depend=before:234.hunk1.com:235.hunk1.com
```

```
/tmp/script
```

```
qsub script.sh -W depend=afterokarray:427 []
```

(This assumes every job in array 427 has to finish successfully for the dependency to be satisfied.)

```
qsub script.sh -W depend=afterokarray:427 [] [5]
```

(This means that 5 of the jobs in array 427 have to successfully finish in order for the dependency to be satisfied.)

## Operands

The `qsub` command accepts a script operand that is the path to the script of the job. If the path is relative, it will be expanded relative to the working directory of the `qsub` command.

If the script operand is not provided or the operand is the single character "-", the `qsub` command reads the script from standard input. When the script is being read from Standard Input, `qsub` will copy the file to a temporary file. This temporary file is passed to the library interface routine `pbs_submit`. The temporary file is removed by `qsub` after `pbs_submit` returns or upon the receipt of a signal which would cause `qsub` to terminate.

## Standard input

The `qsub` command reads the script for the job from standard input if the script operand is missing or is the single character "-".

## Input files

The script file is read by the `qsub` command. `qsub` acts upon any directives found in the script.

When the job is created, a copy of the script file is made and that copy cannot be modified.

## Standard output

Unless the `-z` option is set, the job identifier assigned to the job will be written to standard output if the job is successfully created.

## Standard error

The `qsub` command will write a diagnostic message to standard error for each error occurrence.

## Environment variables

The values of some or all of the variables in the `qsub` commands environment are exported with the job (see the `-v` and `-V` options).

The environment variable `PBS_DEFAULT` defines the name of the default server. Typically, it corresponds to the system name of the host on which the server is running. If `PBS_DEFAULT` is not set, the default is defined by an administrator established file.

The environment variable `PBS_DPREFIX` determines the prefix string which identifies directives in the script.

The environment variable `PBS_CLIENTRETRY` defines the maximum number of seconds `qsub` will block (see the `-b` option). Despite the name, currently `qsub` is the only client that supports this option.

## torque.cfg

The `torque.cfg` file, located in `PBS_SERVER_HOME` (`/var/spool/torque` by default) controls the behavior of the `qsub` command. This file contains a list of parameters and values separated by whitespace.

- *QSUBSLEEP* – takes an integer operand which specifies time to sleep when running `qsub` command. Used to prevent users from overwhelming the scheduler.
- *SUBMITFILTER* – specifies the path to the submit filter used to pre-process job submission. The default path is `libexecdir/qsub_filter`, which falls back to `/usr/local/sbin/torque_submitfilter` for backwards compatibility. This `torque.cfg` parameter overrides this default.
- *SERVERHOST*
- *QSUBHOST*
- *QSUBSENDUID*
- *XAUTHPATH*
- *CLIENTRETRY*
- *VALIDATEGROUP*
- *DEFAULTCKPT*
- *VALIDATEPATH*
- *RERUNNABLEBYDEFAULT*

For example:

```
QSUBSLEEP 2
```

```
RERUNNABLEBYDEFAULT false
```

## Extended description

### Script Processing:

A job script may consist of PBS directives, comments and executable statements. A PBS directive provides a way of specifying job attributes in addition to the command line options. For example:

```

:
#PBS -N Job_name
#PBS -l walltime=10:30,mem=320kb
#PBS -m be
#
step1 arg1 arg2
step2 arg3 arg4

```

The `qsub` command scans the lines of the script file for directives. An initial line in the script that begins with the characters `#!/` or the character `:` will be ignored and scanning will start with the next line. Scanning will continue until the first executable line, that is a line that is not blank, not a directive line, nor a line whose first nonwhite space character is `#`. If directives occur on subsequent lines, they will be ignored.

A line in the script file will be processed as a directive to `qsub` if and only if the string of characters starting with the first nonwhite space character on the line and of the same length as the directive prefix matches the directive prefix.

The remainder of the directive line consists of the options to `qsub` in the same syntax as they appear on the command line. The option character is to be preceded with the `-` character.

If an option is present in both a directive and on the command line, that option and its argument, if any, will be ignored in the directive. The command line takes precedence.

If an option is present in a directive and not on the command line, that option and its argument, if any, will be processed as if it had occurred on the command line.

The directive prefix string will be determined in order of preference from:

- The value of the `-c` option argument if the option is specified on the command line.
- The value of the environment variable `PBS_DPREFIX` if it is defined.
- The four character string `#PBS`.

If the `-c` option is found in a directive in the script file, it will be ignored.

### User Authorization:

When the user submits a job from a system other than the one on which the PBS Server is running, the name under which the job is to be executed is selected according to the rules listed under the `-u` option. The user submitting the job must be authorized to run the job under the execution user name. This authorization is provided if:

- The host on which `qsub` is run is trusted by the execution host (see `/etc/hosts.equiv`).
- The execution user has an `.rhosts` file naming the submitting user on the submitting host.

## C-Shell .logout File:

The following warning applies for users of the c-shell, csh. If the job is executed under the csh and a `.logout` file exists in the home directory in which the job executes, the exit status of the job is that of the `.logout` script, not the job script. This may impact any inter-job dependencies. To preserve the job exit status, either remove the `.logout` file or place the following line as the first line in the `.logout` file:

```
set EXITVAL = $status
```

and the following line as the last executable line in `.logout`:

```
exit $EXITVAL
```

## Interactive Jobs:

If the `-i` option is specified on the command line or in a script directive, or if the "interactive" job attribute declared true via the `-W` option, `-W interactive=true`, either on the command line or in a script directive, the job is an interactive job. The script will be processed for directives, but will not be included with the job. When the job begins execution, all input to the job is from the terminal session in which `qsub` is running.

When an interactive job is submitted, the `qsub` command will not terminate when the job is submitted. `qsub` will remain running until the job terminates, is aborted, or the user interrupts `qsub` with a SIGINT (the control-C key). If `qsub` is interrupted prior to job start, it will query if the user wishes to exit. If the user response "yes", `qsub` exits and the job is aborted.

Once the interactive job has started execution, input to and output from the job pass through `qsub`. Keyboard generated interrupts are passed to the job. Lines entered that begin with the tilde (~) character and contain special sequences are escaped by `qsub`. The recognized escape sequences are:

Sequence	Description
~.	<code>qsub</code> terminates execution. The batch job is also terminated.
~susp	Suspend the <code>qsub</code> program if running under the C shell. "susp" is the suspend character (usually CNTL-Z).
~asusp	Suspend the input half of <code>qsub</code> (terminal to job), but allow output to continue to be displayed. Only works under the C shell. "asusp" is the auxiliary suspend character, usually CNTL-Y.

## Exit status

Upon successful processing, the `qsub` exit status will be a value of zero.

If the `qsub` command fails, the command exits with a value greater than zero.

## qterm

Terminate processing by a PBS batch server.

### Synopsis

```
qterm [-t type] [server...]
```

### Description

The `qterm` command terminates a batch server. When a server receives a terminate command, the server will go into the "Terminating" state. No new jobs will be allowed to be started into execution or enqueued into the server. The impact on jobs currently being run by the server depends

In order to execute `qterm`, the user must have PBS Operation or Manager privileges.

## Options

Option	Name	Description
<b>-t</b>	type	<p>Specifies the type of shut down. The types are:</p> <ul style="list-style-type: none"> <li>• <i>immediate</i> – If checkpointing is supported, all running jobs are to immediately stop execution. If checkpointing is supported, running jobs that can be checkpointed are checkpointed, terminated, and requeued. If checkpoint is not supported or the job cannot be checkpointed, running jobs are requeued if the rerunable attribute is true. Otherwise, jobs are killed.</li> <li>• <i>delay</i> – If checkpointing is supported, running jobs that can be checkpointed are checkpointed, terminated, and requeued. If a job cannot be checkpointed, but can be rerun, the job is terminated and requeued. Otherwise, running jobs are allowed to continue to run.</li> </ul> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin: 10px 0;"> <p> Note, the operator or administrator may use the <a href="#">qrerun</a> and <a href="#">qdel</a> commands to remove running jobs.</p> </div> <ul style="list-style-type: none"> <li>• <i>quick</i> – This is the default action if the <code>-t</code> option is not specified. This option is used when you wish that running jobs be left running when the server shuts down. The server will cleanly shutdown and can be restarted when desired. Upon restart of the server, jobs that continue to run are shown as running; jobs that terminated during the server's absence will be placed into the exiting state.</li> </ul>

## Operands

The server operand specifies which servers are to shut down. If no servers are given, then the default server will be terminated.

## Standard error

The `qterm` command will write a diagnostic message to standard error for each error occurrence.

## Exit status

Upon successful processing of all the operands presented to the `qterm` command, the exit status will be a value of zero.

If the `qterm` command fails to process any operand, the command exits with a value greater than zero.

## trqauthd

(TORQUE authorization daemon)

### Synopsis

```
trqauthd -D
trqauthd -d
```

### Description

The `trqauthd` daemon, introduced in TORQUE 4.0.0, replaced the `pbs_iff` authentication process. When users connect to `pbs_server` by calling one of the TORQUE utilities or by using the TORQUE APIs, the new user connection must be authorized by a trusted entity which runs as root. The advantage of `trqauthd`'s doing this rather than `pbs_iff` is that `trqauthd` is resident, meaning you do not need to be loaded every time a connection is made; multi-threaded; scalable; and more easily adapted to new functionality than `pbs_iff`.

Beginning in TORQUE 4.2.6, `trqauthd` can remember the currently active `pbs_server` host, enhancing high availability functionality. Previously, `trqauthd` tried to connect to each host in the `$TORQUE_HOME/<server_name>` file until it could successfully connect. Because it now remembers the active server, it tries to connect to that server first. If it fails to connect, it will go through the `<server_name>` file and try to connect to a host where an active `pbs_server` is running.

### Options

-D — Debug	
<b>Format</b>	---
<b>Default</b>	---
<b>Description</b>	Run <code>trqauthd</code> in debug mode.
<b>Example</b>	<code>trqauthd -D</code>

-d — Terminate	
<b>Format</b>	---

<b>-d — Terminate</b>	
<b>Default</b>	---
<b>Description</b>	Terminate trqauthd.
<b>Example</b>	<code>trqauthd -d</code>

## Appendix B: Server parameters

TORQUE server parameters are specified using the [qmgr](#) command. The `set` subcommand is used to modify the **server** object. For example:

```
> qmgr -c 'set server default_queue=batch'
```

### Parameters

<b>acl_hosts</b>	
<b>Format</b>	<HOST>[,<HOST>]... <i>or</i> <HOST>[range] <i>or</i> <HOST*> where the asterisk (*) can appear anywhere in the host name
<b>Default</b>	(Only the host running <code>pbs_server</code> may submit jobs.)
<b>Description</b>	<p>Specifies a list of hosts from which jobs may be submitted. Hosts in the server nodes file located at <code>\$TORQUE/server_priv/nodes</code> cannot be added to the list using the <code>acl_hosts</code> parameter (see <a href="#">Server node file configuration on page 2572</a>). To submit batch or interactive jobs (see <a href="#">Server configuration on page 2566</a>) through hosts that are specified in the server nodes file, use the <a href="#">submit_hosts</a> parameter.</p> <pre>Qmgr: set queue batch acl_hosts = "hostA,hostB" Qmgr: set queue batch acl_hosts += "hostE,hostF,hostG"</pre> <p>In version 2.5 and later, the wildcard (*) character can appear anywhere in the host name, and ranges are supported; these specifications also work for managers and operators.</p> <pre>Qmgr: set server acl_hosts = "galaxy*.tom.org" Qmgr: set server acl_hosts += "galaxy[0-50].tom.org" Qmgr: set server managers+=tom@galaxy[0-50].tom.org</pre>

acl_host_enable	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <b>TRUE</b> , specifies that the <a href="#">acl_hosts</a> value is enabled.

acl_logic_or	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <b>TRUE</b> , the user and group queue ACL's are logically OR'd. When set to <b>FALSE</b> , they are AND'd.

allow_node_submit	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <b>TRUE</b> , specifies that users can submit jobs directly from any trusted compute host directly or from within batch jobs (see <a href="#">Configuring job submission hosts on page 2566</a> ). <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;">  When you enable <b>allow_node_submit</b>, you must also enable the <a href="#">allow_proxy_user on page 2767</a> parameter to allow user proxying when submitting and running jobs. </div>

allow_proxy_user	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <b>TRUE</b> , specifies that users can proxy from one user to another. Proxy requests will be either validated by <code>ruserok()</code> or by the scheduler (see <a href="#">Job submission on page 2583</a> ).

auto_node_np	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>DISABLED</b>
<b>Description</b>	When set to <code>TRUE</code> , automatically configures a node's np (number of processors) value based on the ncpus value from the status update. Requires full manager privilege to set or alter.

automatic_requeue_exit_code	
<b>Format</b>	<LONG>
<b>Default</b>	---
<b>Description</b>	This is an exit code, defined by the admin, that tells pbs_server to requeue the job instead of considering it as completed. This allows the user to add some additional checks that the job can run meaningfully, and if not, then the job script exits with the specified code to be requeued.

checkpoint_defaults	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies for a queue the default checkpoint values for a job that does not have checkpointing specified. The checkpoint_defaults parameter only takes effect on execution queues. <pre>set queue batch checkpoint_defaults="enabled, periodic, interval=5"</pre>

clone_batch_delay	
<b>Format</b>	<INTEGER>
<b>Default</b>	1
<b>Description</b>	Specifies the delay (in seconds) between clone batches (see <a href="#">clone_batch_size</a> ).

## clone\_batch\_size

<b>Format</b>	<INTEGER>
<b>Default</b>	256
<b>Description</b>	Job arrays are created in batches of size <i>X</i> . <i>X</i> jobs are created, and after the <a href="#">clone_batch_delay</a> , <i>X</i> more are created. This repeats until all are created.

## cray\_enabled

<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <code>TRUE</code> , specifies that this instance of <code>pbs_server</code> has Cray hardware that reports to it. See <a href="#">Installation Notes for Moab and TORQUE for Cray on page 1236</a> .

## default\_queue

<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Indicates the queue to assign to a job if no queue is explicitly specified by the submitter.

## disable\_server\_id\_check

<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	<p>When set to <code>TRUE</code>, makes it so the user for the job doesn't have to exist on the server. The user must still exist on all the compute nodes or the job will fail when it tries to execute.</p> <div style="border: 1px solid red; padding: 5px; margin-top: 10px;">  If you have <code>disable_server_id_check</code> set to <code>TRUE</code>, a user could request a group to which they do not belong. Setting <code>VALIDATEGROUP</code> to <code>TRUE</code> in the <code>torque.cfg</code> file prevents such a scenario (see <a href="#">Appendix K: "torque.cfg" configuration file on page 2828</a>). </div>

display_job_server_suffix	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>TRUE</b>
<b>Description</b>	<p>When set to <b>TRUE</b>, TORQUE will display both the job ID and the host name. When set to <b>FALSE</b>, only the job ID will be displayed.</p> <div style="border: 1px solid #0070c0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> If set to <b>FALSE</b>, the environment variable <code>NO_SERVER_SUFFIX</code> must be set to <b>TRUE</b> for <code>pbs_track</code> to work as expected.</p> </div>

interactive_jobs_can_roam	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	<p>By default, interactive jobs run from the login node that they submitted from. When <b>TRUE</b>, interactive jobs may run on login nodes other than the one where the jobs were submitted to. See <a href="#">Installation Notes for Moab and TORQUE for Cray on page 1236</a>.</p>

job_force_cancel_time	
<b>Format</b>	<INTEGER>
<b>Default</b>	Disabled
<b>Description</b>	<p>If a job has been deleted and is still in the system after <i>x</i> seconds, the job will be purged from the system. This is mostly useful when a job is running on a large number of nodes and one node goes down. The job cannot be deleted because the MOM cannot be contacted. The <code>qdel</code> fails and none of the other nodes can be reused. This parameter can be used to remedy such situations.</p>

job_log_file_max_size	
<b>Format</b>	<INTEGER>
<b>Default</b>	---

**job\_log\_file\_max\_size**

<b>Description</b>	This specifies a soft limit (in kilobytes) for the job log's maximum size. The file size is checked every five minutes and if the <i>current day</i> file size is greater than or equal to this value, it is rolled from <filename> to <filename.1> and a new empty log is opened. If the current day file size exceeds the maximum size a second time, the <filename.1> log file is rolled to <filename.2>, the current log is rolled to <filename.1>, and a new empty log is opened. Each new log causes all other logs to roll to an extension that is one greater than its current number. Any value less than 0 is ignored by <code>pbs_server</code> (meaning the log will not be rolled).
--------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**job\_log\_file\_roll\_depth**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Default</b>	---
----------------	-----

<b>Description</b>	This sets the maximum number of new log files that are kept in a day if the <a href="#">job_log_file_max_size</a> parameter is set. For example, if the roll depth is set to 3, no file can roll higher than <filename.3>. If a file is already at the specified depth, such as <filename.3>, the file is deleted so it can be replaced by the incoming file roll, <filename.2>.
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**job\_log\_keep\_days**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Default</b>	---
----------------	-----

<b>Description</b>	This maintains logs for the number of days designated. If set to 4, any log file older than 4 days old is deleted.
--------------------	--------------------------------------------------------------------------------------------------------------------

**job\_nanny**

<b>Format</b>	<BOOLEAN>
---------------	-----------

<b>Default</b>	<b>FALSE</b>
----------------	--------------

<b>Description</b>	When set to <code>TRUE</code> , enables the experimental "job deletion nanny" feature. All job cancels will create a repeating task that will resend <code>KILL</code> signals if the initial job cancel failed. Further job cancels will be rejected with the message "job cancel in progress." This is useful for temporary failures with a job's execution node during a job delete request.
--------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**job\_stat\_rate**

<b>Format</b>	<INTEGER>
<b>Default</b>	300 (30 in TORQUE 1.2.0p5 and earlier)
<b>Description</b>	If the mother superior has not sent an update by the specified time, at the specified time pbs_server requests an update on job status from the mother superior.

**job\_start\_timeout**

<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Specifies the pbs_server to pbs_mom TCP socket timeout in seconds that is used when the pbs_server sends a job start to the pbs_mom. It is useful when the MOM has extra overhead involved in starting jobs. If not specified, then the <a href="#">tcp_timeout</a> parameter is used.

**job\_sync\_timeout**

<b>Format</b>	<INTEGER>
<b>Default</b>	60
<b>Description</b>	When a stray job is reported on multiple nodes, the server sends a kill signal to one node at a time. This timeout determines how long the server waits between kills if the job is still being reported on any nodes.

**keep\_completed**

<b>Format</b>	<INTEGER>
<b>Default</b>	---
	 If you ran <code>torque.setup</code> on TORQUE installation, the default is 300.
<b>Description</b>	The amount of time a job will be kept in the queue after it has entered the completed state. <code>keep_completed</code> <i>must</i> be set for job dependencies to work. For more information, see <a href="#">Keeping completed jobs on page 2600</a> .

lock_file	
<b>Format</b>	<STRING>
<b>Default</b>	torque/server_priv/server.lock
<b>Description</b>	<p>Specifies the name and location of the lock file used to determine which high availability server should be active.</p> <p>If a full path is specified, it is used verbatim by TORQUE. If a relative path is specified, TORQUE will prefix it with <code>torque/server_priv</code>.</p>

lock_file_update_time	
<b>Format</b>	<INTEGER>
<b>Default</b>	3
<b>Description</b>	Specifies how often (in seconds) the thread will update the lock file.

lock_file_check_time	
<b>Format</b>	<INTEGER>
<b>Default</b>	9
<b>Description</b>	Specifies how often (in seconds) a high availability server will check to see if it should become active.

log_events	
<b>Format</b>	Bitmap
<b>Default</b>	---

## log\_events

**Description**

By default, all events are logged. However, you can customize things so that only certain events show up in the log file. These are the bitmaps for the different kinds of logs:

```
#define PBSEVENT_ERROR 0x0001 /* internal errors */
#define PBSEVENT_SYSTEM 0x0002 /* system (server) events */
#define PBSEVENT_ADMIN 0x0004 /* admin events */
#define PBSEVENT_JOB 0x0008 /* job related events */
#define PBSEVENT_JOB_USAGE 0x0010 /* End of Job accounting */
#define PBSEVENT_SECURITY 0x0020 /* security violation events */
#define PBSEVENT_SCHED 0x0040 /* scheduler events */
#define PBSEVENT_DEBUG 0x0080 /* common debug messages */
#define PBSEVENT_DEBUG2 0x0100 /* less needed debug messages */
#define PBSEVENT_FORCE 0x8000 /* set to force a message */
```

If you want to log only error, system, and job information, use `qmgr` to set `log_events` to 11:

```
set server log_events = 11
```

## log\_file\_max\_size

**Format**

&lt;INTEGER&gt;

**Default**

0

**Description**

Specifies a soft limit, in kilobytes, for the server's log file. The file size is checked every 5 minutes, and if the *current day* file size is greater than or equal to this value then it will be rolled from *X* to *X.1* and a new empty log will be opened. Any value less than or equal to 0 will be ignored by `pbs_server` (the log will not be rolled).

## log\_file\_roll\_depth

**Format**

&lt;INTEGER&gt;

**Default**

1

**Description**

Controls how deep the current day log files will be rolled, if `log_file_max_size` is set, before they are deleted.

## log\_keep\_days

**Format**

&lt;INTEGER&gt;

log_keep_days	
<b>Default</b>	0
<b>Description</b>	Specifies how long (in days) a server or MOM log should be kept.

log_level	
<b>Format</b>	<INTEGER>
<b>Default</b>	0
<b>Description</b>	Specifies the <code>pbs_server</code> logging verbosity. Maximum value is 7.

mail_body_fmt	
<b>Format</b>	A printf-like format string
<b>Default</b>	PBS Job Id: %i Job Name: %j Exec host: %h %m %d
<b>Description</b>	<p>Override the default format for the body of outgoing mail messages. A number of printf-like format specifiers and escape sequences can be used:</p> <ul style="list-style-type: none"> <li>\n new line</li> <li>\t tab</li> <li>\\ backslash</li> <li>\' single quote</li> <li>\" double quote</li> <li>%d details concerning the message</li> <li>%h PBS host name</li> <li>%i PBS job identifier</li> <li>%j PBS job name</li> <li>%m long reason for message</li> <li>%r short reason for message</li> <li>%% a single %</li> </ul>

mail_domain	
<b>Format</b>	<STRING>
<b>Default</b>	---

## mail\_domain

<b>Description</b>	Override the default domain for outgoing mail messages. If set, emails will be addressed to <user>@<hostdomain>. If unset, the job's Job_Owner attribute will be used. If set to <code>never</code> , TORQUE will never send emails.
--------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## mail\_from

<b>Format</b>	<STRING>
---------------	----------

<b>Default</b>	adm
----------------	-----

<b>Description</b>	Specify the name of the sender when TORQUE sends emails.
--------------------	----------------------------------------------------------

## mail\_subject\_fmt

<b>Format</b>	A printf-like format string
---------------	-----------------------------

<b>Default</b>	PBS JOB %i
----------------	------------

<b>Description</b>	Override the default format for the subject of outgoing mail messages. A number of printf-like format specifiers and escape sequences can be used: \n new line \t tab \\ backslash \' single quote \" double quote %d details concerning the message %h PBS host name %i PBS job identifier %j PBS job name %m long reason for message %r short reason for message %% a single %
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## managers

<b>Format</b>	<user>@<host.sub.domain>[,<user>@<host.sub.domain>...]
---------------	--------------------------------------------------------

<b>Default</b>	root@localhost
----------------	----------------

## managers

<b>Description</b>	List of users granted batch administrator privileges. The host, sub-domain, or domain name may be wildcarded by the use of an asterisk character (*). Requires full manager privilege to set or alter.
--------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

## max\_job\_array\_size

<b>Format</b>	<INTEGER>
<b>Default</b>	Unlimited
<b>Description</b>	Sets the maximum number of jobs that can be in a single job array.

## max\_slot\_limit

<b>Format</b>	<INTEGER>
<b>Default</b>	Unlimited
<b>Description</b>	<p>This is the maximum number of jobs that can run concurrently in any job array. Slot limits can be applied at submission time with <a href="#">qsub</a>, or it can be modified with <a href="#">qalter</a>.</p> <pre>qmgr -c 'set server max_slot_limit=10'</pre> <p>No array can request a slot limit greater than 10. Any array that does not request a slot limit receives a slot limit of 10. Using the example above, slot requests greater than 10 are rejected with the message: "Requested slot limit is too large, limit is 10."</p>

## max\_threads

<b>Format</b>	<INTEGER>
<b>Default</b>	The value of min_threads $((2 * \text{the number of procs listed in } /proc/cpuinfo) + 1) * 20$
<b>Description</b>	This is the maximum number of threads that should exist in the thread pool at any time. See <a href="#">Setting min_threads and max_threads on page 2652</a> for more information.

## max\_user\_queuable

<b>Format</b>	<INTEGER>
---------------	-----------

max_user_queuable	
<b>Default</b>	Unlimited
<b>Description</b>	<p>When set, <code>max_user_queuable</code> places a system-wide limit on the amount of jobs that an individual user can queue.</p> <pre>qmgr -c 'set server max_user_queuable=500'</pre>

min_threads	
<b>Format</b>	<INTEGER>
<b>Default</b>	(2 * the number of procs listed in <code>/proc/cpuinfo</code> ) + 1. If TORQUE is unable to read <code>/proc/cpuinfo</code> , the default is 10.
<b>Description</b>	This is the minimum number of threads that should exist in the thread pool at any time. See <a href="#">Setting min_threads and max_threads on page 2652</a> for more information.

moab_array_compatible	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	This parameter places a hold on jobs that exceed the <a href="#">slot limit</a> in a job array. When one of the active jobs is completed or deleted, one of the held jobs goes to a queued state.

mom_job_sync	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	<p>When set to <code>TRUE</code>, specifies that the <code>pbs_server</code> will synchronize its view of the job queue and resource allocation with compute nodes as they come online. If a job exists on a compute node, it will be automatically cleaned up and purged. (Enabled by default in TORQUE 2.2.0 and higher.)</p> <p>Jobs that are no longer reported by the mother superior are automatically purged by <code>pbs_server</code>. Jobs that <code>pbs_server</code> instructs the MOM to cancel have their processes killed in addition to being deleted (instead of leaving them running as in versions of TORQUE prior to 4.1.1).</p>

next_job_number	
<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	<p>Specifies the ID number of the next job. If you set your job number too low and TORQUE repeats a job number that it has already used, the job will fail. Before setting <code>next_job_number</code> to a number lower than any number that TORQUE has already used, you must clear out your <code>.e</code> and <code>.o</code> files.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> If you use Moab Workload Manager and have configured it to synchronize job IDs with TORQUE), then Moab will generate the job ID and <code>next_job_number</code> will have no effect on the job ID. See <a href="#">Resource Manager Configuration on page 588</a> for more information.</p> </div>

node_check_rate	
<b>Format</b>	<INTEGER>
<b>Default</b>	600
<b>Description</b>	Specifies the minimum duration (in seconds) that a node can fail to send a status update before being marked down by the <code>pbs_server</code> daemon.

node_pack	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	Controls how multiple processor nodes are allocated to jobs. If this attribute is set to <code>TRUE</code> , jobs will be assigned to the multiple processor nodes with the fewest free processors. This packs jobs into the fewest possible nodes leaving multiple processor nodes free for jobs which need many processors on a node. If set to <code>false</code> , jobs will be scattered across nodes reducing conflicts over memory between jobs. If unset, the jobs are packed on nodes in the order that the nodes are declared to the server (in the nodes file). Default value: unset - assigned to nodes as nodes in order that were declared.

node_ping_rate	
<b>Format</b>	<INTEGER>

## node\_ping\_rate

<b>Default</b>	300
<b>Description</b>	Specifies the maximum interval (in seconds) between successive "pings" sent from the <code>pbs_server</code> daemon to the <code>pbs_mom</code> daemon to determine node/daemon health.

## no\_mail\_force

<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <code>TRUE</code> , eliminates all e-mails when <code>mail_options</code> (see <a href="#">qsub on page 2744</a> ) is set to "n". The job owner won't receive e-mails when a job is deleted by a different user or a job failure occurs. If <code>no_mail_force</code> is unset or is <code>FALSE</code> , then the job owner receives e-mails when a job is deleted by a different user or a job failure occurs.

## np\_default

<b>Format</b>	<INTEGER>
<b>Default</b>	---
<b>Description</b>	Allows the administrator to unify the number of processors ( <code>np</code> ) on all nodes. The value can be dynamically changed. A value of 0 tells <code>pbs_server</code> to use the value of <code>np</code> found in the nodes file. The maximum value is 32767.

## operators

<b>Format</b>	<user>@<host.sub.domain>[,<user>@<host.sub.domain>...]
<b>Default</b>	root@localhost
<b>Description</b>	List of users granted batch operator privileges. Requires full manager privilege to set or alter.

## pass\_cpuclock

<b>Format</b>	<BOOLEAN>
---------------	-----------

pass_cpuclock	
<b>Default</b>	<b>TRUE</b>
<b>Description</b>	<p>If set to <b>TRUE</b>, the <code>pbs_server</code> daemon passes the option and its value to the <code>pbs_mom</code> daemons for direct implementation by the daemons, making the CPU frequency adjustable as part of a <a href="#">resource request</a> by a job submission.</p> <p>If set to <b>FALSE</b>, the <code>pbs_server</code> daemon creates and passes a <code>PBS_CPUCLOCK</code> job environment variable to the <code>pbs_mom</code> daemons that contains the value of the <code>cpuclock</code> attribute used as part of a resource request by a job submission. The CPU frequencies on the MOMs are not adjusted. The environment variable is for use by prologue and epilogue scripts, enabling administrators to log and research when users are making <code>cpuclock</code> requests, as well as researchers and developers to perform CPU clock frequency changes using a method outside of that employed by the TORQUE <code>pbs_mom</code> daemons.</p>

poll_jobs	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>TRUE</b> (FALSE in TORQUE 1.2.0p5 and earlier)
<b>Description</b>	<p>If set to <b>TRUE</b>, <code>pbs_server</code> will poll job info from MOMs over time and will not block on handling requests which require this job information.</p> <p>If set to <b>FALSE</b>, no polling will occur and if requested job information is stale, <code>pbs_server</code> may block while it attempts to update this information. For large systems, this value should be set to <b>TRUE</b>.</p>

query_other_jobs	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	When set to <b>TRUE</b> , specifies whether or not non-admin users may view jobs they do not own.

record_job_info	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	This must be set to <b>TRUE</b> in order for job logging to be enabled.

record_job_script	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	<b>FALSE</b>
<b>Description</b>	<p>If set to <code>TRUE</code>, this adds the contents of the script executed by a job to the log.</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p> For <code>record_job_script</code> to take effect, <a href="#">record_job_info</a> on page 2781 must be set to <code>TRUE</code>.</p> </div>

resources_available	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	<p>Allows overriding of detected resource quantity limits (see <a href="#">Assigning queue resource limits on page 2636</a>). <code>pbs_server</code> must be restarted for changes to take effect. Also, <code>resources_available</code> is constrained by the smallest of <code>queue.resources_available</code> and the <code>server.resources_available</code>.</p>

scheduling	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	---
<b>Description</b>	<p>Allows <code>pbs_server</code> to be scheduled. When <code>FALSE</code>, <code>pbs_server</code> is a resource manager that works on its own. When <code>TRUE</code>, TORQUE allows a scheduler, such as Moab or Maui, to dictate what <code>pbs_server</code> should do.</p>

submit_hosts	
<b>Format</b>	"<HOSTNAME>[,<HOSTNAME>]..."
<b>Default</b>	---
<b>Description</b>	<p>Indicates which hosts included in the server nodes file located at <code>\$TORQUE/server_priv/nodes</code> (see <a href="#">Server node file configuration on page 2572</a>) can submit batch or interactive jobs (see <a href="#">Configuring job submission hosts on page 2566</a>). For more information on adding hosts that are not included in the first nodes file, see the <a href="#">acl_hosts</a> parameter.</p>

tcp_timeout	
<b>Format</b>	<INTEGER>
<b>Default</b>	300
<b>Description</b>	<p>Specifies the timeout for idle TCP connections. If no communication is received by the server on the connection after the timeout, the server closes the connection. There is an exception for connections made to the server on port 15001 (default); timeout events are ignored on the server for such connections established by a client utility or scheduler. Responsibility rests with the client to close the connection first (See <a href="#">Appendix F: Large cluster considerations on page 2811</a> for additional information.).</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> If you use Moab Workload Manager, prevent communication errors by giving <b>tcp_timeout</b> at least twice the value of the Moab <a href="#">RMPOLLINTERVAL</a>.</p> </div>

thread_idle_seconds	
<b>Format</b>	<INTEGER>
<b>Default</b>	300
<b>Description</b>	<p>This is the number of seconds a thread can be idle in the thread pool before it is deleted. If threads should not be deleted, set to -1. TORQUE will always maintain at least <a href="#">min_threads</a> number of threads, even if all are idle.</p>

## Appendix C: Node manager (MOM) configuration

Under TORQUE, MOM configuration is accomplished using the `mom_priv/config` file located in the PBS directory on each execution server. You must create this file and insert any desired lines in a text editor (blank lines are allowed). When you modify the `mom_priv/config` file, you must restart `pbs_mom`.

The following examples demonstrate two methods of modifying the `mom_priv/config` file:

```
> echo "\$loglevel 3" > /var/spool/torque/mom_priv/config
```

```
> vim /var/spool/torque/mom_priv/config
...
$loglevel 3
```

For details, see these topics:

- [Parameters on page 2784](#)
- [Node features and generic consumable resource specification on page 2801](#)

- [Command-line arguments on page 2801](#)

## Parameters

These parameters go in the `mom_priv/config` file. They control various behaviors for the MOMs.

arch	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the architecture of the local machine. This information is used by the scheduler only.
<b>Example</b>	<code>arch ia64</code>

\$attempt_to_make_dir	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	<p>When set to <i>TRUE</i>, specifies that you want TORQUE to attempt to create the output directories for jobs if they do not already exist. Default is <i>FALSE</i>.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> TORQUE uses this parameter to make the directory as the <i>user</i> and not as <i>root</i>. TORQUE will create the directory (or directories) <b>ONLY</b> if the user has permissions to do so.</p> </div>
<b>Example</b>	<code>\$attempt_to_make_dir true</code>

\$clienthost	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies the machine running <code>pbs_server</code>.</p> <div style="border: 1px solid red; padding: 5px; margin-top: 10px;"> <p> This parameter is deprecated. Use <a href="#">\$pbsserver</a>.</p> </div>
<b>Example</b>	<code>\$clienthost node01.teracluster.org</code>

\$check_poll_time	
<b>Format</b>	<STRING>
<b>Description</b>	Amount of time between checking running jobs, polling jobs, and trying to resend obituaries for jobs that haven't sent successfully. Default is 45 seconds.
<b>Example</b>	<code>\$check_poll_time 90</code>

\$configversion	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the version of the config file data.
<b>Example</b>	<code>\$configversion 113</code>

\$cputmult	
<b>Format</b>	<FLOAT>
<b>Description</b>	CPU time multiplier. <div style="border: 1px solid #0070c0; border-radius: 10px; padding: 5px; margin-top: 10px;">  If set to 0.0, MOM level cputime enforcement is disabled.         </div>
<b>Example</b>	<code>\$cputmult 2.2</code>

\$down_on_error	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Causes the MOM to report itself as state "down" to <code>pbs_server</code> in the event of a failed health check. This feature is experimental. For more information, see <a href="#">Parameters on page 2784</a> .
<b>Example</b>	<code>\$down_on_error true</code>

**\$enablemomrestart**

<b>Format</b>	<BOOLEAN>
<b>Description</b>	Enables automatic restarts of the MOM. If enabled, the MOM will check if its binary has been updated and restart itself at a safe point when no jobs are running; thus making upgrades easier. The check is made by comparing the mtime of the <code>pbs_mom</code> executable. Command-line args, the process name, and the PATH env variable are preserved across restarts. It is recommended that this not be enabled in the config file, but enabled when desired with <code>momctl</code> (see <a href="#">Parameters on page 2784</a> for more information.)
<b>Example</b>	<code>\$enablemomrestart true</code>

**\$exec\_with\_exec**

<b>Format</b>	<BOOLEAN>
<b>Description</b>	<code>pbs_mom</code> uses the <code>exec</code> command to start the job script rather than the TORQUE default method, which is to pass the script's contents as the input to the shell. This means that if you trap signals in the job script, they will be trapped for the job. Using the default method, you would need to configure the shell to also trap the signals. Default is FALSE.
<b>Example</b>	<code>\$exec_with_exec true</code>

**\$ext\_pwd\_retry**

<b>Format</b>	<INTEGER>
<b>Description</b>	(Available in TORQUE 2.5.10, 3.0.4, and later.) Specifies the number of times to retry checking the password. Useful in cases where external password validation is used, such as with LDAP. The default value is 3 retries.
<b>Example</b>	<code>\$ext_pwd_retry = 5</code>

**\$ideal\_load**

<b>Format</b>	<FLOAT>
<b>Description</b>	Ideal processor load.
<b>Example</b>	<code>\$ideal_load 4.0</code>

\$igncput	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Ignores limit violation pertaining to CPU time. Default is FALSE.
<b>Example</b>	\$igncput true

\$ignmem	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Ignores limit violations pertaining to physical memory. Default is FALSE.
<b>Example</b>	\$ignmem true

\$ignvmem	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Ignores limit violations pertaining to virtual memory. Default is FALSE.
<b>Example</b>	\$ignvmem true

\$ignwalltime	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	Ignore walltime (do not enable MOM based walltime limit enforcement).
<b>Example</b>	\$ignwalltime true

\$jobdirectory_sticky	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	When this option is set ( <code>true</code> ), the job directory on the MOM can have a sticky bit set. The default is <code>false</code> .

**\$jobdirectory\_sticky**

<b>Example</b>	<code>\$jobdirectory_sticky true</code>
----------------	-----------------------------------------

**\$job\_exit\_wait\_time**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Description</b>	This is the timeout to clean up parallel jobs after one of the sister nodes for the parallel job goes down or is otherwise unresponsive. The MOM sends out all of its kill job requests to sisters and marks the time. Additionally, the job is placed in the substate <code>JOB_SUBSTATE_EXIT_WAIT</code> . The MOM then periodically checks jobs in this state and if they are in this state for more than the specified time, death is assumed and the job gets cleaned up. Default is 10 minutes.
--------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$job_exit_wait_time 300</code>
----------------	---------------------------------------

**\$job\_output\_file\_unmask**

<b>Format</b>	<STRING>
---------------	----------

<b>Description</b>	Uses the specified umask when creating job output and error files. Values can be specified in base 8, 10, or 16; leading 0 implies octal and leading 0x or 0X hexadecimal. A value of "userdefault" will use the user's default umask. This parameter is in version 2.3.0 and later.
--------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$job_output_file_umask 027</code>
----------------	------------------------------------------

**\$job\_starter**

<b>Format</b>	<STRING>
---------------	----------

<b>Description</b>	Specifies the fully qualified pathname of the job starter. If this parameter is specified, instead of executing the job command and job arguments directly, the MOM will execute the job starter, passing the job command and job arguments to it as its arguments. The job starter can be used to launch jobs within a desired environment.
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<pre> \$job_starter /var/torque/mom_priv/job_starter.sh &gt; cat /var/torque/mom_priv/job_starter.sh #!/bin/bash export FOOHOME=/home/foo ulimit -n 314 \$*</pre>
----------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------

\$log_directory	
<b>Format</b>	<STRING>
<b>Description</b>	Changes the log directory. Default is TORQUE_HOME/mom_logs/. TORQUE_HOME default is /var/spool/torque/ but can be changed in the ./configure script. The value is a string and should be the full path to the desired MOM log directory.
<b>Example</b>	<code>\$log_directory /opt/torque/mom_logs/</code>

\$log_file_suffix	
<b>Format</b>	<STRING>
<b>Description</b>	Optional suffix to append to log file names. If %h is the suffix, pbs_mom appends the hostname for where the log files are stored if it knows it, otherwise it will append the hostname where the MOM is running.
<b>Example</b>	<code>\$log_file_suffix %h = 20100223.mybox</code> <code>\$log_file_suffix foo = 20100223.foo</code>

\$logevent	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies a bitmap for event types to log.
<b>Example</b>	<code>\$logevent 255</code>

\$loglevel	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies the verbosity of logging with higher numbers specifying more verbose logging. Values may range between 0 and 7.
<b>Example</b>	<code>\$loglevel 4</code>

**\$log\_file\_max\_size**

<b>Format</b>	<INTEGER>
<b>Description</b>	Soft limit for log file size in kilobytes. Checked every 5 minutes. If the log file is found to be greater than or equal to <code>log_file_max_size</code> the current log file will be moved from X to X.1 and a new empty file will be opened.
<b>Example</b>	<code>\$log_file_max_size = 100</code>

**\$log\_file\_roll\_depth**

<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies how many times a log file will be rolled before it is deleted.
<b>Example</b>	<code>\$log_file_roll_depth = 7</code>

**\$log\_keep\_days**

<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies how many days to keep log files. <code>pbs_mom</code> deletes log files older than the specified number of days. If not specified, <code>pbs_mom</code> won't delete log files based on their age.
<b>Example</b>	<code>\$log_keep_days 10</code>

**\$max\_conn\_timeout\_micro\_sec**

<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies how long <code>pbs_mom</code> should wait for a connection to be made. Default value is 10000 (.1 sec).
<b>Example</b>	<code>\$max_conn_timeout_micro_sec 30000</code> This sets the connection timeout on the MOM to .3 seconds.

**\$max\_join\_job\_wait\_time**

<b>Format</b>	<INTEGER>
<b>Description</b>	The interval to wait for jobs stuck in a prerun state before deleting them from the MOMs and requeueing them on the server. Default is 10 minutes.
<b>Example</b>	\$max_join_job_wait_time 300

**\$max\_load**

<b>Format</b>	<FLOAT>
<b>Description</b>	Maximum processor load.
<b>Example</b>	\$max_load 4.0

**\$memory\_pressure\_duration**

<b>Format</b>	<INTEGER>
<b>Description</b>	<i>(Applicable in version 3.0 and later.)</i> Memory pressure duration sets a limit to the number of times the value of memory_pressure_threshold can be exceeded before a process is terminated. This can only be used with <a href="#">\$memory_pressure_threshold</a> .
<b>Example</b>	\$memory_pressure_duration 5

**\$memory\_pressure\_threshold**

<b>Format</b>	<INTEGER>
---------------	-----------

**\$memory\_pressure\_threshold**

<b>Description</b>	<p>(Applicable in version 3.0 and later.) The memory_pressure of a cpuset provides a simple per-cpuset running average of the rate that the processes in a cpuset are attempting to free up in-use memory on the nodes of the cpuset to satisfy additional memory requests. The memory_pressure_threshold is an integer number used to compare against the reclaim rate provided by the memory_pressure file. If the threshold is exceeded and memory_pressure_duration is set, then the process terminates after exceeding the threshold by the number of times set in memory_pressure_duration. If memory_pressure duration is not set, then a warning is logged and the process continues. Memory_pressure_threshold is only valid with memory_pressure enabled in the root cpuset.</p> <p>To enable, log in as the super user and execute the command <code>echo 1 &gt;&gt; /dev/cpuset/memory_pressure_enabled</code>. See the cpuset man page for more information concerning memory pressure.</p>
<b>Example</b>	<code>\$memory_pressure_threshold 1000</code>

**\$mom\_hierarchy\_retry\_time**

<b>Format</b>	<SECONDS>
<b>Description</b>	Specifies the amount of time that a MOM waits to retry a node in the hierarchy path after a failed connection to that node. The default is 90 seconds.
<b>Example</b>	<code>\$mom_hierarchy_retry_time 30</code>

**\$mom\_host**

<b>Format</b>	<STRING>
<b>Description</b>	Sets the local hostname as used by pbs_mom.
<b>Example</b>	<code>\$mom_host node42</code>

**\$node\_check\_script**

<b>Format</b>	<STRING>
<b>Description</b>	Specifies the fully qualified pathname of the health check script to run (see <a href="#">Compute node health check on page 2677</a> for more information).
<b>Example</b>	<code>\$node_check_script /opt/batch_tools/nodecheck.pl</code>

\$node_check_interval	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies the number of MOM intervals between subsequent executions of the specified health check. This value default to 1 indicating the check is run every MOM interval (see <a href="#">Compute node health check on page 2677</a> for more information).</p> <p>\$node_check_interval has two special strings that can be set:</p> <ul style="list-style-type: none"> <li>• <i>jobstart</i> – makes the node health script run when a job is started.</li> <li>• <i>jobend</i> – makes the node health script run after each job has completed on a node.</li> </ul>
<b>Example</b>	<code>\$node_check_interval 5</code>

\$nodefile_suffix	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the suffix to append to a host names to denote the data channel network adapter in a multi-homed compute node.
<b>Example</b>	<p><code>\$nodefile_suffix i</code></p> <p>with the suffix of "i" and the control channel adapter with the name <i>node01</i>, the data channel would have a hostname of <i>node01i</i>.</p>

\$nospool_dir_list	
<b>Format</b>	<STRING>
<b>Description</b>	<p>If this is configured, the job's output is spooled in the working directory of the job or the specified output directory.</p> <p>Specify the list in full paths, delimited by commas. If the job's working directory (or specified output directory) is in one of the paths in the list (or a subdirectory of one of the paths in the list), the job is spooled directly to the output location. \$nospool_dir_list * is accepted.</p> <p>The user that submits the job must have write permission on the folder where the job is written, and read permission on the folder where the file is spooled.</p> <p>Alternatively, you can use the \$spool_as_final_name parameter to force the job to spool directly to the final output.</p> <div style="border: 1px solid #0070c0; border-radius: 10px; padding: 10px; margin-top: 10px;"> <p> This should generally be used only when the job can run on the same machine as where the output file goes, or if there is a shared filesystem. If not, this parameter can slow down the system or fail to create the output file.</p> </div>
<b>Example</b>	<code>\$nospool_dir_list /home/mike/jobs/,/var/tmp/spool/</code>

opsys	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the operating system of the local machine. This information is used by the scheduler only.
<b>Example</b>	<code>opsys RHEL3</code>

\$pbsclient	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies machines which the MOM daemon will trust to run resource manager commands via <a href="#">momctl</a> . This may include machines where monitors, schedulers, or admins require the use of this command.
<b>Example</b>	<code>\$pbsclient node01.teracluster.org</code>

\$pbserver	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the machine running pbs_server. <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;">  This parameter replaces the deprecated parameter <a href="#">\$clienthost</a>. </div>
<b>Example</b>	<code>\$pbserver node01.teracluster.org</code>

\$prologalarm	
<b>Format</b>	<INTEGER>
<b>Description</b>	Specifies maximum duration (in seconds) which the MOM will wait for the job prologue or job epilogue to complete. The default value is 300 seconds (5 minutes). The maximum value is 300 and when set to anything higher than that, it is treated as 300.
<b>Example</b>	<code>\$prologalarm 60</code>

\$rcpcmd	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the full path and optional additional command line args to use to perform remote copies.
<b>Example</b>	<pre>mom_priv/config: \$rcpcmd /usr/local/bin/scp -i /etc/sshauth.dat</pre>

\$remote_reconfig	
<b>Format</b>	<STRING>
<b>Description</b>	Enables the ability to remotely reconfigure pbs_mom with a new config file. Default is disabled. This parameter accepts various forms of true, yes, and 1. For more information on how to reconfigure MOMs, see <a href="#">momctl-r</a> .
<b>Example</b>	<pre>\$remote_reconfig true</pre>

\$remote_checkpoint_dirs	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies which server checkpoint directories are remotely mounted. It tells the MOM which directories are shared with the server. Using remote checkpoint directories eliminates the need to copy the checkpoint files back and forth between the MOM and the server. All entries must be on the same line, separated by a space.
<b>Example</b>	<pre>\$remote_checkpoint_dirs /checkpointFiles /bigStorage /fast</pre> <p><i>This informs the MOM that the /checkpointFiles, /bigStorage, and /fast directories are remotely mounted checkpoint directories.</i></p>

\$reduce_prolog_checks	
<b>Format</b>	<STRING>
<b>Description</b>	If enabled, TORQUE will only check if the file is a regular file and is executable, instead of the normal checks listed on the prologue and epilogue page. Default is FALSE.

**\$reduce\_prolog\_checks**

<b>Example</b>	<code>\$reduce_prolog_checks true</code>
----------------	------------------------------------------

**\$reject\_job\_submission**

<b>Format</b>	<BOOLEAN>
---------------	-----------

<b>Description</b>	If set to <b>TRUE</b> , jobs will be rejected and the user will receive the message, "Jobs cannot be run on mom %s." Default is FALSE.
--------------------	----------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$reject_job_submission job01</code>
----------------	--------------------------------------------

**\$resend\_join\_job\_wait\_time**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Description</b>	This is the timeout for the Mother Superior to re-send the join job request if it didn't get a reply from all the sister MOMs. The resend happens only once. Default is 5 minutes.
--------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$resend_join_job_wait_time 120</code>
----------------	----------------------------------------------

**\$restricted**

<b>Format</b>	<STRING>
---------------	----------

<b>Description</b>	Specifies hosts which can be trusted to access MOM services as non-root. By default, no hosts are trusted to access MOM services as non-root.
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$restricted *.teracluster.org</code>
----------------	---------------------------------------------

**\$rpp\_throttle**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Description</b>	This integer is in microseconds and causes a sleep after every RPP packet is sent. It is for systems that experience job failures because of incomplete data.
--------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$rpp_throttle 100</code> (will cause a 100 microsecond sleep)
----------------	-------------------------------------------------------------------------

size[fs=<FS>]	
<b>Format</b>	N/A
<b>Description</b>	<p>Specifies that the available and configured disk space in the &lt;FS&gt; filesystem is to be reported to the pbs_server and scheduler.</p> <div style="border: 1px solid #ccc; padding: 5px; margin: 5px 0;"> <p><b>i</b> To request disk space on a per job basis, specify the file resource as in <code>qsub -l nodes=1, file=1000kb</code>.</p> </div> <div style="border: 1px solid #ccc; padding: 5px; margin: 5px 0;"> <p><b>i</b> Unlike most MOM config options, the <code>size</code> parameter is not preceded by a "\$" character.</p> </div>
<b>Example</b>	<pre>size[fs=/localscratch]</pre> <p>The available and configured disk space in the <code>/localscratch</code> filesystem will be reported.</p>

\$source_login_batch	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies whether or not MOM will source the <code>/etc/profile</code>, etc. type files for <i>batch</i> jobs. Parameter accepts various forms of true, false, yes, no, 1 and 0. Default is TRUE. This parameter is in version 2.3.1 and later.</p>
<b>Example</b>	<pre>\$source_login_batch False</pre> <p>MOM will bypass the sourcing of <code>/etc/profile</code>, etc. type files.</p>

\$source_login_interactive	
<b>Format</b>	<STRING>
<b>Description</b>	<p>Specifies whether or not MOM will source the <code>/etc/profile</code>, etc. type files for <i>interactive</i> jobs. Parameter accepts various forms of true, false, yes, no, 1 and 0. Default is TRUE. This parameter is in version 2.3.1 and later.</p>
<b>Example</b>	<pre>\$source_login_interactive False</pre> <p>MOM will bypass the sourcing of <code>/etc/profile</code>, etc. type files.</p>

\$spool_as_final_name	
<b>Format</b>	<BOOLEAN>

**\$spool\_as\_final\_name**

<b>Description</b>	This makes the job write directly to its output destination instead of a spool directory. This allows users easier access to the file if they want to watch the jobs output as it runs.
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<code>\$spool_as_final_name true</code>
----------------	-----------------------------------------

**\$status\_update\_time**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Description</b>	Specifies the number of seconds between subsequent MOM-to-server update reports. Default is 45 seconds.
--------------------	---------------------------------------------------------------------------------------------------------

<b>Example</b>	<pre>status_update_time: \$status_update_time 120</pre> <p>MOM will send server update reports every 120 seconds.</p>
----------------	-----------------------------------------------------------------------------------------------------------------------

**\$thread\_unlink\_calls**

<b>Format</b>	<BOOLEAN>
---------------	-----------

<b>Description</b>	Threads calls to unlink when deleting a job. Default is false. If it is set to TRUE, pbs_mom will use a thread to delete the job's files.
--------------------	-------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<pre>thread_unlink_calls: \$thread_unlink_calls true</pre>
----------------	------------------------------------------------------------

**\$timeout**

<b>Format</b>	<INTEGER>
---------------	-----------

<b>Description</b>	<p>Specifies the number of seconds before a TCP connection on the MOM will timeout. Default is 300 seconds.</p> <p>In version 3.x and earlier, this specifies the number of seconds before MOM-to-MOM messages will timeout if RPP is disabled. Default is 60 seconds.</p>
--------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

<b>Example</b>	<pre>\$timeout 120</pre> <p>A TCP connection will wait up to 120 seconds before timing out.</p> <p>For 3.x and earlier, MOM-to-MOM communication will allow up to 120 seconds before timing out.</p>
----------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

\$tmpdir	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies a directory to create job-specific scratch space (see <a href="#">Creating Per-Job Temporary Directories</a> ).
<b>Example</b>	\$tmpdir /localscratch

\$usecp	
<b>Format</b>	<HOST>:<SRCDIR> <DSTDIR>
<b>Description</b>	Specifies which directories should be staged (see <a href="#">NFS and other networked filesystems on page 2656</a> )
<b>Example</b>	\$usecp *.fte.com:/data /usr/local/data

\$use_smt	
<b>Format</b>	<BOOLEAN>
<b>Description</b>	<p>Indicates that the user would like to use SMT. If set, each logical core inside of a physical core will be used as a normal core for cpusets. This parameter is on by default.</p> <div style="border: 1px solid black; padding: 5px; margin-top: 10px;"> <p> If SMT is used, you will need to set the <i>np</i> attribute so that each logical processor is counted.</p> </div>
<b>Example</b>	\$use_smt false

\$varattr	
<b>Format</b>	<INTEGER> <STRING>

\$varattr	
<b>Description</b>	<p>Provides a way to keep track of dynamic attributes on nodes.</p> <p>&lt;INTEGER&gt; is how many seconds should go by between calls to the script to update the dynamic values. If set to -1, the script is read only one time.</p> <p>&lt;STRING&gt; is the script path. This script should check for whatever dynamic attributes are desired, and then output lines in this format:</p> <pre>name=value</pre> <p>Include any arguments after the script's full path. These features are visible in the output of <a href="#">pbsnodes -a</a></p> <pre>varattr=Matlab=7.1;Octave=1.0.</pre> <p>For information about using \$varattr to request dynamic features in Moab, see <a href="#">Resource Manager Extensions on page 618</a>.</p>
<b>Example</b>	<code>\$varattr 25 /usr/local/scripts/nodeProperties.pl arg1 arg2 arg3</code>

\$wallmult	
<b>Format</b>	<FLOAT>
<b>Description</b>	<p>Sets a factor to adjust walltime usage by multiplying a default job time to a common reference system. It modifies real walltime on a per-MOM basis (MOM configuration parameters). The factor is used for walltime calculations and limits in the same way that cputmult is used for cpu time.</p> <div style="border: 1px solid #0070C0; border-radius: 10px; padding: 5px; margin-top: 10px;"> <p> If set to 0.0, MOM level walltime enforcement is disabled.</p> </div>
<b>Example</b>	<code>\$wallmult 2.2</code>

\$xauthpath	
<b>Format</b>	<STRING>
<b>Description</b>	Specifies the path to the xauth binary to enable X11 forwarding.
<b>Example</b>	<code>\$xauthpath /opt/bin/xauth/</code>

## Node features and generic consumable resource specification

Node features (a.k.a. "node properties") are opaque labels which can be applied to a node. They are not consumable and cannot be associated with a value. (Use generic resources described below for these purposes). Node features are configured within the nodes file on the [pbs\\_server](#) head node. This file can be used to specify an arbitrary number of node features.

Additionally, per node consumable generic resources may be specified using the format "<ATTR> <VAL>" with no leading dollar ("\$\$") character. When specified, this information is routed to the scheduler and can be used in scheduling decisions. For example, to indicate that a given host has two tape drives and one node-locked matlab license available for batch jobs, the following could be specified:

mom\_priv/config:

```
$clienthost 241.13.153.7
tape 2
matlab 1
```

Dynamic consumable resource information can be routed in by specifying a path preceded by an exclamation point (!) as in the example below. If the resource value is configured in this manner, the specified file will be periodically executed to load the effective resource value.

mom\_priv/config:

```
$clienthost 241.13.153.7
tape !/opt/rm/gettapecount.pl
matlab !/opt/tools/getlicensecount.pl
```

## Command-line arguments

Below is a table of `pbs_mom` command-line startup flags.

Flag	Description
<b>a</b> <integer>	Alarm time in seconds.
<b>c</b> <file>	Config file path.
<b>C</b> <dir- ectory>	Checkpoint path.
<b>d</b> <dir- ectory>	Home directory.
<b>L</b> <file>	Log file.

Flag	Description
<b>M</b> <integer>	MOM port to listen on.
<b>p</b>	Perform 'poll' based job recovery on restart (jobs persist until associated processes terminate).
<b>P</b>	On restart, deletes all jobs that were running on MOM (Available in 2.4.X and later).
<b>q</b>	On restart, requeues all jobs that were running on MOM (Available in 2.4.X and later).
<b>r</b>	On restart, kills all processes associated with jobs that were running on MOM, and then requeues the jobs.
<b>R</b> <integer>	MOM 'RM' port to listen on.
<b>S</b> <integer>	pbs_server port to connect to.
<b>v</b>	Display version information and exit.
<b>x</b>	Disable use of privileged port.
<b>?</b>	Show usage information and exit.

For more details on these command-line options, see [pbs\\_mom on page 2693](#).

## Appendix D: Diagnostics and error codes

TORQUE has a diagnostic script to assist you in giving TORQUE Support the files they need to support issues. It should be run by a user that has access to run all TORQUE commands and access to all TORQUE directories (this is usually root).

The script (`contrib/diag/tdiag.sh`) is available in TORQUE 2.3.8, TORQUE 2.4.3, and later. The script grabs the node file, server and MOM log files, and captures the output of `qmgr -c 'p s'`. These are put in a tar file.

The script also has the following options (this can be shown in the command line by entering `./tdiag.sh -h`):

```
USAGE: ./torque_diag [-d DATE] [-h] [-o OUTPUT_FILE] [-t TORQUE_HOME]
```

- *DATE* should be in the format YYYYmmdd. For example, "20091130" would be the date for November 30th, 2009. If no date is specified, today's date is used.
- *OUTPUT\_FILE* is the optional name of the output file. The default output file is `torque_diag<today's_date>.tar.gz`. *TORQUE\_HOME* should be the path to your TORQUE directory. If no directory is specified, `/var/spool/torque` is the default.

Table 4-6: TORQUE error codes

Error code name	Number	Description
PBSE_FLOOR	15000	No error
PBSE_UNKJOBID	15001	Unknown job ID error
PBSE_NOATTR	15002	Undefined attribute
PBSE_ATTRRO	15003	Cannot set attribute, read only or insufficient permission
PBSE_IVALREQ	15004	Invalid request
PBSE_UNKREQ	15005	Unknown request
PBSE_TOOMANY	15006	Too many submit retries
PBSE_PERM	15007	Unauthorized Request
PBSE_IFF_NOT_FOUND	15008	trqauthd unable to authenticate
PBSE_MUNGE_NOT_FOUND	15009	Munge executable not found, unable to authenticate
PBSE_BADHOST	15010	Access from host not allowed, or unknown host
PBSE_JOBEXIST	15011	Job with requested ID already exists
PBSE_SYSTEM	15012	System error
PBSE_INTERNAL	15013	PBS server internal error
PBSE_REGROUTE	15014	Dependent parent job currently in routing queue
PBSE_UNKSIG	15015	Unknown/illegal signal name

Error code name	Number	Description
PBSE_BADATVAL	15016	Illegal attribute or resource value for
PBSE_MODATTRUN	15017	Cannot modify attribute while job running
PBSE_BADSTATE	15018	Request invalid for state of job
PBSE_UNKQUE	15020	Unknown queue
PBSE_BADCRED	15021	Invalid credential
PBSE_EXPIRED	15022	Expired credential
PBSE_QUNOENB	15023	Queue is not enabled
PBSE_QACCESS	15024	Access to queue is denied
PBSE_BADUSER	15025	Bad UID for job execution
PBSE_HOPCOUNT	15026	Job routing over too many hops
PBSE_QUEEXIST	15027	Queue already exists
PBSE_ATTRTYPE	15028	Incompatible type
PBSE_QUEBUSY	15029	Cannot delete busy queue
PBSE_QUENBIG	15030	Queue name too long
PBSE_NOSUP	15031	No support for requested service
PBSE_QUENOEN	15032	Cannot enable queue, incomplete definition
PBSE_PROTOCOL	15033	Batch protocol error
PBSE_BADATLST	15034	Bad attribute list structure
PBSE_NOCONNECTS	15035	No free connections
PBSE_NOSERVER	15036	No server specified

Error code name	Number	Description
PBSE_UNKRESC	15037	Unknown resource type
PBSE_EXCQRESC	15038	Job exceeds queue resource limits
PBSE_QUENODFLT	15039	No default queue specified
PBSE_NORERUN	15040	Job is not rerunnable
PBSE_ROUTEREJ	15041	Job rejected by all possible destinations (check syntax, queue resources, ...)
PBSE_ROUTEEXPD	15042	Time in Route Queue Expired
PBSE_MOMREJECT	15043	Execution server rejected request
PBSE_BADSCRIPT	15044	(qsub) cannot access script file
PBSE_STAGEIN	15045	Stage-in of files failed
PBSE_RESCUNAV	15046	Resource temporarily unavailable
PBSE_BADGRP	15047	Bad GID for job execution
PBSE_MAXQUED	15048	Maximum number of jobs already in queue
PBSE_CKPSY	15049	Checkpoint busy, may retry
PBSE_EXLIMIT	15050	Resource limit exceeds allowable
PBSE_BADACCT	15051	Invalid Account
PBSE_ALRDYEXIT	15052	Job already in exit state
PBSE_NOCOPYFILE	15053	Job files not copied
PBSE_CLEANEOUT	15054	Unknown job id after clean init
PBSE_NOSYNCMSTR	15055	No master found for sync job set

Error code name	Number	Description
PBSE_BADDEPEND	15056	Invalid Job Dependency
PBSE_DUPLIST	15057	Duplicate entry in list
PBSE_DISPROTO	15058	Bad DIS based Request Protocol
PBSE_EXECTHERE	15059	Cannot execute at specified host because of checkpoint or stagein files
PBSE_SISREJECT	15060	Sister rejected
PBSE_SISCOMM	15061	Sister could not communicate
PBSE_SVRDOWN	15062	Request not allowed: Server shutting down
PBSE_CKPSHORT	15063	Not all tasks could checkpoint
PBSE_UNKNODE	15064	Unknown node
PBSE_UNKNODEATR	15065	Unknown node-attribute
PBSE_NONODES	15066	Server has no node list
PBSE_NODENBIG	15067	Node name is too big
PBSE_NODEEXIST	15068	Node name already exists
PBSE_BADNDATVAL	15069	Illegal value for
PBSE_MUTUALEX	15070	Mutually exclusive values for
PBSE_GMODERR	15071	Modification failed for
PBSE_NORELYMOM	15072	Server could not connect to MOM
PBSE_NOTSNODE	15073	No time-share node available
PBSE_JOBTYPE	15074	Wrong job type

Error code name	Number	Description
PBSE_BADACLHOST	15075	Bad ACL entry in host list
PBSE_MAXUSERQUED	15076	Maximum number of jobs already in queue for user
PBSE_BADDISALLOWTYPE	15077	Bad type in disallowed_types list
PBSE_NOINTERACTIVE	15078	Queue does not allow interactive jobs
PBSE_NOBATCH	15079	Queue does not allow batch jobs
PBSE_NORERUNABLE	15080	Queue does not allow rerunable jobs
PBSE_NONONRERUNABLE	15081	Queue does not allow nonrerunable jobs
PBSE_UNKARRAYID	15082	Unknown Array ID
PBSE_BAD_ARRAY_REQ	15083	Bad Job Array Request
PBSE_BAD_ARRAY_DATA	15084	Bad data reading job array from file
PBSE_TIMEOUT	15085	Time out
PBSE_JOBNOTFOUND	15086	Job not found
PBSE_NOFAULTTOLERANT	15087	Queue does not allow fault tolerant jobs
PBSE_NOFAULTINTOLERANT	15088	Queue does not allow fault intolerant jobs
PBSE_NOJOBARRAYS	15089	Queue does not allow job arrays
PBSE_RELAYED_TO_MOM	15090	Request was relayed to a MOM
PBSE_MEM_MALLOC	15091	Error allocating memory - out of memory
PBSE_MUTEX	15092	Error allocating controlling mutex (lock/unlock)
PBSE_THREADATTR	15093	Error setting thread attributes
PBSE_THREAD	15094	Error creating thread

Error code name	Number	Description
PBSE_SELECT	15095	Error in socket select
PBSE_SOCKET_FAULT	15096	Unable to get connection to socket
PBSE_SOCKET_WRITE	15097	Error writing data to socket
PBSE_SOCKET_READ	15098	Error reading data from socket
PBSE_SOCKET_CLOSE	15099	Socket close detected
PBSE_SOCKET_LISTEN	15100	Error listening on socket
PBSE_AUTH_INVALID	15101	Invalid auth type in request
PBSE_NOT_IMPLEMENTED	15102	This functionality is not yet implemented
PBSE_QUEENOTAVAILABLE	15103	Queue is currently not available
PBSE_TMPDIFFOWNER	15104	tmpdir owned by another user
PBSE_TMPNOTDIR	15105	tmpdir exists but is not a directory
PBSE_TMPNONAME	15106	tmpdir cannot be named for job
PBSE_CANTOPENSOCKET	15107	Cannot open demux sockets
PBSE_CANTCONTACTSISTERS	15108	Cannot send join job to all sisters
PBSE_CANTCREATETMPDIR	15109	Cannot create tmpdir for job
PBSE_BADMOMSTATE	15110	Mom is down, cannot run job
PBSE_SOCKET_INFORMATION	15111	Socket information is not accessible
PBSE_SOCKET_DATA	15112	Data on socket does not process correctly
PBSE_CLIENT_INVALID	15113	Client is not allowed/trusted
PBSE_PREMATURE_EOF	15114	Premature End of File

Error code name	Number	Description
PBSE_CAN_NOT_SAVE_FILE	15115	Error saving file
PBSE_CAN_NOT_OPEN_FILE	15116	Error opening file
PBSE_CAN_NOT_WRITE_FILE	15117	Error writing file
PBSE_JOB_FILE_CORRUPT	15118	Job file corrupt
PBSE_JOB_RERUN	15119	Job can not be rerun
PBSE_CONNECT	15120	Can not establish connection
PBSE_JOBWORKDELAY	15121	Job function must be temporarily delayed
PBSE_BAD_PARAMETER	15122	Parameter of function was invalid
PBSE_CONTINUE	15123	Continue processing on job. (Not an error)
PBSE_JOBSTATE	15124	Current sub state does not allow trasaction.
PBSE_CAN_NOT_MOVE_FILE	15125	Error moving file
PBSE_JOB_RECYCLED	15126	Job is being recycled
PBSE_JOB_ALREADY_IN_QUEUE	15127	Job is already in destination queue.
PBSE_INVALID_MUTEX	15128	Mutex is NULL or otherwise invalid
PBSE_MUTEX_ALREADY_LOCKED	15129	The mutex is already locked by this object
PBSE_MUTEX_ALREADY_UNLOCKED	15130	The mutex has already been unlocked by this object
PBSE_INVALID_SYNTAX	15131	Command syntax invalid
PBSE_NODE_DOWN	15132	A node is down. Check the MOM and host

Error code name	Number	Description
PBSE_SERVER_NOT_FOUND	15133	Could not connect to batch server
PBSE_SERVER_BUSY	15134	Server busy. Currently no available threads

## Appendix E: Considerations before upgrading

TORQUE is flexible in regards to how it can be upgraded. In most cases, a TORQUE "shutdown" followed by a *configure, make, make install* procedure as documented in this guide is all that is required (see [Installing on page 1](#)). This process will preserve existing configuration and in most cases, existing workload.

A few considerations are included below:

- If upgrading from OpenPBS, PBSPro, or TORQUE 1.0.3 or earlier, queued jobs whether active or idle will be lost. In such situations, job queues should be completely drained of all jobs.
- If not using the `pbs_mom -r` or `-p` flag (see [Command-line arguments on page 2801](#)), running jobs may be lost. In such cases, running jobs should be allowed to be completed or should be requeued before upgrading TORQUE.
- `pbs_mom` and `pbs_server` daemons of differing versions may be run together. However, not all combinations have been tested and unexpected failures may occur.
- When upgrading from early versions of TORQUE (pre-4.0) and Moab, you may encounter a problem where Moab core files are regularly created in `/opt/moab`. This can be caused by old TORQUE library files used by Moab that try to authorize with the old TORQUE `pbs_iff` authorization daemon. You can resolve the problem by removing the old version library files from `/usr/local/lib`.

### To upgrade

1. Build new release (do not install).
2. Stop all TORQUE daemons (see [qterm](#) and [momctl -s](#)).
3. Install new TORQUE (use *make install*).
4. Start all TORQUE daemons.

### Rolling upgrade

If you are upgrading to a new point release of your current version (for example, from 4.2.2 to 4.2.3) and not to a new major release from your current version (for example, from 4.1 to 4.2), you can use the following procedure to upgrade TORQUE without taking your nodes offline.

**i** Because TORQUE version 4.1.4 changed the way that `pbs_server` communicates with the MOMs, it is not recommended that you perform a rolling upgrade of TORQUE from version 4.1.3 to 4.1.4.

## To perform a rolling upgrade in TORQUE

1. Enable the [pbs\\_mom](#) on page 2693 flag on the MOMs you want to upgrade. The `enablemomrestart` option causes a MOM to check if its binary has been updated and restart itself at a safe point when no jobs are running. You can enable this in the MOM configuration file, but it is recommended that you use `momctl` instead.

```
> momctl -q enablemomrestart=1 -h :ALL
```

*The `enablemomrestart` flag is enabled on all nodes.*

2. Replace the `pbs_mom` binary, located in `/usr/local/bin` by default. `pbs_mom` will continue to run uninterrupted because the `pbs_mom` binary has already been loaded in RAM.

```
> torque-package-mom-linux-x86_64.sh --install
```

The next time `pbs_mom` is in an idle state, it will check for changes in the binary. If `pbs_mom` detects that the binary on disk has changed, it will restart automatically, causing the new `pbs_mom` version to load.

After the `pbs_mom` restarts on each node, the `enablemomrestart` parameter will be set back to false (0) for that node.

**i** If you have cluster with high utilization, you may find that the nodes never enter an idle state so `pbs_mom` never restarts. When this occurs, you must manually take the nodes offline and wait for the running jobs to complete before restarting `pbs_mom`. To set the node to an offline state, which will allow running jobs to complete but will not allow any new jobs to be scheduled on that node, use `pbsnodes -o <nodeName>`. After the new MOM has started, you must make the node active again by running `pbsnodes -c <nodeName>`.

## Appendix F: Large cluster considerations

TORQUE has enhanced much of the communication found in the original OpenPBS project. This has resulted in a number of key advantages including support for:

- larger clusters.
- more jobs.
- larger jobs.
- larger messages.

In most cases, enhancements made apply to all systems and no tuning is required. However, some changes have been made configurable to allow site specific modification. The configurable communication parameters are: [node\\_check\\_rate](#), [node\\_ping\\_rate](#), and [tcp\\_timeout](#).

For details, see these topics:

- [Scalability guidelines](#) on page 2812
- [End user command caching](#) on page 2812
- [Moab and TORQUE configuration for large clusters](#) on page 2814
- [Starting TORQUE in large environments](#) on page 2815
- [Other considerations](#) on page 2815

## Scalability guidelines

In very large clusters (in excess of 1,000 nodes), it may be advisable to tune a number of communication layer timeouts. By default, PBS MOM daemons timeout on inter-MOM messages after 60 seconds. In TORQUE 1.1.0p5 and higher, this can be adjusted by setting the timeout parameter in the `mom_priv/config` file (see [Appendix C: Node manager \(MOM\) configuration](#) on page 2783). If 15059 errors (cannot receive message from sisters) are seen in the MOM logs, it may be necessary to increase this value.

Client-to-server communication timeouts are specified via the `tcp_timeout` server option using the `qmgr` command.

**i** On some systems, *ulimit* values may prevent large jobs from running. In particular, the open file descriptor limit (i.e., `ulimit -n`) should be set to at least the maximum job size in procs + 20. Further, there may be value in setting the `fs.file-max` in `sysctl.conf` to a high value, such as:

```
/etc/sysctl.conf:
fs.file-max = 65536
```

### Related topics

- [Appendix F: Large cluster considerations](#) on page 2811

## End user command caching

### qstat

In a large system, users may tend to place excessive load on the system by manual or automated use of resource manager end user client commands. A simple way of reducing this load is through the use of client command wrappers which cache data. The example script below will cache the output of the command `'qstat -f'` for 60 seconds and report this info to end users.

```

#!/bin/sh

# USAGE: qstat $@

CMDPATH=/usr/local/bin/qstat
CACHETIME=60
TMPFILE=/tmp/qstat.f.tmp

if [ "$1" != "-f" ] ; then
    #echo "direct check (arg1=$1) "
    $CMDPATH $1 $2 $3 $4
    exit $?
fi

if [ -n "$2" ] ; then
    #echo "direct check (arg2=$2)"
    $CMDPATH $1 $2 $3 $4
    exit $?
fi

if [ -f $TMPFILE ] ; then
    TMPFILEMTIME=`stat -c %Z $TMPFILE`
else
    TMPFILEMTIME=0
fi

NOW=`date +%s`
AGE=$(( $NOW - $TMPFILEMTIME ))

#echo AGE=$AGE

for i in 1 2 3;do
    if [ "$AGE" -gt $CACHETIME ] ; then
        #echo "cache is stale "

        if [ -f $TMPFILE.1 ] ; then
            #echo someone else is updating cache

            sleep 5

            NOW=`date +%s`

            TMPFILEMTIME=`stat -c %Z $TMPFILE`

            AGE=$(( $NOW - $TMPFILEMTIME ))
        else
            break;
        fi
    fi
done

if [ -f $TMPFILE.1 ] ; then
    #echo someone else is hung

    rm $TMPFILE.1
fi

if [ "$AGE" -gt $CACHETIME ] ; then
    #echo updating cache

    $CMDPATH -f > $TMPFILE.1
mv $TMPFILE.1 $TMPFILE

fi

#echo "using cache"

```

```
cat $TMPFILE
exit 0
```

The above script can easily be modified to cache any command and any combination of arguments by changing one or more of the following attributes:

- script name
- value of \$CMDPATH
- value of \$CACHETIME
- value of \$TMPFILE

For example, to cache the command [pbsnodes](#) -a, make the following changes:

- Move original `pbsnodes` command to `pbsnodes.orig`.
- Save the script as 'pbsnodes'.
- Change \$CMDPATH to `pbsnodes.orig`.
- Change \$TMPFILE to `/tmp/pbsnodes.a.tmp`.

## Moab and TORQUE configuration for large clusters

There are a few basic configurations for Moab and TORQUE that can potentially improve performance on large clusters.

### Moab configuration

In the `moab.cfg` file, add:

1. `RMPOLLINTERVAL 30, 30` - This sets the minimum and maximum poll interval to 30 seconds.
2. `RMCFG[<name>] FLAGS=ASYNCSTART` - This tells Moab not to block until it receives a confirmation that the job starts.
3. `RMCFG[<name>] FLAGS=ASYNCDELETE` - This tells Moab not to block until it receives a confirmation that the job was deleted.

### TORQUE configuration

1. Follow the [Starting TORQUE in large environments](#) recommendations.
2. Increase `job_start_timeout` on `pbs_server`. The default is `300` (5 minutes), but for large clusters the value should be changed to something like `600` (10 minutes). Sites running very large parallel jobs might want to set this value even higher.
3. Use a node health check script on all MOM nodes. This helps prevent jobs from being scheduled on bad nodes and is especially helpful for large parallel jobs.

4. Make sure that `ulimit -n` (maximum file descriptors) is set to *unlimited*, or a very large number, and not the default.
5. For clusters with a high job throughput it is recommended that the server parameter `max_threads` be increased from the default. The default is  $(2 * \text{number of cores} + 1) * 10$ .

#### Related topics

- [Appendix F: Large cluster considerations on page 2811](#)

## Starting TORQUE in large environments

If running TORQUE in a large environment, use these tips to help TORQUE start up faster.

### Fastest possible start up

1. Create a [MOM hierarchy](#), even if your environment has a one-level MOM hierarchy (meaning all MOMs report directly to `pbs_server`), and copy the file to the `mom_priv` directory on the MOMs.
2. Start `pbs_server` with the [-n option](#). This specifies that `pbs_server` won't send the hierarchy to the MOMs unless a MOM requests it.
3. Start the MOMs normally.

### If no daemons are running

1. Start `pbs_server` with the [-c option](#).
2. Start the MOMs without the `-w` option.

### If MOMs are running and just restarting `pbs_server`

1. Start `pbs_server` without the `-c` option.

### If restarting a MOM or all MOMs

1. Start `pbs_server` without the `-w` option. Starting it with `-w` causes the MOMs to appear to be down.

#### Related topics

- [Appendix F: Large cluster considerations on page 2811](#)

## Other considerations

### `job_stat_rate`

In a large system, there may be many users, many jobs, and many requests for information. To speed up response time for users and for programs using the API the [job\\_stat\\_rate](#) can be used to tweak when the `pbs_server` daemon will query MOMs for job information. By increasing this number, a system will not be constantly querying job information and causing other commands to block.

## poll\_jobs

The [poll\\_jobs](#) parameter allows a site to configure how the `pbs_server` daemon will poll for job information. When set to `TRUE`, the `pbs_server` will poll job information in the background and not block on user requests. When set to `FALSE`, the `pbs_server` may block on user requests when it has stale job information data. Large clusters should set this parameter to `TRUE`.

## Internal settings

On large, slow, and/or heavily loaded systems, it may be desirable to increase the `pbs_tcp_timeout` setting used by the `pbs_mom` daemon in MOM-to-MOM communication. This setting defaults to 20 seconds and requires rebuilding code to adjust. For client-server based communication, this attribute can be set using the [qmgr](#) command. For MOM-to-MOM communication, a source code modification is required. To make this change, edit the `$TORQUEBUILDDIR/src/lib/Libifl/tcp_dis.c` file and set `pbs_tcp_timeout` to the desired maximum number of seconds allowed for a MOM-to-MOM request to be serviced.

**i** A system may be heavily loaded if it reports multiple 'End of File from addr' or 'Premature end of message' failures in the `pbs_mom` or `pbs_server` logs.

## Scheduler settings

If using Moab, there are a number of parameters which can be set on the scheduler which may improve TORQUE performance. In an environment containing a large number of short-running jobs, the `JOBAGGREGATIONTIME` parameter (see [Appendix A: Moab Parameters on page 923](#)) can be set to reduce the number of workload and resource queries performed by the scheduler when an event based interface is enabled. If the `pbs_server` daemon is heavily loaded and PBS API timeout errors (i.e. "Premature end of message") are reported within the scheduler, the "TIMEOUT" attribute of the `RMCFG` parameter may be set with a value of between 30 and 90 seconds.

## File system

TORQUE can be configured to disable file system blocking until data is physically written to the disk by using the `--disable-filesync` argument with *configure*. While having `filesync` enabled is more reliable, it may lead to server delays for sites with either a larger number of nodes, or a large number of jobs. `Filesync` is enabled by default.

## Network ARP cache

For networks with more than 512 nodes it is mandatory to increase the kernel's internal ARP cache size. For a network of ~1000 nodes, we use these values in `/etc/sysctl.conf` on all nodes and servers:

```

/etc/sysctl.conf

# Don't allow the arp table to become bigger than this
net.ipv4.neigh.default.gc_thresh3 = 4096
# Tell the gc when to become aggressive with arp table cleaning.
# Adjust this based on size of the LAN.
net.ipv4.neigh.default.gc_thresh2 = 2048
# Adjust where the gc will leave arp table alone
net.ipv4.neigh.default.gc_thresh1 = 1024
# Adjust to arp table gc to clean-up more often
net.ipv4.neigh.default.gc_interval = 3600
# ARP cache entry timeout
net.ipv4.neigh.default.gc_stale_time = 3600

```

Use `sysctl -p` to reload this file.

The ARP cache size on other Unixes can presumably be modified in a similar way.

An alternative approach is to have a static `/etc/ethers` file with all hostnames and MAC addresses and load this by `arp -f /etc/ethers`. However, maintaining this approach is quite cumbersome when nodes get new MAC addresses (due to repairs, for example).

- [Appendix F: Large cluster considerations on page 2811](#)

## Appendix G: Prologue and epilogue scripts

TORQUE provides administrators the ability to run scripts before and/or after each job executes. With such a script, a site can prepare systems, perform node health checks, prepend and append text to output and error log files, cleanup systems, and so forth.

The following table shows which MOM runs which script. All scripts must be in the `TORQUE_HOME/mom_priv/` directory and be available on every compute node. The "Mother Superior" is the `pbs_mom` on the first node allocated for a job. While it is technically a sister node, it is not a "Sister" for the purposes of the following table.

 The execution directory for each script is `TORQUE_HOME/mom_priv/`.

Script	Execution location	Execute as	File permissions
<b>prologue</b>	Mother Superior	root	Readable and executable by root and NOT writable by anyone but root (e.g., <code>-r-x-----</code> )
<b>epilogue</b>		root	
<b>prologue.user</b>		user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code> )
<b>epilogue.user</b>		user	

Script	Execution location	Execute as	File permissions
<b>prologue.parallel</b>	Sister	root	Readable and executable by root and NOT writable by anyone but root (e.g., <code>-r-x-----</code> )
<b>epilogue.parallel</b>		root	
<b>prologue.user.parallel</b>		user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code> )
<b>epilogue.user.parallel</b>		user	
<b>epilogue.precancel</b>	Mother Superior This script runs after a job cancel request is received from pbs_server and before a kill signal is sent to the job process.	user	Readable and executable by root and other (e.g., <code>-r-x--r-x</code> )

**i** `epilogue.parallel` is available in version 2.1 and later.

This section contains these topics:

- [Script order of execution on page 2818](#)
- [Script environment on page 2819](#)
- [Per job prologue and epilogue scripts on page 2820](#)
- [Prologue and epilogue scripts time out on page 2821](#)
- [Prologue error processing on page 2821](#)

## Script order of execution

When jobs start, the order of script execution is `prologue` followed by `prologue.user`. On job exit, the order of execution is `epilogue.user` followed by `epilogue` unless a job is canceled. In that case, `epilogue.precancel` is executed first. `epilogue.parallel` is executed only on the Sister nodes when the job is completed.

**i** The `epilogue` and `prologue` scripts are controlled by the system administrator. However, beginning in TORQUE version 2.4 a user `epilogue` and `prologue` script can be used on a per job basis. (See [Per job prologue and epilogue scripts on page 2820](#) for more information.)

**i** Root squashing is now supported for `epilogue` and `prologue` scripts.

Related topics

- [Appendix G: Prologue and epilogue scripts on page 2817](#)

## Script environment

The `prologue` and `epilogue` scripts can be very simple. On most systems, the script must declare the execution shell using the `#!<SHELL>` syntax (for example, `#!/bin/sh`). In addition, the script may want to process context sensitive arguments passed by TORQUE to the script.

### Prologue Environment

The following arguments are passed to the `prologue`, `prologue.user`, and `prologue.parallel` scripts:

Argument	Description
<code>argv[1]</code>	job id
<code>argv[2]</code>	job execution user name
<code>argv[3]</code>	job execution group name
<code>argv[4]</code>	job name (TORQUE 1.2.0p4 and higher only)
<code>argv[5]</code>	list of requested resource limits (TORQUE 1.2.0p4 and higher only)
<code>argv[6]</code>	job execution queue (TORQUE 1.2.0p4 and higher only)
<code>argv[7]</code>	job account (TORQUE 1.2.0p4 and higher only)

### Epilogue Environment

TORQUE supplies the following arguments to the `epilogue`, `epilogue.user`, `epilogue.precancel`, and `epilogue.parallel` scripts:

Argument	Description
<code>argv[1]</code>	job id
<code>argv[2]</code>	job execution user name
<code>argv[3]</code>	job execution group name
<code>argv[4]</code>	job name

Argument	Description
<code>argv[5]</code>	session id
<code>argv[6]</code>	list of requested resource limits
<code>argv[7]</code>	list of resources used by job
<code>argv[8]</code>	job execution queue
<code>argv[9]</code>	job account
<code>argv[10]</code>	job exit code

The `epilogue.precancel` script is run after a job cancel request is received by the MOM and before any signals are sent to job processes. If this script exists, it is run whether the canceled job was active or idle.

**i** The cancel job command (`qdel`) will take as long to return as the `epilogue.precancel` script takes to run. For example, if the script runs for 5 minutes, it takes 5 minutes for `qdel` to return.

For all scripts, the environment passed to the script is empty. However, if you submit the job using `msub` rather than `qsub`, some Moab environment variables are available in the TORQUE prologue and epilogue script environment: `MOAB_CLASS`, `MOAB_GROUP`, `MOAB_JOBARRAYINDEX`, `MOAB_JOBARRAYRANGE`, `MOAB_JOBID`, `MOAB_JOBNAME`, `MOAB_MACHINE`, `MOAB_NODECOUNT`, `MOAB_NODELIST`, `MOAB_PARTITION`, `MOAB_PROCCOUNT`, `MOAB_QOS`, `MOAB_TASKMAP`, and `MOAB_USER`. For more information, see [msub -E](#).

Also, standard input for both scripts is connected to a system dependent file. Currently, for all systems this is `/dev/null`. Except for epilogue scripts of an interactive job, `prologue.parallel`, `epilogue.precancel`, and `epilogue.parallel`, the standard output and error are connected to output and error files associated with the job. For an interactive job, since the pseudo terminal connection is released after the job completes, the standard input and error point to `/dev/null`. For `prologue.parallel` and `epilogue.parallel`, the user will need to redirect `stdout` and `stderr` manually.

#### Related topics

## Per job prologue and epilogue scripts

TORQUE supports per job prologue and epilogue scripts when using the `qsub -l` option. The syntax is:

```
qsub -l prologue=<prologue_script_path> epilogue=<epilogue_script_path>
<script>
```

The path can be either relative (from the directory where the job is submitted) or absolute. The files must be owned by the user with at least execute and read privileges, and the permissions must not be writeable by group or other.

```
/home/usertom/dev/
```

```
-r-x----- 1 usertom usertom 24 2009-11-09 16:11 prologue_script.sh
-r-x----- 1 usertom usertom 24 2009-11-09 16:11 epilogue_script.sh
```

**Example 4-29:**

```
$ qsub -l prologue=/home/usertom/dev/prologue_script.sh,epilogue=/home/usertom/dev/epilogue_script.sh job14.pl
```

This job submission executes the `prologue` script first. When the `prologue` script is complete, `job14.pl` runs. When `job14.pl` completes, the `epilogue` script is executed.

Related topics

- [Appendix G: Prologue and epilogue scripts on page 2817](#)

## Prologue and epilogue scripts time out

TORQUE takes preventative measures against prologue and epilogue scripts by placing an alarm around the scripts execution. By default, TORQUE sets the alarm to go off after 5 minutes of execution. If the script exceeds this time, it will be terminated and the node will be marked down. This timeout can be adjusted by setting the `$prologalarm` parameter in the `mom_priv/config` file.

**i** While TORQUE is executing the `epilogue`, `epilogue.user`, or `epilogue.precancel` scripts, the job will be in the *E* (exiting) state.

If an `epilogue.parallel` script cannot open the `.OU` or `.ER` files, an error is logged but the script is continued.

Related topics

- [Appendix G: Prologue and epilogue scripts on page 2817](#)

## Prologue error processing

If the `prologue` script executes successfully, it should exit with a zero status. Otherwise, the script should return the appropriate error code as defined in the table below. The `pbs_mom` will report the script's exit status to `pbs_server` which will in turn take the associated action. The following table describes each exit code for the prologue scripts and the action taken.

Error	Description	Action
-4	The script timed out	Job will be requeued

Error	Description	Action
-3	The wait(2) call returned an error	Job will be requeued
-2	Input file could not be opened	Job will be requeued
-1	Permission error (script is not owned by root, or is writable by others)	Job will be requeued
0	Successful completion	Job will run
1	Abort exit code	Job will be aborted
>1	other	Job will be requeued

Example 4-30:

Following are example prologue and epilogue scripts that write the arguments passed to them in the job's standard out file:

prologue	
<b>Script</b>	<pre>#!/bin/sh echo "Prologue Args:" echo "Job ID: \$1" echo "User ID: \$2" echo "Group ID: \$3" echo ""  exit 0</pre>
<b>stdout</b>	<pre>Prologue Args: Job ID: 13724.node01 User ID: user1 Group ID: user1</pre>

epilogue	
<b>Script</b>	<pre>#!/bin/sh echo "Epilogue Args:" echo "Job ID: \$1" echo "User ID: \$2" echo "Group ID: \$3" echo "Job Name: \$4" echo "Session ID: \$5" echo "Resource List: \$6" echo "Resources Used: \$7" echo "Queue Name: \$8" echo "Account String: \$9" echo ""  exit 0</pre>
<b>stdout</b>	<pre>Epilogue Args: Job ID: 13724.node01 User ID: user1 Group ID: user1 Job Name: script.sh Session ID: 28244 Resource List: neednodes=node01,nodes=1,walltime=00:01:00 Resources Used: cput=00:00:00,mem=0kb,vmem=0kb,walltime=00:00:07 Queue Name: batch Account String:</pre>

**Example 4-31:**

The Ohio Supercomputer Center contributed the following scripts:

"prologue creates a unique temporary directory on each node assigned to a job before the job begins to run, and epilogue deletes that directory after the job completes.

Having a separate temporary directory on each node is probably not as good as having a good, high performance parallel filesystem.

```

prologue

#!/bin/sh
# Create TMPDIR on all the nodes
# Copyright 1999, 2000, 2001 Ohio Supercomputer Center
# prologue gets 3 arguments:
# 1 -- jobid
# 2 -- userid
# 3 -- grpuid
#
jobid=$1
user=$2
group=$3
nodefile=/var/spool/pbs/aux/$jobid
if [ -r $nodefile ] ; then
    nodes=$(sort $nodefile | uniq)
else
    nodes=localhost
fi
tmp=/tmp/pbstmp.$jobid
for i in $nodes ; do
    ssh $i mkdir -m 700 $tmp \&\& chown $user.$group $tmp
done
exit 0

```

```

epilogue

#!/bin/sh
# Clear out TMPDIR
# Copyright 1999, 2000, 2001 Ohio Supercomputer Center
# epilogue gets 9 arguments:
# 1 -- jobid
# 2 -- userid
# 3 -- grpuid
# 4 -- job name
# 5 -- sessionid
# 6 -- resource limits
# 7 -- resources used
# 8 -- queue
# 9 -- account
#
jobid=$1
nodefile=/var/spool/pbs/aux/$jobid
if [ -r $nodefile ] ; then
    nodes=$(sort $nodefile | uniq)
else
    nodes=localhost
fi
tmp=/tmp/pbstmp.$jobid
for i in $nodes ; do
    ssh $i rm -rf $tmp
done
exit 0

```

**i** prologue, prologue.user, and prologue.parallel scripts can have dramatic effects on job scheduling if written improperly.

### Related topics

## Appendix H: Running multiple TORQUE servers and MOMs on the same node

TORQUE can be configured to allow multiple servers and MOMs to run on the same node. This example will show how to configure, compile and install two different TORQUE servers and MOMs on the same node. For details, see these topics:

- [Configuring the first TORQUE on page 2825](#)
- [Configuring the second TORQUE on page 2825](#)
- [Bringing the first TORQUE server online on page 2825](#)
- [Bringing the second TORQUE server online on page 2826](#)

### Configuring the first TORQUE

```
./configure --with-server-home=/usr/spool/PBS1 --bindir=/usr/spool/PBS1/bin --
sbindir=/usr/spool/PBS1/sbin
```

Then `make` and `make install` will place the first TORQUE into `/usr/spool/PBS1` with the executables in their corresponding directories.

### Configuring the second TORQUE

```
./configure --with-server-home=/usr/spool/PBS2 --bindir=/usr/spool/PBS2/bin --
sbindir=/usr/spool/PBS2/sbin
```

Then `make` and `make install` will place the second TORQUE into `/usr/spool/PBS2` with the executables in their corresponding directories.

### Bringing the first TORQUE server online

Each command, including `pbs_server` and `pbs_mom`, takes parameters indicating which servers and ports to connect to or listen on (when appropriate). Each of these is documented in their corresponding man pages (configure with `--enable-docs`).

In this example the first TORQUE server will accept batch requests on port 35000, communicate with the MOMs on port 35001, and communicate via RPP on port 35002. The first TORQUE MOM will try to connect to the server on port 35000, it will listen for requests from the server on port 35001 and will communicate via RPP on port 35002. (Each of these command arguments is discussed in further details on the corresponding man page. In particular, `-t create` is only used the first time a server is run.)

```
> pbs_server -p 35000 -M 35001 -R 35002 -t create
> pbs_mom -S 35000 -M 35001 -R 35002
```

Afterwards, when using a client command to make a batch request it is necessary to specify the server name and server port (35000):

```
> pbsnodes -a -s node01:35000
```

Submitting jobs can be accomplished using the `-q` option (`[[queue]][@host[:port]]`):

```
> qsub -q @node01:35000 /tmp/script.pbs
```

## Bringing the second TORQUE server online

In this example the second TORQUE server will accept batch requests on port 36000, communicate with the MOMS on port 36002, and communicate via RPP on port 36002. The second TORQUE MOM will try to connect to the server on port 36000, it will listen for requests from the server on port 36001 and will communicate via RPP on port 36002.

```
> pbs_server -p 36000 -M 36001 -R 36002 -t create
> pbs_mom -S 36000 -M 36001 -R 36002
```

Afterward, when using a client command to make a batch request it is necessary to specify the server name and server port (36002):

```
> pbsnodes -a -s node01:36000
> qsub -q @node01:36000 /tmp/script.pbs
```

## Appendix I: Security overview

The authorization model for TORQUE changed in version 4.0.0 from `pbs_iff` to a daemon called `trqauthd`. The job of the `trqauthd` daemon is the same as `pbs_iff`. The difference is that `trqauthd` is a resident daemon whereas `pbs_iff` is invoked by each client command. `pbs_iff` is not scalable and is prone to failure under even small loads. `trqauthd` is very scalable and creates the possibility for better security measures in the future.

### trqauthd and pbs\_iff authorization theory

The key to security of both `trqauthd` and `pbs_iff` is the assumption that any host which has been added to the TORQUE cluster has been secured by the administrator. Neither `trqauthd` nor `pbs_iff` do authentication. They only do authorization of users. Given that the host system is secure the following is the procedure by which `trqauthd` and `pbs_iff` authorize users to `pbs_server`.

1. Client utility makes a connection to `pbs_server` on a dynamic port.
2. Client utility sends a request to `trqauthd` with the user name and port.
3. `trqauthd` verifies the user ID and then sends a request to `pbs_server` on a privileged port with the user ID and dynamic port to authorize the connection.
4. `trqauthd` reports results of the server to client utility.

Both `trqauthd` and `pbs_iff` use Unix domain sockets for communication from the client utility. Unix domain sockets have the ability to verify that a user is who they say they are by using security features that are part of the file system.

## Appendix J: Job submission filter ("qsub wrapper")

When a "submit filter" exists, TORQUE will send the command file (or contents of STDIN if piped to `qsub`) to that script/executable and allow it to evaluate the submitted request based on specific site policies. The resulting file is then handed back to `qsub` and processing continues. Submit filters can check user jobs for correctness based on site policies. They can also modify user jobs as they are submitted. Some examples of what a submit filter might evaluate and check for are:

- Memory Request - Verify that the job requests memory and rejects if it does not.
- Job event notifications - Check if the job does one of the following and rejects it if it:
  - explicitly requests no notification.
  - requests notifications but does not provide an email address.
- Walltime specified - Verify that the walltime is specified.
- Global Walltime Limit - Verify that the walltime is below the global max walltime.
- Test Walltime Limit - If the job is a test job, this check rejects the job if it requests a walltime longer than the testing maximum.

The script below reads the original submission request from STDIN and shows how you could insert parameters into a job submit request:

```
#!/bin/sh
# add default memory constraints to all requests
# that did not specify it in user's script or on command line
echo "#PBS -l mem=16MB"
while read i
do
echo $i
done
```

**i** If you use a `qsub` script that includes `#PBS` directives to pass arguments instead of on the command line; for example,

```
#!/bin/sh
#
#This is an example script example.sh
#
#These commands set up the Grid Environment for your job:
#PBS -N ExampleJob
#PBS -l nodes=1,walltime=00:01:00
#PBS -q np_workq
#PBS -M YOURUNIQNAME@umich.edu
#PBS -m abe

#print the time and date
date

#wait 10 seconds
sleep 10

#print the time and date again
date
```

then your submit filter script must detect these directives and print them to stdout in order for `qsub` to see them.,

The same command line arguments passed to `qsub` will be passed to the submit filter and in the same order. Exit status of `-1` will cause `qsub` to reject the submission with a message stating that it failed due to administrative policies.

The "submit filter" must be executable, must be available on each of the nodes where users may submit jobs, and by default must be located at `${libexecdir}/qsub_filter` (for version 2.1 and older: `/usr/local/sbin/torque_submitfilter`). At run time, if the file does not exist at this new preferred path then `qsub` will fall back to the old hard-coded path. The submit filter location can be customized by setting the `SUBMITFILTER` parameter inside the file (see [Appendix K: "torque.cfg" configuration file on page 2828](#)), as in the following example:

torque.cfg:

```
SUBMITFILTER /opt/torque/submit.pl
...
```

**i** Initial development courtesy of Oak Ridge National Laboratories.

## Appendix K: "torque.cfg" configuration file

### CLIENTRETRY

<b>Format</b>	<INT>
---------------	-------

CLIENTRETRY	
<b>Default</b>	0
<b>Description</b>	Seconds between retry attempts to talk to pbs_server.
<b>Example</b>	<pre>CLIENTRETRY 10</pre> <p><i>TORQUE waits 10 seconds after a failed attempt before it attempts to talk to pbs_server again.</i></p>

DEFAULTCKPT	
<b>For mat</b>	One of <i>None, Enabled, Shutdown, Periodic, Interval=minutes, depth=number, or dir=path</i>
<b>Default</b>	<i>None</i>
<b>Description</b>	Default value for job's checkpoint attribute. For a description of all possible values, see <a href="#">qsub on page 2744</a> . <div style="border: 1px solid #005596; border-radius: 5px; padding: 5px; margin-top: 5px;">  This default setting can be overridden at job submission with the <code>qsub -c</code> option.           </div>
<b>Example</b>	<pre>DEFAULTCKPT Shutdown</pre> <p><i>By default, TORQUE checkpoints at pbs_mom shutdown.</i></p>

FAULT_TOLERANT_BY_DEFAULT	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Sets all jobs to fault tolerant by default. (See <a href="#">qsub -f</a> for more information on fault tolerance.)
<b>Example</b>	<pre>FAULT_TOLERANT_BY_DEFAULT TRUE</pre> <p><i>Jobs are fault tolerant by default. They will not be canceled based on failed polling, no matter how many nodes fail to report.</i></p>

HOST_NAME_SUFFIX	
<b>Format</b>	<STRING>
<b>Default</b>	---
<b>Description</b>	Specifies a hostname suffix. When <code>qsub</code> submits a job, it also submits the username of the submitter and the name of the host from which the user submitted the job. TORQUE appends the value of <code>HOST_NAME_SUFFIX</code> to the hostname. This is useful for multi-homed systems that may have more than one name for a host.
<b>Example</b>	<pre>HOST_NAME_SUFFIX -ib</pre> <p><i>When a job is submitted, the -ib suffix is appended to the host name.</i></p>

QSUBHOST	
<b>Format</b>	<HOSTNAME>
<b>Default</b>	---
<b>Description</b>	The hostname given as the argument of this option will be used as the <code>PBS_O_HOST</code> variable for job submissions. By default, <code>PBS_O_HOST</code> is the hostname of the submission host. This option allows administrators to override the default hostname and substitute a new name.
<b>Example</b>	<pre>QSUBHOST host1</pre> <p><i>The default hostname associated with a job is host1.</i></p>

QSUBSENDUID	
<b>Format</b>	N/A
<b>Default</b>	---
<b>Description</b>	Integer for job's <code>PBS_OUID</code> variable. Specifying the parameter name anywhere in the config file enables the feature. Removing the parameter name disables the feature.
<b>Example</b>	<pre>QSUBSENDUID</pre> <p><i>TORQUE assigns a unique ID to a job when it is submitted by <code>qsub</code>.</i></p>

QSUBSLEEP	
<b>Format</b>	<INT>
<b>Default</b>	0
<b>Description</b>	Specifies time, in seconds, to sleep between a user's submitting and TORQUE's starting a <code>qsub</code> command. Used to prevent users from overwhelming the scheduler.
<b>Example</b>	<pre>QSUBSLEEP 2</pre> <p><i>When a job is submitted with <code>qsub</code>, it will sleep for 2 seconds.</i></p>

RERUNNABLEBYDEFAULT	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Specifies if a job is re-runnable by default. Setting this to false causes the re-runnable attribute value to be false unless the users specifies otherwise with the <code>qsub -r</code> option. (New in TORQUE 2.4.)
<b>Example</b>	<pre>RERUNNABLEBYDEFAULT FALSE</pre> <p><i>By default, <code>qsub</code> jobs cannot be rerun.</i></p>

SERVERHOST	
<b>Format</b>	<STRING>
<b>Default</b>	localhost
<b>Description</b>	If set, the <a href="#">qsub on page 2744</a> command will open a connection to the host specified by the SERVERHOST string.
<b>Example</b>	<pre>SERVERHOST orion15</pre> <p><i>The server will open socket connections and and communicate using serverhost <code>orion15</code>.</i></p>

SUBMITFILTER	
<b>Format</b>	<STRING>
<b>Default</b>	`\${libexecdir}/qsub_filter (for version 2.1 and older: /usr/local/sbin/torque_submitfilter)
<b>Description</b>	Specifies the location of the submit filter (see <a href="#">Appendix J: Job submission filter ("qsub wrapper") on page 2827</a> used to pre-process job submission.
<b>Example</b>	<pre>SUBMITFILTER /usr/local/sbin/qsub_filter</pre> <p><i>The location of the submit filter is specified as /usr/local/sbin/qsub_filter.</i></p>

TRQ_IFNAME	
<b>Format</b>	<STRING>
<b>Default</b>	null
<b>Description</b>	Allows you to specify a specific network interface to use for outbound TORQUE requests. The string is the name of a network interface, such as <i>eth0</i> or <i>eth1</i> , depending on which interface you want to use.
<b>Example</b>	<pre>TRQ_IFNAME eth1</pre> <p><i>Outbound TORQUE requests are handled by eth1.</i></p>

VALIDATEGROUP	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	FALSE
<b>Description</b>	Validate submit user's group on <a href="#">qsub</a> commands. For TORQUE builds released after 2/8/2011, <i>VALIDATEGROUP</i> also checks any groups requested in <i>group_list</i> at the submit host. Set <i>VALIDATEGROUP</i> to "TRUE" if you set <a href="#">disable_server_id_check</a> to TRUE.
<b>Example</b>	<pre>VALIDATEGROUP TRUE</pre> <p><i>qsub verifies the submitter's group ID.</i></p>

VALIDATEPATH	
<b>Format</b>	<BOOLEAN>
<b>Default</b>	TRUE
<b>Description</b>	Validate local existence of '-d' working directory.
<b>Example</b>	<pre>VALIDATEPATH FALSE</pre> <p><i>qsub does not validate the path.</i></p>

## Appendix L: TORQUE Quick Start Guide

### Initial installation

TORQUE is now hosted at <https://github.com> under the adaptivecomputing organization. To download source, you will need to use the [git](#) utility. For example:

```
[root]# git clone https://github.com/adaptivecomputing.com/torque.git -b 5.0.0 5.0.0
```

To download a different version, replace each 5.0.0 with the desired version. After downloading a copy of the repository, you can list the current branches by typing `git branch -a` from within the directory of the branch you cloned.

**i** If you're checking source out from git, read the `README.building-40` file in the repository.

Extract and build the distribution on the machine that will act as the "TORQUE server" - the machine that will monitor and control all compute nodes by running the `pbs_server` daemon. See the example below:

```
> tar -xzf torque.tar.gz
> cd torque
> ./configure
> make
> make install
```

**i** OSX 10.4 users need to change the `#define _TDARWIN` in `src/include/pbs_config.h` to `#define _TDARWIN_8`.

**i** After installation, verify you have PATH environment variables configured for `/usr/local/bin/` and `/usr/local/sbin/`. Client commands are installed to `/usr/local/bin` and server binaries are installed to `/usr/local/sbin`.

**i** In this document, TORQUE\_HOME corresponds to where TORQUE stores its configuration files. The default is `/var/spool/torque`.

## Initialize/Configure TORQUE on the server (pbs\_server)

- Once installation on the TORQUE server is complete, configure the pbs\_server daemon by executing the command `torque.setup <USER>` found packaged with the distribution source code, where `<USER>` is a username that will act as the TORQUE admin. This script will set up a basic batch queue to get you started. If you experience problems, make sure that the most recent TORQUE executables are being executed, or that the executables are in your current PATH.

**i** If you are upgrading from TORQUE 2.5.9, run `pbs_server -u` before running `torque.setup`.

```
[root]# pbs_server -u
```

- If doing this step manually, be certain to run the command `pbs_server -t create` to create the new batch database. If this step is not taken, the pbs\_server daemon will be unable to start.
- Proper server configuration can be verified by following the steps listed in Testing server configuration.

## Install TORQUE on the compute nodes

To configure a compute node do the following on each machine (see page 19, Section 3.2.1 of *PBS Administrators Manual* for full details):

- Create the self-extracting, distributable packages with `make packages` (See the `INSTALL` file for additional options and features of the distributable packages) and use the parallel shell command from your cluster management suite to copy and execute the package on all nodes (i.e. xCAT users might do `prcp torque-package-linux-i686.sh main:/tmp/; psh main /tmp/torque-package-linux-i686.sh --install`). Optionally, distribute and install the clients package.

## Configure TORQUE on the compute nodes

- For each compute host, the MOM daemon must be configured to trust the pbs\_server daemon. In TORQUE 2.0.0p4 and earlier, this is done by creating the `TORQUE_HOME/mom_priv/config` file and setting the `$pbsserver` parameter. In TORQUE 2.0.0p5 and later, this can also be done by creating the `TORQUE_HOME/server_name` file and placing the server hostname inside.
- Additional config parameters may be added to `TORQUE_HOME/mom_priv/config` (see [Appendix C: Node manager \(MOM\) configuration on page 2783](#) for details).

## Configure data management on the compute nodes

Data management allows jobs' data to be staged in/out or to and from the server and compute nodes.

- For shared filesystems (i.e., NFS, DFS, AFS, etc.) use the [\\$usecp](#) parameter in the `mom_priv/config` files to specify how to map a user's home directory.  
(Example: `$usecp gridmaster.tmx.com:/home /home`)
- For local, non-shared filesystems, `rcp` or `scp` must be configured to allow direct copy without prompting for passwords (key authentication, etc.)

## Update TORQUE server configuration

On the TORQUE server, append the list of newly configured compute nodes to the `TORQUE_HOME/server_priv/nodes` file:

```
server_priv/nodes
computenode001.cluster.org
computenode002.cluster.org
computenode003.cluster.org
```

## Start the pbs\_mom daemons on compute nodes

- Next start the `pbs_mom` daemon on each compute node by running the `pbs_mom` executable.

Run the `trqauthd` daemon to run client commands (see [Configuring trqauthd for client commands on page 2556](#)). This enables running client commands.

## Verifying correct TORQUE installation

The `pbs_server` daemon was started on the TORQUE server when the `torque.setup` file was executed or when it was manually configured. It must now be restarted so it can reload the updated configuration changes.

```
# shutdown server
> qterm # shutdown server

# start server
> pbs_server

# verify all queues are properly configured
> qstat -q

# view additional server configuration
> qmgr -c 'p s'

# verify all nodes are correctly reporting
> pbsnodes -a

# submit a basic job
> echo "sleep 30" | qsub

# verify jobs display
> qstat
```

At this point, the job will not start because there is no scheduler running. The scheduler is enabled in the next step below.

## Enabling the scheduler

Selecting the cluster scheduler is an important decision and significantly affects cluster utilization, responsiveness, availability, and intelligence. The default TORQUE scheduler, `pbs_sched`, is very basic and will provide poor utilization of your cluster's resources. Other options, such as [Maui Scheduler](#) or [Moab Workload Manager](#) are highly recommended. If using Maui/Moab, refer to the [Moab-TORQUE Integration Guide on page 1228](#). If using `pbs_sched`, start this daemon now.

 If you are installing ClusterSuite, TORQUE and Moab were configured at installation for interoperability and no further action is required.

## Startup/Shutdown service script for TORQUE/Moab (OPTIONAL)

Optional startup/shutdown service scripts are provided as an example of how to run TORQUE as an OS service that starts at bootup. The scripts are located in the `contrib/init.d/` directory of the TORQUE tarball you downloaded. In order to use the script you must:

- Determine which `init.d` script suits your platform the best.
- Modify the script to point to TORQUE's install location. This should only be necessary if you used a non-default install location for TORQUE (by using the `--prefix` option of `./configure`).
- Place the script in the `/etc/init.d/` directory.
- Use a tool like `chkconfig` to activate the start-up scripts or make symbolic links (`S99moab` and `K15moab`, for example) in desired runtimes (`/etc/rc.d/rc3.d/` on Redhat, etc.).

### Test environment

All these tests assume the following test program and shell script, `test.sh`.

```
#include
int main( int argc, char *argv[] )
{
  int i;

  for (i=0; i<100; i++)
  {
    printf("i = %d\n", i);
    fflush(stdout);
    sleep(1);
  }
}
#!/bin/bash

/home/test/test
```

## Test 1 - Basic operation

### Introduction

This test determines if the proper environment has been established.

### Test steps

Submit a test job and the issue a hold on the job.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
```

### Possible failures

Normally the result of `qhold` is nothing. If an error message is produced saying that `qhold` is not a supported feature then one of the following configuration errors might be present.

- The TORQUE images may have not be configured with `--enable-blcr`
- BLCR support may not be installed into the kernel with `insmod`.
- The config script in `mom_priv` may not exist with `$checkpoint_script` defined.
- The config script in `mom_priv` may not exist with `$restart_script` defined.
- The config script in `mom_priv` may not exist with `$checkpoint_run_exe` defined.
- The scripts referenced in the config file may not exist.
- The scripts referenced in the config file may not have the correct permissions.

## Successful results

If no configuration was done to specify a specific directory location for the checkpoint file, the default location is off of the TORQUE directory, which in my case is `/var/spool/torque/checkpoint`.

Otherwise, go to the specified directory for the checkpoint image files. This was done by either specifying an option on job submission, i.e. `-c dir=/home/test` or by setting an attribute on the execution queue. This is done with the command `qmgr -c 'set queue batch checkpoint_dir=/home/test'`.

Doing a directory listing shows the following.

```
# find /var/spool/torque/checkpoint
/var/spool/torque/checkpoint
/var/spool/torque/checkpoint/999.xxx.yyy.CK
/var/spool/torque/checkpoint/999.xxx.yyy.CK/ckpt.999.xxx.yyy.1205266630
# find /var/spool/torque/checkpoint |xargs ls -l
-r----- 1 root root 543779 2008-03-11 14:17
/var/spool/torque/checkpoint/999.xxx.yyy.CK/ckpt.999.xxx.yyy.1205266630

/var/spool/torque/checkpoint:
total 4
drwxr-xr-x 2 root root 4096 2008-03-11 14:17 999.xxx.yyy.CK

/var/spool/torque/checkpoint/999.xxx.yyy.CK:
total 536
-r----- 1 root root 543779 2008-03-11 14:17 ckpt.999.xxx.yyy.1205266630
```

Doing a `qstat -f` command should show the job in a held state, `job_state = H`. Note that the attribute `checkpoint_name` is set to the name of the file seen above.

If a checkpoint directory has been specified, there will also be an attribute `checkpoint_dir` in the output of `qstat -f`.

```

$ qstat -f
Job Id: 999.xxx.yyy
Job_Name = test.sh
Job_Owner = test@xxx.yyy
resources_used.cput = 00:00:00
resources_used.mem = 0kb
resources_used.vmem = 0kb
resources_used.walltime = 00:00:06
job_state = H
queue = batch

## Test 2 - Persistence of checkpoint images

### Introduction

This test determines if the checkpoint files remain in the default directory after the job is removed from the TORQUE queue.

Note that this behavior was requested by a customer but in fact may not be the right thing to do as it leaves the checkpoint files on the execution node. These will gradually build up over time on the node being limited only by disk space. The right thing would seem to be that the checkpoint files are copied to the user's home directory after the job is purged from the execution node.

## Test steps

Assuming the steps of Test 1 (see [Test 1 - Basic operation on page 2837](#)), delete the job and then wait until the job leaves the queue after the completed job hold time. Then look at the contents of the default checkpoint directory to see if the files are still there.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
> qdel 999
> sleep 100
> qstat
>
> find /var/spool/torque/checkpoint
... files ...
```

## Possible failures

The files are not there, did Test 1 actually pass?

## Successful results

The files are there.

## Test 3 - Restart after checkpoint

### Introduction

This test determines if the job can be restarted after a checkpoint hold.

### Test steps

Assuming the steps of Test 1 (see [Test 1 - Basic operation on page 2837](#)), issue a `qrls` command. Have another window open into the `/var/spool/torque/spool` directory and tail the job.

### Successful results

After the `qrls`, the job's output should resume.

Related topics

- [Appendix M: BLCR acceptance tests on page 2836](#)

## Test 4 - Multiple checkpoint/restart

### Introduction

This test determines if the checkpoint/restart cycle can be repeated multiple times.

### Test steps

Start a job and then while tailing the job output, do multiple [qhold/qrls](#) operations.

```
> qsub -c enabled test.sh
999.xxx.yyy
> qhold 999
> qrls 999
> qhold 999
> qrls 999
> qhold 999
> qrls 999
```

#### Successful results

After each `qrls`, the job's output should resume. Also tried "while true; do `qrls 999`; `qhold 999`; done" and this seemed to work as well.

#### Related topics

- [Appendix M: BLCR acceptance tests on page 2836](#)

## Test 5 - Periodic checkpoint

### Introduction

This test determines if automatic periodic checkpoint will work.

### Test steps

Start the job with the option `-c enabled,periodic,interval=1` and look in the checkpoint directory for checkpoint images to be generated about every minute.

```
> qsub -c enabled,periodic,interval=1 test.sh
999.xxx.yyy
```

#### Successful results

After each `qrls`, the job's output should resume. Also tried "while true; do `qrls 999`; `qhold 999`; done" and this seemed to work as well.

#### Related topics

- [Appendix M: BLCR acceptance tests on page 2836](#)

## Test 6 - Restart from previous image

### Introduction

This test determines if the job can be restarted from a previous checkpoint image.

### Test steps

Start the job with the option `-c enabled,periodic,interval=1` and look in the checkpoint directory for checkpoint images to be generated about every minute. Do a [qhold](#) on the job to stop it. Change the attribute `checkpoint_name` with the [qalter](#) command. Then do a [qrls](#) to restart the job.

```
> qsub -c enabled,periodic,interval=1 test.sh
999.xxx.yyy
> qhold 999
> qalter -W checkpoint_name=ckpt.999.xxx.yyy.1234567
> qrls 999
```

### Successful results

The job output file should be truncated back and the count should resume at an earlier number.
