Welcome

Revised: 03/30/2017

Welcome to the Administrator Guide for Nitro 2.1.1.

The following chapters are provided to assist in understanding, getting started with, and using Nitro.

- [Nitro Overview on page 2](#) - Provides basic information on Nitro, including theory of operation.
- [Installation and Configuration on page 11](#) - Provides basic installation, configuration, and upgrade information.
- [System Administration on page 63](#) - Contains procedures and reference information for system administrators.
- [Using Nitro on page 69](#) - Contains procedures and reference information on using Nitro.
- [References on page 81](#) - Provides additional conceptual information about Nitro, including a glossary of key terms used throughout this guide.
- [Troubleshooting on page 105](#) - Identifies common sources of reference for troubleshooting and provides troubleshooting information for task errors.

Documentation Changes

This topic lists miscellaneous edits to the Nitro Administrator Guide Edits are listed in descending order by revision date.

- Jan 31, 2017 – Initial release for version 2.1.1. See [Release Notes](#) for more information.
- Nov 10, 2016 – Initial release for version 2.1.0. See [Release Notes](#) for more information.

Chapter 1 Nitro Overview

Nitro is the Adaptive Computing High Throughput Computing (HTC) product designed to integrate with either High Performance Computing (HPC), such as Moab Workload Manager, or datacenter schedulers to schedule and run workloads consisting of large quantities (tens of thousands to millions) of small jobs (seconds to minutes to complete) without affecting the throughput of the HPC or datacenter scheduler.

In this chapter:

- [Nitro Origins and Purpose on page 2](#)
- [Workload Solutions and Use Cases on page 3](#)
- [Theory of Operation on page 5](#)
- [Nitro and System Scheduler Policies on page 9](#)
- [Key Terminology and Usage on page 10](#)

Nitro Origins and Purpose

This topic describes the motivation and purpose behind the creation of Nitro.

In this topic:

- [Origins on page 2](#)
- [Purpose on page 3](#)

Origins

Until recently, Adaptive Computing's traditional market has been scheduling batch jobs for HPC systems, colloquially known as "supercomputers". These HPC systems are typically composed of hundreds to tens of thousands of "compute nodes" (servers designed for fast computations and large amounts of I/O), which are increasingly "off-the-shelf" servers. Part of scheduling workloads on such large HPC systems is optimizing the use of all the system's resources. This can be a complex process involving a large amount of computation which can take a significant amount of time.

Complicating the scheduling of HPC systems is the increasing use of workloads consisting of small jobs. These workloads do not need multiple servers but can execute on a single server or even on a single core, and may execute in a short amount of time, sometimes just seconds or even sub-seconds. Such workloads typically fall under the category of HTC and do not need the optimization performed by HPC schedulers.

When an HPC scheduler must schedule large quantities of HTC workloads, these workloads severely slow down the HPC scheduler and reduce its scheduling throughput. To counteract the effects of HTC workloads on HPC schedulers, Adaptive Computing created Nitro. Nitro schedules and runs HTC workloads on any HPC cluster or in any datacenter without affecting the throughput of the HPC or the datacenter scheduling software.

Nitro runs large quantities of HTC workloads as a single job submitted to any HPC or datacenter scheduler (it is scheduler-agnostic) using the resources allocated to it by the HPC or datacenter

scheduler. This permits the scheduler to operate normally and eliminates the impact the scheduling of thousands or millions of HTC workloads would have on it.

Purpose

Nitro runs workloads small enough to execute on a single compute node or server, regardless whether HTC in nature, with as little overhead as possible in order to speed up the execution of HTC-like workloads through the elimination of regular scheduler overhead. This is its primary intended purpose.

Nitro runs a single workload submitted to any HPC or datacenter scheduler and executes hundreds, thousands, or even millions of HTC-like workloads using the resources allocated to it by the HPC or datacenter scheduler. This permits the scheduler to operate normally by eliminating the impact that scheduling of thousands or millions of HTC workloads would have on the scheduler.

Workload Solutions and Use Cases

This topic provides an operational overview of workload solutions available with Nitro. Use cases are also provided to showcase some of the solutions and benefits with using Nitro.

In this topic:

- [Workloads on page 3](#)
- [Use Cases on page 3](#)

Workloads

Nitro easily schedules and executes these typical workloads:

- Serial applications that use only a single core.
- Multi-threaded applications that run on a single node.
- Short-running applications.
- "Embarrassingly Parallel" applications such as Monte Carlo-based simulations.
- Serial or parallel applications that run on a single node.
- Regression testing.

Use Cases

This section contains use cases of Nitro workload solutions.

In this section:

- [Many Independent Short Workloads on page 4](#)
- [Large Queues on page 4](#)
- [Multi-threaded HTC Applications on page 4](#)
- [Regression Testing on page 5](#)

Many Independent Short Workloads

Let's say a user wants to submit a workload of 50,000 HTC jobs to execute on a system, this means submitting each job separately to the system's scheduler. Submitting all 50,000 jobs at once to the work queue slows down the scheduler sufficiently that other users complain of reduced job response times (turnaround time between job submission and job completion). This reduced response time is due to the overhead the scheduler incurs scheduling so many HTC jobs and the overhead of starting and managing so many individual short jobs. In other words, the shorter the HTC job, the greater the percentage of the job's response time is consumed by job scheduling, startup, and management overhead.

Using Nitro, a user can submit a single "Nitro job" with the 50,000 HTC jobs (now referred to as Nitro tasks) to the system's scheduler. Nitro will quickly execute this workload using its very low scheduling overhead and very quick workload management. In other words, Nitro's low scheduling overhead provides improved response time for executing many short jobs when compared to a normal scheduler.

For example, let's look at a Nitro demonstration with an investment trading enterprise. The investment trading enterprise normally submitted a workload of 10,000 of its own HTC jobs to a commercial scheduler that took 110 seconds to execute the 10,000 jobs on ten 12-core nodes. Submitted as a single Nitro job to the same commercial scheduler, a very early version of Nitro took only 9 seconds to execute the same 10,000 jobs (again now called tasks) on the same ten 12-cores nodes. Resulting in a response time speedup of 12x!

Large Queues

Let's say an HPC cluster or a datacenter has a large job queue where a significant portion of the job queue consists of HTC workloads (thousands to millions of short jobs taking seconds to minutes to complete). This causes reduced job response times from the system scheduler.

However, by using Nitro, users can consolidate these workloads into a few Nitro jobs (tens or hundreds) to improve the system scheduler's job response times. Those Nitro jobs will execute the HTC workloads on the nodes the scheduler allocates to the Nitro jobs, thereby speeding their own workload turnarounds as well as improving the other users' job turnaround times due to a large reduction in the queue size.

For example, let's say a scheduler has a job queue containing 100,000 jobs and of those 95,000 can be consolidated into 95 Nitro jobs (each executing 1,000 tasks). By consolidating, the scheduler's job queue will drop from 100,000 jobs to 5,095 jobs, which the scheduler can process in 5% of the time required for processing 100,000 jobs, for a 20x scheduling cycle speedup. This speedup also benefits all the other jobs in the queue.

Multi-threaded HTC Applications

Let's say a user has a multi-threaded application that runs on a single node and wants to run the same application many times, but each time with different parameters or datasets. The user will either submit a single job that executes the application one instance at a time with the different parameters or datasets, or submits many jobs that execute the application only once, each with different parameters or datasets. The former method does not take advantage of the many available nodes on which many application instances can execute simultaneously for a shorter overall response time but does have the advantage of not affecting the system scheduler's scheduling time. The latter method has a greater potential for a shorter overall response time but has the disadvantage of affecting the system scheduler's job throughput.

Using Nitro, the user can run multiple instances of an application on the nodes the system scheduler allocates to the Nitro job without affecting the system scheduler's scheduling time or throughput. In addition, the Nitro job will usually execute all instances in a shorter time than the system scheduler could due to much lower overhead since Nitro's orientation and optimization quickly starts the next application instance as soon as an existing application instance completes.

Regression Testing

Let's say an institution performs large quantities of regression tests each night for the applications it develops. Many regression tests are similar and can execute independently of each other. The regression test framework submits the tests as individual jobs to the system scheduler, which means many jobs for it to schedule.

Using Nitro can increase the regression test throughput due to its much lower workload management overhead; that is, it can immediately start the next regression workload as soon as an existing workload completes without the overhead a system scheduler incurs communicating job completion, scheduling the next job to start, and then starting the next job.

Theory of Operation

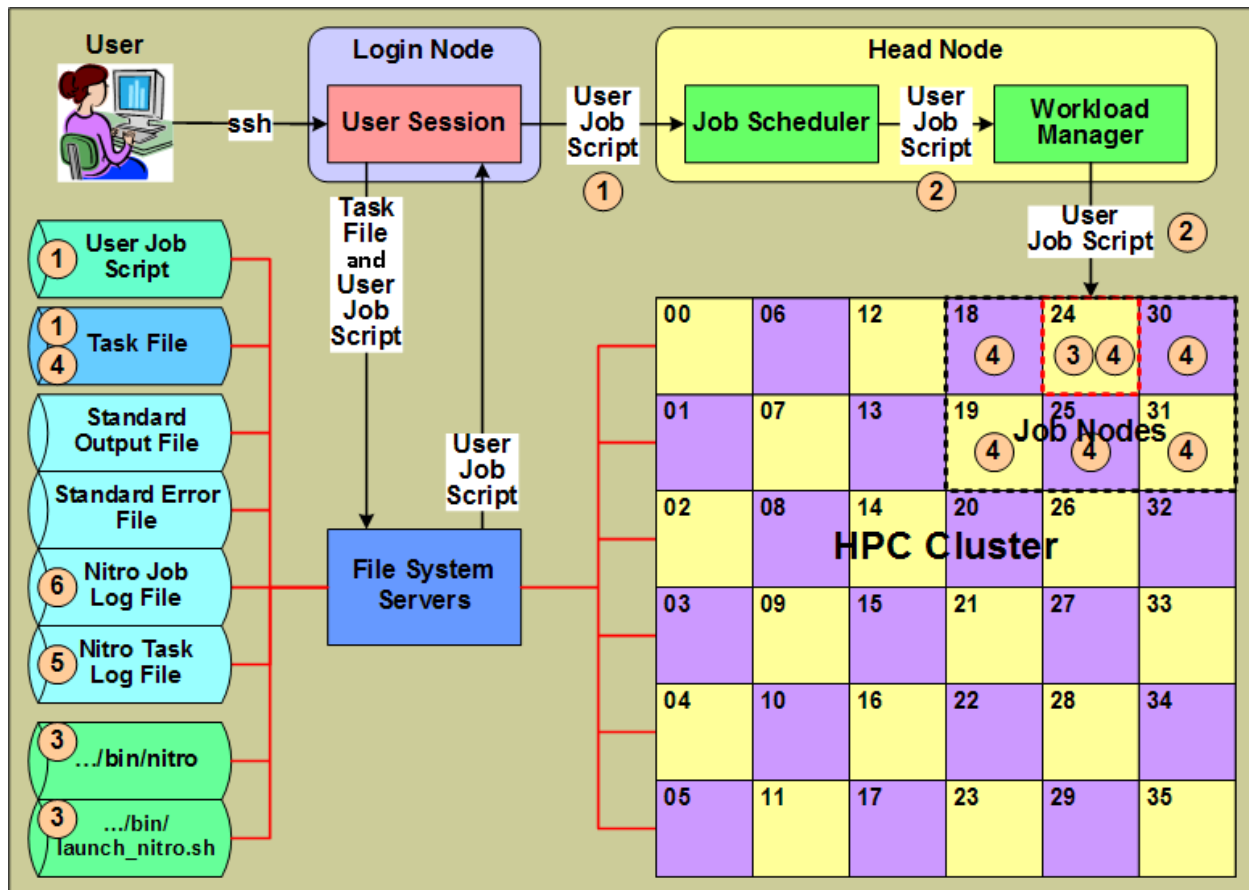

This topic identifies the various components of Nitro, describes their purpose, and illustrates how they interact with the user, the system scheduler, the system hardware, and each other.

In this topic:

- [Nitro High-Level Architecture and Flow on page 5](#)
- [Nitro Job Startup Architecture and Flow on page 7](#)
- [Nitro Job Architecture and Processing Flow on page 8](#)

Nitro High-Level Architecture and Flow

This section identifies Nitro components from a high-level Nitro product architecture perspective that most closely aligns with the perspective of a user submitting a Nitro job that uses the Nitro application to execute workloads with minimal scheduling overhead.

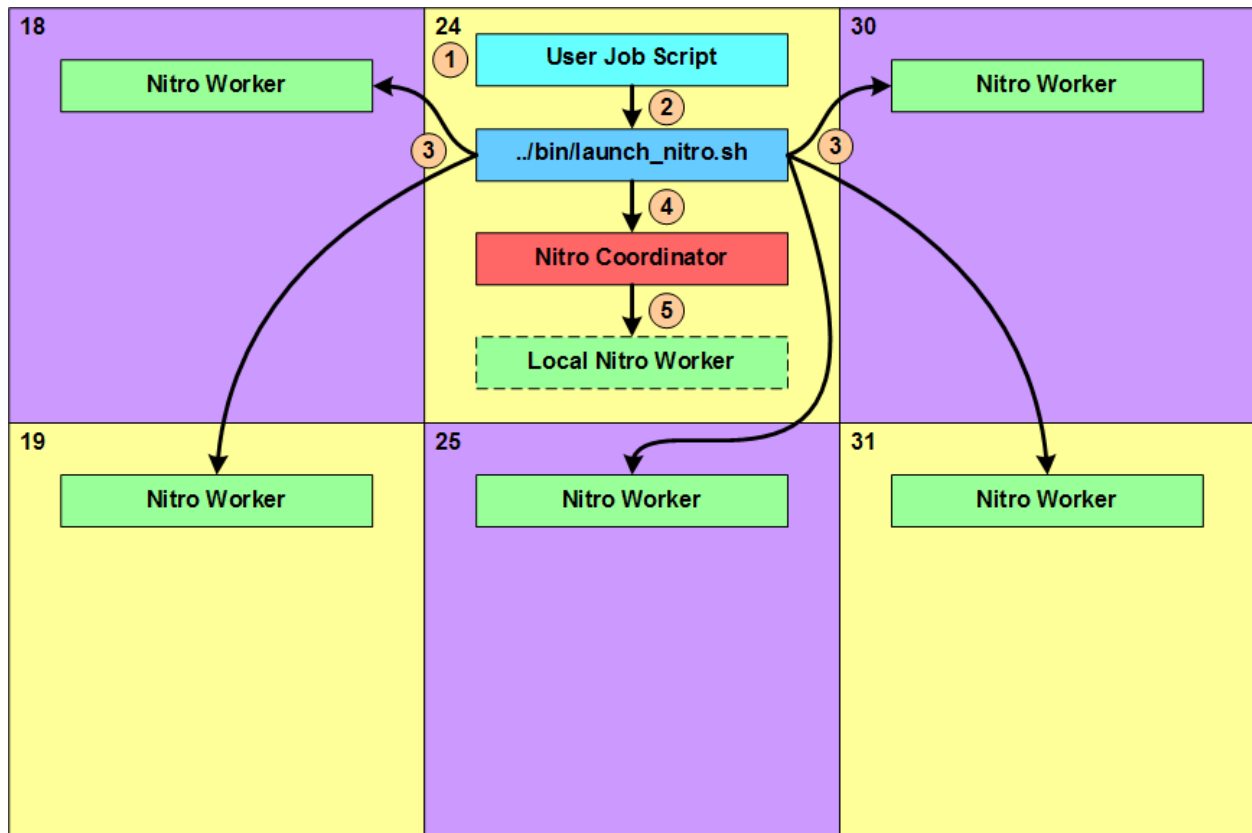

1. A user creates a "user job script" that executes Nitro with a task file (containing task definitions created by the user) that execute the user's workloads, and submits the job script to the system's job scheduler. The user job script can be scheduler-agnostic, which means the user can submit the same script to different schedulers on other systems or on the same system if its scheduler changes.
2. The scheduler allocates nodes to the Nitro job and, using a workload and/or resource manager, starts the execution of the job script on one of the job's allocated nodes.
3. The user job script executes Nitro (`.../bin/nitro`) using the Nitro launch script (`.../bin/launch_nitro.sh`). The Nitro launch script is scheduler-specific and allows the user job script to be scheduler-agnostic.
4. Nitro reads the task file containing the user-defined task definitions and then executes the tasks on its allocated nodes. A Nitro task definition is the equivalent of an HTC job running an application in that the user converts individual HTC jobs previously submitted to a scheduler into tasks executed by Nitro.
5. As tasks complete their execution, Nitro records information for each task in the Nitro task log file.
6. As Nitro processes task definitions from the task file and executes them, Nitro periodically updates the Nitro job log file with job progress and statistical task information to keep the user informed of its progress.

Also while Nitro executes, it records information about its environment and progress in the job's standard output file. Likewise, any unusual or unexpected errors it encounters it records in the job's standard error file.

Nitro Job Startup Architecture and Flow

This section identifies Nitro components from a job-level architecture perspective and indicates which Nitro components start and interact with other components during a Nitro job startup.

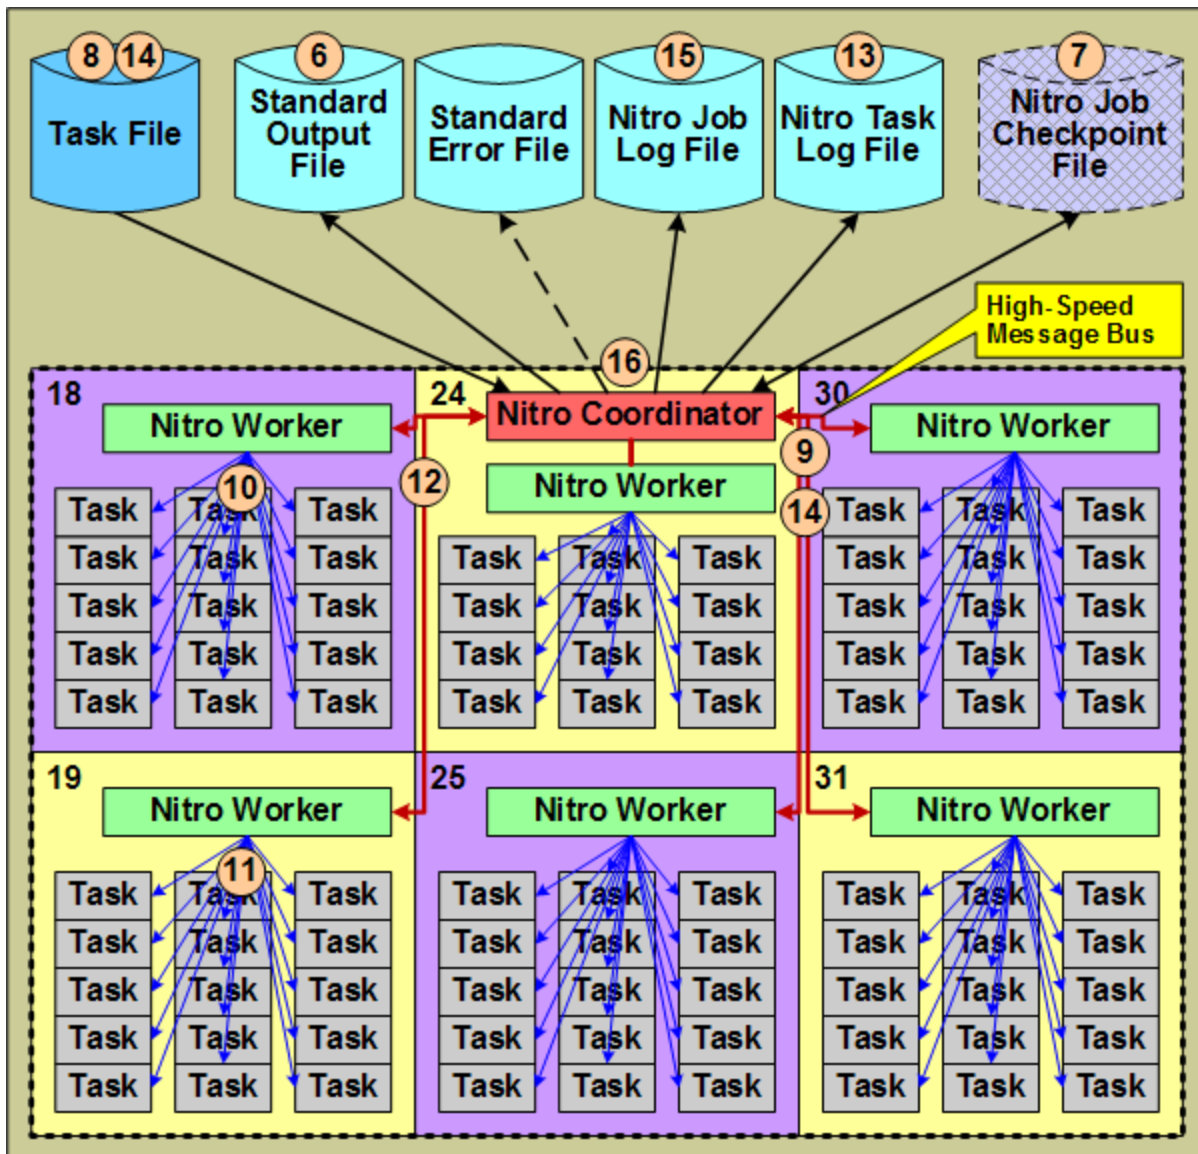

1. The user job script executes and does whatever the user specified. This can include things such as setting the Nitro environment variable for the task file path, setting other Nitro-recognized environment variables with values that affect Nitro's behavior, and performing any other preparatory work needed by the tasks Nitro will execute.
2. The last action performed by the user job script is to execute the Nitro launch script (`../bin/launch_nitro.sh`) that starts up Nitro.
3. Using scheduler- or resource manager-specific commands, the Nitro launch script starts up one Nitro worker on each of the nodes allocated to the Nitro job.
4. Lastly, the Nitro launch script starts up the Nitro coordinator on the node on which it is executing.
5. If the user job script or the Nitro launch script specified the Nitro coordinator should start up a Nitro worker (Local Nitro Worker) on its node, the coordinator does so after it starts up.

Nitro Job Architecture and Processing Flow

This section identifies the other Nitro components used and/or produced by the Nitro coordinator from a job-level architecture perspective and shows their interactions.

This section continues the job-level perspective narrative relative to Nitro's operation shown in [Nitro Job Startup Architecture and Flow on page 7](#).

6. The Nitro coordinator outputs information about its environment, including file path information, the job itself (with the job id), to the job's Standard Output File.
7. Nitro coordinator checks for the existence of a Nitro job checkpoint file. If it is present, the coordinator reads the checkpoint file and resumes the Nitro job; otherwise, the Nitro coordinator creates a checkpoint file for the Nitro job.

i A user can take advantage of restarting a Nitro job from where it left off if the user or an administrator cancelled the job or the scheduler preempted the job.

8. The Nitro coordinator opens and starts reading the task file in the user job script or via an environment variable. If the checkpoint file already exists, the coordinator resumes reading the task file from where it stopped and reassigns any uncompleted tasks to workers for execution.
9. The Nitro coordinator processes the task definitions in the task file and creates task "assignments" from the task definitions in the task file that it sends to the Nitro workers via a message bus.
10. The Nitro workers each process their own task assignment and start up tasks using their "task launch" threads. Each task launch thread starts up and executes one task.
11. When a task finishes executing, the worker asynchronously uses the task launch thread to obtain statistical information about the task's execution.
12. When all tasks within a task assignment have completed, the worker returns the tasks' statistical information to the coordinator via the message bus and then starts processing its next task assignment.
13. The coordinator records the tasks' statistical information in the Nitro task Log file
14. The coordinator continues reading task definitions from the task file, creating task assignments, and sending the task assignments to the workers. To keep the workers busy (fully utilizing the nodes allocated to the Nitro job), the coordinator sends another task assignment to a worker when the worker processed a majority of the current task assignment (while worker still has tasks in its queue). This overlapping of task assignments keeps all of the node's cores executing workload for a very high percentage of the time.
15. The coordinator periodically updates the Nitro job's statistical information in the Nitro job log file. The user can refer to the job log file to follow the Nitro job's progress.
16. When the coordinator has reached the end of the task file *and* the workers have executed all tasks, the coordinator shuts down the workers, deletes the checkpoint file, and then terminates itself. At this point the user job completes.

Nitro and System Scheduler Policies

Nitro is an HTC scheduler application executed by a job script just like any other application a user might execute. By design, Nitro does not and will not perform scheduling functions like a regular system scheduler, such as, enforcing per-user, per-group, and/or per-account resource or usage limit policies, supporting fair-share policies, maintaining separation between users in a multi-tenancy environment, etc. This means Nitro will not perform functions such as launching tasks from one Nitro job as different users, etc.

Nitro and Users

If users are subject to different constraints and policies, requiring the users to submit their own Nitro jobs and not combine the Nitro tasks allows the system scheduler to enforce policies on the

users, which is the system scheduler's responsibility. Thus with Nitro, the administrator will continue to use the system scheduler to enforce policies in the normal manner.

For example, if three users (A, B and C) each want to execute Nitro tasks that are the same application and perhaps even use the same data, they each must submit their own Nitro job with its own task file (could be the same file but the users must specify it for their own job). If they are each subject to different policies and constraints, the system scheduler enforces those constraints and, by design, Nitro is ignorant of the policies and constraints and will remain so.

Nitro and Host Resources

If a user wants to execute workloads that require certain hardware resources or constraints, the user must use the system scheduler's resource request capabilities to allocate or constrain such.

For example if a Nitro job will execute workloads that require an accelerator, such as NVIDIA/AMD GPU or Intel MIC (Xeon Phi), the user must request hosts with the required accelerator(s) for the Nitro job so the workloads have accelerator(s) available to them.

Key Terminology and Usage

This document includes a glossary of key terms used through this guide. This is to help simplify and clarify the information presented.

For example, instead of using terms specific to the traditional HPC (research, university, and government institutions) and commercial enterprise markets, such as "HPC cluster" and "datacenter" and their corresponding "compute node" and "server" terms, this guide uses the generic terms "system" and "host", respectively. Also this guide uses the term "workload" to represent an arbitrary amount of work to execute on a system while "job" refers to workload submitted by a user to a system's scheduler for eventual execution on one or more of the system's hosts.

Refer often to [Glossary on page 100](#) for a complete list of terms used in this guide.

Chapter 2 Installation and Configuration

This chapter provides Nitro installation and configuration instructions. This chapter is designed for system administrators.

In this chapter:

- [Understand and Plan Your System Environment on page 11](#)
- [System Requirements on page 12](#)
- [Manual Installation and Upgrade on page 13](#)
- [RPM Installation and Upgrade on page 37](#)

Understand and Plan Your System Environment

This topic provides information that is important to understand before you begin your Nitro installation.

In this topic:

- [Nitro Licenses and Licensing on page 11](#)
- [Nitro Product Packaging on page 11](#)
- [Default Installation Directory and Subdirectories on page 12](#)

Nitro Licenses and Licensing

Nitro is a licensed software product that requires licenses conveyed via a license file and managed by the RLM license server in order to execute. Adaptive Computing must generate a license file for your Nitro product and you must install the license file onto the RLM server where the RLM license daemon can read it. Without the proper installation of the license file, Nitro will not execute.

Adaptive Computing licenses Nitro in two mutually-exclusive ways, by node and by core.

- Sites running parallel jobs that request multiple whole host systems (HPC compute nodes or servers) will want to license Nitro by node since their schedulers often allocate job resources by whole hosts for speed.
- Sites running mainly serial (single-core) jobs that request one or a few cores will want to license Nitro by core since their schedulers tend to fragment host system resources such that it may be very difficult for a Nitro job to obtain whole host systems.

The Nitro license file indicates the license model, by-node or by-core, the Nitro product will operate under.

Nitro Product Packaging

With Nitro 2.0, you will need access to an RLM Server for licensing.

A Nitro Web Services interface is also introduced with 2.0. Moab Viewpoint requires Nitro Web Services to track Nitro job status.

Depending on your system configuration, you may need some or all of the components. The Nitro Download page includes bundles that let you download all the components.

Nitro Web Services is currently not available for SUSE 11-based systems; it is not in the Tarball or RPM bundles for that OS.

The RLM Server is included in the bundles as a courtesy. If your company already has access to an RLM (for example, you installed one as part of your Remote Visualization package), you will not need to install another RLM Server.

Default Installation Directory and Subdirectories

Nitro will be installed to the `/opt/nitro` directory by default. This directory includes the following subdirectories.

```
# cd /opt/nitro
# ls -l
drwxr-xr-x. 2 root root 4096 Jun  9 16:20 bin
drwxr-xr-x. 6 root root 4096 Jun  9 16:20 scripts
drwxr-xr-x. 1 root root 4096 Jun  9 16:20 etc
```

- The `bin` directory contains the binary executable program files and executable scripts that make up the Nitro product for your site.
- The `scripts` directory contains reference launch `_nitro.sh` scripts for different job schedulers and resource managers, which include Cray ALPS with Torque or Slurm, Platform LSF, Slurm, and Torque (Moab and Maui schedulers).
- The `etc` directory contains the `nitro.cfg` file. Nitro has some default settings that can be changed by setting values in the `/opt/nitro/etc/nitro.cfg` file. See [Nitro Configuration File on page 64](#) for more information.

System Requirements

This topic identifies the system requirements for your Nitro installation.

In this topic:

- [Hardware Requirements on page 12](#)
- [Supported Operating Systems on page 13](#)
- [Reprise License Manager Server Requirements on page 13](#)
- [Software Requirements on page 13](#)

Hardware Requirements

- Nitro requires one or more multi-core processors per host. Generally the more processors (sockets) and/or OS cores a host has, the more tasks Nitro can execute simultaneously on

each host; although this will be application-dependent.

- It is recommended that hosts should have sufficient memory to execute as many applications as possible so that Nitro can run them at a rate of one application instance per OS core (especially if they are not multi-threaded). This eliminates the need for users to have to request memory in their Nitro task definitions.

i See [Task File on page 93](#) for more information on specifying memory requirements.

Supported Operating Systems

Nitro supports these operating systems:

- CentOS 6.x, 7.x
- Red Hat 6.x, 7.x
- Scientific Linux 6.x, 7.x
- SUSE Linux Enterprise Server 11, 12

i SUSE Linux Enterprise Server (SLES) 11 is not available as an RPM installation method.

Reprise License Manager Server Requirements

As of version 2.0, Nitro is a licensed software product that requires the Reprise License Manager (RLM) software to check out and check in Nitro licenses. The RLM web server/license daemon software must execute on a central server accessible by all host systems on which Nitro will execute.

The RLM software itself is extremely light-weight and does not require its own server. Meaning that you can install the RLM server on the same host as your job scheduler or resource manager server.

i If your company does not already utilize an RLM, you will need to install one. See the RLM Installation documentation available from the [Nitro download site](http://www.adaptivecomputing.com/support/download-center/nitro/) (<http://www.adaptivecomputing.com/support/download-center/nitro/>).

Software Requirements

Nitro is built with all needed libraries statically linked. This provides for a quick and simple installation and helps avoid troublesome library mismatches. No additional packages need to be installed on the compute nodes.

However, users running nitrosub and the nitrostat utility require Python 2.6.6 or later on the system from which they are running it.

Manual Installation and Upgrade

This section provides installation, configuration, and upgrading information using the Manual Installation method.

In this section:

- [Preparing for Manual Installation or Upgrade on page 14](#)
- Install
 - [Installing RLM Server on page 15](#)
 - [Installing Nitro on page 17](#)
 - [Installing Nitro Web Services on page 21](#)
- Upgrade
 - [Upgrading RLM Server on page 29](#)
 - [Upgrading Nitro on page 30](#)
 - [Upgrading Nitro Web Services on page 32](#)

Preparing for Manual Installation or Upgrade

This topic contains instructions on how to download and unpack the Nitro Tarball Bundle for all the hosts in your configuration.

 Whether you are installing tarballs on one host or on several hosts, each host (physical machine) on which a server is installed (RLM Server, Nitro, Nitro Web Services) *must* have the Nitro Tarball Bundle.

 Nitro Web Services is currently not available for SUSE 11-based systems; it is not in the Tarball bundle for that OS.

Set Up Proxies

If your site uses a proxy to connect to the Internet, do the following:

```
export http_proxy=http://<proxy_server_id>:<port>
export https_proxy=http://<proxy_server_id>:<port>
```

Download and Unpack the Nitro Tarball Bundle

The Nitro Tarball Bundle contains all the tarballs available for Nitro. However, not every tarball may be installed on the same host.

On each host (physical machine), do the following:

1. Using a web browser, navigate to the [Adaptive Computing Nitro Download](http://www.adaptivecomputing.com/support/download-center/nitro/) website (<http://www.adaptivecomputing.com/support/download-center/nitro/>).
2. Download the Nitro Tarball Bundle (nitro-tarball-bundle-<version>-<OS>.tar.gz).

 The variable marked <version> indicates the build's version, revision, and changeset information. The variable marked <OS> indicates the OS for which the build was designed.

3. Unpack the Nitro Tarball Bundle.

```
[root]# tar xzvf nitro-tarball-bundle-<version>-<OS>.tar.gz
```

Installing

Installing RLM Server

Access to a Reprise License Manager (RLM) server is required when using Nitro.

 The RLM Server can run multiple licenses. If your company already uses an RLM Server, you do not need to install a new one for Nitro. Skip this topic and follow the instructions in [Installing Nitro on page 17](#).

This topic contains instructions on how to install an RLM Server.

In this topic:

- [Open Necessary Ports on page 15](#)
- [Install the RLM Server on page 16](#)
- [Change the Default Passwords on page 17](#)

Open Necessary Ports

 These instructions assume you are using the default ports. If your configuration will use other ports, then substitute your port numbers when opening the ports.

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

Location	Ports	Functions	When Needed
RLM Server Host	5053	RLM Server Port	Always
RLM Server Host	5054	RLM Web Interface Port	Always

Location	Ports	Functions	When Needed
RLM Server Host	5135	ISV adaptiveco Port (for the Adaptive license-enabled products)	Always

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

Install the RLM Server

i If your configuration uses firewalls, you *must also* open the necessary ports before installing Nitro. See [Open Necessary Ports on page 15](#).

On the host where the RLM Server will reside, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. Identify the RLM tarball (`ac-rlm-<version>.tar.gz`).
3. Create a non-root user and group (rlm is used in the example).

```
[root]# groupadd -r rlm
[root]# useradd -r -g rlm -d /opt/rlm -c "A non-root user under which to run
Reprise License Manager" rlm
```

4. Create a directory and install the tarball files in that location (we are using `/opt/rlm` as the install location in the example).

```
[root]# mkdir -p -m 0744 /opt/rlm
[root]# cd /opt/rlm
[root]# tar -xzf /tmp/ac-rlm-<version>.tar.gz --strip-components=1
[root]# chown -R rlm:rlm /opt/rlm
```

i The `--strip-components=1` removes the `"ac-rlm-<version>/"` from the relative path so that they are extracted into the current directory.

5. Install the startup scripts.

i If you are using a user:group other than `rlm:rlm` or a location other than `/opt/rlm`, then edit the following files to reflect those changes after copying them.

- Red Hat 6-based or SUSE 11-based systems

```
[root]# cp init.d/rlm /etc/init.d
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# cp systemd/rlm.service /etc/systemd/system
```

6. Start the services and configure the RLM Server to start automatically at system reboot.

- Red Hat 6-based or SUSE 11-based systems

```
[root]# chkconfig --add rlm
[root]# chkconfig rlm on
[root]# service rlm start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl start rlm.service
[root]# systemctl enable rlm.service
```

Change the Default Passwords

The RLM Web interface includes two usernames (admin and user) by default. These usernames have the default password "changeme!".

If you do not change this password, RLM, and Remote Visualization, will not be secure. For tips on choosing a good password, see <https://www.us-cert.gov/ncas/tips/ST04-002>.

Do the following for *both* the user and the admin usernames:

1. Using a web browser, navigate to your RLM instance (http://<RLM_host>:5054; where <RLM_host> is the IP address or name of the RLM Server Host).
2. Log in.
3. Select **Change Password** and change the password according to your password security process.

Installing Nitro

This topic contains instructions on how to install Nitro.

Nitro

- needs to be available to all of the nodes that will be used as part of the Nitro job.
- can be installed either to each node individually *or* to a shared file system that each node can access.

Some Nitro functionality, such as using the nitrosub command, is not available unless you are using a shared file system.

- can be installed to integrate with a scheduler, such as Moab Workload Manager, or without (Nitro standalone). The instructions are the same.

In this topic:

- [Obtain a Nitro License on page 18](#)
- [Open Necessary Ports on page 19](#)
- [Install Nitro on page 20](#)
- [Verify Network Communication on page 21](#)

Obtain a Nitro License

The Nitro license file is installed on an RLM Server.

These instructions assume you already have access to an RLM Server. See [Installing RLM Server on page 15](#) for instructions on how to set up a new RLM Server.

Do the following:

1. On the RLM server, obtain the hostid and hostname.

- hostid

```
[root]# /opt/rlm/rlmhostid
```

You should see output similar to the following.

```
rlmhostid v12.1
Copyright (C) 2006-2016, Reprise Software, Inc. All rights reserved.

Hostid of this machine: 00259096f004
```

- hostname

```
[root]# /opt/rlm/rlmhostid host
```

You should see output similar to the following.

```
rlmhostid v12.1
Copyright (C) 2006-2016, Reprise Software, Inc. All rights reserved.

Hostid of this machine: host=<your-host-name>
```

2. Email licenses@adaptivecomputing.com for a license and include the hostid and hostname you just obtained.
3. Adaptive Computing will generate the license and send you the Nitro license file (typically, `nitro.lic`) file in a return email.
4. On the RLM server, do the following:
 - a. Download and install the license file.

```
[root]# cd /opt/rlm
[root]# chown rlm:rlm nitro.lic
```

- b. If the RLM Server in your configuration uses a firewall, edit the license file to reference the ISV `adaptiveco` port for the Adaptive license-enabled products. This is the same port

number you opened during the RLM Server installation. See the instructions to open necessary ports in the [Installing RLM Server on page 15](#) (manual installation method) or [Installing RLM Server on page 40](#) (RPM installation method) for more information.

```
[root]# vi /opt/rlm/nitro.lic
```

```
ISV adaptiveco port=5135
```

The license file already references the RLM Server port (5053 by default).

i If the RLM Server in your configuration uses different ports, you will need to modify the license file to reflect the actual ports. See the instructions to open necessary ports in the [Installing RLM Server on page 15](#) (manual installation method) or [Installing RLM Server on page 40](#) (RPM installation method) for more information.

- c. If you did *not* install an RLM Server using the file available from Adaptive Computing (for example, because your system configuration already uses one), do the following:
 - i. Download the 'adaptiveco.set' file from the [Adaptive Computing Nitro Download Center](https://www.adaptivecomputing.com/support/download-center/nitro/) (<https://www.adaptivecomputing.com/support/download-center/nitro/>).
 - ii. Copy the 'adaptiveco.set' file into the same directory where the Nitro license resides (/opt/rlm).
- d. Perform a reread to update the RLM Server with your license.

```
[root]# /opt/rlm/rlmreread
```

Open Necessary Ports

Nitro uses several ports for communication between the workers and the coordinator.

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

i The listed ports is for configurations that have only one coordinator. If multiple coordinators are run on a single compute host, then sets of ports (range of 4) must be opened for the number of expected simultaneous coordinators.

Location	Ports	Functions	When Needed
Compute Hosts (Nitro Coordinator)	47000	Coordinator/Worker communication	Always
Compute Hosts (Nitro Coordinator)	47001	Coordinator PUB/SUB channel - publishes status information	Always

Location	Ports	Functions	When Needed
Compute Hosts (Nitro Coordinator)	47002	Reserved for future functionality	
Compute Hosts (Nitro Coordinator)	47003	API communication channel	Always

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

Install Nitro

i You *must* complete the tasks to obtain a Nitro license before installing Nitro. See [Obtain a Nitro License on page 18](#).
If your configuration uses firewalls, you *must also* open the necessary ports before installing Nitro. See [Open Necessary Ports on page 19](#).

On the host where Nitro will reside, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. Change the directory to the root of the unpacked Nitro tarball bundle.

```
[root]# cd nitro-tarball-bundle-<version>-<OS>
```

3. Identify the Nitro product tarball (nitro-<version>-<OS>.tar.gz).
4. Run each of the following commands in order.

```
[root]# mkdir /opt/nitro
[root]# tar xzvpf nitro-<version>-<OS>.tar.gz -C /opt/nitro --strip-components=1
```

5. Copy the license file you generated earlier in this topic to each compute node (coordinator). On each compute node, *or* on the shared file system, do the following:

```
[root]# cp <licenseFileName>.lic /opt/nitro/bin/
```

6. Copy the provided scripts and the nitrosub command from the /opt/nitro/scripts directory.

i This is a "copy" file operation and not a "move" operation. This allows you to customize your version and always have the factory version available for consultation and/or comparison.

- a. Copy the `launch_nitro.sh` and `launch_worker.sh` scripts for your resource manager to the `bin` directory. Each resource manager has a subdirectory with the scripts directory that contains the scripts. This example uses Torque as the resource manager.

```
[root]# cp /opt/nitro/scripts/torque/launch_nitro.sh /opt/nitro/bin/
[root]# cp /opt/nitro/scripts/torque/launch_worker.sh /opt/nitro/bin/
```

- b. Copy the `nitrosub` command to the `bin` directory.

```
[root]# cp /opt/nitro/scripts/nitrosub /opt/nitro/bin/
```

- c. Copy the `nitro_job.sh` and the `worker_job.sh` scripts to the `etc` directory.

```
[root]# cp /opt/nitro/scripts/nitro_job.sh /opt/nitro/etc/
[root]# cp /opt/nitro/scripts/worker_job.sh /opt/nitro/etc/
```

7. Now that you have copied the scripts and the `nitrosub` command, edit the copies for your site's administrative policies.
 - `bin/nitrosub` command (applicable only if using a shared file system). At a *minimum*, do the following:
 - a. Uncomment the "`_resource_manager`" line for your resource manager.
 - b. Uncomment the "`resource_type`" line for your licensing model's allocation (nodes or cores).
 - c. If your system will be using dynamic jobs, set the "`_dynamic_size`" value to the number of resources to allocate to a dynamic job.

See [nitrosub Command on page 81](#) for more information.

- `bin/launch_nitro.sh` and `bin/launch_worker.sh` scripts. See [Launch Scripts on page 91](#) for more information.
8. If your system configuration allows multiple coordinators on the same node, additional configuration may be needed. See [Running Multiple Coordinators on the Same Node on page 62](#) for more information.
 9. If you are *not* using a shared file system, copy the Nitro installation directory to *all* hosts.

```
[root]# scp -r /opt/nitro root@host002:/opt
```

i If you are *not* using a shared file system, you may not be able to use the `nitrosub` command.

Verify Network Communication

Verify that the nodes that will be running Nitro are able to communicate with the Nitro ports *and* that the nodes are able to communicate with one another.

Installing Nitro Web Services

This topic contains instructions on how to install Nitro Web Services.

Nitro Web Services is not available for SUSE 11-based systems.

Do the following in the order presented:

1. [Open Necessary Ports on page 22](#)
2. [Install MongoDB on page 22](#)
3. [Install and Configure Nitro Web Services on page 24](#)
4. [Configure Viewpoint for Nitro Web Services on page 26](#)
5. [Grant Users Nitro Permissions in Viewpoint on page 28](#)
6. [Publish Nitro Events to Nitro Web Services on page 28](#)

Open Necessary Ports

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

Location	Ports	Functions	When Needed
Nitro Web Services Host	9443	Tornado Web Port	Always
Nitro Web Services Host	47100	ZMQ Port	Always
Nitro Web Services Database Host	27017	Nitro Web Services MongoDB Server Port	If you will be installing the Nitro Web Services Database on a different host from Nitro Web Services

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

In this section:

Install MongoDB

On the Nitro Web Services MongoDB Database Host, do the following:

1. Add the MongoDB Repository.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# cat > /etc/yum.repos.d/mongodb-org-3.2.repo <<'EOF'
[mongodb-org-3.2]
name=MongoDB Repository
baseurl=https://repo.mongodb.org/yum/redhat/$releasever/mongodb-org/3.2/x86_64/
gpgcheck=1
enabled=1
gpgkey=https://www.mongodb.org/static/pgp/server-3.2.asc
EOF
```

- SUSE 12-based systems

```
[root]# zypper addrepo --refresh --no-gpgcheck
https://repo.mongodb.org/zypper/suse/12/mongodb-org/3.2/x86_64 mongodb
```

2. Install MongoDB.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum install -y mongodb-org
```

- SUSE 12-based systems

```
[root]# zypper -n install mongodb-org
```

3. Enable and start MongoDB.

- Red Hat 6-based systems

```
[root]# chkconfig mongod on
[root]# service mongod start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

4. Add the required MongoDB users.

i The passwords used below (`secret1` and `secret5`) are examples. Choose your own passwords for these users.

```
[root]# mongo
> use admin
> db.createUser({"user": "admin_user", "pwd": "secret1", "roles": ["root"]})

> use nitro-db
> db.createUser({"user": "nitro_user", "pwd": "secret5", "roles": ["dbOwner"]})

> exit
```

i Because the `admin_user` has read and write rights to the `admin` database, it also has read and write rights to all other databases. See [Control Access to MongoDB Instances with Authentication](http://docs.mongodb.org/manual/tutorial/control-access-to-mongodb-with-authentication) (at <http://docs.mongodb.org/manual/tutorial/control-access-to-mongodb-with-authentication>) for more information.

5. Set MongoDB Configuration Options.

- The configuration file for MongoDB is `/etc/mongod.conf`. See <https://docs.mongodb.com/manual/reference/configuration-options> for information.
- Adaptive Computing recommends that you set `security.authorization` to `enabled`. See <https://docs.mongodb.com/manual/reference/configuration-options/#security-options> for more information.

i By default, `/etc/mongod.conf` sets `net.bindIp` to `127.0.0.1`. You will need to change this setting if the MongoDB server needs to be accessible from other hosts or from other interfaces besides loopback. See <https://docs.mongodb.com/manual/reference/configuration-options/#net-options> for more information.

```
# Sample /etc/mongod.conf file
net:
  port: 27017
  # bindIp: 127.0.0.1
processManagement:
  fork: true
  pidFilePath: /var/run/mongodb/mongod.pid
security:
  authorization: enabled
storage:
  dbPath: /var/lib/mongo
  journal:
    enabled: true
systemLog:
  destination: file
  logAppend: true
  path: /var/log/mongodb/mongod.log
```

6. Restart MongoDB.

- Red Hat 6-based systems

```
[root]# service mongod restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl restart mongod.service
```

Install and Configure Nitro Web Services

i You *must* complete the tasks earlier in this topic before installing Nitro Web Services.

On the host where Nitro Web Services will reside, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. Identify and unpack the Nitro Web Services tarball (nitro-web-services-*<version>*-*<OS>*.tar.gz).

```
[root]# tar -xvzpf nitro-web-services-<version>-<OS>.tar.gz
```

3. Install Nitro Web Services.

```
[root]# cd /opt/nitro-web-services-<version>
[root]# ./install <directory>
# <directory> is optional; defaults to /opt/nitro-web-services when not given
```

4. Understand and edit the the Nitro Web Services web application configuration file (/opt/nitro-web-services/etc/nitro.cfg). This includes clarifying what the configuration file is for and what to expect the first time the NWS service is started vs. each subsequent start.

 The nitro_user with dbOwner permissions was set up earlier in the procedure (see [Install MongoDB on page 22](#)).

When you first start nitro-web-services, the nitro-db Mongo database (including its collections and indexes) is created. The nitro-db 'user' collection is also populated with the default Nitro Web Services API users/passwords. Several of the options defined in the configuration files influence this process.

MongoDB user, table, and index creation is performed at initial startup. Many of the options defined in the Nitro Web Service configuration files influence Mongo user/password and index creation.

 Usernames and passwords are created *only* if they do not yet exist. Changing a password in the configuration file after initial startup will not update the password.

The /opt/nitro-web-services/etc/nitro.cfg configuration file includes default password values. If you want to use passwords other than the default value, change the lines in the file as shown below.

- Before initial startup, set the db_password to be the nitro_user password. It is also recommended that you change all other default passwords before starting Nitro Web Services. If you do not change the passwords at this point, it will be more difficult to change them later.

```
db_password = <password goes here>
ws_admin_password = <ws_admin_password goes here>
ws_readonly_password = <ws_readonly_password goes here>
ws_writeonly_password = <ws_writeonly_password goes here>
```

- By default, NWS uses an auto-generated self-signed SSL certificate to encrypt the link between the web server and the browser clients. The auto-generated self-signed SSL certificate is created at service start up; not during the installation process.

However, you can use your own certfile, keyfile, and ca_certs files if you wish.

i If you choose to use your own `ssl_certfile` and `ssl_keyfile`, `ssl_create_self_signed_cert=true` is ignored.

- By default, NWS does *not* encrypt network traffic with MongoDB. You should set the `db_ssl_*` properties if you choose to enable TLS/SSL when installing MongoDB earlier in this topic.
5. Understand and edit the Nitro ZMQ Job Status Adapter configuration file (`/opt/nitro-web-services/etc/zmq_job_status_adapter.cfg`). This includes clarifying what the configuration file is for and what to expect the first time the NWS service is started vs. each subsequent start.
 - The Nitro ZMQ Job Status Adapter listens to job status updates on the ZMQ bus and publishes them to MongoDB using the Nitro Web Services REST API.
 - The username and password must be set to a Nitro Web Services API user with write permissions. At minimum, set the password for `nitro-writeonly-user` to the password defined in `/opt/nitro-web-services/etc/nitro.cfg` and make sure the SSL options are set correctly based on SSL settings in `/opt/nitro-web-services/etc/nitro.cfg`.

```
password = <ws_writeonly_password goes here>
```

6. If you did not need to install the Nitro Web Services MongoDB database earlier in this topic, verify that the `mongodb_hostlist` in `/opt/nitro-web-services/etc/nitro.cfg` is set correctly (`localhost:27017` is the default).
7. Start the services and configure Nitro Web Services to start automatically at system boot.
 - Red Hat 6-based systems

```
[root]# chkconfig --add nitro-web-services
[root]# chkconfig --add nitro-zmq-job-status-adapter
[root]# service nitro-web-services start
[root]# service nitro-zmq-job-status-adapter start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl enable nitro-web-services.service
[root]# systemctl enable nitro-zmq-job-status-adapter.service
[root]# systemctl start nitro-web-services.service
[root]# systemctl start nitro-zmq-job-status-adapter.service
```

Configure Viewpoint for Nitro Web Services

Do the following:

1. Using a web browser, navigate to your Viewpoint instance (`http://<server>:8081`) and then log in as the MWS administrative user (`moab-admin`, by default).
2. Click **Configuration** from the menu and then click **Nitro Services** from the left pane. The following is an example of the Nitro Services Configuration page.

3. Enter the configuration information. The following table describes the required information.

Field	Description
Nitro WS URL	Hostname (or IP address) and port number for the host on which you installed Nitro Web Services. For example, <code>https://<hostname>:9443</code>
Username	Name of the user. This typically <code>nitro-readonly-user</code> .
Password	The user's password.
Trust Self Signed	Indicates whether Nitro Web Services was set up using self-signed certificates.

4. Click **TEST** to confirm the settings are correct. This confirms whether Nitro Web Services is up and receiving connections.
5. Click **SAVE**.
6. (Recommended) Use `curl` to test Nitro Web Services connectivity.

```
[root]# curl --insecure --data '{"username": "nitro-admin", "password":
"ChangeMe2!"}' \
https://<hostname>:9443/auth
```

You should see output similar to the following.

```
{
  "status": 200,
  "data": {
    "nitro-key": "3e0fb95e9a0e44ae91daef4deb500dcc67a3714880e851d781512a49",
    "user": {
      "username": "nitro-admin",
      "last_updated": "2016-02-26 23:34:55.604000",
      "name": "Nitro Admin",
      "created": "2016-02-26 23:34:55.604000",
      "auth": {
        "job": [
          "read",
          "write",
          "delete"
        ],
        "user": [
          "read",
          "write",
          "delete"
        ]
      }
    }
  }
}
```

Grant Users Nitro Permissions in Viewpoint

Viewpoint comes packed with base (default) roles for Nitro jobs. Any user who will be working with Nitro Web Services, must have the appropriate role added to the Viewpoint user principal.

These are the Viewpoint roles for Nitro:

- NitroAdmin – Administrative user, with permission to create Nitro application templates and manage other user's Nitro jobs.
- NitroUser – Basic user, with permission to create and manage their own Nitro jobs.

See *Creating or Editing Principals* in the *Moab Viewpoint Reference Guide* for instructions on setting up principals.

Publish Nitro Events to Nitro Web Services

You need to configure the Nitro coordinators to send job status updates to the Nitro Web Services's ZMQ Job Status Adapter. The ZMQ Job Status Adapter is responsible for reading job status updates off of the ZMQ bus and persisting them to Mongo. Nitro Web Services can then be used to access Nitro job status.

Each Nitro job has a Nitro Coordinator. Nitro Coordinators can be configured to publish job status updates to ZMQ by setting the "nws-connector-address" configuration option in Nitro's `nitro.cfg` file. Each compute node allocated/scheduled to a Nitro Job can play the role of a Nitro coordinator. Therefore, you must update the "nws-connector-address" in each compute node's `nitro.cfg` file.

i Configuring `nws-connector-address` is simplified if each node is sharing Nitro's configuration over a shared filesystem. If you are *not* using a shared filesystem, update the Nitro configuration on *each* compute node.

Do the following:

1. If you have not already done so, on the Nitro Web Services Host, locate the `msg_port` number in the `/opt/nitro-web-services/etc/zmq_job_status_adapter.cfg` file. This is the port number you need to specify for the `nws-connector-address`.
2. On *each* Nitro compute node (Torque MOM Host), specify the `nws-connector-address` in the `/opt/nitro/etc/nitro.cfg` file.

```
...
# Viewpoint connection allows Nitro to communicate job status information
# to viewpoint. This option indicates name and port of the remote server
# in the form: <host>:<port>
nws-connector-address <nitro-web-services-hostname>:47100
...
```

Upgrading

Upgrading RLM Server

This topic contains instructions on how to upgrade the RLM Server.

The RLM v12.1 (build:2) release resolved memory leak and security issues. The RLM package available with Moab HPC Suite 9.0.2, contains the v12.1 (build:2) release. Adaptive Computing *strongly* recommends that your RLM Server is v12.1 (build:2).

Upgrade the RLM Server

These instructions assume you used `/opt/rlm` as the install location.

On the RLM Server Host, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. Identify the RLM tarball (`ac-rlm-<version>.tar.gz`).
3. Stop the RLM service.

- Red Hat 6-based or SUSE 11-based systems

```
[root]# service rlm stop
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl stop rlm.service
```

4. Archive the existing RLM installation, including the license file(s).

```
[root]# mv /opt/rlm/ /opt/rlm-<archive_version>/
```

5. Install the new tarball files.

```
[root]# mkdir -p -m 0744 /opt/rlm
[root]# cd /opt/rlm
[root]# tar -xzf /<unpack-directory>/ac-rlm-<version>.tar.gz --strip-components=1
[root]# chown -R rlm:rlm /opt/rlm
```

i The `--strip-components=1` removes the "ac-rlm-<version>/" from the relative path so that they are extracted into the current directory.

6. Install the startup scripts.

i If you are using a user:group other than rlm:rlm or a location other than /opt/rlm, then edit the following files to reflect those changes after copying them.

- Red Hat 6-based or SUSE 11-based systems

```
[root]# cp init.d/rlm /etc/init.d
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# cp systemd/rlm.service /etc/systemd/system
```

7. Restore the license file(s).

```
[root]# cp /opt/rlm-<archive_version>/*.lic /opt/rlm/
```

8. Restart the RLM service.

- Red Hat 6-based or SUSE 11-based systems

```
[root]# service rlm restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl daemon-reload
[root]# systemctl restart rlm.service
```

Upgrading Nitro

This topic contains the steps and procedures to follow to upgrade Nitro using the Manual upgrade method.

In this topic:

- [Upgrade from a Version Prior to 2.0 on page 30](#)
- [Upgrade Nitro on page 31](#)
- [Verify Network Communication on page 32](#)

Upgrade from a Version Prior to 2.0

i Beginning with Nitro 2.0, the licensing procedure changed to use an RLM server. If your company already uses an RLM Server, you can skip this procedure.

The following steps are required if you are upgrading a Nitro version prior to 2.0.

1. Install or obtain access to an RLM server. See [Installing RLM Server on page 15](#).

i Beginning with Nitro 2.0, the licensing procedure changed to use an RLM server. If your company already uses an RLM Server, you can skip this procedure.

2. Obtain and install the Nitro license. This requires access to an RLM server. See [Obtain a Nitro License on page 18](#).
3. Copy the license file to each compute node (coordinator). On each compute node, *or* on the shared file system, do the following:

```
[root]# cp <licenseFileName>.lic /opt/nitro/bin/
```

Upgrade Nitro

On the Nitro Host, do the following::

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. Back up your existing, customized launch scripts, job scripts, and the nitrosub command (if applicable).
 - a. In `/opt/nitro/bin/`, back up the following:
 - `launch_nitro.sh`
 - `launch_worker.sh` (version 2.1 or later)
 - `nitrosub` command (version 2.1 or later)
 - b. In `/opt/nitro/etc/`, back up the following:
 - `nitro_job.sh` (version 2.1 or later)
 - `worker_job.sh` (version 2.1 or later)
3. Change the directory to the root of the unpacked Nitro tarball bundle.

```
[root]# cd nitro-tarball-bundle-<version>-<OS>
```

4. Identify the Nitro product tarball (`nitro-<version>-<OS>.tar.gz`) and unpack the tarball into the same directory you created when you first installed Nitro (for example, `/opt/nitro`).

```
[root]# tar xzvpf nitro-<version>-<OS>.tar.gz -C /opt/nitro --strip-components=1
```

5. Copy the provided scripts and the nitrosub command from the /opt/nitro/scripts directory.

i This is a "copy" file operation and not a "move" operation. This allows you to customize your version and always have the factory version available for consultation and/or comparison.

- a. Copy the `launch_nitro.sh` and `launch_worker.sh` scripts for your resource manager to the bin directory. Each resource manager has a subdirectory with the scripts directory that contains the scripts. This example uses Torque as the resource manager.

```
[root]# cp /opt/nitro/scripts/torque/launch_nitro.sh /opt/nitro/bin/
[root]# cp /opt/nitro/scripts/torque/launch_worker.sh /opt/nitro/bin/
```

- b. Copy the nitrosub command to the bin directory.

```
[root]# cp /opt/nitro/scripts/nitrosub /opt/nitro/bin/
```

- c. Copy the `nitro_job.sh` and the `worker_job.sh` scripts to the etc directory.

```
[root]# cp /opt/nitro/scripts/nitro_job.sh /opt/nitro/etc/
[root]# cp /opt/nitro/scripts/worker_job.sh /opt/nitro/etc/
```

6. Merge any customizations from your existing launch scripts, job scripts, and the nitrosub command (if applicable) into the new launch scripts, job scripts, and the nitrosub command that you copied from the scripts directory.
7. If your system configuration allows multiple coordinators on the same node, additional configuration may be needed. See [Running Multiple Coordinators on the Same Node on page 62](#) for more information.
8. If you are not using a shared file system, copy the updated Nitro installation directory to *all* hosts.

```
[root]# scp -r /opt/nitro root@host002:/opt
```

i If you are *not* using a shared file system, you may not be able to use the nitrosub command.

Verify Network Communication

Verify that the nodes that will be running Nitro are able to communicate with the Nitro ports *and* that the nodes are able to communicate with one another.

Upgrading Nitro Web Services

This topic contains instructions on how to upgrade Nitro Web Services.

In this topic:

- [Upgrade to MongoDB 3.2.x on page 33](#), if you are upgrading Nitro Web Services from a version *prior* to 2.1.0
- [Back up the MongoDB Databases on page 33](#), if you are upgrading Nitro Web Services from version 2.1.0 or later
- [Upgrade Nitro Web Services on page 33](#)
- [Grant Users Nitro Permissions in Viewpoint on page 35](#)

Upgrade to MongoDB 3.2.x

Beginning with version 9.1.0, Nitro Web Services requires MongoDB 3.2.x.

On the Nitro Web Services MongoDB host, do the following:

1. Check your MongoDB server version.

```
[root]# rpm -qa | grep mongo
```

2. If the MongoDB server version is older than 3.2.x, then you will need to upgrade the databases. See [Upgrading to MongoDB 3.2.x on page 35](#) for more information.

Back up the MongoDB Databases

i This procedure is only applicable if you did not have to upgrade the MongoDB databases earlier in this topic. See [Upgrade to MongoDB 3.2.x on page 33](#) for more information.

On the Nitro Web Services MongoDB host, do the following:

1. Stop all services that are using the MongoDB databases.
2. Back up the MongoDB databases.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
```

3. Restart the services.

Upgrade Nitro Web Services

On the Nitro Web Services Host, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for Manual Installation or Upgrade on page 14](#).
2. If you are upgrading Nitro Web Services from a version *prior* to 2.1.0, confirm the MongoDB database is upgraded to 3.2.x. See [Upgrading to MongoDB 3.2.x on page 35](#) for more information.
3. If you are upgrading Nitro Web Services from version 2.1.0 or later, do the following on the Nitro Web Services MongoDB host.

- a. Stop all services on the host.
- b. Back up the Nitro Web Service MongoDB database.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
```

- c. Restart the services.

4. Stop the services.

- Red Hat 6-based systems

```
[root]# service nitro-web-services stop
[root]# service nitro-zmq-job-status-adapter stop
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl stop nitro-web-services.service
[root]# systemctl stop nitro-zmq-job-status-adapter.service
```

5. Back up the contents of the `/opt/nitro-web-services/etc` directory (at least the `nitro.cfg` and the `zmq_job_status_adapter.cfg` files).
6. Remove the `/opt/nitro-web-services` directory.

```
[root]# rm -rf /opt/nitro-web-services
```

7. Change the directory to the root of the unpacked Nitro tarball bundle.

```
[root]# cd nitro-tarball-bundle-<version>-<OS>
```

8. Identify and unpack the Nitro Web Services tarball (`nitro-web-services-<version>.<OS>.tar.gz`).

```
[root]# tar xzvpf nitro-web-services-<version>.<OS>.tar.gz
```

9. Install Nitro Web Services.

```
[root]# cd ./nitro-web-services-<version>.<OS>
[root]# ./install <directory>
# <directory> is where you want to install Nitro Web Services (defaults to /opt)
```

10. Merge any customizations from the `nitro.cfg` and the `zmq_job_status_adapter.cfg` files (and any other files) you backed up earlier in this procedure into the new files.

i See the steps in [Install and Configure Nitro Web Services on page 24](#) for more information on the configuration files.

11. Start the services.

- Red Hat 6-based systems

```
[root]# service nitro-web-services start
[root]# service nitro-zmq-job-status-adapter start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl start nitro-web-services.service
[root]# systemctl start nitro-zmq-job-status-adapter.service
```

Grant Users Nitro Permissions in Viewpoint

Verify that the users who work with Nitro Web Services have the appropriate role in their Viewpoint user principal.

These are the Viewpoint roles for Nitro:

- NitroAdmin – Administrative user, with permission to create Nitro application templates and manage other user's Nitro jobs.
- NitroUser – Basic user, with permission to create and manage their own Nitro jobs.

See *Creating or Editing Principals* in the *Moab Viewpoint Reference Guide* for instructions on setting up principals.

Upgrading to MongoDB 3.2.x

Nitro Web Services 2.1.0 and after requires MongoDB 3.2.x.

Do the following:

1. Stop the service that uses MongoDB.

- Red Hat 6-based systems

```
[root]# service nitro-web-services stop
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl stop nitro-web-services.service
```

2. Confirm that nothing is connected to MongoDB.

```
[root]# netstat -antp | egrep '(27017|28017).*ESTABLISHED'
```

3. Dump the database.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
[root]# cp -a dump dump.save
[root]# rm -rf dump/admin/system.users.* # Cannot restore users.
```

4. Install MongoDB 3.2.x.

- Red Hat 6-based systems

```
[root]# service mongod stop
[root]# chkconfig mongod off
[root]# cat > /etc/yum.repos.d/mongodb-org-3.2.repo <<'EOF'
[mongodb-org-3.2]
name=MongoDB Repository
baseurl=https://repo.mongodb.org/yum/redhat/$releasever/mongodb-org/3.2/x86_64/
gpgcheck=1
enabled=1
gpgkey=https://www.mongodb.org/static/pgp/server-3.2.asc
EOF
[root]# rpm -e --nodeps $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
[root]# yum install mongodb-org
[root]# chkconfig mongod on
[root]# service mongod start
```

- Red Hat 7-based systems

```
[root]# systemctl stop mongodb.service
[root]# systemctl disable mongodb.service
[root]# cat > /etc/yum.repos.d/mongodb-org-3.2.repo <<'EOF'
[mongodb-org-3.2]
name=MongoDB Repository
baseurl=https://repo.mongodb.org/yum/redhat/$releasever/mongodb-org/3.2/x86_64/
gpgcheck=1
enabled=1
gpgkey=https://www.mongodb.org/static/pgp/server-3.2.asc
EOF
[root]# rpm -e --nodeps --noscripts $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
/usr/lib/systemd/system/mongodb.service
[root]# yum install mongodb-org
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

- SUSE 12-based systems

```
[root]# systemctl stop mongodb.service
[root]# systemctl disable mongodb.service
[root]# zypper addrepo --refresh --no-gpgcheck
https://repo.mongodb.org/zypper/suse/12/mongodb-org/3.2/x86_64 mongo-server
[root]# rpm -e --nodeps $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
[root]# zypper -n install mongodb-org
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

5. Restore the database.

```
[root]# cd /root
[root]# mongorestore
```

6. Create the users.

```
[root]# mongo
      use admin
      db.createUser({"user": "admin_user", "pwd": "secret1", "roles": ["root"]})

      use nitro-db
      db.createUser({"user": "nitro_user", "pwd": "secret5", "roles":
["dbOwner"]})

      exit
```

7. Set MongoDB Configuration Options.

- The configuration file for MongoDB is `/etc/mongod.conf`. See <https://docs.mongodb.com/manual/reference/configuration-options> for information.
- Adaptive Computing recommends that you set `security.authorization` to `enabled`. See <https://docs.mongodb.com/manual/reference/configuration-options/#security-options> for more information.

i By default, `/etc/mongod.conf` sets `net.bindIp` to `127.0.0.1`. You will need to change this setting if the MongoDB server needs to be accessible from other hosts or from other interfaces besides loopback. See <https://docs.mongodb.com/manual/reference/configuration-options/#net-options> for more information.

```
# Sample /etc/mongod.conf file
net:
  port: 27017
  # bindIp: 127.0.0.1
processManagement:
  fork: true
  pidFilePath: /var/run/mongodb/mongod.pid
security:
  authorization: enabled
storage:
  dbPath: /var/lib/mongo
  journal:
    enabled: true
systemLog:
  destination: file
  logAppend: true
  path: /var/log/mongodb/mongod.log
```

8. Restart MongoDB.

- Red Hat 6-based systems

```
[root]# service mongod restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl restart mongod.service
```

RPM Installation and Upgrade

This section provides installation, configuration, and upgrading information using the RPM Installation method.

 The RPM Installation method is not applicable for SUSE 11-based systems.

In this section:

- [Preparing for RPM Installation or Upgrade on page 38](#)
- Install
 - [Installing RLM Server on page 40](#)
 - [Installing Nitro on page 42](#)
 - [Installing Nitro Web Services on page 46](#)
- Upgrade
 - [Upgrading RLM Server \(RPM\) on page 53](#)
 - [Upgrading Nitro on page 54](#)
 - [Upgrading Nitro Web Services \(RPM\) on page 56](#)

Preparing for RPM Installation or Upgrade

This topic contains instructions on how to download the Nitro RPM Bundle and enable the Adaptive Computing repository for all the hosts in your configuration.

 Whether you are installing or upgrading RPMs on one host or on several hosts, each host (physical machine) on which a server is installed (RLM Server, Nitro, Nitro Web Services) *must* have the Adaptive Computing Package Repository enabled.

 Nitro Web Services is currently not available for SUSE 11-based systems; it is not in the RPM bundle for that OS.

Set Up Proxies

If your site uses a proxy to connect to the Internet, do the following:

```
export http_proxy=http://<proxy_server_id>:<port>
export https_proxy=http://<proxy_server_id>:<port>
```

Enable the Adaptive Computing Package Repository

The Nitro RPM Bundle contains all the RPMs for Nitro. However, not every RPM may be installed on the same host.

On each host (physical machine), do the following:

1. Download the Nitro 2.1.1 RPM Bundle from the [Adaptive Computing](#) website.
2. Untar the Nitro RPM bundle.

```
[root]# tar xzf nitro-rpm-bundle-<version>-<OS>.tar.gz
```

3. Change directories into the untarred directory.

i Consider reviewing the README file for additional details on using the RPM distribution tarball.

4. Install the suite repositories. The `-y` option installs with the default settings for the RPM suite.

i For a description of the options of the repository installer script, run:

```
[root]# ./install-rpm-repos.sh -h
```

```
[root]# ./install-rpm-repos.sh [<repository-directory>] [-y]
```

i If the installation returns the following warning line:

```
Warning: RPMDB altered outside of yum.
```

This is normal and can safely be ignored.

The `[<repository-directory>]` option is the directory where you want to copy the RPMs. If no argument is given, run `"install-rpm-repos.sh -h"` to view usage information and identify the default directory location. If the `[<repository-directory>]` already exists, RPMs will be added to the existing directory. No files are overwritten in `[<repository-directory>]`.

A repository file is also created and points to the `[<repository-directory>]` location. For Red Hat 6-based or Red Hat 7-based systems, the repository file is created in `/etc/yum.repos.d/`. For SUSE 12-based systems, the repository file is created in `/etc/zypp/repos.d/`.

For ease in repository maintenance, the install script fails if Adaptive Computing RPMs are copied to different directories. If a non-default `[<repository-directory>]` is specified, please use the same directory for future updates.

The script installs the `createrepo` package and its dependencies. You must answer "y" to all the questions in order for the RPM install of the suite to work.

Additionally, the script installs:

- The EPEL and 10gen repositories on Red Hat 6-based and Red Hat 7-based systems.
- The openSUSE Apache:Modules, devel:languages:python, devel:languages:perl, and server:database repositories on SUSE 12-based systems.

5. Test the repository.

- Red-Hat 6-based or Red Hat 7-based systems

```
[root]# yum search nitro
```

- SUSE 12-based systems

```
[root]# zypper search nitro
```

If no error is given, the repository is correctly installed. The following is an example of the output after verifying the repository.

```
Loaded plugins: fastestmirror, security
Loading mirror speeds from cached hostfile
*epel: linux.mirrors.es.net
===== N/S Matched: nitro
=====
nitro.x86_64 : Adaptive Nitro for High Throughput Computing
nitro-web-services.x86_64 : Nitro Web Services
```

Installing

Installing RLM Server

Access to a Reprise License Manager (RLM) server is required when using Nitro.

The RLM Server can run multiple licenses. If your company already uses an RLM Server, you do not need to install a new one for Nitro. Skip this topic and follow the instructions in [Installing Nitro on page 42](#).

This topic contains instructions on how to install an RLM Server.

In this topic:

- [Open Necessary Ports on page 40](#)
- [Install the RLM Server on page 41](#)
- [Change the Default Passwords on page 41](#)

Open Necessary Ports

These instructions assume you are using the default ports. If your configuration will use other ports, then substitute your port numbers when opening the ports.

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

Location	Ports	Functions	When Needed
RLM Server Host	5053	RLM Server Port	Always
RLM Server Host	5054	RLM Web Interface Port	Always
RLM Server Host	5135	ISV adaptiveco Port (for the Adaptive license-enabled products)	Always

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

Install the RLM Server

i If your configuration uses firewalls, you *must also* open the necessary ports before installing the RLM Server . See [Open Necessary Ports on page 40](#).

On the host where the RLM Server will reside, do the following:

1. If you are installing RLM Server on its own host *or* on a host that does not have another RPM installation, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).
2. Install the RPM.
 - Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum install ac-rlm
```

- SUSE 12-based systems

```
[root]# zypper install ac-rlm
```

Change the Default Passwords

The RLM Web interface includes two usernames (admin and user) by default. These usernames have the default password "changeme!".

! If you do not change this password, RLM will not be secure. For tips on choosing a good password, see <https://www.us-cert.gov/ncas/tips/ST04-002>.

Do the following for *both* the user and the admin usernames:

1. Using a web browser, navigate to your RLM instance (http://<RLM_host>:5054; where <RLM_host> is the IP address or name of the RLM Server Host).
2. Log in.
3. Select **Change Password** and change the password according to your password security process.

Installing Nitro

This topic contains instructions on how to install Nitro.

Nitro

- needs to be available to all of the nodes that will be used as part of the Nitro job.
- can be installed either to each node individually *or* to a shared file system that each node can access.

Some Nitro functionality, such as using the `nitrosub` command, is not available unless you are using a shared file system.

- can be installed to integrate with a scheduler, such as Moab Workload Manager, or without (Nitro standalone). The instructions are the same.

In this topic:

- [Obtain a Nitro License on page 42](#)
- [Open Necessary Ports on page 44](#)
- [Install Nitro on page 44](#)
- [Verify Network Communication on page 46](#)

Obtain a Nitro License

The Nitro license file is installed on an RLM Server.

These instructions assume you already have access to an RLM Server. See [Installing RLM Server on page 40](#) for instructions on how to set up a new RLM Server.

Do the following:

1. On the RLM server, obtain the `hostid` and `hostname`.
 - `hostid`

```
[root]# /opt/rlm/rlmhostid
```

You should see output similar to the following.

```
rlmhostid v12.1
Copyright (C) 2006-2016, Reprise Software, Inc. All rights reserved.

Hostid of this machine: 00259096f004
```

- hostname

```
[root]# /opt/rlm/rlmhostid host
```

You should see output similar to the following.

```
rlmhostid v12.1
Copyright (C) 2006-2016, Reprise Software, Inc. All rights reserved.

Hostid of this machine: host=<your-host-name>
```

2. Email licenses@adaptivecomputing.com for a license and include the hostid and hostname you just obtained.
3. Adaptive Computing will generate the license and send you the Nitro license file (typically, `nitro.lic`) file in a return email.
4. On the RLM server, do the following:
 - a. Download and install the license file.

```
[root]# cd /opt/rlm
[root]# chown rlm:rlm nitro.lic
```

- b. If the RLM Server in your configuration uses a firewall, edit the license file to reference the ISV adaptiveco port for the Adaptive license-enabled products. This is the same port number you opened during the RLM Server installation. See the instructions to open necessary ports in the [Installing RLM Server on page 15](#) (manual installation method) or [Installing RLM Server on page 40](#) (RPM installation method) for more information.

```
[root]# vi /opt/rlm/nitro.lic

ISV adaptiveco port=5135
```

The license file already references the RLM Server port (5053 by default).

i If the RLM Server in your configuration uses different ports, you will need to modify the license file to reflect the actual ports. See the instructions to open necessary ports in the [Installing RLM Server on page 15](#) (manual installation method) or [Installing RLM Server on page 40](#) (RPM installation method) for more information.

- c. If you did *not* install an RLM Server using the file available from Adaptive Computing (for example, because your system configuration already uses one), do the following:
 - i. Download the 'adaptiveco.set' file from the [Adaptive Computing Nitro Download Center](https://www.adaptivecomputing.com/support/download-center/nitro/) (<https://www.adaptivecomputing.com/support/download-center/nitro/>).

- ii. Copy the 'adaptiveco.set' file into the same directory where the Nitro license resides (/opt/rlm).
- d. Perform a reread to update the RLM Server with your license.

```
[root]# /opt/rlm/rlmreread
```

Open Necessary Ports

Nitro uses several ports for communication between the workers and the coordinator.

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

i The listed ports is for configurations that have only one coordinator. If multiple coordinators are run on a single compute host, then sets of ports (range of 4) must be opened for the number of expected simultaneous coordinators.

Location	Ports	Functions	When Needed
Compute Hosts (Nitro Coordinator)	47000	Coordinator/Worker communication	Always
Compute Hosts (Nitro Coordinator)	47001	Coordinator PUB/SUB channel - publishes status information	Always
Compute Hosts (Nitro Coordinator)	47002	Reserved for future functionality	
Compute Hosts (Nitro Coordinator)	47003	API communication channel	Always

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

Install Nitro

i You *must* complete the tasks to obtain a Nitro license before installing Nitro. See [Obtain a Nitro License on page 42](#).
If your configuration uses firewalls, you *must also* open the necessary ports before installing Nitro. See [Open Necessary Ports on page 44](#).

On the host where Nitro will reside, do the following:

1. If you are installing Nitro on its own host *or* on a host that does not have another RPM installation, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).

2. Install the RPM.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum install nitro
```

- SUSE 12-based systems

```
[root]# zypper install nitro
```

3. Copy the license file you generated earlier in this topic to each compute node (coordinator). On each compute node, *or* on the shared file system, do the following:

```
[root]# cp <licenseFileName>.lic /opt/nitro/bin/
```

4. Copy the provided scripts and the nitrosub command from the /opt/nitro/scripts directory.

i This is a "copy" file operation and not a "move" operation. This allows you to customize your version and always have the factory version available for consultation and/or comparison.

- a. Copy the `launch_nitro.sh` and `launch_worker.sh` scripts for your resource manager to the bin directory. Each resource manager has a subdirectory with the scripts directory that contains the scripts. This example uses Torque as the resource manager.

```
[root]# cp /opt/nitro/scripts/torque/launch_nitro.sh /opt/nitro/bin/
[root]# cp /opt/nitro/scripts/torque/launch_worker.sh /opt/nitro/bin/
```

- b. Copy the nitrosub command to the bin directory.

```
[root]# cp /opt/nitro/scripts/nitrosub /opt/nitro/bin/
```

- c. Copy the `nitro_job.sh` and the `worker_job.sh` scripts to the etc directory.

```
[root]# cp /opt/nitro/scripts/nitro_job.sh /opt/nitro/etc/
[root]# cp /opt/nitro/scripts/worker_job.sh /opt/nitro/etc/
```

5. Now that you have copied the scripts and the nitrosub command, edit the copies for your site's administrative policies.
 - `bin/nitrosub` command (applicable only if using a shared file system). At a *minimum*, do the following:
 - a. Uncomment the "`_resource_manager`" line for your resource manager.
 - b. Uncomment the "`resource_type`" line for your licensing model's allocation (nodes or cores).

- c. If your system will be using dynamic jobs, set the "`_dynamic_size`" value to the number of resources to allocate to a dynamic job.

See [nitrosub Command on page 81](#) for more information.

- `bin/launch_nitro.sh` and `bin/launch_worker.sh` scripts. See [Launch Scripts on page 91](#) for more information.
6. If your system configuration allows multiple coordinators on the same node, additional configuration may be needed. See [Running Multiple Coordinators on the Same Node on page 62](#) for more information.
 7. If you are *not* using a shared file system, copy the Nitro installation directory to *all* hosts.

```
[root]# scp -r /opt/nitro root@host002:/opt
```

i If you are *not* using a shared file system, you may not be able to use the `nitrosub` command.

Verify Network Communication

Verify that the nodes that will be running Nitro are able to communicate with the Nitro ports *and* that the nodes are able to communicate with one another.

Installing Nitro Web Services

This topic contains instructions on how to install Nitro Web Services.

Nitro Web Services is not available for SUSE 11-based systems.

Do the following in the order presented:

1. [Open Necessary Ports on page 46](#)
2. [Install MongoDB on page 47](#)
3. [Install and Configure Nitro Web Services on page 49](#)
4. [Configure Viewpoint for Nitro Web Services on page 51](#)
5. [Grant Users Nitro Permissions in Viewpoint on page 52](#)
6. [Publish Nitro Events to Nitro Web Services on page 52](#)

Open Necessary Ports

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the necessary ports.

Location	Ports	Functions	When Needed
Nitro Web Services Host	9443	Tomado Web Port	Always
Nitro Web Services Host	47100	ZMQ Port	Always
Nitro Web Services Database Host	27017	Nitro Web Services MongoDB Server Port	If you will be installing the Nitro Web Services Database on a different host from Nitro Web Services

See [Opening Ports in a Firewall on page 61](#) for general instructions and an example of how to open ports in the firewall.

Install MongoDB

On the Nitro Web Services MongoDB Database Host, do the following:

1. Install MongoDB.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum install -y mongodb-org
```

- SUSE 12-based systems

```
[root]# zypper -n install mongodb-org
```

2. Enable and start MongoDB.

- Red Hat 6-based systems

```
[root]# chkconfig mongod on
[root]# service mongod start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

3. Add the required MongoDB users.

i The passwords used below (`secret1` and `secret5`) are examples. Choose your own passwords for these users.

```
[root]# mongo
> use admin
> db.createUser({"user": "admin_user", "pwd": "secret1", "roles": ["root"]})

> use nitro-db
> db.createUser({"user": "nitro_user", "pwd": "secret5", "roles": ["dbOwner"]})

> exit
```

i Because the `admin_user` has read and write rights to the `admin` database, it also has read and write rights to all other databases. See [Control Access to MongoDB Instances with Authentication](http://docs.mongodb.org/manual/tutorial/control-access-to-mongodb-with-authentication) (at <http://docs.mongodb.org/manual/tutorial/control-access-to-mongodb-with-authentication>) for more information.

4. Set MongoDB Configuration Options.

- The configuration file for MongoDB is `/etc/mongod.conf`. See <https://docs.mongodb.com/manual/reference/configuration-options> for information.
- Adaptive Computing recommends that you set `security.authorization` to `enabled`. See <https://docs.mongodb.com/manual/reference/configuration-options/#security-options> for more information.

i By default, `/etc/mongod.conf` sets `net.bindIp` to `127.0.0.1`. You will need to change this setting if the MongoDB server needs to be accessible from other hosts or from other interfaces besides loopback. See <https://docs.mongodb.com/manual/reference/configuration-options/#net-options> for more information.

```
# Sample /etc/mongod.conf file
net:
  port: 27017
  # bindIp: 127.0.0.1
processManagement:
  fork: true
  pidFilePath: /var/run/mongodb/mongod.pid
security:
  authorization: enabled
storage:
  dbPath: /var/lib/mongo
  journal:
    enabled: true
systemLog:
  destination: file
  logAppend: true
  path: /var/log/mongodb/mongod.log
```

5. Restart MongoDB.

- Red Hat 6-based systems

```
[root]# service mongod restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl restart mongod.service
```

Install and Configure Nitro Web Services

 You *must* complete the tasks earlier in this topic before installing Nitro Web Services.

On the host where Nitro Web Services will reside, do the following:

1. If you have not already done so, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).

2. Install the Nitro Web Services RPM.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum install -y nitro-web-services
```

- SUSE 12-based systems

```
[root]# zypper --non-interactive install nitro-web-services
```

3. Understand and edit the the Nitro Web Services web application configuration file (/opt/nitro-web-services/etc/nitro.cfg). This includes clarifying what the configuration file is for and what to expect the first time the NWS service is started vs. each subsequent start.

 The `nitro_user` with `dbOwner` permissions was set up earlier in the procedure (see [Install MongoDB on page 47](#)).

When you first start `nitro-web-services`, the `nitro-db` Mongo database (including its collections and indexes) is created. The `nitro-db` 'user' collection is also populated with the default Nitro Web Services API users/passwords. Several of the options defined in the configuration files influence this process.

MongoDB user, table, and index creation is performed at initial startup. Many of the options defined in the Nitro Web Service configuration files influence Mongo user/password and index creation.

 Usernames and passwords are created *only* if they do not yet exist. Changing a password in the configuration file after initial startup will not update the password.

The `/opt/nitro-web-services/etc/nitro.cfg` configuration file includes default password values. If you want to use passwords other than the default value, change the lines in the file as shown below.

- Before initial startup, set the `db_password` to be the `nitro_user` password. It is also recommended that you change all other default passwords before starting Nitro Web Services. If you do not change the passwords at this point, it will be more difficult to change them later.

```
db_password = <password goes here>
ws_admin_password = <ws_admin_password goes here>
ws_readonly_password = <ws_readonly_password goes here>
ws_writeonly_password = <ws_writeonly_password goes here>
```

- By default, NWS uses an auto-generated self-signed SSL certificate to encrypt the link between the web server and the browser clients. The auto-generated self-signed SSL certificate is created at service start up; not during the installation process.

However, you can use your own certfile, keyfile, and `ca_certs` files if you wish.

i If you choose to use your own `ssl_certfile` and `ssl_keyfile`, `ssl_create_self_signed_cert=true` is ignored.

- By default, NWS does *not* encrypt network traffic with MongoDB. You should set the `db_ssl_*` properties if you choose to enable TLS/SSL when installing MongoDB earlier in this topic.
4. Understand and edit the Nitro ZMQ Job Status Adapter configuration file (`/opt/nitro-web-services/etc/zmq_job_status_adapter.cfg`). This includes clarifying what the configuration file is for and what to expect the first time the NWS service is started vs. each subsequent start.
 - The Nitro ZMQ Job Status Adapter listens to job status updates on the ZMQ bus and publishes them to MongoDB using the Nitro Web Services REST API.
 - The username and password must be set to a Nitro Web Services API user with write permissions. At minimum, set the password for `nitro-writeonly-user` to the password defined in `/opt/nitro-web-services/etc/nitro.cfg` and make sure the SSL options are set correctly based on SSL settings in `/opt/nitro-web-services/etc/nitro.cfg`.

```
password = <ws_writeonly_password goes here>
```

5. If you did not need to install the Nitro Web Services MongoDB database earlier in this topic, verify that the `mongodb_hostlist` in `/opt/nitro-web-services/etc/nitro.cfg` is set correctly (`localhost:27017` is the default).
6. Start the services and configure Nitro Web Services to start automatically at system boot.
 - Red Hat 6-based systems

```
[root]# chkconfig --add nitro-web-services
[root]# chkconfig --add nitro-zmq-job-status-adapter
[root]# service nitro-web-services start
[root]# service nitro-zmq-job-status-adapter start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl enable nitro-web-services.service
[root]# systemctl enable nitro-zmq-job-status-adapter.service
[root]# systemctl start nitro-web-services.service
[root]# systemctl start nitro-zmq-job-status-adapter.service
```

Configure Viewpoint for Nitro Web Services

Do the following:

1. Using a web browser, navigate to your Viewpoint instance (`http://<server>:8081`) and then log in as the MWS administrative user (moab-admin, by default).
2. Click **Configuration** from the menu and then click **Nitro Services** from the left pane. The following is an example of the Nitro Services Configuration page.

3. Enter the configuration information. The following table describes the required information.

Field	Description
Nitro WS URL	Hostname (or IP address) and port number for the host on which you installed Nitro Web Services. For example, <code>https://<hostname>:9443</code>
Username	Name of the user. This typically <code>nitro-readonly-user</code> .
Password	The user's password.
Trust Self Signed	Indicates whether Nitro Web Services was set up using self-signed certificates.

4. Click **TEST** to confirm the settings are correct. This confirms whether Nitro Web Services is up and receiving connections.

5. Click **SAVE**.
6. (Recommended) Use curl to test Nitro Web Services connectivity.

```
[root]# curl --insecure --data '{"username": "nitro-admin", "password":
"ChangeMe2!"}' \
https://<hostname>:9443/auth
```

You should see output similar to the following.

```
{
  "status": 200,
  "data": {
    "nitro-key": "3e0fb95e9a0e44ae91daef4deb500dcc67a3714880e851d781512a49",
    "user": {
      "username": "nitro-admin",
      "last_updated": "2016-02-26 23:34:55.604000",
      "name": "Nitro Admin",
      "created": "2016-02-26 23:34:55.604000",
      "auth": {
        "job": [
          "read",
          "write",
          "delete"
        ],
        "user": [
          "read",
          "write",
          "delete"
        ]
      }
    }
  }
}
```

Grant Users Nitro Permissions in Viewpoint

Viewpoint comes packed with base (default) roles for Nitro jobs. Any user who will be working with Nitro Web Services, must have the appropriate role added to the Viewpoint user principal.

These are the Viewpoint roles for Nitro:

- NitroAdmin – Administrative user, with permission to create Nitro application templates and manage other user's Nitro jobs.
- NitroUser – Basic user, with permission to create and manage their own Nitro jobs.

See *Creating or Editing Principals in the Moab Viewpoint Reference Guide* for instructions on setting up principals.

Publish Nitro Events to Nitro Web Services

You need to configure the Nitro coordinators to send job status updates to the Nitro Web Services's ZMQ Job Status Adapter. The ZMQ Job Status Adapter is responsible for reading job status updates off of the ZMQ bus and persisting them to Mongo. Nitro Web Services can then be used to access Nitro job status.

Each Nitro job has a Nitro Coordinator. Nitro Coordinators can be configured to publish job status updates to ZMQ by setting the "nws-connector-address" configuration option in Nitro's nitro.cfg

file. Each compute node allocated/scheduled to a Nitro Job can play the role of a Nitro coordinator. Therefore, you must update the "nws-connector-address" in each compute node's `nitro.cfg` file.

i Configuring `nws-connector-address` is simplified if each node is sharing Nitro's configuration over a shared filesystem. If you are *not* using a shared filesystem, update the Nitro configuration on *each* compute node.

Do the following:

1. If you have not already done so, on the Nitro Web Services Host, locate the `msg_port` number in the `/opt/nitro-web-services/etc/zmq_job_status_adapter.cfg` file. This is the port number you need to specify for the `nws-connector-address`.
2. On *each* Nitro compute node (Torque MOM Host), specify the `nws-connector-address` in the `/opt/nitro/etc/nitro.cfg` file.

```
...
# Viewpoint connection allows Nitro to communicate job status information
# to viewpoint. This option indicates name and port of the remote server
# in the form: <host>:<port>
nws-connector-address <nitro-web-services-hostname>:47100
...
```

Upgrading

Upgrading RLM Server (RPM)

This topic contains instructions on how to upgrade the RLM Server using the RPM upgrade method.

! The RLM v12.1 (build:2) release resolved memory leak and security issues. The RLM package available with Moab HPC Suite 9.0.2, contains the v12.1 (build:2) release. Adaptive Computing *strongly* recommends that your RLM Server is v12.1 (build:2).

Install the RLM Server

On the RLM Server Host, do the following:

1. If you installed the RLM Server on its own host *or* if the RLM Server is the first component being upgraded on a host with other RPM installations, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).
2. Stop the RLM service.

```
[root]# service rlm stop
```

```
[root]# systemctl stop rlm.service
```

```
[root]# systemctl stop rlm.service
```

3. Install the upgrade.

```
[root]# yum update ac-rlm*
```

```
[root]# zypper update ac-rlm*
```

4. Restart the RLM service.

```
[root]# service rlm restart
```

```
[root]# systemctl daemon-reload
[root]# systemctl restart rlm.service
```

```
[root]# systemctl daemon-reload
[root]# systemctl restart rlm.service
```

Upgrading Nitro

i You must be a root user when installing or upgrading Nitro.

This topic contains the steps and procedures to follow to upgrade Nitro using the RPM upgrade method.

In this topic:

- [Upgrade from a Version Prior to 2.0 on page 54](#)
- [Upgrade Nitro on page 54](#)

Upgrade from a Version Prior to 2.0

The following steps are required if you are upgrading a Nitro version prior to 2.0.

1. Install or obtain access to an RLM server. See [Installing RLM Server on page 40](#).

i Beginning with Nitro 2.0, the licensing procedure changed to use an RLM server. If your company already uses an RLM Server, you can skip this procedure.

2. Obtain and install the Nitro license. This requires access to an RLM server. See [Obtain a Nitro License on page 42](#).
3. Copy the license file to each compute node (coordinator). On each compute node, *or* on the shared file system, do the following:

```
[root]# cp <licenseFileName>.lic /opt/nitro/bin/
```

Upgrade Nitro

On the Nitro Host, do the following:

1. If you installed Nitro on its own host *or* if Nitro is the first component being upgraded on a host with other RPM installations, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).
2. Back up your existing, customized launch scripts, job scripts, and the nitrosub command (if applicable).
 - a. In `/opt/nitro/bin/`, back up the following:
 - `launch_nitro.sh`
 - `launch_worker.sh` (version 2.1 or later)
 - `nitrosub` command (version 2.1 or later)
 - b. In `/opt/nitro/etc/`, back up the following:
 - `nitro_job.sh` (version 2.1 or later)
 - `worker_job.sh` (version 2.1 or later)
3. Install the upgrade.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum update nitro
```

- SUSE 12-based systems

```
[root]# zypper update nitro
```

4. Copy the provided scripts and the nitrosub command from the `/opt/nitro/scripts` directory.

i This is a "copy" file operation and not a "move" operation. This allows you to customize your version and always have the factory version available for consultation and/or comparison.

- a. Copy the `launch_nitro.sh` and `launch_worker.sh` scripts for your resource manager to the `bin` directory. Each resource manager has a subdirectory with the scripts directory that contains the scripts. This example uses Torque as the resource manager.

```
[root]# cp /opt/nitro/scripts/torque/launch_nitro.sh /opt/nitro/bin/
[root]# cp /opt/nitro/scripts/torque/launch_worker.sh /opt/nitro/bin/
```

- b. Copy the `nitrosub` command to the `bin` directory.

```
[root]# cp /opt/nitro/scripts/nitrosub /opt/nitro/bin/
```

- c. Copy the `nitro_job.sh` and the `worker_job.sh` scripts to the `etc` directory.

```
[root]# cp /opt/nitro/scripts/nitro_job.sh /opt/nitro/etc/
[root]# cp /opt/nitro/scripts/worker_job.sh /opt/nitro/etc/
```

5. Merge any customizations from your existing launch scripts, job scripts, and the nitrosub command (if applicable) into the new launch scripts, job scripts, and the nitrosub command that you copied from the scripts directory.
6. If your system configuration allows multiple coordinators on the same node, additional configuration may be needed. See [Running Multiple Coordinators on the Same Node on page 62](#) for more information.
7. If you are not using a shared file system, copy the updated Nitro installation directory to *all* hosts.

```
[root]# scp -r /opt/nitro root@host002:/opt
```

If you are *not* using a shared file system, you may not be able to use the nitrosub command.

Upgrading Nitro Web Services (RPM)

This topic contains instructions on how to upgrade Nitro Web Services using the RPM upgrade method.

Upgrade Steps

Do the following:

- [Upgrade to MongoDB 3.2.x on page 56](#), if you are upgrading Nitro Web Services from a version *prior* to 2.1.0
- [Back up the MongoDB Databases on page 56](#), if you are upgrading Nitro Web Services from version 2.1.0 or later
- [Upgrade Nitro Web Services on page 57](#)
- [Grant Users Nitro Permissions in Viewpoint on page 58](#)

Upgrade to MongoDB 3.2.x

Beginning with version 2.1.0, Nitro Web Services requires MongoDB 3.2.x.

On the Nitro Web Services MongoDB host, do the following:

1. Check your MongoDB server version.

```
[root]# rpm -qa | grep mongo
```

2. If the MongoDB server version is older than 3.2.x, then you will need to upgrade the databases. See [Upgrading to MongoDB 3.2.x \(RPM\) on page 58](#) for more information.

Back up the MongoDB Databases

i This procedure is only applicable if you did not have to upgrade the MongoDB databases earlier in this topic. See [Upgrade to MongoDB 3.2.x on page 56](#) for more information.

On the Nitro Web Services MongoDB host, do the following:

1. Stop all services that are using the MongoDB databases.
2. Back up the MongoDB databases.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
```

3. Restart the services.

Upgrade Nitro Web Services

On the Nitro Web Services Host, do the following:

1. If you installed Nitro Web Services on its own host *or* if Nitro Web Services is the first component being upgraded on a host with other RPM installations, complete the steps to prepare the host. See [Preparing for RPM Installation or Upgrade on page 38](#).
2. If you are upgrading Nitro Web Services from a version *prior* to 2.1.0, confirm the MongoDB database is upgraded to 3.2.x. See [Upgrading to MongoDB 3.2.x \(RPM\) on page 58](#) for more information.
3. Stop the services.

- Red Hat 6-based systems

```
[root]# service nitro-web-services stop
[root]# service nitro-zmq-job-status-adapter stop
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl stop nitro-web-services.service
[root]# systemctl stop nitro-zmq-job-status-adapter.service
```

4. If you are upgrading Nitro Web Services from version 2.1.0 or later, do the following on the Nitro Web Services MongoDB host.

- a. Stop all services on the host.
- b. Back up the Nitro Web Service MongoDB database.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
```

- c. Restart the services.

5. Install the upgrade.

- Red Hat 6-based or Red Hat 7-based systems

```
[root]# yum update nitro-web-services
```

- SUSE 12-based systems

```
[root]# zypper update nitro-web-services
```

6. If you are upgrading Nitro from 2.0.0, re-enable the services.

- Red Hat 6-based systems

```
[root]# chkconfig nitro-web-services on
[root]# chkconfig nitro-zmq-job-status-adapter restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl enable nitro-web-services.service
[root]# systemctl enable nitro-zmq-job-status-adapter.service
```

7. Merge any customizations from the `nitro.cfg` and the `zmq_job_status_adapter.cfg` files (and any other files) you backed up earlier in this procedure into the new files.

i See the steps in [Install and Configure Nitro Web Services on page 24](#) for more information on the configuration files.

8. Start the services.

- Red Hat 6-based systems

```
[root]# service nitro-web-services start
[root]# service nitro-zmq-job-status-adapter start
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl start nitro-web-services.service
[root]# systemctl start nitro-zmq-job-status-adapter.service
```

Grant Users Nitro Permissions in Viewpoint

Verify that the users who work with Nitro Web Services have the appropriate role in their Viewpoint user principal.

These are the Viewpoint roles for Nitro:

- NitroAdmin – Administrative user, with permission to create Nitro application templates and manage other user's Nitro jobs.
- NitroUser – Basic user, with permission to create and manage their own Nitro jobs.

See *Creating or Editing Principals* in the *Moab Viewpoint Reference Guide* for instructions on setting up principals.

Upgrading to MongoDB 3.2.x (RPM)

Nitro Web Services 2.1.0 and after requires MongoDB 3.2.x.

Do the following:

1. Stop the service that uses MongoDB.

- Red Hat 6-based systems

```
[root]# service nitro-web-services stop
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl stop nitro-web-services.service
```

2. Confirm that nothing is connected to MongoDB.

```
[root]# netstat -antp | egrep '(27017|28017).*ESTABLISHED'
```

3. Dump the database.

```
[root]# cd /root
[root]# mongodump -u admin_user -p secret1
[root]# cp -a dump dump.save
[root]# rm -rf dump/admin/system.users.* # Cannot restore users.
```

4. Install MongoDB 3.2.x.

- Red Hat 6-based systems

```
[root]# service mongod stop
[root]# chkconfig mongod off
[root]# rpm -e --nodeps $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
[root]# yum install mongodb-org
[root]# chkconfig mongod on
[root]# service mongod start
```

- Red Hat 7-based systems

```
[root]# systemctl stop mongod.service
[root]# systemctl disable mongod.service
[root]# rpm -e --nodeps --noscripts $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
/usr/lib/systemd/system/mongod.service
[root]# yum install mongodb-org
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

- SUSE 12-based systems

```
[root]# systemctl stop mongod.service
[root]# systemctl disable mongod.service
[root]# rpm -e --nodeps $(rpm -qa 'mongo*')
[root]# rm -rf /tmp/mongo*.sock /var/run/mongo* /var/lib/mongo* /var/log/mongo*
[root]# zypper -n install mongodb-org
[root]# systemctl enable mongod.service
[root]# systemctl start mongod.service
```

5. Restore the database.

```
[root]# cd /root
[root]# mongorestore
```

6. Create the users.

```
[root]# mongo
use admin
db.createUser({"user": "admin_user", "pwd": "secret1", "roles": ["root"]})

use nitro-db
db.createUser({"user": "nitro_user", "pwd": "secret5", "roles":
["dbOwner"]})

exit
```

7. Set MongoDB Configuration Options.

- The configuration file for MongoDB is `/etc/mongod.conf`. See <https://docs.mongodb.com/manual/reference/configuration-options> for information.
- Adaptive Computing recommends that you set `security.authorization` to `enabled`. See <https://docs.mongodb.com/manual/reference/configuration-options/#security-options> for more information.

i By default, `/etc/mongod.conf` sets `net.bindIp` to `127.0.0.1`. You will need to change this setting if the MongoDB server needs to be accessible from other hosts or from other interfaces besides loopback. See <https://docs.mongodb.com/manual/reference/configuration-options/#net-options> for more information.

```
# Sample /etc/mongod.conf file
net:
  port: 27017
  # bindIp: 127.0.0.1
processManagement:
  fork: true
  pidFilePath: /var/run/mongodb/mongod.pid
security:
  authorization: enabled
storage:
  dbPath: /var/lib/mongo
  journal:
    enabled: true
systemLog:
  destination: file
  logAppend: true
  path: /var/log/mongodb/mongod.log
```

8. Restart MongoDB.

- Red Hat 6-based systems

```
[root]# service mongod restart
```

- Red Hat 7-based or SUSE 12-based systems

```
[root]# systemctl restart mongod.service
```

Additional Configuration

This section contains additional configuration procedures; depending on your system configuration, some or all of these procedures may be required.

In this section:

- [Opening Ports in a Firewall on page 61](#)
- [Running Multiple Coordinators on the Same Node on page 62](#)

Opening Ports in a Firewall

If your site is running firewall software on its hosts, you will need to configure the firewall to allow connections to the products in your installation.

This topic provides an example and general instructions for how to open ports in your firewall. The actual port numbers for the various products will be provided in the installation instructions for that product.

In this topic:

- [Red Hat 6-Based Systems on page 61](#)
- [Red Hat 7-Based Systems on page 61](#)
- [SUSE 11-Based Systems on page 62](#)
- [SUSE 12-Based Systems on page 62](#)

Red Hat 6-Based Systems

Red Hat 6-based systems use iptables as the default firewall software. For the ip6tables service, replace all occurrences of iptables with ip6tables in the example. If you use different firewall software, refer to your firewall documentation for opening ports in your firewall.

The following is an example of adding port 1234 when using iptables.

```
[root]# iptables-save > /tmp/iptables.mod
[root]# vi /tmp/iptables.mod

# Add the following lines immediately *before* the line matching
# "-A INPUT -j REJECT --reject-with icmp-host-prohibited"

-A INPUT -p tcp --dport 1234 -j ACCEPT

[root]# iptables-restore < /tmp/iptables.mod
[root]# service iptables save
```

Red Hat 7-Based Systems

Red Hat 7-based systems use `firewalld` as the default firewall software. If you use different firewall software, refer to your firewall documentation for opening ports in your firewall.

The following is an example of adding port 1234 when using `firewalld`.

```
[root]# firewall-cmd --add-port=1234/tcp --permanent
[root]# firewall-cmd --reload
```

SUSE 11-Based Systems

SUSE 11-based systems use `SuSEfirewall2` as the default firewall software. If you use different firewall software, refer to your firewall documentation for opening ports in your firewall.

The following is an example of adding port 1234 when using `SuSEfirewall2`.

```
[root]# vi /etc/sysconfig/SuSEfirewall2
FW_SERVICES_EXT_TCP="7112"
[root]# service SuSEfirewall2_setup restart
```

SUSE 12-Based Systems

SUSE 12-based systems use `SuSEfirewall2` as the default firewall software. If you use different firewall software, refer to your firewall documentation for opening ports in your firewall.

The following is an example of adding port 1234 when using `SuSEfirewall2`.

```
[root]# vi /etc/sysconfig/SuSEfirewall2
FW_SERVICES_EXT_TCP="1234"
[root]# service SuSEfirewall2 restart
```

Running Multiple Coordinators on the Same Node

Nitro provides the ability to run multiple coordinators on the same node.

i Running multiple coordinators on the same node, is not available if your system configuration uses a policy to limit nodes to a single job (i.e., `NODEACCESSPOLICY=SINGLEJOB` on Moab).

If your system is configured to allow multiple coordinators on the node:

- It is recommended that you instruct your users to submit Nitro jobs using the `nitrosub` command. See [nitrosub Command on page 81](#) for more information.
- If you prefer that your users do *not* use the `nitrosub` command, and instead you prefer that they submit the Nitro jobs directly to your scheduler/resource manager, then you will need to add the `--port-file` option to the `bin/launch_nitro.sh` and `bin/launch_worker.sh` scripts to ensure that all coordinators will be able to run.

```
NITRO_OPTIONS="--port-file --job-id ${NITROJOBID} ${NITRO_OPTIONS}"
```

Add the `--port-file` option **before** the `--job-id` information.

Chapter 3 System Administration

This chapter provides additional configuration and resources, including troubleshooting, for system administrators.

In this chapter:

- [Job Submission Methods on page 63](#)
- [Nitro Configuration File on page 64](#)
- [File System Configuration on page 65](#)
- [Run Nitro Without a Scheduler on page 66](#)

Job Submission Methods

Nitro enables system administrators to choose what level of detail users need to know in order to submit Nitro jobs.

Nitro provides these options for users when submitting Nitro Jobs:

- User-customized job scripts (high level of detail, static jobs only)
- `nitrosub` command (minimal level of detail; static or dynamic jobs)

This topic provides information on the different options.

In this topic:

- [User-Customized Job Script on page 63](#)
- [nitrosub Command on page 63](#)

User-Customized Job Script

 The User-customized job script methodology is only available for static jobs.

With the initial release of Nitro, system administrators copied a sample job script packaged with Nitro and then customized it for their system. The system administrators then gave a copy of the customized sample script to the user, who would then make a copy of it and further customize it when submitting a job for the task file.

Nitro is now packaged with a `nitro_job.sh` and a `worker_job.sh` script. For static jobs, only the `nitro_job.sh` script is applicable.

The `nitro_job.sh` script can be customized by the system administrators for their systems. The system administrators can then have the user copy that script and make further customizations (such as configuring environment variables) that affect the respective `launch_nitro.sh` script. Users will then use the resource manager's job submission command (for example, `qsub` for Torque) to execute the user's customized `nitro_job.sh` script.

See [Job Scripts on page 88](#) for more information.

nitrosub Command

i The `nitrosub` command is only available for systems that use a shared file system.

The `nitrosub` command lets users submit Nitro jobs without having to copy and customize the `nitro_job.sh` script for their task file.

The user only needs to specify the user's task file path, a resource quantity, and a wall-time limit when they submit a Nitro job for the task file. The `nitrosub` command will then execute the system's `nitro_job.sh` script and the `worker_job.sh` script (as needed for dynamic jobs).

See [nitrosub Command on page 81](#) for more information.

Nitro Configuration File

The `nitro.cfg` file is available to system administrators.

Nitro looks for this configuration file in the `/opt/nitro/etc` directory, which must be a peer to the `/opt/nitro/bin` directory. If found, Nitro will load configuration options specified in the `nitro.cfg` file.

`nitro.cfg` Configuration Options

These configuration options are available to customize the `nitro.cfg` file:

- `assignment-size <size>` – Sets the default assignment size. Valid values are 0 - 1000. 0 is the default, and allows the coordinator to automatically determine the assignment size based on the assignment duration.

i There is also an "`--assignment-size`" command line option, that if set, overrides the `<size>` specified here (`nitro.cfg` file).

- `coord-threads <count>` – Indicates to the coordinator how many threads to reserve for the coordinator when allocating cores to a local worker (when using "`--run-local-worker`" on the coordinator command line). Default is 2. Adaptive Computing recommends setting the `<count>` value to 1 if all jobs will use less than 20 hosts and setting the `<count>` value to 4 if the jobs require a large number of hosts (greater than 50) to run.

i There is also a "`--coord-threads`" command line option, that if set, overrides the `<count>` specified here (`nitro.cfg` file).

- `default-shell <shell path>` – Allows the configuration of the default shell used by Nitro to launch tasks. The default value is `/bin/bash`. In high throughput usages where many very small tasks need to be launched as quickly as possible, it may be beneficial to use a more compact shell such as the Bourne shell or Korn shell. To set this value, specify the fully qualified path to the shell such as `/bin/sh`.
- `default-shell-command <command>` – Allows configuration of the command line parameter to the shell that Nitro uses when launching a task. The default shell command is `"-c"` so that Nitro will execute `/bin/bash -c <task command line>`. Set this value if you

need to customize the launch command or are using a shell that uses a different command line option to launch a command line.

- `disable-affinity` – Instructs the workers that they should not track and set the task's affinity.

 There is also a "--disable-affinity" command line option, that if set, overrides the setting here (nitro.cfg file).

- `max-cpu-threshold <value>` – Causes Nitro to reduce task threads when the threshold is reached. The `<value>` is a percentage of system load, where 100% is equivalent to the number of cores in the node and is measured by the 60 second load average.
- `maxtime-limit <period>` – Lets you set the maxtime option's upper limit for all Nitro job task definitions. If this option is not specified, the coordinator will use its default of 1 day (86400 seconds). This value can be specified as a number of seconds, or by using the Days:Hours:Minutes:Seconds format (ie: 7:0:0:0 = 7 days).
- `min-memory-threshold <threshold MB>` – If set to a value other than 0 (zero), causes Nitro to check the workers available physical memory before starting tasks. If the available physical memory drops below this value, Nitro will stop running tasks until available memory rises above the threshold. This can be used to throttle tasks or account for background activity that is consuming memory and causing the system to swap memory to disk. It is important to select a threshold that will allow the system to throttle before swapping starts to happen. 2GB (2000MB) is a good threshold to start with.
- `throttle-period <period>` – Sets the amount of time (in seconds) that Nitro will wait before checking for throttling conditions (such as the memory threshold). Nitro defaults to checking every 2 seconds. Setting this to 0 (zero) causes Nitro to check when tasks complete, or 1 second whichever comes first.
- `task-output-limit <value>` – Sets the number of bytes that will be captured by stdout and stderr (each) and written to the task log file. The default value is 512 bytes. Nitro captures the stdout and stderr strings output by tasks, but only retains the last n characters as set by the limit to reduce communication and storage overhead.

File System Configuration

This topic provides details regarding the file system configuration.

Users will normally submit Nitro jobs to a scheduler. A Nitro job runs in the user's workspace on the nodes allocated to the job by the scheduler. There are two Nitro output file locations (task log and job log) that *must* be available to the hosts running the workers and coordinator.

In this topic:

- [Nitro Launch Script Location on page 66](#)
- [Task File Location on page 66](#)

- [Job Output Directory on page 66](#)
- [Recommended NFS Settings on page 66](#)

Nitro Launch Script Location

The Nitro launch script must be installed in a shared file location or a location that is accessible to the users that will be running Nitro jobs. While users won't need to run the Nitro application itself, they should have read access to the Nitro launch script.

Task File Location

The task file a Nitro job will use must be accessible to the job. Most schedulers will copy the user job script, but will not copy the task file the user must provide. Users may need to stage this task file into a location accessible to Nitro job hosts. Nitro only needs read access to this file.

Job Output Directory

If the user does not specify a Nitro job directory (using "--job-dir" command line option), Nitro defaults to the `$HOME/nitro/<job id>` directory.

This directory contains the Nitro job and task log files, Nitro diagnostic log files, and temporary files Nitro uses to recover a canceled job. Users' home directories on these hosts should be mapped to a shared file location accessible to the users either from the system's login hosts, or outside of the cluster. Nitro will need to create directories and files in the Nitro job directory.

Recommended NFS Settings

If the job directory and task file are located on an NFS, then depending on the NFS cache settings, system administrators and users should be aware of the following:

- Job Directory - Users may not see job progress for several seconds after Nitro writes the files.
- Task File - If using Nitro in *linger mode*, Nitro may not recognize that new tasks have been added to the task file for up to 30 seconds.
- System Configuration (caching/tuning) - Add "lookupcache=none" to the NFS file system mount options in `/etc/fstab` for all the hosts using the NFS to prevent caching delays.

Run Nitro Without a Scheduler

Nitro works well running as a job invoked via a scheduler and/or resource manager.

However, if you have a set of nodes that are dedicated to high-throughput computing and would like to run Nitro jobs on these machines, or have Nitro always waiting (ready to run tasks at any time), you can run Nitro without the use of a scheduler.

This topic explains how to run Nitro without the use of a scheduler (also referred to Nitro standalone).

In this topic:

- [Selecting a Job ID on page 67](#)
- [Starting Workers on page 67](#)
- [Starting the Coordinator on page 67](#)
- [\(Optional\) Changing the Job Directory on page 68](#)

Selecting a Job ID

Since you do not have a scheduler to supply a job ID, Nitro will create a default job ID based on the current date and time in the format "YYMMDDHHMMSS". Since the workers and coordinator will be started separately, it is recommended that you designate a job ID and set the "--job-id <job id>" command line option on the worker and coordinator command lines with that job ID. Setting the job ID provides consistency between the workers and the coordinator when referencing the job; for example, when viewing job output and log files.

Starting Workers

You must start a worker on each node you want to execute Nitro tasks by starting it manually on a terminal on that node, or by running a remote command through ssh.

A worker command line must include an "--coord" argument that lists the node's host name and port number (if other than default port "47000") of the coordinator.

When each worker connects to the coordinator, it identifies itself using the --name option. If --name is not supplied, the worker's identification is the worker node's host name.

i The name supplied to the coordinator via --workers or --workers-file must match the --name argument specified on the worker's command line.

For example, if you have the coordinator running on node "node001" and a worker running on node "node002", then the command line to start the worker would look like the following:

```
/opt/nitro/bin/nitro --mode=worker --job-id MyJob01 --coord node001 --name node002
```

Alternately, to run the worker using ssh (assuming ssh keys have been exchanged between the coordinator and worker), it would look like the following:

```
ssh user@node002 '/opt/nitro/bin/nitro --mode=worker --job-id MyJob01 --coord node001 --name node002'
```

Starting the Coordinator

The coordinator requires either a list of worker names or a session key that workers will use to attach to the coordinator. When supplying a list of worker names, these workers will be the only workers authorized to connect to the coordinator and receive workload assignments. If you specify a session key, any worker with the session key will be able to attach and receive workload.

Using Worker Names

A list of worker names can be specified on the command line, with worker names separated by the plus symbol (+). For example:

```
/opt/nitro/bin/nitro --mode=coord --job-id MyJob01 --workers
node002+node003+node004+node005 ~/taskfile.txt
```

Alternately if it is a large list, it may be written to a file with one name per line, where the name is what the worker identifies itself as to the coordinator. For example:

```
echo -e "node001\nnode002\nnode003\nnode004\nnode005" > nodelist.txt
/opt/nitro/bin/nitro mode=coord --job-id MyJob01 --workers-file nodelist.txt
~/taskfile.txt
```

node node001 is the coordinator and nodes node002-node005 are workers.

Using a Session Key

To start the coordinator with a session key, use the `--key <keyvalue>` or `--key-file <file>` command line option instead of the `--workers` or `--workers-file` command line options. Any worker that is started with the `--key` command line option with the correct `<keyvalue>` will be able to attach to the coordinator. For example:

```
/opt/nitro/bin/nitro --mode=worker --coord node01 --job-id MyJob01 --key password1234
/opt/nitro/bin/nitro --mode=coord --name=node01 --job-id MyJob01 --key password1234
~/taskfile.txt
```

(Optional) Changing the Job Directory

The default job directory (the location to which Nitro will write the job and task log files) is `$HOME/nitro/<job id>`.

If you want to store results in a different directory, use the `--job-dir` command line option on both the coordinator and workers.

Chapter 4 Using Nitro

This chapter provides information and instructions on using Nitro.

In this chapter:

- [Prepare a Nitro Job on page 69](#)
- [Submit a Nitro Job using the nitrosub Command on page 72](#)
- [Submit a Nitro Job with User-Customized Job Scripts on page 73](#)
- [Track Job Progress on page 74](#)

Prepare a Nitro Job

This topic provides information on the Nitro job's task file and performance tuning information.

In this topic:

- [Task File on page 69](#)
- [Performance Tuning on page 71](#)

Task File

The task file is a single file that contains a list of tasks to execute. Each line of the task file should contain only *one* task. You can add comments to your task file to help describe the tasks being performed, the data required, or other information that is pertinent to describing the tasks. Nitro also provides the capability to use task names and labels to help you organize your tasks.

Most of the tasks you create for a task file will probably run to completion fairly quickly, but it is possible that a task gets stuck in a loop or needs to run for a certain amount of time. Nitro by default limits tasks to 3,600 seconds (1 hour), but you can specify the limit to apply to the task by using the "maxtime" token. Time limits are specified in seconds. The following is an example of a task definition that limits a task to 30 seconds.

```
name=S23T01 maxtime=30 cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 1
```

Tasks

A task line can be as simple as the command you want to execute. For example, if you want to run a program called "framegen", input a file from a shared directory, and process the frame starting at time index "0" (zero), the command line might look like as follows.

```
/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 0
```

Nitro uses name/value pairs before the command line that you want to execute to define Nitro-specific information, such as, specifying a task name, task labels (that you can use to categorize the task), maximum time a task will run, and the command to execute to run the tasks itself. The key words for these name/value pairs are:

```
"cores=<count>"
"env=<name=value>[, <name=value>, ...]"
"labels=<label>[, <label>, ...]"
"name=<task name>"
"maxtime=<time limit in seconds>"
"memory=<amount>"
"shell=[default | none | <shell path>]"
"cmd=<command line>"
```

i The optional name/value pairs must be prepended to the line containing the task command line. As soon as Nitro sees something that isn't a name/value pair, the task line parsing stops and the rest is assumed to be part of the command line to execute.

To make it clear where the task options end and your command line begins, include "cmd=" before your task's command line. This token is optional but helps to make the task definition easier to read when you are specifying other options. The following is an example command line with the "cmd=" token.

```
cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 0
```

Nitro organizes the tasks for tracking.

Nitro tracks tasks by a task ID and line number. Nitro automatically generates a task ID for each task definition in the task file. The first task definition receives task ID "1".

i Only a task definition will increment the task ID. Because a task file can have empty or comment lines, the task ID and the line number in the task file may not be the same for the task.

Nitro will create a report of all tasks run and will include the task ID and line number in this report. The task ID is passed to the task via the **\$NITROTASKID** environment variable.

To make Nitro tasks easier to track, or to search for specific tasks in the task completion report, add a unique task name to your task definition. Task names don't have to be unique, but creating a unique task name helps you identify specific tasks.

i You can use any naming scheme you want, as long as the name does not include spaces (which would indicate an end to the name/value pair).

For example, if you are processing data for scenes 21, 22, and 23, you can name the tasks according to scene and time index.

```
name=S21T00 cmd=/opt/framemaker/bin/framegen -i /shared/scene21.def -tindex 0
name=S21T01 cmd=/opt/framemaker/bin/framegen -i /shared/scene21.def -tindex 1
name=S22T00 cmd=/opt/framemaker/bin/framegen -i /shared/scene22.def -tindex 0
name=S22T01 cmd=/opt/framemaker/bin/framegen -i /shared/scene22.def -tindex 1
name=S23T00 cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 0
name=S23T01 cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 1
```

Nitro makes the task name available to the task via the **\$NITROTASKNAME** environment variable when it executes the task. If the task command line includes the environment variable, it is substituted by its value before the command executes.

You can also use task labels to organize or identify the tasks. You can use multiple labels to describe a task. Multiple label values are separated by a comma between them; spaces are not allowed.

For example, if scene 22 contains a green screen that needs additional processing after this job completes, you can include the label "green" on all of the tasks for this scene.

```
name=S21T00 cmd=/opt/framemaker/bin/framegen -i /shared/scene21.def -tindex 0
name=S21T01 cmd=/opt/framemaker/bin/framegen -i /shared/scene21.def -tindex 1
name=S22T00 labels=green /opt/framemaker/bin/framegen -i /shared/scene22.def -tindex 0
name=S22T01 labels=green /opt/framemaker/bin/framegen -i /shared/scene22.def -tindex 1
name=S23T00 cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 0
name=S23T01 cmd=/opt/framemaker/bin/framegen -i /shared/scene23.def -tindex 1
```

Performance Tuning

Assignment Size

Each set of tasks that a coordinator sends to a worker is called an assignment. Nitro is most efficient when it can send a large enough assignment to each worker to keep the worker busy for at least 10 seconds before requesting more work. On the other hand, if you have a heterogeneous set of nodes with a wide variance in performance characteristics, you don't want one worker taking a very long time completing its assignment after all of the other workers have finished.

The `nitro.cfg` file lets you specify an assignment size of 0 up to 1000. A size of 0 allows the assignment size to be calculated by the coordinator and dynamically calculated to target an assignment duration of 5 seconds.

You can also use the `--assignment-size` command line option on the coordinator to change the tasks per assignment for your configuration. You can specify an assignment size as "0" (calculated by the coordinator), as small as "1" (which could be useful for tasks that need to use all of the available OS cores), and as large as "1000" (useful to keep worker cores busy with tasks of extremely short duration).

If submitting a job to a job scheduler, you can change the assignment size by setting the **NITRO_COORD_OPTIONS** environment variable so it contains the `--assignment-size` command line option.

For example, if your nodes are all running 16 OS cores and each task takes 2 seconds to complete, each assignment of default size will take 31.25 seconds to complete (250 tasks at 2 seconds each divided by 16 OS cores), so you might want to change the assignment size to "80" to get an assignment time of closer to 10 seconds with the command line option.

```
--assignment-size 80
```

i Assignment sizes don't need to be evenly divisible by the number of OS cores available. Nitro will try to send the worker a second assignment when the worker gets about half way done with the current assignment so the second assignment will start running tasks as soon as an OS core becomes idle from the previous assignment.

i Adaptive Computing recommends a 10-20 second assignment duration to optimize node utilization and to prevent "tailing" jobs (job where at its end there is only one or a few workers executing a large assignment and other workers are idle).

Thread Control

Nitro typically runs one task per available OS core on each worker. However, you can configure Nitro to run more tasks than OS cores (over-subscription), fewer tasks than OS cores (under-subscription) or a specific number of OS cores. You might want to over-subscribe the available OS cores if you are not utilizing the full capacity of the node. You may need to under-subscribe cores if

background tasks are running on the nodes. To over- or under-subscribe, use the `--thread-ratio` command line option.

```
--thread-ratio <ratio>
```

<ratio> only applies to worker nodes. However, if you are using the `--run-local-worker` command line option, then the thread ratio will be passed on to the coordinator's local worker.

`--thread-ratio` also lets you specify over- or under-subscription properly in a heterogeneous node environment where nodes have different numbers of processors, cores, or threads. For example, if your nodes are all single socket, oct-core with hyper-threading enabled (16 total OS cores), but you want to over-subscribe by a factor of 1.5x, you could accomplish this by adding "`--thread-ratio 1.5`" to the worker command line to give each worker the ability to run 24 concurrent tasks. Alternately, if your tasks are all designed to use 2 OS cores each (multi-threaded application), you could use "`--thread-ratio 0.5`".

There may also be cases where you want to specify the *exact* number of OS cores to be used by the worker, such as when you have tasks that will use all available OS cores. In that case, you would use the `--thread-count` command line option to specify a thread count of 1 (`--thread-count 1`).

Run a Worker on the Coordinator Node

In configurations where you will be running less than 20 worker nodes, the coordinator node may be underutilized. To remedy this situation you may want to run a worker on the coordinator node so you can use its resources more effectively. To run a worker on the coordinator node, include the `--run-local-worker` flag on the coordinator's command line *or* you can explicitly start a worker Nitro process on the node.

If using the `nitrosub` command, use `--no-local-worker` to prevent a worker from running on a coordinator node.

i Nitro will calculate the number of threads that the local worker should run so the coordinator is not starved for CPU cycles; causing it to slow down all the other workers.

Task Execution Environment Variables

Nitro will pass several environment variables to your tasks when it executes them. See [Environment Variables on page 87](#) for more information.

⚠ Nitro reads a portion of the task file at a time. While the Nitro job is running, do *not* add or remove any task definitions or comment lines in the task file. Changes to the task file could cause line numbers to be changed and jobs to not run or be accidentally rerun.

Related Topics

Submit a Nitro Job using the `nitrosub` Command

This topic is applicable for static and dynamic jobs. Alternatively, for static jobs, you can submit the jobs using a customized nitro job.sh script and the resource manager's submit command (for example, Torque's qsub). See [Submit a Nitro Job with User-Customized Job Scripts on page 73](#) for more information.

Do the following:

1. Obtain the required information:

- how many resources (nodes or cores) you will need; this can be a static amount or a range (used for dynamic jobs).

Resources are determined by the system's licensing model and configured in the nitrosub command.

- the time limit for the execution (wall-time)
 - location of your task file
2. Determine if you want any additional information included:
- whether a worker will reside on the same host as the coordinator
 - a job ID for the job
 - a job directory for recording job information
 - any customized environment variables
3. Submit the Nitro job. The following example is for a dynamic job requesting 4-10 hosts, with a walltime of 30 minutes.

```
$ nitrosub --resources=4-10--wall-time=30:00--task-file=mytasks.txt
```

Related Topics

Submit a Nitro Job with User-Customized Job Scripts

This topic is only applicable for static jobs submitted using the resource manager's submit command (for example, qsub for Torque). If your configuration uses the nitrosub command, see [Submit a Nitro Job using the nitrosub Command on page 72](#).

Do the following:

1. If you have not already done so,
 - a. Obtain the `etc/nitro_job.sh` script customized for your system.
 - b. Create a copy of that job script.
2. Customize the job script for your task file.
 - a. Specify the path to your task file (`NITRO_TASK_FILE`).
 - b. (Optional) Specify the directory to which Nitro writes log files (`NITROJOBDIR`). This directory can be used to store output files from your tasks.
 - c. Customize any other environment variables referenced by the `launch_nitro.sh` script as needed. See [Environment Variables on page 87](#) for more information.
 - d. Confirm the job script executes the `launch_nitro.sh` script (last line in the script).
3. Save your customized `nitro_job.sh` script.
4. Using your resource manager's submit command, submit the Nitro job for your task file. The following example uses the Torque resource manager and the customized job script saved in the "myscripts" directory.

```
$ qsub \myscripts\nitro_job.sh
```

Track Job Progress

This topic provides information on viewing job progress and output.

In this topic:

- [Introduction on How Nitro Tracks the Job on page 74](#)
- [Job Log on page 75](#)
- [Task Log on page 78](#)

Introduction on How Nitro Tracks the Job

Nitro will print some job information to stdout, such as what workers attached, how many tasks have been run, if any tasks failed, etc.

If your Nitro job is submitted through a scheduler, you may not see any of this until the job has completed and the resource manager has copied the job output to your job's submission directory.

However, Nitro provides a tool called `nitrostat` to display status information while the job is running. `nitrostat` is located in the `nitro/bin` directory where Nitro was installed.

Nitro creates two files that you can use to stay up-to-date on the progress of your job.

- `nitro_<jobid>.joblog.txt` - Information about the job in general.
- `nitro_<jobid>.tasklog.txt` - Listing of individual tasks that have completed along with performance statistics collected from running the task (duration and memory usage) and the task output to stdout and/or stderr.

i Both files are written to the job directory that you provide using the `--job-dir` command line option when submitting your job, or to the default job directory `$HOME/nitro/<jobid>`.

Job Log

To see job status using `nitrostat`, you will need the job ID. The job ID is the job ID reported to you when you submitted the job to the scheduler *or* that you set manually via the `--job-id` command line option in the `NITRO_OPTIONS` environment variable or via the `NITROJOBID` environment variable.

- The default location for the job and task logs are in your "`$HOME/nitro/<jobID>`" directory.
- You can also use the "`--job-dir`" command line option to specify a different job directory if you are not using the default location.

Nitro Job Progress Report

The Nitro job progress reports lets you see the current contents of a job log file.

For example, let's say you have a job that was run by your resource manager as job "23576", running "`/opt/nitro/bin/nitrostat 23576`" shows you the job's progress.

```

Nitro Job Progress Report

Start Time   : 2016-02-10 09:10:11-0600
Current Time : 2016-02-10 09:10:42-0600
Elapsed Time : 31 seconds (00:00:31)

Job Id       : 23576
Coordinator  : node01
  Load Pct   : 5.6%
Task Log     : /home/jdoe/jobs/23576/nitro_23576.tasklog.txt

0       9.3     27.0

```

The following describes the fields and their output descriptions.

- **Start Time** – Date and time the coordinator started running.
- **Current Time** – Current date and time the report was generated (reports are generated every 5 seconds).
- **Elapsed Time** – Amount of time the coordinator has been working on the tasks.
- **Job Id** – Job ID that Nitro was passed on its command line. Typically assigned by the resource manager, but can be assigned by the user.
- **Coordinator** – Host name on which the coordinator is running.
- **Load Pct** – Percentage of coordinator load capacity.
- **Task Log** – Path and file name of the task log file that is generated by the coordinator.
- **Task File** – Path and file name of the task file.
- **File Size** – File size of the task file.
- **Est Tasks** – Number of tasks the coordinator estimates in the task file. Since Nitro doesn't read the entire task file on startup, an estimate is given based on lines read from the file so far.
- **Processed** – Percentage of the task file that has been read by the coordinator.

- **Tasks Section:** Lists the counts of tasks in each category
 - Pending – Number of tasks that have been put into assignments and are waiting to be sent to a worker.
 - In Progress– Number of tasks in assignments sent to the workers for which workers have not yet returned results.
 - Completed – Number of tasks in assignments that have been completed (workers have returned results).
 - Success – Number of completed tasks that were successful (the task returned an exit code of 0).
 - Failure – Number of completed tasks that returned an exit code other than 0.
 - InsufRes – Number of tasks that could not be run because the requested resources for the task were not available.
 - Timeout – Number of completed tasks that ran longer than the task "maxtime" parameter and were terminated by the worker.
 - Invalid – Number of task definitions that contained errors and could not be run.
 - Tasks/sec – Number of tasks per second based on the time that the coordinator sends the first assignment until the time the report is generated. If in *linger mode*, this will only be calculated for the last 60 seconds.
 - Total Tasks – Total number of tasks including completed and invalid tasks.
- **Workers Section:** List by worker
 - Host – Host name and port (if not the default port) of the worker.
 - Pid – Process ID of the worker.
 - Thrds –Number of task launch threads the worker is using to run tasks.
 - Status – Status of the worker. This may be "unconnected", "running", "unresponsive", "closing", or "closed".
 - Assigned – Number of tasks assigned to this worker so far.
 - Running – Number of tasks in assignments currently allocated to the worker.
 - Completed – Number of tasks in assignments the worker has completed.
 - Success – Number of successfully completed tasks.
 - Failure – Number of tasks that returned an exit code other than 0.
 - InsufRes – Number of tasks that could not be run because the requested resources for the task were not available.
 - Timeout – Number of tasks that exceeded the tasks "maxtime" threshold and were terminated by the worker.
 - Tasks/sec – Number of tasks per second that the worker has completed so far. In

linger mode this is only calculated for the last 60 seconds.

- AsgmtDur – Average assignment duration in seconds.

Job Completed Report

Once the job has completed, the job report will show "(final)" on the end of the first line of the report and Current Time is replaced with Finish Time (after Start Time). The following example is based on the previous example for job "23576" .

```
Nitro Job Progress Report (final)

Start Time   : 2016-02-10 09:10:11-0600
Finish Time  : 2016-02-10 09:11:36-0600
Elapsed Time : 85 seconds (00:01:25)

Job Id       : 23576

```

Task Log

The task log file contains a listing of all tasks that have been completed and some statistics about the tasks duration and memory consumption. This file is named `nitro_<JobID>.tasklog.txt` and is located in the same directory as the job log file.

The task log file is tab-delimited, so you can easily import it into a spreadsheet or database, or process it using another program. You can also view the task log using the `nitrostat` utility.

JobID	TaskID	Line	Name	Status	ExitCode	Hostname	StartTime
		Duration	UserCPU	SystemCPU	VirtualMem	PhysicalMem	Labels
Output							
foo	1	1	task001	Success	0	localhost:10004	2015-06-18_
15:26:52.954-0600		1.005	0.000	0.000	0.000	7364608	630784
foo,foobar,foobaz,xyz							
foo	2	2	task002	Success	0	localhost:10004	2015-06-18_
15:26:52.954-0600			1.007	0.000	0.000	87834368	630784 foo,foobar,xyz

15:26:58.994-0600			1.004	0.000	0.000	405946368	626688

The task log contains the following fields.

- JobID – Job ID that was passed to Nitro using the "--job-id" command line option.
- TaskID – Task number within the Nitro job.
- Line – Line number in the task file of the task definition.

- Name – Task name supplied in the task definition by the "name=<name>" option.
- Status – One of "Success", "Failure", "InsufRes", "Timeout", or "Invalid".
- ExitCode – Numerical exit code returned by the task.
- Hostname – Name of the worker that executed the task.
- StartTime – Date and time the worker actually started the task.
- Duration – Number of seconds the task ran (millisecond resolution).
- UserCPU – Number of seconds the task ran in user mode (millisecond resolution).
- SystemCPU – Number of seconds the task run system calls (millisecond resolution).
- VirtualMem – Maximum virtual memory allocated to the task in bytes.

 The operating system may allocate shared memory and may charge a proportion of this shared memory to random tasks.

- PhysicalMem – Maximum physical memory allocated to the task in bytes.
- Labels – Optional task labels specified by the task definition.
- Output – stdout and/or stderr. If a task outputs to both stdout and stderr, both are displayed in the format <stdout>/<stderr>.

nitrosub Command

The nitrosub command lets users easily submit Nitro jobs without having to create their own user job scripts; thereby not requiring the users to modify bash shell scripts. The nitrosub command is designed to submit static or dynamic Nitro jobs.

This topic provides information on the nitrosub command and what system administrators need to do to configure the command for their system.

In this topic:

- [Modify the nitrosub Command for your System on page 81](#)
- [Command Parameters on page 82](#)

Modify the nitrosub Command for your System

When Nitro is first installed, system administrators need to modify the `bin/nitrosub` script for their specific resource manager and licensing model. Specifically,

1. Uncomment the "`_resource_manager`" line for your resource manager
2. Uncomment the "`resource_type`" line for your licensing model's allocation (nodes or cores).
3. If your system will be using dynamic jobs, set the "`_dynamic_size`" value to the number of resources to allocate to a dynamic job.

Command Parameters

The following table describes the parameters for the nitrosub command and how they affect a Nitro job submission.

 The terms "node" and "processor" are mutually-exclusive.

Parameter	Required	Description	Syntax
Environment Variables	No	Passes environment variables to Nitro via by the job scheduler and/or resource manager. Users may specify multiple environment variable names using a comma-delimited list (square brackets indicate optional additional environment variable names).	<code>--env-var=xxx=nnn</code> <code>[,yyy=mmm</code> <code>[,zzz=ooo]]</code>
Job Directory Path	No	Sets the directory path the user desires the Nitro job to use for recording job information. This parameter is required for a Nitro job restart when a user or administrator cancels an executing Nitro job and must have the job directory value of the canceled Nitro job. When not set, it is the default job directory Nitro creates. The directory path <i>must</i> be accessible from a compute node and the job submission node.	<code>--job-dir=xxx</code>
Job ID	No	Sets the job ID the user desires to give the job. This parameter is required for a Nitro job restart when a user or administrator cancels an executing Nitro job and must have the job id value of the canceled Nitro job. When not set, it is the default job ID Nitro creates.	<code>--job-id=xxx</code>
Local Worker	No	Indicates whether the Nitro coordinator should start a local worker on its resources. The default is <code>--local-worker</code> .	<code>--local-worker</code> <code>--no-local-worker</code>
Resources	Yes	Indicates the number of hosts (compute nodes/servers) or hardware cores/threads to be allocated to the Nitro job by the scheduler. <ul style="list-style-type: none"> • If for a static Nitro job, the quantity value (nn) is a positive decimal integer. • If for a dynamic Nitro job, the quantity range values (mm-nn) are positive decimal integers and "mm" must be less than "nn". 	<code>--resources=nn</code> <code>--resources=mm-nn</code>

Parameter	Required	Description	Syntax
Task File Path	Yes	Specifies the path of the Nitro task file created by the user. This path <i>must</i> be accessible from a compute node	--task-file=xxx
Wall Time	Yes	Specifies the time limit for the Nitro job's execution. The parameter's "xxx" value format depends on the job scheduler used.	--wall-time=xxx

Command Line Flags, or Options, and Positional Parameters

This topic identifies the individual command line flags, or options, and positional parameters recognized and/or required by Nitro.

In this topic:

- [Flags on page 83](#)
- [Options on page 84](#)
- [Positional Parameters on page 86](#)
- [Command Line Options per Nitro Mode on page 87](#)

Flags

- **Disable Affinity** – Instructs a worker that it should not track and set the task's affinity.

 This option overrides --disable-affinity in the nitro.cfg file.

```
--disable-affinity
```

- **Linger** – Tells Nitro to keep running after the initial tasks have completed. The `<timeout>` specifies the number of seconds that must pass after the last completed task before Nitro closes (shuts down). A `<timeout>` value of -1 indicates an indefinite period of time; Nitro will not close until a signal is given to close.

```
--linger <timeout>
```

- **Run Local Worker** – Runs a local worker on the coordinator's node.

```
--run-local-worker
```

- **Trust Workers** – Allows any worker to attach to Nitro and accept workload. Without this flag, the coordinator will only connect workers that were specified with the `--workers`,

--workers-file, --key, or --key-file command line option.

```
--trust-workers
```

Options

- **Mode** – Required command line parameter that indicates the role (coord/worker) of Nitro when started on a node.

```
--mode=[coord | worker]
```

- **Coordinator Host** – Specifies the coordinator to connect to when Nitro is running in worker mode (--mode=worker).

```
--coord <HOST[:PORT]>
```

- **Session Key** – Specifies a session key that can be used to authenticate workers to the coordinator. The session key must be provided on the workers and coordinator command lines. Any worker reporting in to the coordinator will be required to provide this key to be able to connect and receive workload. The session key is any string that does not contain spaces or any characters which the shell will interpret.

```
--key <keyvalue>
```

- **Key File** – File containing a passphrase that can be used to authenticate workers to a coordinator. If the file contains newline or tab characters, these will be removed from the passphrase.

```
--key-file <file>
```

- **Worker Hosts** – "+"-separated list of the host names of the worker hosts the job scheduler allocated to the Nitro job for its exclusive use.

```
--workers <hostlist>
```

- **Worker Hosts File** – File containing a list of the host names, one per line, the job scheduler allocated to the Nitro job for its exclusive use.

```
--workers-file <filename>
```

- **Name** – Name the worker uses to reference itself when communicating with the coordinator. For the coordinator, this is the name to which the workers will connect. If not specified, Nitro defaults to the node's host name.

i The name supplied to the coordinator via --workers or --workers-file must match --name. If using --trust-workers, --key, or --key-file, any unique value can be used for --name. Workers' names must be unique within a coordinator group.

```
--name <name>
```

- **Port Base** – Base port number for port assignments (default 47000); used to override first port assignment by Nitro process. Valid range of ports is 47000-65535.

Each Nitro coordinator process requires four ports. A coordinator process will bind a range of four ports starting with the start port specified by this option as the starting point for port assignments.

```
-p <port>
--port1 <port>
```

- **Port File** – File name that the coordinator should use to contain the first port number used by the coordinator. This also indicates that the coordinator should do a port search to find the first set of available ports. If the coordinator cannot find an available port, and when the coordinator closes, "closed" will be written to the file so that workers being started after the coordinator has closed can immediately close.

The file name argument is optional, and if not specified, defaults to a file in the job directory named ".coord_<job id>.port". If supplied, the file name argument must be in the form --arg=<value>, not --arg <value> (with a space between).

```
--port-file=[<file_name>]
```

- **Thread Count** – The quantity of threads the Nitro workers should use when executing tasks. This option is mutually-exclusive with the Thread Ratio option.

If this option and the Thread Ratio option are not given, a worker uses one task launch thread per OS core to which it is pinned.

The primary reason for this option is to explicitly specify a task-launch thread count for Nitro running a specific single application, usually on homogeneous nodes.

```
--thread-count <num>
```

- **Thread Ratio** – The ratio of task launch threads-to-OS "cores" the Nitro workers should use when creating task launch threads. This option is mutually exclusive with the Thread Count option.

If this option and the Thread Count option are not given, the ratio is "1.0", meaning a worker uses one task launch thread per OS core to which it is pinned.

Ratio is a positive real number (e.g., 1.5, 0.5, etc) that when multiplied with the count of OS cores to which a worker is pinned yields a count of the task launch threads it will use. The worker rounds the count to the nearest integer, with a minimum value of 1.

The primary reason for this option is to allow a user to over-subscribe or under-subscribe the task-launch thread count appropriately relative to the OS core count of heterogeneous nodes (e.g., 1.5 means 6 threads for a quad-core node and 24 threads for a 16-core node).

```
--thread-ratio <ratio>
```

- **Assignment Size** – The quantity of tasks the Nitro coordinator should pass to a Nitro worker

at one time; default is 350, maximum value is 1000. Alternatively, you can specify an assignment size of 0; allowing the coordinator to automatically determine the assignment size based on the assignment duration.

 This option overrides the `--assignment-size` setting in the `nitro.cfg` file.

```
--assignment-size <num>
```

- **Job Directory** – Specifies the path for the directory where Nitro will place its Job Progress Log and Completed Task Log files.

```
--job-dir <path>
```

- **Job ID** – Specifies the job ID for a specific Nitro run. The job ID may be used to create the job directory and certain file paths.

```
--job-id <jobID>
```

- **Coordinator Threads** – Indicates to the coordinator how many threads to reserve for the coordinator when allocating cores to a local worker (when using "`--run-local-worker`" on the coordinator command line). Default is 2. Adaptive Computing recommends setting the `<count>` value to 1 if all jobs will use less than 20 nodes and setting the `<count>` value to 4 if the jobs require a large number of nodes (greater than 50) to run.

 This option overrides the `--coord-threads` setting in the `nitro.cfg` file.

```
--coord-threads <count>
```

- **Task Environment** – Specifies the environment variables to set in the task's execution environment. This is used by the worker but is also needed on the coordinator's command line if running a local worker. Multiple values can be specified by separating name/value pairs with a comma.

```
--task-env <ENVVARIABLE=value[,...]>
```

- **Debug Log File** – The path for the optional "debug log" file the Nitro coordinator can produce. If the path is not defined, the coordinator will use the default path `$NITROJOBDIR/nitro_${NITROJOBID}-hostname_pid.log`.

```
--logfile <path>
```

- **Debug Log Level** – The level of debug log information the Nitro coordinator will output when tracing/logging. The default is "3" (information). The highest level allowed is "7" (debug).

```
--loglevel <num>
```

Positional Parameters

- **Task File Name** – Path of text file containing Nitro task definitions. This must be the last parameter on the coordinator's command line.

`path`

Command Line Options per Nitro Mode

The table that follows identifies which command line options Nitro uses in worker or coordinator mode. Some command line options are used in both modes and are listed in this table in the "Both" row.

Nitro Mode	Command Line Option
Coordinator	<div>--assignment-size --coord-threads (if using --run-local-worker with the coordinator) --port1 --run-local-worker --trust-workers --workers --workers-file --key-file</div>
Worker	<div>--coord --disable-affinity (if <i>not</i> using --run-local-worker with the coordinator) --name --task-env (if <i>not</i> using --run-local-worker with the coordinator) --thread-count (if <i>not</i> using --run-local-worker with the coordinator) --thread-ratio (if <i>not</i> using --run-local-worker with the coordinator)</div>
Both	<div>--disable-affinity (if using --run-local-worker with the coordinator) --job-dir --job-id --key --linger --logfile --loglevel --mode --port-file --task-env (if using --run-local-worker with the coordinator) --thread-count (if using --run-local-worker with the coordinator) --thread-ratio (if using --run-local-worker with the coordinator)</div>

Environment Variables

This topic provides information on the Task Execution environment variables available to customize Nitro's operation.

Valid environment variables:

- `$NITROJOBID` – Job ID of the Nitro job.
- `$NITROJOBDIR` – Job directory to which Nitro writes log files. This directory can be used to store output files from your tasks.
- `$NITROTASKCORES` – Number of cores allocated to the task.
- `$NITROTASKID` – Task ID of the task. The task ID is a number that starts at 1 and increments by 1 for each task definition (valid or invalid) in the task file. Commented and empty lines are not counted; if the task file contains such, the task ID and the line number will diverge.
- `$NITROTASKMEMORY` – Amount of memory (in MB) allocated to the task.
- `$NITROTASKNAME` – Task name, if provided by the task definition.
- `$NITROTASKTIME` – Task time limit, specified by "maxtime" in the task definition.
- `$NITRO_TASK_FILE` – Can be used with normal file names that do not use spaces, but **MUST** be used if the user submits more than one task file.
- `$NITRO_LONG_TASK_FILE` - Can be used with normal file names that do contain spaces, but **MUST** be used if the file name contains spaces. This variable can only contain one file name. You cannot submit multiple file names containing spaces.

Job Scripts

This topic provides information about the different job scripts, including customization options (where applicable).

In this topic

- [Nitro Job Script on page 88](#)
- [Worker Job Script on page 89](#)
- [Moab/Torque Customization Commands and Options on page 89](#)

Nitro Job Script

The `nitro_job.sh` script is located in the `/opt/nitro/etc/` directory.

Typically the `nitro_job.sh` script is customized by the system administrator and executed by the `nitrosub` command. This job script is used for static jobs, if resources are not in a range. For dynamic jobs, it sets up the initial resource request (minimum resource value in the range).

Alternatively, the system administrators can modify the `nitro_job.sh` script and then have authorized users copy and customize the script for their task file. This script is then executed using the resource manager's job submission command (for example, Torque's `qsub`). This functionality is similar to the Nitro functionality prior to version 2.1.

The `nitro_job.sh` script:

- Defines path to your task file (`NITRO_TASK_FILE`)
- Defines the directory to which Nitro writes log files (`NITROJOBDIR`). This directory can be used to store output files from your tasks.
- Executes the `launch_nitro.sh` script (last line in the script)

In the `nitro_job.sh` script, you can also customize the `launch_nitro.sh` script.

- `NITROJOBID` – Job ID used by Nitro. If not provided, this ID is based on the resource manager's job ID.

Unless you are restarting a job that partially completed and was canceled, you don't need to set this environment variable. If you specify this environment variable in the job's submission, it will override the resource manager job ID and Nitro will use the value you supplied.

i If your job scheduler and resource manager use different numbering systems, the job ID that Nitro will use is the one that it gets from the resource manager. You may want to submit the job directly to the resource manager in this case to avoid confusion. Check with your system administrator to find out if your job scheduler's and resource manager's job ids are synchronized.

- Command line options – Any command line options you want passed to the `launch_nitro.sh` script must be contained in the `NITRO_OPTIONS`, `NITRO_COORD_OPTIONS`, or `NITRO_WORKER_OPTIONS` environment variables. See [Command Line Flags, or Options, and Positional Parameters on page 83](#) or [Environment Variables on page 87](#) for more information.

Worker Job Script

The `worker_job.sh` script is located in the `/opt/nitro/etc/` directory.

The `worker_job.sh` script is executed *only* by the `nitrosub` command. This job script is used for the dynamic portion of dynamic jobs (resources after the initial request up to the maximum value).

- Defines the job ID for the coordinator set up by the `nitro_job.sh` script for the first part of the dynamic job submission (`NITROJOBID`).
- Defines the directory to which Nitro writes log files (`NITROJOBDIR`). This directory can be used to store output files from your tasks.
- Executes the `launch_worker.sh` script (last line in the script).

Moab/Torque Customization Commands and Options

If using Moab/Torque, be aware of the following:

- Nitro will consume all available OS cores on the nodes on which it runs. However, if the jobs are using the cgroups functionality (provided by the resource manager), then the coordinator and worker will *only* see as many cores as are in the cgroup.
 - If Nitro is running exclusively on nodes, you may want to configure your system to run a single job per node (for example, in Moab, set NODEACCESSPOLICY to SINGLEJOB in the moab.cfg file or during job submission).
 - If you will run other workload on the system that may run multiple jobs per node, you will need to provide a script or instruct users on how to specify their Nitro jobs to run with a single task per node configuration. In Moab and Torque the jobs should be submitted (using either msub or qsub) with the "-l nodes=<node count>:tpn=1" command line option.

Example: Setting Environment Variables at Job Submission

The "-v" option in Moab's msub command sets environment variables before calling the user job script. The user job script inherits these environment variables.

i The user job script can add to or overwrite any environment variable defined in msub's "-v" option.

- User job script (/home/jdoe/user_job_script.sh)

This script must exist on the node where you execute the msub command. In this example, this user job script exists in jdoe's home directory.

```
exec /opt/nitro/bin/launch_nitro.sh
```

- msub example

```
msub -lnodes=5 -ltpn=1 -lwalltime=600 -v "NITRO_TASK_FILE=/home/jdoe/nitro/monte_sim.txt,NITRO_OPTIONS=--job-dir /home/jdoe/monte01,NITRO_COORD_OPTIONS=--run-local-worker" /home/jdoe/user_job_script.sh
```

- The task file monte_sim.txt contains the list of task command lines that you want to execute.
- The "--job-dir" sets the path to which Nitro will write the job and task logs.
- The last parameter is the path of the user job script.

Example: Setting Environment Variables In the User Job Script

- User job script (/home/jdoe/user_job_script.sh)

This script must exist on the node where you execute the msub command. In this example, this user job script exists in jdoe's home directory.

```
NITRO_TASK_FILE=/home/jdoe/nitro/monte_sim.txt
NITRO_OPTIONS="--job-dir /home/jdoe/monte01"
NITRO_COORD_OPTIONS=--run-local-worker
exec /opt/nitro/bin/launch_nitro.sh
```

- **msub example**

```
msub -lnodes=5 -ltpn=1 -lwalltime=600 /home/jdoe/user_job_script.sh
```

- The task file `monte_sim.txt` contains the list of task command lines that you want to execute.
- The `--job-dir` sets the path to which Nitro will write the job and task logs.
- The last parameter is the path of the user job script.
- `NITRO_TASK_FILE`, `NITRO_OPTIONS` and `NITRO_COORD_OPTIONS` are set in the user job script.

Related Topics

- [Launch Scripts on page 91](#)

Launch Scripts

Nitro comes packaged with a `launch_nitro.sh` and a `launch_worker.sh` script for Torque, SLURM, LSF, and Cray resource managers or environments. If you use another resource manager, you may need to build the scripts.

There are several basic points that *each* launch script needs to cover to interface the resource manager with Nitro.

1. Getting the resource manager job ID and passing it to Nitro. See [Resource Manager Job ID on page 91](#).
2. Specifying the location of the Nitro binary. See [Location of the Nitro Binary on page 91](#).
3. Getting the list of nodes that Nitro is to run on for the current job. See [List of Job Nodes on page 92](#).
4. Launching the Nitro workers and coordinator. [Launch Nitro Workers and Coordinator on page 92](#).
5. Customize the command line parameters of workers and/or coordinator. See [Customize Command Line Parameters on page 92](#).

Resource Manager Job ID

Nitro uses the job ID to customize the output files so if several copies of Nitro are running at the same time they don't corrupt each other's information. Torque, for example, defines the `$PBS_JOBID` environment variable that contains a job ID as defined by Torque.

The provided launch scripts add the `--job-id <job id>` parameter to Nitro's command line parameters (to the workers and the coordinator) if a job ID is provided, or if no job ID is found, then it defaults to a job ID with the format "YYYYMMDDHHMMSS" containing the date and time the Nitro launch script runs.

Location of the Nitro Binary

The launch scripts assume the Nitro binary will be found in the `/opt/nitro/bin` directory. This requires that Nitro has been installed all the nodes, or that the `/opt/nitro` directory has been mapped to a remote file system.

If you have installed Nitro to a directory other than the default, you need to customize the launch scripts with this location. For example, if you installed Nitro to `/mysharedfs/nitro`, you need to change the line of the launch scripts

from

```
NITRO=/opt/nitro/bin/nitro
```

to

```
NITRO=/mysharedfs/nitro/bin/nitro
```

List of Job Nodes

Resource managers typically have an environment variable set with the list of nodes allocated to the job. In Torque, this environment variable is "`$PBS_NODEFILE`" and contains the file that is accessible to the job containing the list of nodes allocated to the job.

The file containing the list of nodes is typically a file with a single node name per line, such as:

```
node01
node02
node03
```

Launch Nitro Workers and Coordinator

The launch scripts need to include the resource manager's remote command in order to set up the workers and the coordinator.

- Torque uses the "`pbsdsh`" command.
- SLURM uses the "`srun`" command.
- LSF uses the "`blaunch`" command.
- Cray systems use the "`aprun`" command.

Please refer to your resource manager's documentation for instructions and options to run the remote command.

For static and dynamic jobs, when executing the `launch_nitro.sh` script, the workers are started first and the coordinator will be executed last using "`exec`". This is so the coordinator gains control of the process. The `launch_nitro.sh` script currently uses (and assumes) the first node in the node list is the coordinator and all other nodes are workers.

In addition, for dynamic jobs, the `launch_worker.sh` script is executed to add one or more workers to the coordinator that was executed by the `launch_nitro.sh` script.

Customize Command Line Parameters

The system administrator may customize the Nitro launch script to suit the needs of the system. The launch scripts may examine and modify, or simply pass through, the command line options specified by the environment variables set by the `nitro_job.sh` and/or `worker.job.sh` scripts. The

command line options are then passed via the environment variables to the Nitro workers and coordinator that are started by the launch scripts.

If you want to add command line parameters to Nitro, the best way is to prepend the option to the beginning of either the `NITRO_OPTIONS`, `NITRO_COORD_OPTIONS`, or `NITRO_WORKER_OPTIONS` environment variable(s), as appropriate. See [Command Line Flags, or Options, and Positional Parameters on page 83](#) for more information.

For example, if all of your user's jobs are expected to use less than 20 nodes, you may want to add the option to run a local worker on the coordinator node to maximize task throughput. If you add this option to the `launch_nitro.sh` script, it reduces the parameters necessary to configure the `nitro_job.sh` script. Alternatively, you can add the `--run-local-worker` flag to the `NITRO_COORD_OPTIONS` environment variable in the `nitro_job.sh` script (if using the `nitrosub` command). If your configuration allows users to submit jobs using the resource manager's job submission command (such as Torque's `qsub`), those users can either add this flag to their customized `nitro_job.sh` script (saved in their work directory) or add this flag at job submission.

To add the `--run-local-worker` flag to the coordinator command line, add the following line to the `launch_nitro.sh` script after the line containing the `NITRO_OPTIONS`.

```
NITRO_OPTIONS="--job-id ${NITROJOBID} ${NITRO_OPTIONS}"
NITRO_COORD_OPTIONS="--run-local-worker ${NITRO_COORD_OPTIONS}"
```

The `launch_worker.sh` script must be congruent with the `launch_nitro.sh` script.

Task File

A task file contains a list of Nitro task definitions (task execution options) along with the task command line Nitro will execute. Since the Nitro coordinator will be running on one of the nodes allocated to the Nitro job, the task file must be accessible to the node on which the coordinator will run.

The task file is a text file where each task definition must be contained on a single line. Lines of text may be terminated by either a Linux-style line ending (LF or '\n' new line character) or a Windows-style line ending (CR/LF - '\r\n' carriage return/line feed combination). The line number is reported in the task log so that errors in the task file can be quickly located and fixed.

The task file allows comment and empty lines. A hash symbol (#) in the first column of a line identifies a comment line.

Each task will be assigned a task ID, which will start at 1 and increment with each task line (comment and empty lines are not assigned a task ID). This task ID is passed to the task in the `NITROTASKID` environment variable.

Task Options

Task options are name/value pairs that are listed before the task's command line of the form `"<option>=<value>"`. Task options must be specified *before* the task's command line to be executed. As Nitro parses the line, it will stop looking for name/value pairs as soon as it finds a character string that does not include the name/value delimiter (=) or is the `"cmd"` option. Everything after the `"cmd="` option or the first string that is not delimited as a name/value pair will be considered part of the task command line.

Task definitions that contain errors (such as a misspelled option) are considered "invalid" tasks and will be reported in the task log along with an explanation of the error in the line. Examples of valid command lines are as follows:

```
# Commented line
/opt/framemaker/bin/assemble_frame --input /shared/scene23.def --time-index 0
cmd=/opt/framemaker/bin/assemble_frame --input /shared/scene23.def --time-index 0

name=Scene23Time0 /opt/framemaker/bin/assemble_frame --input /shared/scene23.def --
time-index 0
name=Scene23Time0 maxtime=30 cmd=/opt/framemaker/bin/assemble_frame --input
/shared/scene23.def --time-index 0
```

The following describes the various task options.

- **Application Command** – The coordinator considers everything immediately after the equal sign (= in "cmd=") as the task's "application" command line, which a worker will execute. There must be at least one non-whitespace character immediately after the "=" or the coordinator declares the task definition invalid. The application command line permits standard I/O redirection and environment variable substitution.

```
cmd=<xxx -y zzz>
```

Do not place any task options after the command line or the coordinator will not parse them; assumes they are part of the command line.

- **Labels** – Specifies the labels assigned to a task.

This is optional and there is no default value.

If given, a label must be composed of letters, digits, underscore, hyphen, and/or period. Use a comma to separate multiple labels.

If the option's value violates the conditions above, the coordinator will declare the task definition invalid and will not send the task to a worker.

When the coordinator logs the task in the Completed Tasks Log file, it outputs this option's value "as is", meaning without alteration and with no substitution of spaces for commas.

```
labels=<list>
```

- **Maximum Time** – Maximum time (in seconds) a task may execute after which the worker will terminate it. This is optional; the default value is 3,600 seconds (1 hour).

If given, the value must be less than the `maxtime-limit <period>` value. See [Nitro Configuration File on page 64](#) for more information on the `maxtime-limit` configuration option.

If the option's value is non-numeric, non-decimal, or outside the allowed range, the coordinator will declare the task definition invalid and will not send the task to a worker.

```
maxtime=<nn>
```

- **Name** – Unique name assigned to your task definition. Task names do not have to be

unique, but creating a unique task name will help to identify tasks.

```
name=<task name>
```

- **Task Cores** – Number of OS cores that the task requires. Nitro will allocate the number of cores requested and set the affinity of the task to the available cores.

```
cores=<count>
```

The command line options "--thread-count" or "--thread-ratio" affect the number of available cores. If you use either of these options and they specify more cores than the node has available, Nitro will not pin the task to a specific core. If a task is specified to require more cores than the node that receives the task assignment, the task will not run.

Users should submit their jobs so that tasks can run on any of the nodes that are allocated to the job. If, for example, you have some tasks that require 20 processors, but there are some 16 core nodes in the cluster, the job should be submitted so that it only allows 20 proc nodes to be allocated to the job. If a Nitro worker is assigned a job with requirements that it cannot fulfill (either too many cores, or too much memory) the task will be counted as failed, and Nitro will show the status of "InsufRes" for that task in the task log file.

- **Task Environment Variables** – Specifies a list of user supplied environment variables that will be set in the context of the task. The list of environment variables can be one or more name/value pairs separated by commas. Environment variable name value pairs cannot contain spaces.

```
env=<name=value>[, <name=value>, ...]
```

- **Task Memory** – Maximum amount of memory that the task requires. Nitro determines the amount of physical memory available on the system and uses this number as the limit that can be allocated by concurrent tasks. If no units are specified, GB is assumed. Available unit specifications include "GB" (10⁹ bytes), "GiB" (2³⁰ bytes), "MB" (10⁶ bytes), and "MiB" (2²⁰ bytes). Nitro uses MB units in debug logs.

```
memory=<amount>
```

Users should submit their jobs so that tasks can run on any of the nodes that are allocated to the job. If, for example, you have some tasks that require 32 GB, but there are some 16 GB nodes in the cluster, the job should be submitted so that it only allows 32 GB nodes to be allocated to the job. If a Nitro worker is assigned a job with requirements that it cannot fulfill (either too many cores, or too much memory) the task will be counted as failed, and Nitro will show the status of "InsufRes" for that task in the task log file.

- **Task Shell** – Specifies the task shell, if any, to use. Tasks are normally executed by running

`"/bin/bash -c <task command line>".`

```
shell=[default | none | <shell path>]
```

- The default shell provides translation of environment variables into command line options and other command line processing benefits.
- In high-throughput environments performance gains can be realized by using a lighter weight shell such as the Bourne shell or Korn shell.
- If no command line processing is needed, the task can be run without a shell.
- Executing a task directly instead of using the shell can speed task invocation by more than 50% over the default shell.

When specifying a shell other than the default shell, the fully qualified path should be used. For example, if you want to use the Bourne shell you should specify the shell as `"/bin/sh"` as opposed to just `"sh"`.

nitrostat

`nitrostat` is a utility found in the `/opt/nitro/bin` directory that will display the status of a Nitro job or of individual tasks. `nitrostat` lets you quickly find specific tasks or list all failed, invalid, or timed out tasks. `nitrostat` also offers a "wait" mode that will monitor the task log for tasks matching the specified criteria until the job completes.

Running nitrostat

To run `nitrostat`, you'll need to know the job ID of the job you want to monitor. For example, if you have a job with ID "3145", you can monitor the job progress with the following command:

```
/opt/nitro/bin/nitrostat 3145 -w
```

`nitrostat` assumes that the job information can be found in `$HOME/nitro/<job id>`.

If you have specified a different location for the job directory using the Nitro `--job-dir` command line option, then you'll need to specify the same location using the `nitrostat --job-dir` command line option.

For example, if your job directory is in `$HOME/projects/survey03` then use the following command:

```
/opt/nitro/bin/nitrostat 3145 --job-dir $HOME/projects/survey03 -w
```

`nitrostat` will show the following information when job status is requested:

Nitro Job Progress Report

```

Start Time   : 2015-06-17 09:10:11-0600
Current Time : 2015-06-17 09:10:42-0600
Elapsed Time : 31 seconds (00:00:31)

```

```

Searching for Task Records

You can use `nitrostat` to search the task log by task name, task ID, or label using regular expressions. You can also combine criteria to further refine your search.

For example, if you want to search for tasks containing the task name "Survey03" and the label "NYC" you can specify the command line as follows:

```
/opt/nitro/bin/nitrostat Job01 --name Survey03 --label NYC
```

The following identifies the `nitrostat` command line options.

- `--all, -a` – Shows all tasks.
- `--completed, -c` – Shows completed tasks.
- `--failed, -f` – Shows failed tasks.
- `--invalid, -i` – Shows invalid tasks.
- `--timedout, -o` – Shows tasks that timed out (exceeded `maxtime`).
- `--wait, -w` – Continues updating results until entire job is completed.
- `--name, -n <task name>` – Shows task(s) with the specified task name.
- `--task, -t <task id>` – Shows the task with the specified task ID.

- `--label, -l <label list>` – Shows all tasks that contain the specified label. *<label list>* is a comma-separated list of labels that may *not* contain spaces.
- `--working-dir, -d <directory>` — Uses the specified working directory to locate the job and task log files. The default working directory is `$HOME/nitro`.
- `--regex` – If set, uses regular expression as the matching mode for *<task name>*, *<task id>*, and *<label list>*. The default is literal (exact string).

Job Recovery

Jobs run under a scheduler can, depending on job priority and settings, be preempted by a higher priority job, or even canceled by the user or administrator, or may fail due to hardware failure. Depending on the scheduler's configuration, a preempted job may be restarted later by the scheduler using the same job ID as the original job.

The job ID is the key to recovering jobs since Nitro uses the job ID as part of the path to the files associated with that job. Nitro tracks its progress by storing a checkpoint file that indicates which tasks have been completed and which have not. When Nitro is restarted, it looks for a checkpoint file and will continue from where it left off if one is found. If a job was canceled or preempted without a restart policy, then you will need to restart the job manually. Again, the key to restarting the job is to use the job ID of the original job.

The job ID is usually the ID that was returned when the job was submitted. There can be some differences between the scheduler's job ID and the resource manager's job ID depending on scheduler and resource manager settings. When you submitted your Nitro job, you may have set a Nitro job directory. If you didn't, it defaults to `$HOME/nitro/<jobid>`. This directory will contain the job log and task log files, along with checkpoint and Nitro log files. You can therefore use the directory name that Nitro created as the job directory with which to resubmit the job by passing the `--job-dir` option with the directory name through the `NITRO_OPTIONS` environment variable.

To restart the job you must set the `NITROJOBID` environment variable to the original job ID. Setting this environment variable will override the job ID provided by the resource manager and Nitro will resume from the line number of the task file described in the checkpoint file.

The checkpoint file is updated periodically when assignments are completed by workers and are returned to the coordinator. If a job is canceled, the workers will do their best to respond to the coordinator with the tasks that have been completed so far, but depending on how quickly the resource manager forces the applications to close, the checkpoint file may or may not be fully updated. Therefore, it is possible that restarting a job will result in a particular task or set of tasks being run a second time. Users should take this into account and program their tasks so that if running the task a second time would cause a problem, transactions are recorded by the task that would prevent the second run.

If a job is canceled for reasons of task failure (for example, because of a typo in the task command line), you may want to submit the job as a new job instead of trying to resume the job with failed tasks.

Failed and invalid tasks are marked as complete in the checkpoint file; they won't be re-run if the job is just restarted.

Coordinator Resiliency

Nitro has the ability to detect workers that have become unresponsive due to hardware, network, or software failure. During normal operation, workers periodically send an update to the coordinator. If the coordinator doesn't receive a status update after 45 seconds, the worker is deemed to be unresponsive, and any outstanding assignments will be revoked and reassigned to responsive workers. However, if the worker reports back to the coordinator before the assignment has been assigned to another worker, the assignment will be recovered and completed by that originally-assigned worker.

Dynamic Workload

This topic identifies activities pertaining to dynamic workload.

Nitro jobs are flexible in the number of resources they can use to accomplish the tasks given them. Worker nodes can be added to a job or taken away without any adverse consequences (other than the job running more slowly). You can also add workload by appending the task file.

In this topic:

- [Removing Worker Nodes on page 99](#)
- [Adding Worker Nodes to a Running Job on page 99](#)
- [Linger Mode on page 99](#)

Removing Worker Nodes

If nodes are needed for a more important task, the workers can be killed, and their assignments will be returned to the coordinator.

i Killing the worker with a SIGTERM signal will allow the worker to send a partial assignment completion report to the coordinator. Be aware that if a worker is killed, the tasks that are running, may be run again when the assignment is given to a different worker to complete. Therefore, it is important to program your tasks to exit if the work has already been completed or overwrite the previous result.

Adding Worker Nodes to a Running Job

While the workload is being executed, workers can be added to the coordinator. The coordinator requires either a list of worker names or a session key that workers will use to attach to the coordinator to receive workload assignments. If you specify a list of worker names, only those workers will be authorized to connect to the coordinator. If you specify a session key, any worker with the session key will be able to connect to the coordinator.

Once the coordinator exits, the job is finished and workers won't be able to connect.

Linger Mode

If you need to keep a coordinator up continually to respond to workload that could be added at any time, you can use the "--linger" command line option on the workers and coordinator to allow Nitro to stay resident and not exit when the tasks are completed.

Nitro provides a message-based process to dynamically add workload to Nitro. Contact Adaptive Computing Professional Services for more information on dynamically adding workload.

Glossary

C

Compute Node

Term for a server designed for high-performance computing and managed by an HPC administrator as part of an HPC cluster.

Coordinator

Nitro component responsible for scheduling Nitro tasks to the Worker components for execution, recording the tasks' information in the Task Log file and job information in the Nitro Job Log file, and checkpointing the Nitro job's state information in the Nitro Checkpoint file.

Core

An individual hardware-based execution unit within a processor that can independently execute a software execution thread and maintain its execution state separate from the execution state of all other cores within the processor.

CPU

See Processor, Core, Thread, OS Core, and Virtual Core. CPU is too generic, ambiguous, or context-specific for utilization in this guide.

D

Datacenter

A non-HPC cluster system composed of many "servers" that typically are not used for high performance computing.

Dynamic job

Nitro job where the requested resources are specified in a range. Nitro will execute the task file as a static job using the minimum value specified in the range. When resources become available, Nitro will add in more workers until the maximum range value is reached.

H

High Performance Computing

The use of highly parallel and/or specialized "supercomputers" for executing parallel workloads such as large simulations, solving problems that require very complex and extensive calculations, computations that require very long running calculations, etc. Such workloads are characterized by their use of many "compute nodes", often in the thousands, to work on a single problem and have execution times ranging from minutes to months. HPC systems often execute from one to a few dozen or hundreds of simultaneous workloads and have a job (workload) queue with a few hundred to several thousands of pending jobs. In HPC systems, the performance of individual workloads within a time interval is the primary objective and therefore HPC schedulers attempt to optimize their use of an HPC system's resources regardless of the scheduling overhead incurred to do so (within reason).

High Throughput Computing

Describes workloads that often execute on just a single core and may have execution times ranging from sub-seconds to minutes and perhaps hours. HTC systems often execute hundreds to tens of thousands of simultaneous workloads. In HTC systems, the quantity of workloads processed per time interval is the primary objective and therefore HTC schedulers attempt to minimize scheduling overhead in order to maximize workload throughput.

Host

The host name of the HPC system's "compute node" or a datacenter's "server".

HPC

See High Performance Computing.

HPC Cluster

HPC industry's term for a "supercomputer". It is somewhat analogous to a "datacenter", except for the sometimes specialized nature of its hardware.

HT

See Hyper-Threading.

HTC

See High Throughput Computing.

Hyper-Threading

Term used by Intel for its Simultaneous Multi-Threading (SMT) capability in its Atom, Core, Itanium, Pentium 4, Xeon, and Xeon Phi processor families. See also Simultaneous Multi-Threading.

J

Job

HPC term for workload submitted by a user to a scheduler for the purpose of scheduling resources on which the workload executes when started up by the scheduler. This guide will use this term to identify workload, in whatever form, submitted to a scheduler that schedules the workload for execution on a system (HPC cluster or commercial datacenter). Typically, a user creates a script that executes the workload (one or more applications) and submits the script to the scheduler where it becomes a "job". The user also gives information identifying the types of resources, typically one or more nodes and optionally other hardware (such as GPU or MIC accelerators) or software and/or software licenses, required by the workload to execute, either in the job script itself or at the time of job submission (for example, via command line options or web portal form). The scheduler schedules the job for the requested resources and when they are available allocates them to the job and then starts the job by executing the script on one of the allocated nodes. The script executes the workload (s)/application(s) that then use the resources allocated to the job by the scheduler.

Job Scheduler

HPC term for a scheduler that manages submitted workloads (called "jobs") for an HPC cluster. See Scheduler.

M

Multi-threading

The use of multiple software threads, which may or may not be pinned to hardware threads (core affinity), to implement processing in parallel. There are multiple implementations of multi-threading, such as Linux "pthreads", etc.

N

Nitro

HTC task scheduler application offered by Adaptive Computing, Inc.

Node

Shorthand term for "compute node". See Compute Node.

O

OS Core

Term that refers to what the operating system considers an individual hardware-based computation unit, often called a "core" or a "CPU". In actuality, the "OS core" can be a hardware-based core (see "Core") or a hardware-based thread (see "Thread"). This guide uses this term to refer to the basic hardware-based computational unit allocatable by an operating system to a process.

P

Process

An individual executing program managed by an operating system. It has its own resources and memory address space, independent of all other executing processes managed by the operating system. A process may itself be multi-threaded, which means the operating system can execute simultaneously different software execution threads of the process.

Processor

A physical hardware chip (sometimes called a "socket"); regardless of whether it supports a single core or multiple cores ("multi-core" processor). Socket is a strong, unambiguous synonym for processor while CPU (see CPU) is an ambiguous synonym individuals and/or processor vendor documentation may use. In addition, people and literature sometimes use the term processor to refer to a hardware core (see Core) or hardware thread (see Thread). This guide uses the term "processor" to refer to the physical hardware chip.

S

Scheduler

Term used generically in the guide for the specialized software between the user and the HPC cluster/datacenter system that manages submitted workloads or "jobs". Such management includes queuing jobs, prioritizing queued jobs for execution, scheduling and allocating requested resources for each job, and starting jobs when their requested resources become available and the jobs have the

highest priority. This guide uses the term "system scheduler" to refer to the scheduler that schedules jobs for your system, regardless whether it is an HPC cluster or datacenter.

Server

Term for a (typically) "headless" computer used in a data center and managed by a system administrator in an IT department.

Simultaneous Multi-Threading

Processor core's ability to execute (in hardware) instructions from multiple, independent, software execution threads and track their states simultaneously.

SMT

See Simultaneous Multi-Threading.

Static job

Nitro job where the number of resources (nodes or cores) does not change. The task file is not executed until all of the job's resources become available.

T

Task

A single unit of work (HTC job) defined by Nitro task definitions in a user task file (list of HTC jobs now referred to as tasks) that Nitro can schedule and launch for execution as a single OS process.

Task file

The file containing the list of tasks that Nitro should execute.

Task Launch Thread

A Nitro worker "software execution thread" capable of launching one Nitro "task". Unless modified by a Nitro worker command line option, the worker's quantity of task launch threads is identical to the quantity of node OS cores made available to the worker by the system scheduler.

Thread

In SMT or hyper-threading, refers to a hardware-based thread execution capability. For example, the consumer-oriented Intel Core i7 processor has four cores, each of which has hardware that can simultaneously track two software execution thread states and execute the other thread when one thread blocks waiting on a memory access; thus increasing the utilization of each core's computational capability and yielding 8 hardware-based threads for the entire processor. The server-oriented Intel Xeon processor documentation refers to threads as "logical processors". Cray documentation uses the term threads relative to the SMT capability of the Intel Xeon processors in its XC systems. Regardless of vendor terminology, one thread in the context of SMT refers to the hardware capability for tracking and executing one software execution thread. The term threads used in the context of a processor core refers to the quantity of software execution threads the core can simultaneously track; e.g., 2 threads per Intel Xeon E5-2650 v3 core and 20 threads per Intel Xeon E5-2650 v3 processor. BIOS settings enable or disable the SMT capability of SMT-capable processors and therefore determine at boot time whether a processor has only one thread per core or multiple threads per core. See Core and OS Core.

V

Virtual Core

Term often used to refer to a hardware-based thread of a core that is not the first thread (thread 0) within a core. If a processor has SMT or hyper-threading enabled, "thread 0" represents the core and the other threads 1-N represent "virtual cores". The only way to execute using just a core that has SMT/hyper-threading enabled is to use only thread 0 of the core and expressly enforce the non-use of the core's other threads or "virtual cores" through a CPUset or control-group (cgroup).

W

Worker

Nitro component responsible for executing the user's workloads specified by the task definitions in the Task file.

Workload

Generic term used in this guide to refer to some amount of work to be done, typically by executing one or more software applications.

Chapter 6 Troubleshooting

This chapter provides troubleshooting information.

In this topic:

- [Sources of Troubleshooting Information on page 105](#)
- [Troubleshooting Task Errors on page 105](#)

Sources of Troubleshooting Information

These are common sources of reference for troubleshooting:

- **Job Output Files** - Any errors that Nitro reports should be reported on stderr and will be captured to your job's output files (if running Nitro through a job scheduler).
- **Job and Task Log Files in the Job Directory** -
 - Nitro writes a job log indicating the startup parameters, input files, configuration, and the main worker events and statistics. You can review the job log to determine if any tasks failed, timed out, or were invalid (an error parsing the task line).
 - The task log contains a listing of all task results from the job and includes stdout and/or stderr output.
- **Nitro debug logs** - In the job directory you will also find a "logs" directory with worker and coordinator logs. The logs are named according to the role (worker or coordinator), host, job, and process ID so that logs being written to the same directory will not overwrite logs from another Nitro job or worker with the same process ID.

The default log level that Nitro logs at is level 3 (information), but this can be raised as high as 7 (debug) to gather much more information about the messages that Nitro is sending between the workers and coordinator, and the actions Nitro is taking (very large log file).

You can use the "--loglevel" command line parameter to set the log level independently on the workers and coordinator.

Troubleshooting Task Errors

The Nitro job log, and the stdout output from the Nitro coordinator, lists the number of tasks completed, tasks successfully completed (exit code of 0), failed tasks (exit code other than 0), tasks that timed out (exceeded the "maxtime" task option), invalid tasks (tasks that the coordinator could not parse without errors), and tasks with insufficient resources.

i If you encounter a problem you are unable to solve, forward the log files according to your company's escalation process.

Task Command Line Errors

If the command line that you use to specify the task's command line contains an error (for example, the path is incorrect or you are attempting to run a script with noexecute permissions set), then the shell will output an error message to stderr that will be captured and stored in the task log file.

For example, if the task's command line references a binary that doesn't exist, you would see the following error in the task log file.

Job ID	Task ID	Line #	Task Name	Status	Ret	Hostname	Start time	Duration	UserCPU
SysCPU	VirtMem	PhysMem	Labels	Output					
EX01	3	3	S07T2303	Failure	127	node02	07:58:07.868	0.005	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					
EX01	4	4	S07T2304	Failure	127	node02	07:58:07.872	0.007	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					
EX01	5	5	S07T2305	Failure	127	node02	07:58:07.878	0.003	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					

Failed Tasks

Failed tasks were tasks that the worker executed, but have failed because the command line was not valid, or the task ran and returned an exit code other than 0. To diagnose the error, examine the task log file located in the job directory. See [Track Job Progress on page 74](#).

You can also use nitrostat to list failed tasks. See [nitrostat on page 96](#). To list failed tasks using nitrostat use the following command line.

```
/opt/nitro/bin/nitrostat <job id> -f
```

The following is an example of information provided by nitrostat showing failed tasks.

Job ID	Task ID	Line #	Task Name	Status	Ret	Hostname	Start time	Duration	UserCPU
SysCPU	VirtMem	PhysMem	Labels	Output					
EX01	3	3	S07T2303	Failure	127	node02	07:58:07.868	0.005	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					
EX01	4	4	S07T2304	Failure	127	node02	07:58:07.872	0.007	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					
EX01	5	5	S07T2305	Failure	127	node02	07:58:07.878	0.003	0.000
0.000	0	0		bash: /opt/framemaker/bin/framegen: No such file or directory					

The line number of the failed task in the task file is listed so you can easily identify which lines in the task file generated errors. If you need to verify the path to the task file used by Nitro you will find it both in the job log file and in the stdout output from the coordinator, which may also be recorded in the output files provided by your scheduler.

```
Nitro Environment
-----
Job Id       : EX01
Job path     : /home/jdoe/jobs/EX01
Job log      : /home/jdoe/jobs/EX01/nitro_EX01.joblog.txt
Task log     : /home/jdoe/jobs/EX01/nitro_EX01.tasklog.txt
Task file    : /home/jdoe/jobs/example1.tasks
Worker hosts : node02
```

If Nitro cannot access the task file, you will receive an error from the coordinator on stderr indicating that the task file was not found or is not accessible.

Invalid Tasks

Invalid tasks are lines in the task file that Nitro could not parse without errors. Parsing errors usually include misspelling a task option name. If your task line doesn't contain any task options, you should prepend the "cmd=" option to your command line. The "cmd" option indicates that Nitro should stop parsing the task line and accept the rest of the line as the command line to be executed. The following example shows an invalid task.

Job ID	Task ID	Line #	Task Name	Status	Ret	Output
EX01	14	14		Invalid	...	Unrecognized option name: walltime

In this case an invalid option "walltime" was used in a task definition instead of "maxtime".

```
# invalid line:
name=S07T2314 walltime=30 cmd=/opt/framemaker/bin/framegen -i /shared/scene07.def -
tindex 2314

# valid line:
name=S07T2314 maxtime=30 cmd=/opt/framemaker/bin/framegen -i /shared/scene07.def -
tindex 2314
```

The task file may also be rejected if you have any binary data in the file. The task file should only include ASCII text and each task must be on a separate line. The task file allows comment and empty lines. A hash symbol (#) in the first column of a line identifies a comment line.

Insufficient Resources Tasks

If workers are not able to fulfill resource requirements for tasks with cores or memory specifications, an insufficient resources error is logged. The following example show a task with insufficient resources.

JobID	TaskID	Line#	Status	ExitCode	Hostname	StartTime	Duration
UserCPU	SystemCPU	VirtualMem	PhysicalMem	Labels	Output		
425	1	13	Success	0	node02	2016-02-16_17:58:07.052-0700	0.030
0.010	0.000	130211840	1077248	1	1000000	3.142116000	
425	2	14	Success	0	node02	2016-02-16_17:58:07.052-0700	0.030
0.010	0.000	130211840	1081344	2	1000000	3.141296000	
425	3	15	Success	0	node02	2016-02-16_17:58:07.083-0700	0.021
0.010	0.000	275505152	1679360	3	1000000	3.139544000	
425	4	16	InsufRes	-1	node02	2016-02-16_17:58:07.083-0700	0.000
0.000	0.000	0	0				
Error: worker is limited to 2 threads, task is requesting 3 threads
